To avoid having to type the data source names in the dialog box, you can specify them when you plot:

```
plot(x, 'XDataSource', 'real(x)', 'YDataSource', 'imag(x)')
```

If you subsequently change values of  $x$  programmatically or manually, the plot updates accordingly.

---

**Note** Although you can use data brushing on linked plots of complex data, your brush marks only appear in the plot you are brushing, not in other plots or in the Variables editor. This is because function calls, such as `real(x)` and `imag(x)`, that you specify as data sources are not interpreted when brushing graphed data.

---

**How To**

- “Making Graphs Responsive with Data Linking”

# linkprop

---

<b>Purpose</b>	Keep same value for corresponding properties of graphics objects
<b>Syntax</b>	<pre>hlink = linkprop(obj_handles, 'PropertyName') hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})</pre>
<b>Description</b>	Use linkprop to maintain the same values for the corresponding properties of different graphics objects.

---

**Note** Use linkprop only with Handle Graphics objects.

---

`hlink = linkprop(obj_handles, 'PropertyName')` maintains the same value for the property *PropertyName* on all objects whose handles appear in `obj_handles`. `linkprop` returns the link object in `hlink`. See “About Link Objects” on page 1-3823 for more information.

`hlink = linkprop(obj_handles, {'PropertyName1', 'PropertyName2', ...})` maintains the same respective values for all properties passed as a cell array on all objects whose handles appear in `obj_handles`.

MATLAB updates the linked properties of all linked objects immediately when `linkprop` is called. The first object in the list `obj_handles` determines the property values for the other objects.

A set of graphics objects can have only one link object connecting their properties at any given time. Calling `linkprop` creates a new link object. This new link object replaces any existing link object that is associated with the objects specified in `obj_handles`. However, you can manage which properties and which objects are linked by calling methods on that object:

- To add an object to the list of linked objects, use the `addtarget` method.
- To link new properties of currently-linked objects, use the `addprop` method.
- To stop linking an object, use the `removetarget` method.

## About Link Objects

- To stop properties from linking, use the `removeprop` method.

The link object that `linkprop` returns stores the mechanism that links the properties of different graphics objects. Therefore, the link object must exist within the context where you want property linking to occur (such as in the base workspace if users are to interact with the objects from the command line or figure tools).

The following list describes ways to maintain a reference to the link object.

- Return the link object as an output argument from a function and keep it in the base workspace while interacting with the linked objects.
- Make the `hlink` variable global.
- Store the `hlink` variable in an object's `UserData` property or in application data. See the “Examples” on page 1-3824 section for an example that uses application data.

## Updating a Link Object

If you want to change either the graphics objects or the properties that are linked, you need to use the link object methods designed for that purpose. These methods are functions that operate only on link objects. To use them, you must first create a link object using `linkprop`.

Method	Purpose
<code>addtarget</code>	Add specified graphics object to the link object's targets.
<code>removetarget</code>	Remove specified graphics object from the link object's targets.
<code>addprop</code>	Add specified property to the linked properties.
<code>removeprop</code>	Remove specified property from the linked properties.

## Method Syntax

```
ddtarget(hlink, obj_handles)
removetarget(hlink, obj_handles)
addprop(hlink, 'PropertyName')
removeprop(hlink, 'PropertyName')
```

## Method Arguments

- `hlink` — Link object returned by `linkprop`
- `obj_handles` — One or more graphic object handles
- `PropertyName` — Name of a property common to all target objects

## Examples

This example creates four isosurface graphs of fluid flow data, each displaying a different isovalue. The `CameraPosition` and `CameraUpVector` properties of each subplot axes are linked so that the user can rotate all subplots in unison.

After running the example, select **Rotate 3D** from the figure **Tools** menu and observe how all subplots rotate together.

---

**Note** You can run this example or open it in the MATLAB editor.

---

The property linking code is in step 3.

- 1 Define the data using `flow` and specify property values for the isosurface (which is a patch object).

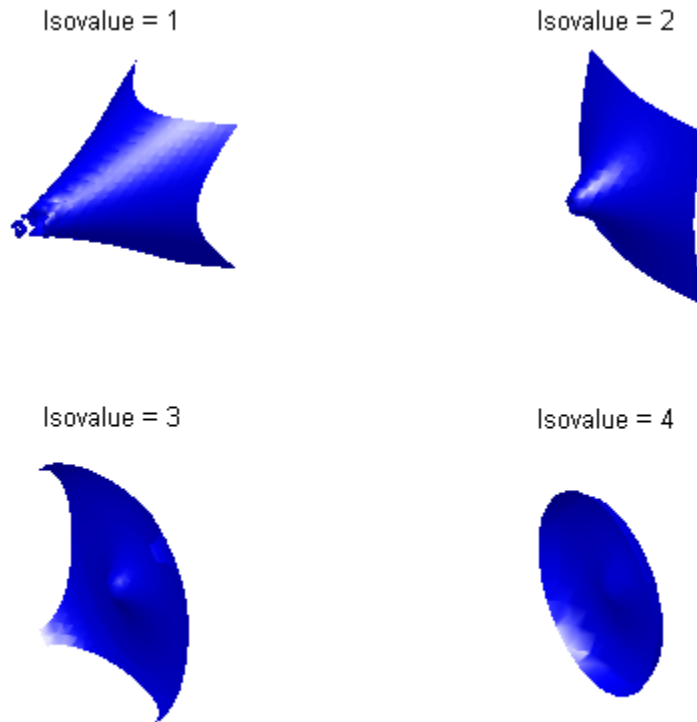

```
[x,y,z,v] = flow;
isoval = [-3,-1,0,1];
props.FaceColor = [0,0,0.5];
props.EdgeColor = 'none';
props.AmbientStrength = 1;
props.FaceLighting = 'gouraud';
```

- 2 Create four subplot axes and add an isosurface graph to each one. Add a title and set viewing and lighting parameters. MATLAB functions used are `subplot`, `patch`, `isosurface`, `title`, and `num2str`. Also set the viewing and lighting parameters for each axes to be the same by calling `view`, `axis`, and `camlight`.

```
figure
% Preallocate h
h = zeros(1,4);
for k = 1:4
 h(k) = subplot(2,2,k);
 patch(isosurface(x,y,z,v,isoval(k)),props)
 title(h(k),['Isovalue = ',num2str(k)])
 % Set the view and add lighting
 view(h(k),3); axis(h(k),'tight','equal')
 camlight left; camlight right
 % Make axes invisible and title visible
 axis(h(k),'off')
 set(get(h(k),'title'),'Visible','on')
end
```

- 3 Link the `CameraPosition` and `CameraTarget` properties of all subplot axes. Since this code already is completed executing when you rotate the subplots, the link object is stored in the first subplot axes application data. See `setappdata` for more information on using application data.

```
if ishghandle(h)
 hlink = linkprop(h,{'CameraPosition','CameraUpVector'});
 key = 'graphics_linkprop';
 % Store link object on first subplot axes
 setappdata(h(1),key,hlink);
end
```

**4** Turn on the **Rotate 3D** tool. Click any object in the figure and rotate it. As you turn it, all three other subplots turn in the same manner.

```
rotate3d on
```

### Linking an Additional Property

Suppose you want to add the axes `PlotBoxAspectRatio` to the linked properties in the previous example. You can do this by modifying the link object that is stored in the first subplot axes' application data.

- 1 First click the first subplot axes to make it the current axes (since its handle was saved only within the creating function). Then get the link object's handle from application data (`getappdata`).

```
hlink = getappdata(gca, 'graphics_linkprop');
```

- 2 Use the `addprop` method to add a new property to the link object.

```
addprop(hlink, 'PlotBoxAspectRatio')
```

Since `hlink` is a reference to the link object (i.e., not a copy), `addprop` can change the object that is stored in application data.

# linsolve

---

**Purpose** Solve linear system of equations

**Syntax**  
`X = linsolve(A,B)`  
`X = linsolve(A,B,opts)`

**Description** `X = linsolve(A,B)` solves the linear system  $A*X = B$  using LU factorization with partial pivoting when A is square and QR factorization with column pivoting otherwise. The number of rows of A must equal the number of rows of B. If A is m-by-n and B is m-by-k, then X is n-by-k. `linsolve` returns a warning if A is square and ill conditioned or if it is not square and rank deficient.

`[X, R] = linsolve(A,B)` suppresses these warnings and returns R, which is the reciprocal of the condition number of A if A is square, or the rank of A if A is not square.

`X = linsolve(A,B,opts)` solves the linear system  $A*X = B$  or  $A'*X = B$ , using the solver that is most appropriate given the properties of the matrix A, which you specify in `opts`. For example, if A is upper triangular, you can set `opts.UT = true` to make `linsolve` use a solver designed for upper triangular matrices. If A has the properties in `opts`, `linsolve` is faster than `mldivide`, because `linsolve` does not perform any tests to verify that A has the specified properties.

---

**Notes** If A does not have the properties that you specify in `opts`, `linsolve` returns incorrect results and does not return an error message. If you are not sure whether A has the specified properties, use `mldivide` instead.

For small problems, there is no speed benefit in using `linsolve` on triangular matrices as opposed to using the `mldivide` function.

---

The `TRANSA` field of the `opts` structure specifies the form of the linear system you want to solve:

- If you set `opts.TRANS_A = false`, `linsolve(A,B,opts)` solves  $A \cdot X = B$ .
- If you set `opts.TRANS_A = true`, `linsolve(A,B,opts)` solves  $A' \cdot X = B$ .

The following table lists all the field of `opts` and their corresponding matrix properties. The values of the fields of `opts` must be logical and the default value for all fields is `false`.

Field Name	Matrix Property
LT	Lower triangular
UT	Upper triangular
UHESS	Upper Hessenberg
SYM	Real symmetric or complex Hermitian
POSDEF	Positive definite
RECT	General rectangular
TRANS_A	Conjugate transpose — specifies whether the function solves $A \cdot X = B$ or $A' \cdot X = B$

The following table lists all combinations of field values in `opts` that are valid for `linsolve`. A true/false entry indicates that `linsolve` accepts either true or false.

LT	UT	UHESS	SYM	POSDEF	RECT	TRANS_A
true	false	false	false	false	true/false	true/false
false	true	false	false	false	true/false	true/false
false	false	true	false	false	false	true/false
false	false	false	true	true/false	false	true/false
false	false	false	false	false	true/false	true/false

# linsolve

---

## Examples

The following code solves the system  $A'x = b$  for an upper triangular matrix  $A$  using both `mldivide` and `linsolve`.

```
A = triu(rand(5,3)); x = [1 1 1 0 0]'; b = A'*x;
y1 = (A')\b
opts.UT = true; opts.TRANS_A = true;
y2 = linsolve(A,b,opts)
```

y1 =

```
1.0000
1.0000
1.0000
0
0
```

y2 =

```
1.0000
1.0000
1.0000
0
0
```

---

**Note** If you are working with matrices having different properties, it is useful to create an options structure for each type of matrix, such as `opts_sym`. This way you do not need to change the fields whenever you solve a system with a different type of matrix  $A$ .

---

## See Also

`mldivide`

**Purpose** Generate linearly spaced vectors

**Syntax** `y = linspace(a,b)`  
`y = linspace(a,b,n)`

**Description** The `linspace` function generates linearly spaced vectors. It is similar to the colon operator `:`, but gives direct control over the number of points.

`y = linspace(a,b)` generates a row vector `y` of 100 points linearly spaced between and including `a` and `b`.

`y = linspace(a,b,n)` generates a row vector `y` of `n` points linearly spaced between and including `a` and `b`. For `n = 1`, `linspace` returns `b`.

**Examples** Create a vector of 100 linearly spaced numbers from 1 to 500:

```
A = linspace(1,500);
```

Create a vector of 12 linearly spaced numbers from 1 to 36:

```
A = linspace(1,36,12);
```

**See Also** `logspace` | `colon operator`

# RandStream.list

---

**Purpose** Random number generator algorithms

**Class** RandStream

**Syntax** RandStream.list

**Description** RandStream.list lists all the generator algorithms that may be used when creating a random number stream with RandStream or RandStream.create. The available generator algorithms and their properties are given in the following table.

<b>Keyword</b>	<b>Generator</b>	<b>Multiple Stream and Substream Support</b>	<b>Approximate Period In Full Precision</b>
mt19937ar	Mersenne twister (used by default stream at MATLAB startup)	No	$2^{19937} - 1$
mcg16807	Multiplicative congruential generator	No	$2^{31} - 2$
mlfg6331_64	Multiplicative lagged Fibonacci generator	Yes	$2^{124}$
mrg32k3a	Combined multiple recursive generator	Yes	$2^{127}$

<b>Keyword</b>	<b>Generator</b>	<b>Multiple Stream and Substream Support</b>	<b>Approximate Period In Full Precision</b>
shr3cong	Shift-register generator summed with linear congruential generator	No	$2^{64}$
swb2712	Modified subtract with borrow generator	No	$2^{1492}$

See “Choosing a Random Number Generator” for details about these generator algorithms. See <http://www.math.sci.hiroshima-u.ac.jp/~m-mat/MT/emt.html> for a full description of the Mersenne twister algorithm.

# listdlg

---

**Purpose** Create and open list-selection dialog box

**Syntax** [Selection,ok] = listdlg('ListString',S)

**Description** [Selection,ok] = listdlg('ListString',S) creates a modal dialog box that enables you to select one or more items from a list. Selection is a vector of indices of the selected strings (in single selection mode, its length is 1). Selection is [] when ok is 0. ok is 1 if you click the **OK** button, or 0 if you click the **Cancel** button or close the dialog box. Double-clicking on an item or pressing **Return** when multiple items are selected has the same effect as clicking the **OK** button. The dialog box has a **Select all** button (when in multiple selection mode) that enables you to select all list items.

Inputs are in parameter/value pairs:

Parameter	Description
'ListString'	Cell array of strings that specify the list box items.
'SelectionMode'	String indicating whether one or many items can be selected: 'single' or 'multiple' (the default).
'ListSize'	List box size in pixels, specified as a two-element vector [width height]. Default is [160 300].
'InitialValue'	Vector of indices of the list box items that are initially selected. Default is 1, the first item.
'Name'	String for the dialog box's title. Default is ''.
'PromptString'	String matrix or cell array of strings that appears as text above the list box. Default is {}.
'OKString'	String for the OK button. Default is 'OK'.
'CancelString'	String for the Cancel button. Default is 'Cancel'.
'uh'	Uicontrol button height, in pixels. Default is 18.

---

Parameter	Description
'fus'	Frame/uicontrol spacing, in pixels. Default is 8.
'ffs'	Frame/figure spacing, in pixels. Default is 8.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

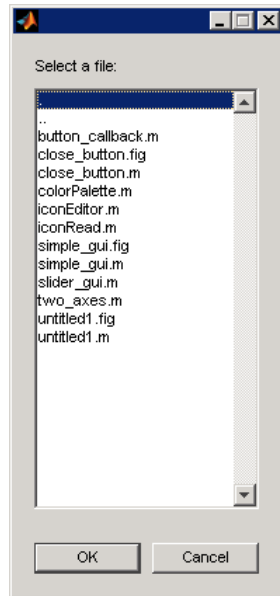

## Examples

This example displays a dialog box that enables the user to select a file from the current directory. The function returns a vector. Its first element is the index to the selected file; its second element is 0 if no selection is made, or 1 if a selection is made.

```
d = dir;
str = {d.name};
[s,v] = listdlg('PromptString','Select a file:',...
 'SelectionMode','single',...
 'ListString',str)
```

# listdlg

---

**Purpose** List available system fonts

**Syntax**  
`c = listfonts`  
`c = listfonts(h)`

**Description** `c = listfonts` returns sorted list of available system fonts.  
`c = listfonts(h)` returns sorted list of available system fonts and includes the `FontName` property of the object with handle `h`.

**Tips** Calling `listfonts` returns a list of all fonts on your system, possibly including fonts that you cannot use with MATLAB. Consider using the `uisetfont` utility (a GUI) to preview fonts to use; it only displays fonts that MATLAB can render in figures and GUIs. Like `uisetfont`, the **Custom Fonts** pane of MATLAB Preferences also previews available fonts and only shows those that MATLAB can render.

## Examples **Example 1**

This example returns a list of available system fonts similar in format to the one shown.

```
list = listfonts

list =
 'Agency FB'
 'Algerian'
 'Arial'
 ...
 'ZapfChancery'
 'ZapfDingbats'
 'ZWAdobeF'
```

## **Example 2**

This example returns a list of available system fonts with the value of the `FontName` property, for the object with handle `h`, included and sorted in the list.

# listfonts

---

```
h = uicontrol('Style','text','String',...
 'My Font','FontName','MyFont');
list = listfonts(h)

list =
 'Agency FB'
 'Algerian'
 'Arial'
 ...
 'MyFont'
 ...
 'ZapfChancery'
 'ZapfDingbats'
 'ZWAdobeF'
```

## See Also

uisetfont

**Purpose** Load variables from file into workspace

**Syntax**

```
load(filename)
load(filename,variables)
load(filename,'-ascii')
load(filename,'-mat')
load(filename,'-mat',variables)

S = load(___)

load filename
```

**Description** `load(filename)` loads data from `filename`.

- If `filename` is a MAT-file, then `load(filename)` loads variables in the MAT-File into the MATLAB workspace.
- If `filename` is an ASCII file, then `load(filename)` creates a double-precision array containing data from the file.

`load(filename,variables)` loads the specified variables from the MAT-file, `filename`.

`load(filename,'-ascii')` treats `filename` as an ASCII file, regardless of the file extension.

`load(filename,'-mat')` treats `filename` as a MAT-file, regardless of the file extension.

`load(filename,'-mat',variables)` loads the specified variables from `filename`.

`S = load( ___ )` loads data into `S`, using any of the input arguments in the previous syntax group.

- If `filename` is a MAT-file, then `S` is a structure array.

# load

---

- If `filename` is an ASCII file, then `S` is a double-precision array containing data from the file.

`load filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to load a file named `durer.mat`, these statements are equivalent:

```
load durer.mat % command form
load('durer.mat') % function form
```

You can include any of the inputs described in previous syntaxes. For example, to load the variable named `X`:

```
load durer.mat X % command form
load('durer.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Input Arguments

### **filename** - Name of file

`matlab.mat` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `load` function searches for a file named `matlab.mat`.

`filename` can include a file extension and a full or partial path. If `filename` has no extension (that is, no text after a period), `load` looks for a file named `filename.mat`. If `filename` has an extension other than `.mat`, the `load` function treats the file as ASCII data.

When using the command form of `load`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, `load 'filename withspace.mat'`.

ASCII files must contain a rectangular table of numbers, with an equal number of elements in each row. The file delimiter (the character between elements in each row) can be a blank, comma, semicolon, or tab character. The file can contain MATLAB comments (lines that begin with a percent sign, %).

**Example:** 'myFile.mat'

### Data Types

char

### variables - Names of variables to load

string

Names of variables to load, specified as one or more strings. When using the command form of `load`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of variables Input	Variables to Load
<i>var1, ..., varN</i>	Load the listed variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>load('filename.mat', 'A*')</code> or <code>load filename.mat A*</code> loads all variables in the file whose names start with A.
'-regexp', <i>expr1, ..., exprN</i>	Load only the variables or fields whose names match the regular expressions, specified as strings. For example, <code>load('filename.mat', '-regexp', '^Mon', '^Tue</code> or <code>load filename.mat -regexp ^Mon ^Tues</code> loads only the variables in the file whose names begin with Mon or Tues.

# load

---

## Data Types

char

## Output Arguments

### S - Loaded variables or data

structure array | m-by-n array

Loaded variables, returned as a structure array, if `filename` is a MAT-File.

Loaded data, returned as an m-by-n array of type `double`, if `filename` is an ASCII file. `m` is equal to the number of lines in the file, and `n` is equal to the number of values on a line.

## Examples

### Load All Variables from MAT-File

Load all variables from the example MAT-file, `gong.mat`. Check the contents of the workspace before and after the load operation.

```
disp('Contents of workspace before loading file:')
whos
```

```
disp('Contents of gong.mat:')
whos('-file','gong.mat')
```

```
load('gong.mat')
disp('Contents of workspace after loading file:')
whos
```

You also can use command syntax to load the variables. Clear the previously loaded variables and repeat the load operation.

```
clear y Fs
```

```
load gong.mat
```

## Load Specific Variable From MAT-File

Load only variable `y` from example file `handel.mat`. If the workspace already contains variable `y`, the load operation overwrites it with data from the file.

```
load('handel.mat','y')
```

You also can use command syntax to load the variable, `y`.

```
load handel.mat y
```

## Use Regular Expressions to Load Specific Variables

View the contents of the example file, `accidents.mat`.

```
whos -file accidents.mat
```

Name	Size	Bytes	Class	Attributes
<code>datasources</code>	3x1	2724	cell	
<code>hwycols</code>	1x1	8	double	
<code>hwydata</code>	51x17	6936	double	
<code>hwyheaders</code>	1x17	2758	cell	
<code>hwyidx</code>	51x1	408	double	
<code>hwyrows</code>	1x1	8	double	
<code>statelabel</code>	51x1	6596	cell	
<code>ushwydata</code>	1x17	136	double	
<code>uslabel</code>	1x1	138	cell	

Use function syntax to load all variables with names not beginning with `'hwy'`, from the file.

```
load('accidents.mat', '-regexp', '^(!hwy)...')
```

Alternatively, use command syntax to load the same variables.

```
load accidents.mat -regexp '^(!hwy)...'
```

## Load List of Variables into Structure Array

The file, `durer.mat`, contains variables `X`, `caption`, and `map`. Create a cell array of variable names to load.

```
filename = 'durer.mat';
myVars = {'X','caption'};
S = load(filename,myVars{:})
```

```
S =

 X: [648x509 double]
 caption: [2x28 char]
```

Only the variables `X` and `caption` are loaded into the structure array, `S`.

## Load ASCII File

Create an ASCII file from several 4-column matrices, and load the data back into a double-precision array.

```
a = magic(4);
b = ones(2, 4) * -5.7;
c = [8 6 4 2];
save -ascii mydata.dat a b c
clear a b c
```

```
load mydata.dat -ascii
```

`load` creates an array of type `double` named `mydata`.

View information about `mydata`.

```
whos mydata
```

Name	Size	Bytes	Class	Attributes
mydata	7x4	224	double	

**Algorithms**

If you do not specify an output for the `load` function, MATLAB creates a variable named after the loaded file (minus any file extension). For example, the command

```
load mydata.dat
```

reads data into a variable called `mydata`.

To create the variable name, `load` precedes any leading underscores or digits in `filename` with an `X` and replaces any other nonalphanumeric characters with underscores. For example, the command

```
load 10-May-data.dat
```

creates a variable called `X10_May_data`.

**Concepts**

- “Supported File Formats for Import and Export”
- “Save, Load, and Delete Workspace Variables”
- “Ways to Import Text Files”
- “Loading Variables within a Function”
- “Import or Export a Sequence of Files”
- “Command vs. Function Syntax”

# load (COM)

---

**Purpose** Initialize control object from file

**Syntax** `h.load('filename')`  
`load(h, 'filename')`

**Description** `h.load('filename')` initializes the COM object associated with the interface represented by the MATLAB COM object `h` from file specified in the string `filename`. The file must have been created previously by serializing an instance of the same control.

`load(h, 'filename')` is an alternate syntax for the same operation.

---

**Note** The COM load function is only supported for controls at this time.

---

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl1.2', [0 0 200 200], f);
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';
h.Radius = 50;
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');
h.get
```

MATLAB displays the original values:

```
ans =
```

```
Label: 'Label'
Radius: 20
```

## See Also

save (COM) | actxcontrol | actxserver | release | delete (COM)

# load (serial)

---

**Purpose** Load serial port objects and variables into MATLAB workspace

**Syntax** `load filename`  
`load filename obj1 obj2...`

**Description** `load filename` returns all variables from the file specified by `filename` into the MATLAB workspace.

`load filename obj1 obj2...` returns the serial port objects specified by `obj1 obj2 ...` from the file `filename` into the MATLAB workspace.

`out = load('filename','obj1','obj2',...)` returns the specified serial port objects from the file `filename` as a structure to `out` instead of directly loading them into the workspace. The field names in `out` match the names of the loaded serial port objects.

**Tips** Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

## Examples

---

**Note** This example is based on a Windows platform.

---

Suppose you create the serial port objects `s1` and `s2`, configure a few properties for `s1`, and connect both objects to their instruments:

```
s1 = serial('COM1');
s2 = serial('COM2');
set(s1,'Parity','mark','DataBits',7);
fopen(s1);
fopen(s2);
```

Save `s1` and `s2` to the file `MyObject.mat`, and then load the objects back into the workspace:

```
save MyObject s1 s2;
load MyObject s1;
```

```
load MyObject s2;

get(s1, {'Parity', 'DataBits'})

ans =
 'mark' [7]

get(s2, {'Parity', 'DataBits'})

ans =
 'none' [8]
```

### See Also

save | Status

# loadlibrary

---

**Purpose** Load shared library into MATLAB

**Syntax**

```
loadlibrary(libname,hfile)
loadlibrary(libname)
loadlibrary(libname,hfile,Name,Value)
```

```
loadlibrary(libname,@protofile)
```

```
[notfound,warnings] = loadlibrary(___)
```

**Description** `loadlibrary(libname,hfile)` loads functions from shared library, `libname`, defined in header file, `hfile`, into MATLAB.

`loadlibrary(libname)` loads the library if the name of the header file is the same as the name of the library file.

`loadlibrary(libname,hfile,Name,Value)` loads the library with one or more `Name,Value` arguments.

`loadlibrary(libname,@protofile)` uses a prototype file, `protofile`, in place of a header file.

`[notfound,warnings] = loadlibrary( ___ )` returns warning information, and can include any of the input arguments in previous syntaxes.

## Limitations

- You must have a supported C compiler and Perl must be available.
- Do not call `loadlibrary` if the library is already in memory. To test this condition, call `libisloaded`.
- `loadlibrary` does not support libraries generated by the MATLAB Compiler™ product.
- The MATLAB Shared Library interface does not support library functions with function pointer inputs.

## Input Arguments

### **libname - Name of shared library**

string

Name of shared library, specified as a string. The name is case-sensitive and must match the file on your system.

On Microsoft Windows systems, `libname` refers to the name of a shared library (.dll) file. On Linux systems, it refers to the name of a shared object (.so) file. On Apple Macintosh systems, it refers to a dynamic shared library (.dylib).

If you do not include a file extension with the `libname` argument, `loadlibrary` attempts to find the library with either the appropriate platform MEX-file extension or the appropriate platform library extension. For a list of MEX-file extensions, use `mexext`.

### **Data Types**

char

### **hfile - Name of C header file**

string

Name of C header file, specified as a string. The name is case-sensitive and must match the file on your system. If you do not include a file extension in the file name, `loadlibrary` uses `.h` for the extension.

### **Data Types**

char

### **protofile - Name of prototype file**

string

Name of prototype file, specified as a string. The name is case-sensitive and must match the file on your system. The string `@protofile` specifies a function handle to the prototype file. When using a prototype file, the only valid Name, Value pair argument is **alias**.

### **Data Types**

char

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### **Example:**

#### **'addheader' - Header file**

string

Header file, specified as the comma-separated pair consisting of `'addheader'` and a string. Specify the file name without a file extension.

Each file specified by `addheader` must have a corresponding `#include` statement in the base header file. To load only the functions defined in the header file that you want to use in MATLAB, use `addheader`.

MATLAB does not verify the existence of header files and ignores any that are not needed.

#### **'alias' - Alternative name for library**

string

Alternative name for library, specified as the comma-separated pair consisting of `'alias'` and a string. Associates the specified name with the library. All subsequent calls to MATLAB functions that reference this library must use this alias until the library is unloaded.

#### **'includepath' - More search path for subordinate header files**

string

more search path for subordinate header files—header files within header files, specified as the comma-separated pair consisting of `'includepath'` and a string.

#### **'mfilename' - Prototype file**

string

Prototype file, specified as the comma-separated pair consisting of 'mfilename' and a string. Generates a prototype file in the current folder. The prototype file name must be different from the library name. Use this file in place of a header file when loading the library.

### 'thunkfilename' - Thunk file

string

Thunk file, specified as the comma-separated pair consisting of 'thunkfilename' and a string. Overrides the default thunk file name.

## Output Arguments

### notfound - Names of functions

cell array

Names of functions found in header files but missing from the library, returned as cell array.

### Data Types

cell

### warnings - Warnings

character array

Warnings produced while processing the header file, returned as character array.

## Examples

### Load Functions in shrlibsampl Library

Add path to examples folder.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

Load shrlibsampl.

```
loadlibrary('shrlibsampl')
```

Cleanup.

```
unloadlibrary shrlibsampl
```

## Load Library Using Header File

The header file for the libmx library is matrix.h.

```
hfile = fullfile(matlabroot,'extern','include','matrix.h');
loadlibrary('libmx',hfile)
```

Cleanup.

```
unloadlibrary libmx
```

## Load Library Using Multiple Header Files

Suppose that you have a library, mylib, with the header file, mylib.h. The header file contains the statement, #include header2.h. To use functions defined in header2.h, call loadlibrary with the addheader option.

```
loadlibrary('mylib','mylib.h','addheader','header2')
```

## Load Library Using an Alias Name

Create an alias, lib, for library, shrlibsampl.

```
loadlibrary('shrlibsampl','alias','lib')
```

Use the alias name, lib, to call a function in the library.

```
str = 'This was a Mixed Case string';
calllib('lib','stringToUpper',str)
```

```
ans =
 THIS WAS A MIXED CASE STRING
```

Cleanup.

```
unloadlibrary lib
```

## Search Alternative Paths for Header Files

Add path to folder containing `shrlibsample` and its header file, `shrlibsample.h`.

```
addpath(fullfile(matlabroot,'extern','examples','shrlib'))
```

The `shrlibsample.h` header file includes the header file, `shrhelp.h`. If `shrhelp.h` is in a different folder, for example, `c:\work`, use the `'includepath'` option to tell MATLAB where to find the file.

```
loadlibrary('shrlibsample','shrlibsample.h','includepath','c:\work')
```

Cleanup.

```
unloadlibrary shrlibsample
```

## Tips

- If you have more than one library file of the same name, load the first using the library file name. Then load the additional libraries using the **alias** option.

## Definitions

### Prototype File

A prototype file is a file of MATLAB commands which you can modify and use in place of a header file.

### Thunk File

A thunk file is a compatibility layer to a 64-bit library generated by MATLAB. The name of the thunk file is `BASENAME_thunk_COMPUTER.c` where *BASENAME* is either the name of the shared library or, if specified, the `mfilename` prototype name. *COMPUTER* is the string returned by the `computer` function.

MATLAB compiles this file and creates the file `BASENAME_thunk_COMPUTER.LIBEXT`, where *LIBEXT* is the platform-dependent default shared library extension, for example, `dll` on Windows.

# localfunctions

---

**Purpose** Function handles to all local functions in MATLAB file

**Syntax** `fcns = localfunctions`

**Description** `fcns = localfunctions` returns a cell array of function handles, `fcns`, to all local functions in the current file.

You cannot define local functions in the context of the command line, scripts, or anonymous functions, so when you call `localfunctions` from these contexts, you get an empty cell array. Within the cell array, `localfunctions` returns the function handles in an undefined order.

## **Examples** **Display Handles to Local Functions in File**

Create a new file, `fileWithLocalFunctions.m`, in your MATLAB path. In the main function, call and display the results of `localfunctions`. In the same file, create two local functions.

```
function fileWithLocalFunctions
```

```
 fcns = localfunctions;
 display(fcns);
```

```
function alocalfunction
```

```
function anotherlocalfunction
```

From the command line, call your function.

```
fileWithLocalFunctions
```

```
fcns =
```

```
 @alocalfunction
 @anotherlocalfunction
```

**See Also** `functiontests`

## Concepts

- “Local Functions”

# log

---

**Purpose** Natural logarithm

**Syntax**  $Y = \log(X)$

**Description**  $Y = \log(X)$  returns the natural logarithm of each element in array  $X$ . The function accepts both real and complex inputs. For real values of  $X$  in the interval  $(0, \text{Inf})$ ,  $\log$  returns real values in the interval  $(-\text{Inf}, \text{Inf})$ . For complex and negative real values of  $X$ ,  $\log$  returns complex values.

**Input Arguments**

**X - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**

single | double

**Complex Number Support:** Yes

**Examples**

**Calculate Scalar Natural Logarithm Values**

Examine several common values of the natural logarithm function.

Calculate the natural logarithm of 1.

```
log(1)
```

```
ans =
```

```
0
```

The result is 0, which is the x-intercept of the function.

Calculate the natural logarithm of Euler's number,  $e$ .

```
log(exp(1))
```

```
ans =
```

---

1

The result is 1 because  $\log$  is the inverse of  $\exp$ .

Calculate the natural logarithm of -1.

$\log(-1)$

ans =

0.0000 + 3.1416i

The result is equal to  $i\pi$ .

Calculate the natural logarithm of 0.

$\log(0)$

ans =

-Inf

The result is -Inf because  $\log$  is a monotonically increasing function over the real domain  $(0, \infty)$ .

### **Plot Real-Valued Natural Logarithm**

Define the domain.

$X = (0.25:0.25:5)'$ ;

Calculate the natural logarithm of the vector, X.

$Y = \log(X)$

Y =

-1.3863

# log

---

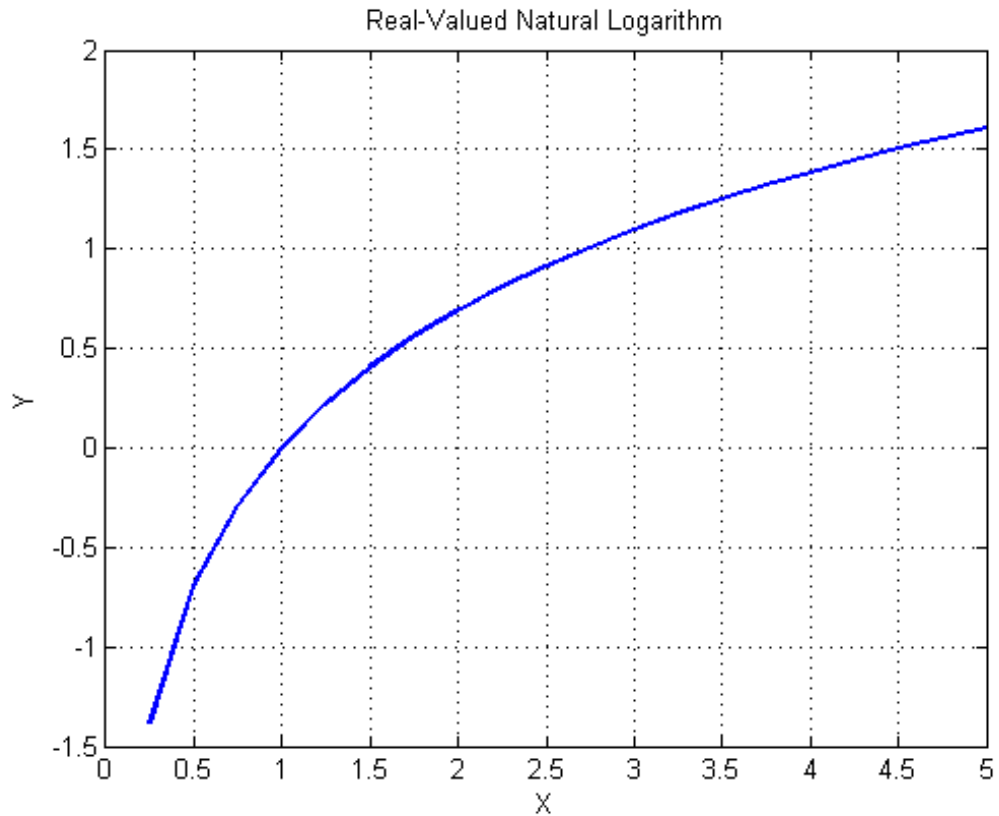

```
-0.6931
-0.2877
 0
 0.2231
 0.4055
 0.5596
 0.6931
 0.8109
 0.9163
 1.0116
 1.0986
 1.1787
 1.2528
 1.3218
 1.3863
 1.4469
 1.5041
 1.5581
 1.6094
```

The result is a vector of natural logarithm values.

Plot the function values.

```
plot(X,Y,'LineWidth',1.5);
grid on;
xlabel('X'); ylabel('Y');
title('Real-Valued Natural Logarithm');
```

The real-valued natural logarithm maps values in the domain  $(0, \infty)$  to the range  $(-\infty, \infty)$ .

### Plot Branches of Complex Logarithm

Define a grid of values for the (X,Y) domain.

```
[X,Y] = meshgrid(-4:0.25:4, -4:0.25:4);
```

Calculate the complex logarithm on the grid.

```
Z = log(X+1i*Y);
```

Make a surface plot of the imaginary portion of the function.

```
surf(X,Y,imag(Z))
grid on; hold on;
title('Principal Branch of Im[$\log(X+iY)$ '],'Interpreter','latex')
xlabel('X'); ylabel('Y'); zlabel('Z');
view(44,42)
```

On the complex plane, the natural logarithm is a multivalued function that winds around the origin.

To obtain a different branch of the function, add  $2\pi i$  to the Z values.

```
z2 = Z + 2*pi*1i;
surf(X,Y,imag(z2))
title('Two Branches of the Complex Logarithm')
view(45,22)
```

# log

---

In this plot, the branches are stacked on top of each other and meet along the negative real axis.

## Algorithms

For complex or negative inputs, `log` computes the complex logarithm  $\log(\text{abs}(z)) + 1i*\text{atan2}(y,x)$ .

## See Also

`log1p` | `log2` | `log10` | `exp` | `logm` | `reallog` | `loglog` | `semilogx` | `semilogy`

**Purpose** Common (base 10) logarithm

**Syntax**  $Y = \log_{10}(X)$

**Description** The `log10` function operates element-by-element on arrays. Its domain includes complex numbers, which may lead to unexpected results if used unintentionally.

$Y = \log_{10}(X)$  returns the base 10 logarithm of the elements of  $X$ .

**Examples** `log10(realmax)` is 308.2547

and

`log10(eps)` is -15.6536

**See Also** `exp` | `log` | `log2` | `logm`

# log1p

---

**Purpose** Compute  $\log(1+x)$  accurately for small values of  $x$

**Syntax**  $y = \log1p(x)$

**Description**  $y = \log1p(x)$  computes  $\log(1+x)$ , compensating for the roundoff in  $1+x$ .  $\log1p(x)$  is more accurate than  $\log(1+x)$  for small values of  $x$ . For small  $x$ ,  $\log1p(x)$  is approximately  $x$ , whereas  $\log(1+x)$  can be zero.

**See Also** `log` | `expm1`

**Purpose** Base 2 logarithm and dissect floating-point numbers into exponent and mantissa

**Syntax**  $Y = \log_2(X)$   
 $[F, E] = \log_2(X)$

**Description**  $Y = \log_2(X)$  computes the base 2 logarithm of the elements of  $X$ .  
 $[F, E] = \log_2(X)$  returns arrays  $F$  and  $E$ . Argument  $F$  is an array of real values, usually in the range  $0.5 \leq \text{abs}(F) < 1$ . For real  $X$ ,  $F$  satisfies the equation:  $X = F \cdot 2.^E$ . Argument  $E$  is an array of integers that, for real  $X$ , satisfy the equation:  $X = F \cdot 2.^E$ .

**Tips** This function corresponds to the ANSI C function `frexp()` and the IEEE floating-point standard function `logb()`. Any zeros in  $X$  produce  $F = 0$  and  $E = 0$ .

**Examples** For IEEE arithmetic, the statement  $[F, E] = \log_2(X)$  yields the values:

<b>X</b>	<b>F</b>	<b>E</b>
1	1/2	1
pi	pi/4	2
-3	-3/4	2
eps	1/2	-51
realmax	1 - eps/2	1024
realmin	1/2	-1021

**See Also** `log` | `pow2`

# logical

---

**Purpose** Convert numeric values to logicals

**Syntax** `L = logical(A)`

**Description** `L = logical(A)` converts numeric input `A` into an array of logical values. Any nonzero element of input `A` is converted to logical 1 (true) and zeros are converted to logical 0 (false). Complex values and NaNs cannot be converted to logical values and result in a conversion error.

**Input Arguments**

**A - Numeric input**

scalar | vector | matrix | multidimensional array

Numeric input, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Examples**

**Pick Odd Elements from Numeric Matrix**

Pick out the odd-numbered elements of a numeric matrix.

Create a numeric matrix.

```
A = [1 -3 2;5 4 7;-8 1 3];
```

Find the modulus, `mod(A,2)`, and convert it to a logical array for indexing.

```
L = logical(mod(A,2))
```

```
L =
```

```
 1 1 0
 1 0 1
 0 1 1
```

The array has logical 1 (true) values where `A` is odd.

Use L as a logical index to pick out the odd elements of A.

```
A(L)
```

```
ans =
```

```
1
5
-3
1
7
3
```

The result is a vector containing all odd elements of A.

Use the logical NOT operator, ~, on L to find the even elements of A.

```
A(~L)
```

```
ans =
```

```
-8
4
2
```

## Tips

- Most arithmetic operations involving logical arrays return double values. For example, adding zero to a logical array returns a double array.
- Logical arrays also are created by the relational operators (==,<,>,<=,>=, etc.) and functions like any, all, isnan, isinf, and isfinite.

## See Also

```
islogical | false | true
```

## Concepts

- “Using Logicals in Array Indexing”
- “Determine if Arrays Are Logical”

# loglog

---

## Purpose

Log-log scale plot

## Syntax

```
loglog(Y)
loglog(X1,Y1,...)
loglog(X1,Y1,LineStyle,...)
loglog(...,'PropertyName',PropertyValue,...)
h = loglog(...)
```

## Description

`loglog(Y)` plots the columns of `Y` versus their index if `Y` contains real numbers. If `Y` contains complex numbers, `loglog(Y)` and `loglog(real(Y),imag(Y))` are equivalent. `loglog` ignores the imaginary component in all other uses of this function.

`loglog(X1,Y1,...)` plots all  $Y_n$  versus  $X_n$  pairs. If only one of  $X_n$  or  $Y_n$  is a matrix, `loglog` plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

`loglog(X1,Y1,LineStyle,...)` plots all lines defined by the  $X_n, Y_n, LineSpec$  triples, where `LineStyle` determines line type, marker symbol, and color of the plotted lines. You can mix  $X_n, Y_n, LineSpec$  triples with  $X_n, Y_n$  pairs, for example,

```
loglog(X1,Y1,X2,Y2,LineStyle,X3,Y3)
```

`loglog(...,'PropertyName',PropertyValue,...)` sets property values for all lineseries properties graphics objects created by `loglog`.

`h = loglog(...)` returns a column vector of lineseries handles, one handle per line.

If you do not specify a color when plotting more than one line, `loglog` automatically cycles through the colors and line styles in the order specified by the current axes.

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

### Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

### Logarithmic Scale for Both Axes

Create a plot using a logarithmic scale for both the x-axis and the y-axis. Set the `LineStyle` string so that `loglog` plots using a line with square markers. Display the grid.

```
x = logspace(-1,2);
y = exp(x);

figure
loglog(x,y,'-s');
grid on
```

# loglog

## See Also

[LineSpec](#) | [plot](#) | [semilogx](#) | [semilogy](#)

**Purpose** Matrix logarithm

**Syntax**  $L = \text{logm}(A)$   
 $[L, \text{exitflag}] = \text{logm}(A)$

**Description**  $L = \text{logm}(A)$  is the principal matrix logarithm of  $A$ , the inverse of  $\text{expm}(A)$ .  $L$  is the unique logarithm for which every eigenvalue has imaginary part lying strictly between  $-\pi$  and  $\pi$ . If  $A$  is singular or has any eigenvalues on the negative real axis, the principal logarithm is undefined. In this case, `logm` computes a nonprincipal logarithm and returns a warning message.

$[L, \text{exitflag}] = \text{logm}(A)$  returns a scalar `exitflag` that describes the exit condition of `logm`:

- If `exitflag` = 0, the algorithm was successfully completed.
- If `exitflag` = 1, too many matrix square roots had to be computed. However, the computed value of  $L$  might still be accurate.

The input  $A$  can have class `double` or `single`.

**Tips** If  $A$  is real symmetric or complex Hermitian, then so is  $\text{logm}(A)$ .

Some matrices, like  $A = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}$ , do not have any logarithms, real or complex, so `logm` cannot be expected to produce one.

**Limitations** For most matrices:

$$\text{logm}(\text{expm}(A)) = A = \text{expm}(\text{logm}(A))$$

These identities may fail for some  $A$ . For example, if the computed eigenvalues of  $A$  include an exact zero, then  $\text{logm}(A)$  generates infinity. Or, if the elements of  $A$  are too large,  $\text{expm}(A)$  may overflow.

**Examples** Suppose  $A$  is the 3-by-3 matrix

$$\begin{bmatrix} 1 & 1 & 0 \\ 0 & 0 & 2 \end{bmatrix}$$

0      0      -1

and  $Y = \text{expm}(A)$  is

Y =  
2.7183      1.7183      1.0862  
0      1.0000      1.2642  
0      0      0.3679

Then  $A = \text{logm}(Y)$  produces the original matrix A.

Y =  
1.0000      1.0000      0.0000  
0      0      2.0000  
0      0      -1.0000

But  $\text{log}(A)$  involves taking the logarithm of zero, and so produces

ans =  
0.0000                      0                      -35.5119  
-Inf                      -Inf                      0.6931  
-Inf                      -Inf                      0.0000 + 3.1416i

## Algorithms

The algorithm `logm` uses is described in [1].

# logspace

---

**Purpose** Generate logarithmically spaced vectors

**Syntax**  
`y = logspace(a,b)`  
`y = logspace(a,b,n)`  
`y = logspace(a,pi)`

**Description** The `logspace` function generates logarithmically spaced vectors. Especially useful for creating frequency vectors, it is a logarithmic equivalent of `linspace` and the “:” or colon operator.

`y = logspace(a,b)` generates a row vector `y` of 50 logarithmically spaced points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,b,n)` generates `n` points between decades  $10^a$  and  $10^b$ .

`y = logspace(a,pi)` generates the points between  $10^a$  and  $\pi$ , which is useful for digital signal processing where frequencies over this interval go around the unit circle.

**Tips** All the arguments to `logspace` must be scalars.

**See Also** `linspace` | colon operator

---

<b>Purpose</b>	Search for keyword in all help entries
<b>Alternatives</b>	As an alternative to the <code>lookfor</code> function, use the Function Browser.
<b>Syntax</b>	<code>lookfor topic</code> <code>lookfor topic -all</code>
<b>Description</b>	<p><code>lookfor topic</code> searches for the string <code>topic</code> in the first comment line (the H1 line) of the help text in all MATLAB program files found on the search path. For all files in which a match occurs, <code>lookfor</code> displays the H1 line.</p> <p><code>lookfor topic -all</code> searches the entire first comment block of a MATLAB program file looking for <code>topic</code>.</p>
<b>Examples</b>	<p>For example:</p> <pre>lookfor inverse</pre> <p>finds at least a dozen matches, including H1 lines containing "inverse hyperbolic cosine," "two-dimensional inverse FFT," and "pseudoinverse." Contrast this with</p> <pre>which inverse</pre> <p>or</p> <pre>what inverse</pre> <p>These functions run more quickly, but probably fail to find anything because MATLAB does not have a function <code>inverse</code>.</p> <p>In summary, <code>what</code> lists the functions in a given folder, <code>which</code> finds the folder containing a given function or file, and <code>lookfor</code> finds all functions in all folders that might have something to do with a given keyword.</p> <p>Even more extensive than the <code>lookfor</code> function are the find features in the Current Folder browser. For example, you can look for all occurrences of a specified word in all the MATLAB program files in</p>

# lookfor

---

the current folder and its subfolders. For more information, see “Find Files and Folders”.

`dir` | `doc` | `filebrowser` | `strfind` | `help` | `regexp` | `what` | `which` | `who`

## How To

- “Find Functions to Use”
- “Search Syntax and Tips”

**Purpose** Convert string to lowercase

**Syntax**  
`t = lower('str')`  
`B = lower(A)`

**Description** `t = lower('str')` returns the string formed by converting any uppercase characters in `str` to the corresponding lowercase characters and leaving all other characters unchanged.

`B = lower(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `lower` to each string within `A`.

**Examples** `lower('MathWorks')` is `mathworks`.

**Tips** Character sets supported:

- PC: Latin-1 for the Microsoft Windows operating system
- Other: ISO Latin-1 (ISO 8859-1)

**See Also** `upper`

# ls

---

**Purpose** List folder contents

**Syntax** `ls`  
`ls name`  
`list = ls(name)`

**Description** `ls` lists the contents of the current folder.

`ls name` lists the files and folders in the current folder that match the specified name. You can use wildcards.

`list = ls(name)` returns the files and folders in the current folder that match the specified **name** to **list**.

**Tips**

- On UNIX platforms, you can add any flags to `ls` that the operating system supports.

**Input Arguments**

**name**  
A string value specifying a file or folder name.

**Output Arguments**

**list**

- On UNIX platforms, **list** is a character row vector of names separated by tab and space characters.
- On Microsoft Windows platforms, **list** is an m-by-n character array of names—**m** is the number of names and **n** is the number of characters in the longest name. MATLAB pads names shorter than **n** characters with space characters.

**Examples** List all the files and folders in the current folder:

```
ls
```

---

List all the files and folders in the current folder that begin with the letter `h`:

```
ls h*
```

---

Return the list of all the files and folders in the current folder to `mylist`:

```
mylist = ls;
```

**Alternatives**

- View files and folders in the Current Folder browser.  
Open the Current Folder browser by issuing the `filebrowser` command.

**See Also**

```
dir | pwd
```

**Purpose** Least-squares solution in presence of known covariance

**Syntax**

```
x = lscov(A,b)
x = lscov(A,b,w)
x = lscov(A,b,V)
x = lscov(A,b,V,alg)
[x,stdx] = lscov(...)
[x,stdx,mse] = lscov(...)
[x,stdx,mse,S] = lscov(...)
```

**Description** `x = lscov(A,b)` returns the ordinary least squares solution to the linear system of equations  $A^*x = b$ , i.e.,  $x$  is the  $n$ -by-1 vector that minimizes the sum of squared errors  $(b - A^*x)'*(b - A^*x)$ , where  $A$  is  $m$ -by- $n$ , and  $b$  is  $m$ -by-1.  $b$  can also be an  $m$ -by- $k$  matrix, and `lscov` returns one solution for each column of  $b$ . When  $\text{rank}(A) < n$ , `lscov` sets the maximum possible number of elements of  $x$  to zero to obtain a "basic solution".

`x = lscov(A,b,w)`, where  $w$  is a vector length  $m$  of real positive weights, returns the weighted least squares solution to the linear system  $A^*x = b$ , that is,  $x$  minimizes  $(b - A^*x)'*diag(w)*(b - A^*x)$ .  $w$  typically contains either counts or inverse variances.

`x = lscov(A,b,V)`, where  $V$  is an  $m$ -by- $m$  real symmetric positive definite matrix, returns the generalized least squares solution to the linear system  $A^*x = b$  with covariance matrix proportional to  $V$ , that is,  $x$  minimizes  $(b - A^*x)'*inv(V)*(b - A^*x)$ .

More generally,  $V$  can be positive semidefinite, and `lscov` returns  $x$  that minimizes  $e'*e$ , subject to  $A^*x + T*e = b$ , where the minimization is over  $x$  and  $e$ , and  $T^*T' = V$ . When  $V$  is semidefinite, this problem has a solution only if  $b$  is consistent with  $A$  and  $V$  (that is,  $b$  is in the column space of  $[A \ T]$ ), otherwise `lscov` returns an error.

By default, `lscov` computes the Cholesky decomposition of  $V$  and, in effect, inverts that factor to transform the problem into ordinary least squares. However, if `lscov` determines that  $V$  is semidefinite, it uses an orthogonal decomposition algorithm that avoids inverting  $V$ .

$x = \text{lscov}(A, b, V, \text{alg})$  specifies the algorithm used to compute  $x$  when  $V$  is a matrix.  $\text{alg}$  can have the following values:

- 'chol' uses the Cholesky decomposition of  $V$ .
- 'orth' uses orthogonal decompositions, and is more appropriate when  $V$  is ill-conditioned or singular, but is computationally more expensive.

$[x, \text{stdx}] = \text{lscov}(\dots)$  returns the estimated standard errors of  $x$ . When  $A$  is rank deficient,  $\text{stdx}$  contains zeros in the elements corresponding to the necessarily zero elements of  $x$ .

$[x, \text{stdx}, \text{mse}] = \text{lscov}(\dots)$  returns the mean squared error. If  $b$  is assumed to have covariance matrix  $\sigma^2 V$  (or  $(\sigma^2) \times \text{diag}(1./W)$ ), then  $\text{mse}$  is an estimate of  $\sigma^2$ .

$[x, \text{stdx}, \text{mse}, S] = \text{lscov}(\dots)$  returns the estimated covariance matrix of  $x$ . When  $A$  is rank deficient,  $S$  contains zeros in the rows and columns corresponding to the necessarily zero elements of  $x$ .  $\text{lscov}$  cannot return  $S$  if it is called with multiple right-hand sides, that is, if  $\text{size}(B, 2) > 1$ .

The standard formulas for these quantities, when  $A$  and  $V$  are full rank, are

- $x = \text{inv}(A' * \text{inv}(V) * A) * A' * \text{inv}(V) * B$
- $\text{mse} = B' * (\text{inv}(V) - \text{inv}(V) * A * \text{inv}(A' * \text{inv}(V) * A) * A' * \text{inv}(V)) * B ./ (m - n)$
- $S = \text{inv}(A' * \text{inv}(V) * A) * \text{mse}$
- $\text{stdx} = \text{sqrt}(\text{diag}(S))$

However,  $\text{lscov}$  uses methods that are faster and more stable, and are applicable to rank deficient cases.

$\text{lscov}$  assumes that the covariance matrix of  $B$  is known only up to a scale factor.  $\text{mse}$  is an estimate of that unknown scale factor, and  $\text{lscov}$  scales the outputs  $S$  and  $\text{stdx}$  appropriately. However, if  $V$  is known to be exactly the covariance matrix of  $B$ , then that scaling is unnecessary.

To get the appropriate estimates in this case, you should rescale  $S$  and  $stdx$  by  $1/mse$  and  $\sqrt{1/mse}$ , respectively.

## Algorithms

The vector  $x$  minimizes the quantity  $(A*x-b)'*inv(V)*(A*x-b)$ . The classical linear algebra solution to this problem is

$$x = inv(A'*inv(V)*A)*A'*inv(V)*b$$

but the `lscov` function instead computes the QR decomposition of  $A$  and then modifies  $Q$  by  $V$ .

## Examples

### Example 1 – Computing Ordinary Least Squares

The MATLAB backslash operator (`\`) enables you to perform linear regression by computing ordinary least-squares (OLS) estimates of the regression coefficients. You can also use `lscov` to compute the same OLS estimates. By using `lscov`, you can also compute estimates of the standard errors for those coefficients, and an estimate of the standard deviation of the regression error term:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';
x2 = [.1 .3 .4 .9 1.1 1.4]';
X = [ones(size(x1)) x1 x2];
y = [.17 .26 .28 .23 .27 .34]';
```

```
a = X\y
a =
 0.1203
 0.3284
 -0.1312
```

```
[b,se_b,mse] = lscov(X,y)
b =
 0.1203
 0.3284
 -0.1312
se_b =
 0.0643
```

```

 0.2267
 0.1488
mse =
 0.0015

```

### Example 2 – Computing Weighted Least Squares

Use `lscov` to compute a weighted least-squares (WLS) fit by providing a vector of relative observation weights. For example, you might want to downweight the influence of an unreliable observation on the fit:

```

w = [1 1 1 1 1 .1]';

[bw,sew_b,msew] = lscov(X,y,w)
bw =
 0.1046
 0.4614
 -0.2621
sew_b =
 0.0309
 0.1152
 0.0814
msew =
 3.4741e-004

```

### Example 3 – Computing General Least Squares

Use `lscov` to compute a general least-squares (GLS) fit by providing an observation covariance matrix. For example, your data may not be independent:

```

V = .2*ones(length(x1)) + .8*diag(ones(size(x1)));

[bg,sew_b,mseg] = lscov(X,y,V)
bg =
 0.1203
 0.3284
 -0.1312
sew_b =

```

```
0.0672
0.2267
0.1488
mse =
0.0019
```

## Example 4 – Estimating the Coefficient Covariance Matrix

Compute an estimate of the coefficient covariance matrix for either OLS, WLS, or GLS fits. The coefficient standard errors are equal to the square roots of the values on the diagonal of this covariance matrix:

```
[b,se_b,mse,S] = lscov(X,y);
```

```
S
S =
 0.0041 -0.0130 0.0075
 -0.0130 0.0514 -0.0328
 0.0075 -0.0328 0.0221
```

```
[se_b sqrt(diag(S))]
ans =
 0.0643 0.0643
 0.2267 0.2267
 0.1488 0.1488
```

## See Also

lsqnonneg | qr

**Purpose** Solve nonnegative least-squares constraints problem

**Equation** Solves nonnegative least-squares curve fitting problems of the form

$$\min_x \|C \cdot x - d\|_2^2, \text{ where } x \geq 0.$$

**Syntax**

```
x = lsqnonneg(C,d)
x = lsqnonneg(C,d,options)
[x,resnorm] = lsqnonneg(...)
[x,resnorm,residual] = lsqnonneg(...)
[x,resnorm,residual,exitflag] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output] = lsqnonneg(...)
[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)
```

**Description**

`x = lsqnonneg(C,d)` returns the vector `x` that minimizes `norm(C*x-d)` subject to `x >= 0`. `C` and `d` must be real.

`x = lsqnonneg(C,d,options)` minimizes with the optimization parameters specified in the structure `options`. You can define these parameters using the `optimset` function. `lsqnonneg` uses these `options` structure fields:

**Display** Level of display. 'off' displays no output; 'final' displays just the final output; 'notify' (default) displays output only if the function does not converge.

**TolX** Termination tolerance on `x`.

`[x,resnorm] = lsqnonneg(...)` returns the value of the squared 2-norm of the residual: `norm(C*x-d)^2`.

`[x,resnorm,residual] = lsqnonneg(...)` returns the residual, `d-C*x`.

`[x,resnorm,residual,exitflag] = lsqnonneg(...)` returns a value `exitflag` that describes the exit condition of `lsqnonneg`:

# lsqnonneg

---

>0            Indicates that the function converged to a solution  $x$ .  
0             Indicates that the iteration count was exceeded.  
              Increasing the tolerance (TolX parameter in options)  
              may lead to a solution.

`[x,resnorm,residual,exitflag,output] = lsqnonneg(...)` returns a structure output that contains information about the operation in the following fields:

algorithm            'active-set'  
iterations            The number of iterations taken  
message              Exit message

`[x,resnorm,residual,exitflag,output,lambda] = lsqnonneg(...)` returns the dual vector (Lagrange multipliers) `lambda`, where `lambda(i) <= 0` when `x(i)` is (approximately) 0, and `lambda(i)` is (approximately) 0 when `x(i) > 0`.

## Examples

Compare the unconstrained least squares solution to the `lsqnonneg` solution for a 4-by-2 problem:

```
C = [
 0.0372 0.2869
 0.6861 0.7071
 0.6233 0.6245
 0.6344 0.6170];
d = [
 0.8587
 0.1781
 0.0747
 0.8405];
[C\d lsqnonneg(C,d)] =
 -2.5627 0
 3.1108 0.6929
[norm(C*(C\d) - d) norm(C*lsqnonneg(C,d) - d)] =
 0.6674 0.9118
```

The solution from `lsqnonneg` does not fit as well (has a larger residual), as the least squares solution. However, the nonnegative least squares solution has no negative components.

## Algorithms

`lsqnonneg` uses the algorithm described in [1]. The algorithm starts with a set of possible basis vectors and computes the associated dual vector `lambda`. It then selects the basis vector corresponding to the maximum value in `lambda` in order to swap out of the basis in exchange for another possible candidate. This continues until `lambda <= 0`.

`optimset`

# lsqr

---

## Purpose

LSQR method

## Syntax

```
x = lsqr(A,b)
lsqr(A,b,tol)
lsqr(A,b,tol,maxit)
lsqr(A,b,tol,maxit,M)
lsqr(A,b,tol,maxit,M1,M2)
lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)
```

## Description

`x = lsqr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$  if  $A$  is consistent, otherwise it attempts to solve the least squares solution  $x$  that minimizes  $\text{norm}(b-A*x)$ . The  $m$ -by- $n$  coefficient matrix  $A$  need not be square but it should be large and sparse. The column vector  $b$  must have length  $m$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A'*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `lsqr` converges, a message to that effect is displayed. If `lsqr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`lsqr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `lsqr` uses the default,  $1e-6$ .

`lsqr(A,b,tol,maxit)` specifies the maximum number of iterations.

`lsqr(A,b,tol,maxit,M)` and `lsqr(A,b,tol,maxit,M1,M2)` use  $n$ -by- $n$  preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system

$A \cdot \text{inv}(M) \cdot y = b$  for  $y$ , where  $y = M \cdot x$ . If  $M$  is `[]` then `lsqr` applies no preconditioner.  $M$  can be a function `mfun` such that `mfun(x, 'notransp')` returns  $M \setminus x$  and `mfun(x, 'transp')` returns  $M' \setminus x$ .

`lsqr(A,b,tol,maxit,M1,M2,x0)` specifies the  $n$ -by-1 initial guess. If `x0` is `[]`, then `lsqr` uses the default, an all zero vector.

`[x,flag] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a convergence flag.

Flag	Convergence
0	<code>lsqr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>lsqr</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	<code>lsqr</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>lsqr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if you specify the `flag` output.

`[x,flag,relres] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns an estimate of the relative residual norm  $\|b - A \cdot x\| / \|b\|$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of the residual norm estimates at each iteration, including  $\|b - A \cdot x_0\|$ .

`[x,flag,relres,iter,resvec,lsvec] = lsqr(A,b,tol,maxit,M1,M2,x0)` also returns a vector of estimates of the scaled normal equations residual at each iteration:

$\text{norm}((A \cdot \text{inv}(M))' * (B - A \cdot X)) / \text{norm}(A \cdot \text{inv}(M), 'fro')$ . Note that the estimate of  $\text{norm}(A \cdot \text{inv}(M), 'fro')$  changes, and hopefully improves, at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);

x = lsqr(A,b,tol,maxit,M1,M2);
```

displays the following message:

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

### Example 2

This example replaces the matrix  $A$  in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in a function `run_lsqr` that

- Calls `lsqr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_lsqr` are available to `afun`.

The following shows the code for `run_lsqr`:

```
function x1 = run_lsqr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
```

```

tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = lsqr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp') % y = A'*x
 y = 4 * x;
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
 elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
 end
end
end

```

When you enter

```
x1=run_lsqr;
```

MATLAB software displays the message

```
lsqr converged at iteration 11 to a solution with relative
residual 3.5e-009
```

**Purpose** Determine less than

**Syntax** A < B  
lt(A,B)

**Description** A < B returns an array with elements set to logical 1 (true) where A is less than B; otherwise, it returns logical 0 (false). The test compares only the real part of numeric arrays. lt returns logical 0 (false) where A or B have NaN or undefined categorical elements.

lt(A,B) is an alternate way to execute A < B, but is rarely used. It enables operator overloading for classes.

**Input Arguments**

**A - Left array**  
numeric array | logical array | character array | ordinal categorical array

Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

**B - Right array**  
numeric array | logical array | character array | ordinal categorical array

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is an ordinal categorical array, the other input can be an ordinal categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. See “Compare Categorical Array Elements” for more details.

## Examples

### Test Vector Elements

Determine if vector elements are less than a given value.

Create a numeric vector.

```
A = [1 12 18 7 9 11 2 15];
```

Test the vector for elements that are less than 12.

```
A < 12
```

```
ans =
```

```
 1 0 0 1 1 1 1 0
```

The result is a vector with values of logical 1 (true) where the elements of A satisfy the expression.

Use the vector of logical values as an index to view the values in A that are less than 12.

```
A(A < 12)
```

```
ans =
```

```
 1 7 9 11 2
```

The result is a subset of the elements in A.

## Replace Elements of Matrix

Create a matrix.

```
A = magic(4)
```

```
A =
```

```
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

Replace all values less than 9 with the value 10.

```
A(A < 9) = 10
```

```
A =
```

```
 16 10 10 13
 10 11 10 10
 9 10 10 12
 10 14 15 10
```

The result is a new matrix whose smallest element is 9.

## Compare Values in Categorical Array

Create an ordinal categorical array.

```
A = categorical({'large' 'medium' 'small'; 'medium' ...
 'small' 'large'},{'small' 'medium' 'large'},'Ordinal',1)
```

```
A =
```

```
 large medium small
 medium small large
```

The array has three categories: 'small', 'medium', and 'large'.

Find all values less than the category 'medium'.

```
A < 'medium'
```

```
ans =
```

```
 0 0 1
 0 1 0
```

A value of logical 1 (true) indicates a value less than the category 'medium'.

Compare the rows of A.

```
A(1,:) < A(2,:)
```

```
ans =
```

```
 0 0 1
```

The function returns logical 1 (true) where the first row has a category value less than the second row.

### Test Complex Numbers

Create a vector of complex numbers.

```
A = [1+i 2-2i 1+3i 1-2i 5-i];
```

Find the values that are less than 3.

```
A(A < 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 + 3.0000i 1.0000 - 2.0000i
```

It compares only the real part of the elements in A.

Use `abs` to find which elements are within a radius of 3 from the origin.

```
A(abs(A) < 3)
```

```
ans =
```

```
1.0000 + 1.0000i 2.0000 - 2.0000i 1.0000 - 2.0000i
```

The result has one less element. The element  $1.0000 + 3.0000i$  is not within a radius of 3 from the origin.

## Concepts

- “Ordinal Categorical Arrays”

**Purpose**

LU matrix factorization

**Syntax**

```
Y = lu(A)
[L,U] = lu(A)
[L,U,P] = lu(A)
[L,U,P,Q] = lu(A)
[L,U,P,Q,R] = lu(A)
[...] = lu(A,'vector')
[...] = lu(A,thresh)
[...] = lu(A,thresh,'vector')
```

**Description**

The `lu` function expresses a matrix  $A$  as the product of two essentially triangular matrices, one of them a permutation of a lower triangular matrix and the other an upper triangular matrix. The factorization is often called the  $LU$ , or sometimes the  $LR$ , factorization.  $A$  can be rectangular.

`Y = lu(A)` returns matrix  $Y$  that, for sparse  $A$ , contains the strictly lower triangular  $L$ , i.e., without its unit diagonal, and the upper triangular  $U$  as submatrices. That is, if `[L,U,P] = lu(A)`, then  $Y = U+L - \text{eye}(\text{size}(A))$ . For nonsparse  $A$ ,  $Y$  is the output from the LAPACK `dgetrf` or `zgetrf` routine. The permutation matrix  $P$  is not returned.

`[L,U] = lu(A)` returns an upper triangular matrix in  $U$  and a permuted lower triangular matrix in  $L$  such that  $A = L*U$ . Return value  $L$  is a product of lower triangular and permutation matrices.

`[L,U,P] = lu(A)` returns an upper triangular matrix in  $U$ , a lower triangular matrix  $L$  with a unit diagonal, and a permutation matrix  $P$ , such that  $L*U = P*A$ . The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q] = lu(A)` for sparse nonempty  $A$ , returns a unit lower triangular matrix  $L$ , an upper triangular matrix  $U$ , a row permutation matrix  $P$ , and a column reordering matrix  $Q$ , so that  $P*A*Q = L*U$ . If  $A$  is empty or not sparse, `lu` displays an error message. The statement `lu(A,'matrix')` returns identical output values.

`[L,U,P,Q,R] = lu(A)` returns unit lower triangular matrix L, upper triangular matrix U, permutation matrices P and Q, and a diagonal scaling matrix R so that  $P*(R\backslash A)*Q = L*U$  for sparse non-empty A. Typically, but not always, the row-scaling leads to a sparser and more stable factorization. The statement `lu(A, 'matrix')` returns identical output values.

`[...] = lu(A, 'vector')` returns the permutation information in two row vectors p and q. You can specify from 1 to 5 outputs. Output p is defined as  $A(p,:) = L*U$ , output q is defined as  $A(p,q) = L*U$ , and output R is defined as  $R(:,p)\backslash A(:,q) = L*U$ .

`[...] = lu(A,thresh)` controls pivoting. This syntax applies to sparse matrices only. The `thresh` input is a one- or two-element vector of type `single` or `double` that defaults to `[0.1, 0.001]`. If A is a square matrix with a mostly symmetric structure and mostly nonzero diagonal, MATLAB uses a symmetric pivoting strategy. For this strategy, the diagonal where

$$A(i,j) \geq \text{thresh}(2) * \max(\text{abs}(A(j:m,j)))$$

is selected. If the diagonal entry fails this test, a pivot entry below the diagonal is selected, using `thresh(1)`. In this case, L has entries with absolute value  $1/\min(\text{thresh})$  or less.

If A is not as described above, MATLAB uses an asymmetric strategy. In this case, the sparsest row i where

$$A(i,j) \geq \text{thresh}(1) * \max(\text{abs}(A(j:m,j)))$$

is selected. A value of 1.0 results in conventional partial pivoting. Entries in L have an absolute value of  $1/\text{thresh}(1)$  or less. The second element of the `thresh` input vector is not used when MATLAB uses an asymmetric strategy.

Smaller values of `thresh(1)` and `thresh(2)` tend to lead to sparser LU factors, but the solution can become inaccurate. Larger values can lead to a more accurate solution (but not always), and usually an increase in the total work and memory usage. The statement `lu(A,thresh, 'matrix')` returns identical output values.

[...] = lu(A,thresh,'vector') controls the pivoting strategy and also returns the permutation information in row vectors, as described above. The thresh input must precede 'vector' in the input argument list.

---

**Note** In rare instances, incorrect factorization results in  $P*A*Q \neq L*U$ . Increase thresh, to a maximum of 1.0 (regular partial pivoting), and try again.

---

## Tips

Most of the algorithms for computing LU factorization are variants of Gaussian elimination. The factorization is a key step in obtaining the inverse with inv and the determinant with det. It is also the basis for the linear equation solution or matrix division obtained with \ and /.

## Arguments

A	Rectangular matrix to be factored.
thresh	Pivot threshold for sparse matrices. Valid values are in the interval [0, 1]. If you specify the fourth output Q, the default is 0.1. Otherwise, the default is 1.0.
L	Factor of A. Depending on the form of the function, L is either a unit lower triangular matrix, or else the product of a unit lower triangular matrix with P'.
U	Upper triangular matrix that is a factor of A.
P	Row permutation matrix satisfying the equation $L*U = P*A$ , or $L*U = P*A*Q$ . Used for numerical stability.
Q	Column permutation matrix satisfying the equation $P*A*Q = L*U$ . Used to reduce fill-in in the sparse case.
R	Row-scaling matrix

**Examples****Example 1**

Start with

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 0 \end{bmatrix};$$

To see the LU factorization, call `lu` with two output arguments.

$$[L1,U] = \text{lu}(A)$$

L1 =

$$\begin{bmatrix} 0.1429 & 1.0000 & 0 \\ 0.5714 & 0.5000 & 1.0000 \\ 1.0000 & 0 & 0 \end{bmatrix}$$

U =

$$\begin{bmatrix} 7.0000 & 8.0000 & 0 \\ 0 & 0.8571 & 3.0000 \\ 0 & 0 & 4.5000 \end{bmatrix}$$

Notice that L1 is a permutation of a lower triangular matrix: if you switch rows 2 and 3, and then switch rows 1 and 2, the resulting matrix is lower triangular and has 1s on the diagonal. Notice also that U is upper triangular. To check that the factorization does its job, compute the product

`L1*U`

which returns the original A. The inverse of the example matrix,  $X = \text{inv}(A)$ , is actually computed from the inverses of the triangular factors

$$X = \text{inv}(U) * \text{inv}(L1)$$

Using three arguments on the left side to get the permutation matrix as well,

$$[L2,U,P] = \text{lu}(A)$$

returns a truly lower triangular L2, the same value of U, and the permutation matrix P.

L2 =

1.0000	0	0
0.1429	1.0000	0
0.5714	0.5000	1.0000

U =

7.0000	8.0000	0
0	0.8571	3.0000
0	0	4.5000

P =

0	0	1
1	0	0
0	1	0

Note that  $L2 = P*L1$ .

P\*L1

ans =

1.0000	0	0
0.1429	1.0000	0
0.5714	0.5000	1.0000

To verify that  $L2*U$  is a permuted version of A, compute  $L2*U$  and subtract it from  $P*A$ :

$P*A - L2*U$

ans =

0	0	0
0	0	0
0	0	0

In this case,  $\text{inv}(U) * \text{inv}(L)$  results in the permutation of  $\text{inv}(A)$  given by  $\text{inv}(P) * \text{inv}(A)$ .

The determinant of the example matrix is

$$d = \det(A)$$

$$d = 27$$

It is computed from the determinants of the triangular factors

$$d = \det(L) * \det(U)$$

The solution to  $Ax = b$  is obtained with matrix division

$$x = A \backslash b$$

The solution is actually computed by solving two triangular systems

$$y = L \backslash b$$

$$x = U \backslash y$$

### **Example 2**

The 1-norm of their difference is within roundoff error, indicating that  $L*U = P*B*Q$ .

Generate a 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster-Fuller geodesic dome.

$$B = \text{bucky};$$

Use the sparse matrix syntax with four outputs to get the row and column permutation matrices.

$$[L,U,P,Q] = \text{lu}(B);$$

Apply the permutation matrices to B, and subtract the product of the lower and upper triangular matrices.

$$Z = P*B*Q - L*U;$$

```
norm(Z,1)

ans =
 7.9936e-015
```

### Example 3

This example illustrates the benefits of using the 'vector' option. Note how much memory is saved by using the `lu(F, 'vector')` syntax.

```
F = gallery('uniformdata',[1000 1000],0);
g = sum(F,2);
[L,U,P] = lu(F);
[L,U,p] = lu(F,'vector');
whos P p
```

Name	Size	Bytes	Class	Attributes
P	1000x1000	8000000	double	
p	1x1000	8000	double	

The following two statements are equivalent. The first typically requires less time:

```
x = U \ (L \ (g(p, :)));
y = U \ (L \ (P * g));
```

# magic

---

**Purpose** Magic square

**Syntax** `M = magic(n)`

**Description** `M = magic(n)` returns an  $n$ -by- $n$  matrix constructed from the integers 1 through  $n^2$  with equal row and column sums. The order  $n$  must be a scalar greater than or equal to 3.

**Tips** A magic square, scaled by its magic sum, is doubly stochastic.

**Examples** The magic square of order 3 is

```
M = magic(3)
```

```
M =
```

```
 8 1 6
 3 5 7
 4 9 2
```

This is called a magic square because the sum of the elements in each column is the same.

```
sum(M) =
```

```
 15 15 15
```

And the sum of the elements in each row, obtained by transposing twice, is the same.

```
sum(M')' =
```

```
 15
 15
 15
```

This is also a special magic square because the diagonal elements have the same sum.

```
sum(diag(M)) =
```

```
15
```

The value of the characteristic sum for a magic square of order  $n$  is

```
sum(1:n^2)/n
```

which, when  $n = 3$ , is 15.

## Algorithms

There are three different algorithms:

- $n$  odd
- $n$  even but not divisible by four
- $n$  divisible by four

To make this apparent, type

```
for n = 3:20
 A = magic(n);
 r(n) = rank(A);
end
```

For  $n$  odd, the rank of the magic square is  $n$ . For  $n$  divisible by 4, the rank is 3. For  $n$  even but not divisible by 4, the rank is  $n/2 + 2$ .

```
[(3:20)', r(3:20)']
```

```
ans =
 3 3
 4 3
 5 5
 6 5
 7 7
 8 3
 9 9
 10 7
 11 11
 12 3
```

# magic

---

13	13
14	9
15	15
16	3
17	17
18	11
19	19
20	3

Plotting  $A$  for  $n = 18, 19, 20$  shows the characteristic plot for each category.

## Limitations

If you supply  $n$  less than 3, `magic` returns either a nonmagic square, or else the degenerate magic squares `1` and `[]`.

## See Also

`ones` | `rand`

**Purpose** Create 4-by-4 transform matrix

**Syntax**

```
M = makehgtform
M = makehgtform('translate',[tx ty tz])
M = makehgtform('scale',s)
M = makehgtform('scale',[sx,sy,sz])
M = makehgtform('xrotate',t)
M = makehgtform('yrotate',t)
M = makehgtform('zrotate',t)
M = makehgtform('axisrotate',[ax,ay,az],t)
```

**Description** Use `makehgtform` to create transform matrices for translation, scaling, and rotation of graphics objects. Apply the transform to graphics objects by assigning the transform to the `Matrix` property of a parent `hgtransform` object. See [Examples](#) for more information.

`M = makehgtform` returns an identity transform.

`M = makehgtform('translate',[tx ty tz])` or `M = makehgtform('translate',tx,ty,tz)` returns a transform that translates along the *x*-axis by `tx`, along the *y*-axis by `ty`, and along the *z*-axis by `tz`.

`M = makehgtform('scale',s)` returns a transform that scales uniformly along the *x*-, *y*-, and *z*-axes.

`M = makehgtform('scale',[sx,sy,sz])` returns a transform that scales along the *x*-axis by `sx`, along the *y*-axis by `sy`, and along the *z*-axis by `sz`.

`M = makehgtform('xrotate',t)` returns a transform that rotates around the *x*-axis by `t` radians.

`M = makehgtform('yrotate',t)` returns a transform that rotates around the *y*-axis by `t` radians.

`M = makehgtform('zrotate',t)` returns a transform that rotates around the *z*-axis by `t` radians.

`M = makehgtform('axisrotate',[ax,ay,az],t)` Rotate around axis [`ax ay az`] by `t` radians.

# makehgtform

---

Note that you can specify multiple operations in one call to `makehgtform` and the MATLAB software returns a transform matrix that is the result of concatenating all specified operations. For example,

```
m = makehgtform('xrotate',pi/2,'yrotate',pi/2);
```

is the same as

```
mx = makehgtform('xrotate',pi/2);
my = makehgtform('yrotate',pi/2);
m = mx*my;
```

## How To

- “Group Objects”

<b>Purpose</b>	Map values to unique keys
<b>Description</b>	A Map object is a data structure that allows you to retrieve values using a corresponding key. Keys can be real numbers or text strings and provide more flexibility for data access than array indices, which must be positive integers. Values can be scalar or nonscalar arrays.
<b>Construction</b>	<p><code>mapObj = containers.Map</code> constructs an empty Map container <code>mapObj</code>.</p> <p><code>mapObj = containers.Map(keySet,valueSet)</code> constructs a Map that contains one or more values and a unique key for each value.</p> <p><code>mapObj = containers.Map(keySet,valueSet,'UniformValues',isUniform)</code> specifies whether all values must be uniform (either all scalars of the same data type, or all strings). Possible values for <code>isUniform</code> are logical true (1) or false (0).</p> <p><code>mapObj = containers.Map('KeyType',kType,'ValueType',vType)</code> constructs an empty Map object and sets the <code>KeyType</code> and <code>ValueType</code> properties. The order of the key type and value type argument pairs is not important, but both pairs are required.</p>

## Input Arguments

### **keySet**

1-by-n array that specifies n unique keys for the map.

All keys in a Map object are real numeric values or all keys are strings. If  $n > 1$  and the keys are strings, `keySet` must be a cell array. The number of keys in `keySet` must equal the number of values in `valueSet`.

### **valueSet**

1-by-n array of any class that specifies n values for the map. The number of values in `valueSet` must equal the number of keys in `keySet`.

### **'UniformValues'**

# containers.Map

---

Parameter string to use with the `isUniform` argument.

## **isUniform**

Logical value that specifies whether all values are uniform. If `isUniform` is `true` (1), all values must be scalars of the same data type, or all values must be strings. If `isUniform` is `false` (0), then `containers.Map` sets the `ValueType` to `'any'`.

**Default:** `true` for empty `Map` objects, otherwise determined by the data types of values in `valueSet`.

## **'KeyType'**

Parameter string to use with the `kType` argument.

## **kType**

String that specifies the data type for the keys. Possible values are `'char'`, `'double'`, `'single'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'char'` for empty `Map` objects, otherwise determined by the data types of keys in `keySet`. If you specify keys of different numeric types, `kType` is `'double'`.

## **'ValueType'**

Literal string parameter to use with the `vType` argument.

## **vType**

String that specifies the data type for the values. Possible values are `'any'`, `'char'`, `'logical'`, `'double'`, `'single'`, `'int8'`, `'uint8'`, `'int16'`, `'uint16'`, `'int32'`, `'uint32'`, `'int64'`, or `'uint64'`.

**Default:** `'any'` when you create an empty `Map` object or when you specify values of different sizes or types, otherwise determined by the data type of `valueSet`.

## Properties

### Count

Unsigned 64-bit integer that represents the total number of key-value pairs contained in the `Map` object. Read only.

### KeyType

Character array that indicates the data type of all keys in the `Map` object. The default `KeyType` for empty `Map` objects is `'char'`. Otherwise, `KeyType` is determined from the data type of the `keySet` inputs. Read only.

### ValueType

Character array that indicates the data type of all values in the `Map` object. If you construct an empty `Map` object or specify values with different data types, then the value of `ValueType` is `'any'`. Otherwise, `ValueType` is determined from the data type of the `valueSet` inputs. Read only.

## Methods

<code>isKey</code>	Determine if <code>containers.Map</code> object contains key
<code>keys</code>	Identify keys of <code>containers.Map</code> object
<code>length</code>	Length of <code>containers.Map</code> object
<code>remove</code>	Remove key-value pairs from <code>containers.Map</code> object
<code>size</code>	Size of <code>containers.Map</code> object
<code>values</code>	Identify values in <code>containers.Map</code> object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

# containers.Map

---

## Examples

### Construct a Map and View Properties

Construct a Map object that contains rainfall data for several months:

```
keySet = {'Jan', 'Feb', 'Mar', 'Apr'};
valueSet = [327.2, 368.2, 197.6, 178.4];
mapObj = containers.Map(keySet,valueSet)
```

This code returns a description of the map, including the property values:

```
mapObj =

 containers.Map handle
 Package: containers

 Properties:
 Count: 4
 KeyType: 'char'
 ValueType: 'double'

 Methods, Events, Superclasses
```

Get a specific property using dot notation, such as

```
mapObj.Count
```

which returns

```
ans =

 4
```

### Look Up Values in a Map

Use the map created in the previous example to find the rainfall data for February:

```
rainFeb = mapObj('Feb')
```

This code returns

```
rainFeb =
 368.2000
```

## Add a Single Value and Key to a Map

Add data for the month of May to the map created in the first example:

```
mapObj('May') = 100.0;
```

## Add Multiple Values and Keys by Concatenating Maps

Create a map that contains rainfall data for June, July, and August, and add the data to `mapObj` (from previous examples):

```
keySet = {'Jun', 'Jul', 'Aug'};
valueSet = [69.9, 32.3, 37.3];
newMap = containers.Map(keySet,valueSet);
```

```
mapObj = [mapObj; newMap];
```

Map objects only support vertical concatenation (that is, adding columns with a semicolon, `;`). When concatenating maps, the data type of all values must be consistent with the `ValueType` of the leftmost map. In this example, both maps have the a `ValueType` of `double`.

## Get the Keys or Values in a Map

Determine all the keys of `mapObj` (from previous examples) by calling the `keys` method:

```
allKeys = keys(mapObj)
```

This method returns the keys in alphabetical order:

```
allKeys =
 'Apr' 'Aug' 'Feb' 'Jan' 'Jul' 'Jun' 'Mar' 'M
```

Get multiple values from the map by calling the `values` method. Like the `keys` method, you can request all values with the syntax `values(mapObj)`. Alternatively, request values for specific keys. For example, view the values for March, April, and May in `mapObj`:

# containers.Map

---

```
springValues = values(mapObj, {'Mar', 'Apr', 'May'})
```

This method returns the values in a cell array, in the order corresponding to the specified keys:

```
springValues =
 [197.6000] [178.4000] [100]
```

## Remove Keys and Values

Remove the data for March and April from mapObj (from previous examples) by calling the remove method, and view the remaining keys:

```
remove(mapObj, {'Mar', 'Apr'});
keys(mapObj)
```

This code returns

```
ans =
 'Aug' 'Feb' 'Jan' 'Jul' 'Jun' 'May'
```

## Create a Map with Nonscalar Values

Map integer keys to nonscalar arrays, and view the value for one of the keys:

```
keySet = [5,10,15];
valueSet = {magic(5),magic(10),magic(15)};
mapObj = containers.Map(keySet,valueSet);
mapObj(5)
```

This code returns

```
ans =
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

## Construct an Empty Map

Construct a map with no values, but set the `KeyType` and `ValueType` properties:

```
mapObj = containers.Map('KeyType','char','ValueType','int32')
```

This code returns

```
mapObj =

 containers.Map handle
 Package: containers

 Properties:
 Count: 0
 KeyType: 'char'
 ValueType: 'int32'
```

Methods, Events, Superclasses

## Specify Whether Values Are Uniform

Construct a map with numeric values, and specify that the values do not have to be uniform:

```
keySet = {'a','b','c'};
valueSet = {1,2,3};
mapObj = containers.Map(keySet,valueSet,'UniformValues',false);
```

This map allows nonnumeric values, so

```
mapObj('d') = 'OK';
values(mapObj)
```

returns

```
ans =
 [1] [2] [3] 'OK'
```

# containers.Map

---

## See Also

keys | isKey | values

**Purpose** Convert array to cell array with potentially different sized cells

**Syntax**

```
C = mat2cell(A,dim1Dist,...,dimNDist)
C = mat2cell(A,rowDist)
```

**Description** `C = mat2cell(A,dim1Dist,...,dimNDist)` divides array `A` into smaller arrays within cell array `C`. Vectors `dim1Dist,...,dimNDist` specify how to divide the rows, columns, and (when applicable) higher dimensions of `A`.

`C = mat2cell(A,rowDist)` divides array `A` into an `n`-by-1 cell array `C`, where `n == numel(rowDist)`.

**Input Arguments**

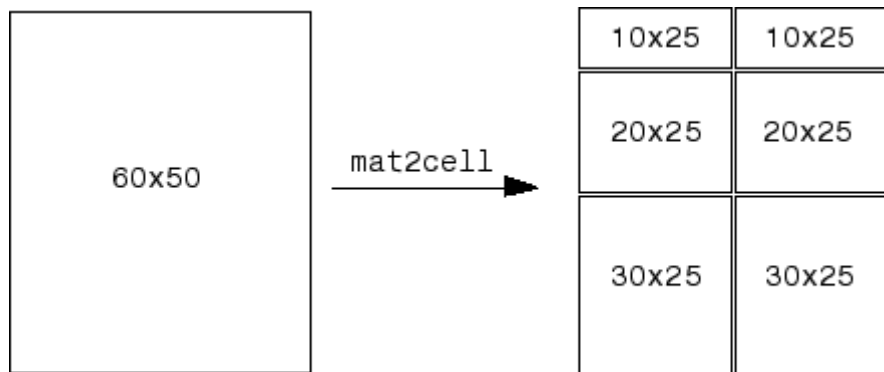

**A**  
Any type of array.

**dim1Dist,...,dimNDist**

Numeric vectors that describe how to divide each dimension of `A`. For example, this command

```
c = mat2cell(x, [10, 20, 30], [25, 25])
```

divides a 60-by-50 array into six arrays contained in a cell array.

# mat2cell

---

For the  $k$ th dimension, `sum(dimkDist) == size(A, k)`.

If the  $k$ th dimension of  $A$  is zero, set the corresponding `dimkDist` to the empty array, `[]`. For example,

```
a = rand(3, 0, 4);
c = mat2cell(a, [1, 2], [], [2, 1, 1]);
```

## rowDist

Numeric vector that describes how to divide the rows of  $A$ . When you do not specify distributions for any other dimension, the `mat2cell` function creates an  $n$ -by-1 cell array  $C$ , where  $n == \text{numel}(\text{rowDist})$ .

## Output Arguments

### C

Cell array. The  $k$ th dimension of array  $C$  is given by `size(C, k) == numel(dimkDist)`. The  $k$ th dimension of the  $i$ th cell of  $C$  is given by `size(C{i}, k) == dimkDist(i)`.

## Examples

Divide the 5-by-4 matrix  $X$  into 2-by-3 and 2-by-2 matrices contained in a cell array.

```
X = reshape(1:20,5,4)'
C = mat2cell(X, [2 2], [3 2])
celldisp(C)
```

This code returns

```
X =
 1 2 3 4 5
 6 7 8 9 10
 11 12 13 14 15
 16 17 18 19 20
```

```
C =
 [2x3 double] [2x2 double]
 [2x3 double] [2x2 double]
```

```

C{1,1} =
 1 2 3
 6 7 8

C{2,1} =
 11 12 13
 16 17 18

C{1,2} =
 4 5
 9 10

C{2,2} =
 14 15
 19 20

```

---

Divide X (created in the previous example) into a 2-by-1 cell array.

```

C = mat2cell(X, [1 3])
celldisp(C)

```

This code returns

```

C =
 [1x5 double]
 [3x5 double]

C{1} =
 1 2 3 4 5

C{2} =
 6 7 8 9 10
 11 12 13 14 15
 16 17 18 19 20

```

## See Also

[cell2mat](#) | [num2cell](#)

# mat2str

---

**Purpose** Convert matrix to string

**Syntax**

```
str = mat2str(A)
str = mat2str(A,n)
str = mat2str(A, 'class')
str = mat2str(A, n, 'class')
```

**Description**

`str = mat2str(A)` converts matrix `A` into a string. This string is suitable for input to the `eval` function such that `eval(str)` produces the original matrix to within 15 digits of precision.

`str = mat2str(A,n)` converts matrix `A` using `n` digits of precision.

`str = mat2str(A, 'class')` creates a string with the name of the class of `A` included. This option ensures that the result of evaluating `str` will also contain the class information.

`str = mat2str(A, n, 'class')` uses `n` digits of precision and includes the class information.

**Limitations** The `mat2str` function is intended to operate on scalar, vector, or rectangular array inputs only. An error will result if `A` is a multidimensional array.

## Examples

### Example 1

Consider the matrix

```
x = [3.85 2.91; 7.74 8.99]
x =
 3.8500 2.9100
 7.7400 8.9900
```

The statement

```
A = mat2str(x)
```

produces

```
A =
 [3.85 2.91;7.74 8.99]
```

where A is a string of 21 characters, including the square brackets, spaces, and a semicolon.

`eval(mat2str(x))` reproduces x.

## Example 2

Create a 1-by-6 matrix of signed 16-bit integers, and then use `mat2str` to convert the matrix to a 1-by-33 character array, A. Note that output string A includes the class name, `int16`:

```
x1 = int16([-300 407 213 418 32 -125]);
```

```
A = mat2str(x1, 'class')
```

```
A =
 int16([-300 407 213 418 32 -125])
```

```
class(A)
```

```
ans =
 char
```

Evaluating the string A gives you an output x2 that is the same as the original `int16` matrix:

```
x2 = eval(A);
```

```
if isnumeric(x2) && isa(x2, 'int16') && all(x2 == x1)
 disp 'Conversion back to int16 worked'
end
```

```
Conversion back to int16 worked
```

## See Also

# material

---

**Purpose** Control reflectance properties of surfaces and patches

**Syntax**

```
material shiny
material dull
material metal
material([ka kd ks])
material([ka kd ks n])
material([ka kd ks n sc])
material default
```

**Description** `material` sets the lighting characteristics of surface and patch objects.

`material shiny` sets the reflectance properties so that the object has a high specular reflectance relative to the diffuse and ambient light, and the color of the specular light depends only on the color of the light source.

`material dull` sets the reflectance properties so that the object reflects more diffuse light and has no specular highlights, but the color of the reflected light depends only on the light source.

`material metal` sets the reflectance properties so that the object has a very high specular reflectance, very low ambient and diffuse reflectance, and the color of the reflected light depends on both the color of the light source and the color of the object.

`material([ka kd ks])` sets the ambient/diffuse/specular strength of the objects.

`material([ka kd ks n])` sets the ambient/diffuse/specular strength and specular exponent of the objects.

`material([ka kd ks n sc])` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects.

`material default` sets the ambient/diffuse/specular strength, specular exponent, and specular color reflectance of the objects to their defaults.

## Tips

The `material` command sets the `AmbientStrength`, `DiffuseStrength`, `SpecularStrength`, `SpecularExponent`, and `SpecularColorReflectance` properties of all surface and patch objects in the axes. There must be visible `light` objects in the axes for lighting to be enabled. Look at the `material.m` file to see the actual values set (enter the command `type material`).

## See Also

`light` | `lighting` | `patch` | `surface`

## How To

- “Lighting Overview”

# matfile

---

**Purpose** Access and change variables directly in MAT-files, without loading into memory

**Syntax**  
`m = matfile(filename)`  
`m = matfile(filename, 'Writable', isWritable)`

**Description** `m = matfile(filename)` creates a MAT-file object, `m`, connected to the MAT-file named `filename`. The object allows you to access and change variables directly in a MAT-file, without having to load the variables into memory.

The partial loading and saving that the `matfile` function provides requires less memory than the `load` and `save` commands, which always operate on entire variables.

`m = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file.

## Input Arguments

### **filename - Name of MAT-file**

string

Name of a MAT-file, specified as a string. If the file is not in the current folder, `filename` must include a full or a relative path. If `filename` does not include an extension, then `matfile` appends `.mat`.

If the file does not exist, then `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports efficient partial loading and saving for MAT-files in Version 7.3 format. If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

**Example:** `'myFile.mat'`

### **Data Types**

char

### **isWritable - Write access to MAT-file**

true | false

Write access to the MAT-file, specified as either `true` or `false`.

- `true` enables saving to the MAT-file. If the file is read only, MATLAB changes the system permissions with the `fileattrib` function.
- `false` disables saving to the MAT-file. MATLAB does not change the system permissions.

The default value is `true` for new files, and `false` for existing files.

### Data Types

logical

## Output Arguments

### **m** - MAT-file object

`matlab.io.MatFile` object

MAT-file object connected to a MAT-file.

Access variables in the MAT-file with dot notation similar to accessing fields of structure arrays:

- To load part of variable `varName` from the MAT-file corresponding to `m`, call:

```
loadedData = m.varName(indices);
```

- To save part of variable `varName` to the MAT-file corresponding to `m`, call:

```
m.varName(indices) = dataToSave;
```

When accessing variables, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (`:`); for example:

```
m.varName(100:500,200:600)
```

```
m.varName(:,501:1000)
```

```
m.varName(1:2:1000,80)
```

## Examples

### Load Entire Variable

Load variable `topo` from the example file, `topography.mat`.

Open the example MAT-file, `topography.mat`.

```
filename = 'topography.mat';
m = matfile(filename);
```

Read the variable `topo` from the MAT-file.

```
topo = m.topo;
```

MATLAB loads the entire variable, `topo`, into the workspace.

### Save Entire Variable to Existing MAT-file

Generate a 20-by-20 example array, `x`, and save it to a MAT-file called `myFile.mat`.

```
x = magic(20);
save('myFile.mat', 'x');
```

Create a MAT-file object connected to the existing MAT-file named `myFile.mat`. Enable write access to the MAT-file by setting `Writable` to `true`.

```
m = matfile('myFile.mat', 'Writable', true);
```

Generate a 15-by-15 example array, `y`.

```
y = magic(15);
```

Save `y` to the MAT-file. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y = y;
```

MATLAB adds a variable named `y` to the file.

Display all variables stored in the MAT-file, `myFile.mat`.

```
whos('-file','myFile.mat')
```

Name	Size	Bytes	Class	Attributes
x	20x20	3200	double	
y	15x15	1800	double	

### Load and Save Parts of Variables

Access specific elements of a MAT-file variable.

Open a new MAT-file, myFile2.mat.

```
m = matfile('myFile2.mat');
```

Save a 20-by-20 example array to part of a variable, y, in myFile2.mat. Specify the variable in the MAT-file using dot notation similar to accessing fields of structure arrays.

```
m.y(81:100,81:100) = magic(20);
```

MATLAB inserts the 20-by-20 array into the elements of y specified by the indices (81:100,81:100).

Read a subset of array y into a new workspace variable, z.

```
z = m.y(85:94,85:94);
```

MATLAB reads the 10-by-10 subarray specified by the indices (85:94,85:94) from the MAT-file into workspace variable z.

### Determine Size of Variables

Determine the size of a variable, and then calculate the average of each column.

Open the example MAT-file, stocks.mat.

```
filename = 'stocks.mat';
m = matfile(filename);
```

Determine the size of the variable, `stocks`, in `stocks.mat`.

```
[nrows,ncols] = size(m,'stocks');
```

Compute the average of each column of the variable `stocks`.

```
avgs = zeros(1,ncols);
for i = 1:ncols
 avgs(i) = mean(m.stocks(:,i));
end
```

## Enable Write Access to MAT-file

Enable write access to the MAT-file, `myFile.mat`, by setting `Writable` to `true` when you open the MAT-file.

```
filename = 'myFile.mat';
m = matfile(filename,'Writable',true);
```

Alternatively, set `Properties.Writable` in a separate step after you open the MAT-file.

```
m.Properties.Writable = true;
```

## Tips

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in **Out of Memory** errors. Rather than using `end`, determine the extent of a variable, `myVar`, with the `size` method, such as:

```
sizeMyVar = size(m,'myVar')
```

## Limitations

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Variables of tables
  - Cells of cell arrays

- Fields of structure arrays
- User-defined classes
- Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using the `m` output. For example, if your MAT-file contains function handle `myfunc`, the syntax `m.myfunc()` attempts to index into the function handle, and does not invoke the function.
- Efficient partial loading and saving requires Version 7.3 MAT-files. To create a Version 7.3 MAT-file, call the `save` function with the `'-v7.3'` option. For example, to convert an existing MAT-file named `durer.mat` to Version 7.3, call:

```
load('durer.mat');
save('mycopy_durer.mat', '-v7.3');
```

## Concepts

- “Load Parts of Variables from MAT-Files”
- “Save Parts of Variables to MAT-Files”
- MAT-File Versions

# matlab.codetools.requiredFilesAndProducts

---

**Purpose** List dependencies of MATLAB program files

**Syntax**

```
fList = matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] =
matlab.codetools.requiredFilesAndProducts(files)
[fList, pList] =
matlab.codetools.requiredFilesAndProducts(___,
 'toponly')
```

**Description** `fList = matlab.codetools.requiredFilesAndProducts(files)` returns a list of the MATLAB program files required to run the program files specified by `files`.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts(files)` also returns a list of the MathWorks products required to run the program files specified by `files`.

`[fList, pList] = matlab.codetools.requiredFilesAndProducts(___, 'toponly')` indicates that for a file or product to be included in the output, it must be used directly by at least one file specified in `files`. The 'toponly' input string is case insensitive.

**Input Arguments** **files - List of files for analysis**

string or cell array of strings

List of files for analysis, specified as a string or cell array of strings. Each string is the name of a single MATLAB program file. For example, `files` is a list of MATLAB program files that you intend to provide to other users. The `matlab.codetools.requiredFilesAndProducts` function provides you with requirements information to pass along with your files.

To ensure an accurate dependency report, `files` and dependencies must be on the MATLAB path.

`matlab.codetools.requiredFilesAndProducts` does not return information about dependent files not on the path.

**Example:** `'myFile.m'` or `'C:\Program Files\MATLAB\R2014a\my_work\myFile.m'`

**Example:** `{'myFile.m','myOtherFile.m'}`

**Example:** `cellstr(ls('*.*'))`

## Output Arguments

### **fList** - List of user-authored MATLAB program files

cell array of strings

List of user-authored MATLAB program files required by `files`, returned as a cell array of strings. Each string indicates the full path of the required file. `fList` does not include built-in MATLAB files, since these files are installed with the products listed in `pList`.

### **pList** - List of MathWorks products

structure or array of structures

List of MathWorks products required by `files`, returned as a structure or array of structures. Each required product is described by name (`Name` field), version (`Version` field) and product number (`ProductNumber` field).

The `matlab.codetools.requiredFilesAndProducts` function is intended to provide you with information to pass on to consumers of your MATLAB program files. The version numbers indicate the version of the products you have installed when you execute the function. `Version` is not an indicator of backward compatibility.

## Examples

### **Identify Required Files and Products for MATLAB Toolbox Function**

Determine the required files and products for the `edge` function in the Image Processing Toolbox.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('edge.m')
```

```
fList =

 {}

pList =

1x2 struct array with fields:

 Name
 Version
 ProductNumber
```

There are no required MATLAB files, but there are two required products.

List the required products.

```
{pList.Name}'
```

```
ans =

 'MATLAB'
 'Image Processing Toolbox'
```

## Identify Required Files and Products for Your MATLAB Program Files

In your current working folder, create a function in the file `getRandomNumber.m`.

```
function a = getRandomNumber
 rng('shuffle')
 a = rand;
end
```

Now, at the command line, determine the required files and products for `getRandomNumber.m`.

# matlab.codetools.requiredFilesAndProducts

---

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('getRandomNumber.m')
```

```
fList =
```

```
 'C:\work\getRandomNumber.m'
```

```
pList =
```

```
 Name: 'MATLAB'
 Version: '8.3'
 ProductNumber: 1
```

The only file required to run the `getRandomNumber` function is the function file itself. The only required MathWorks product is MATLAB.

In your current working folder, create a function in the file `displayNumber.m`.

```
function displayNumber
 a = getRandomNumber;
 disp(['Your number is ' num2str(a)]);
end
```

Now, at the command line, determine the required files and products for `displayNumber.m`.

```
[fList,pList] = matlab.codetools.requiredFilesAndProducts('displayNumber.m')
```

```
fList =
```

```
 'C:\work\displayNumber.m' 'C:\work\getRandomNumber.m'
```

```
pList =
```

```
 Name: 'MATLAB'
 Version: '8.3'
```

# matlab.codetools.requiredFilesAndProducts

---

```
ProductNumber: 1
```

In addition to the function file itself, the `displayNumber` function requires the `getRandomNumber.m` file. The only required MathWorks product is MATLAB.

## Identify Top-Level Dependencies Only

In your current working folder, create a handle class in the file `ExampleHandle.m`.

```
classdef ExampleHandle < handle
 % class content
end
```

In your current working folder, create a class in the file `AnotherExampleHandle.m` that inherits from `ExampleHandle`.

```
classdef AnotherExampleHandle < ExampleHandle
 % class content
end
```

In your current working folder, create a function in the file `getHandles.m` that instantiates `AnotherExampleHandle` objects.

```
function [h1,h2] = getHandles()
 h1 = AnotherExampleHandle;
 h2 = AnotherExampleHandle;
end
```

Now, at the command line, determine the required files for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m');
fList'
```

```
ans =
```

```
'C:\work\AnotherExampleHandle.m'
```

# matlab.codetools.requiredFilesAndProducts

---

```
'C:\work\ExampleHandle.m'
'C:\work\getHandles.m'
```

Determine the required files that are directly required for `getHandles.m`.

```
[fList,~] = matlab.codetools.requiredFilesAndProducts('getHandles.m',
fList =
```

```
'C:\work\AnotherExampleHandle.m' 'C:\work\getHandles.m'
```

Although `AnotherExampleHandle.m` requires `ExampleHandle.m`, that file is not a direct requirement for `getHandles.m`.

## Concepts

- “Identify Program Dependencies”

# matlab.io.MatFile

---

**Purpose** Load and save parts of variables in MAT-files

**Description** The `matfile` function constructs a `matlab.io.MatFile` object that corresponds to a MAT-File, such as

```
matObj = matfile('myFile.mat')
```

Access variables in the MAT-file as properties of `matObj`, with dot notation similar to accessing fields of structs. The syntax for loading and saving part of variable `varName` in the MAT-file corresponding to `matObj` is:

```
loadedData = matObj.varName(indices); % Load into workspace
matObj.varName(indices) = dataToSave; % Save to file
```

When indexing, specify indices for all dimensions. Indices can be a single value, an equally spaced range of increasing values, or a colon (:), such as

```
matObj.varName(100:500, 200:600)
matObj.varName(:, 501:1000)
matObj.varName(1:2:1000, 80)
```

## Limitations

- Using the `end` keyword as part of an index causes MATLAB to load the entire variable into memory. For very large variables, this load operation results in Out of Memory errors. Rather than using `end`, determine the extent of a variable with the `size` method, such as:

```
sizeMyVar = size(matObj, 'myVar')
```

- `matfile` does not support linear indexing. You must specify indices for all dimensions.
- `matfile` does not support indexing into:
  - Cells of cell arrays
  - Fields of structs

- User-defined classes
- Sparse arrays
- You cannot assign complex values to an indexed portion of a real array.
- You cannot evaluate function handles using a `MatFile` object. For example, if your MAT-file contains function handle `myfunc`, the syntax `matObj.myfunc()` attempts to index into the function handle, and does not invoke the function.

## Construction

`matObj = matfile(filename)` constructs a `matlab.io.MatFile` object that can load or save parts of variables in MAT-file `filename`. MATLAB does not load any data from the file into memory when creating the object.

`matObj = matfile(filename, 'Writable', isWritable)` enables or disables write access to the file for object `matObj`. Possible values for `isWritable` are logical true (1) or false (0).

## Input Arguments

### **filename**

String enclosed in single quotation marks that specifies the name of a MAT-file.

`filename` can include a full or partial path, otherwise `matfile` searches for the file along the MATLAB search path. If `filename` does not include an extension, `matfile` appends `.mat`.

If the file does not exist, `matfile` creates a Version 7.3 MAT-file on the first assignment to a variable.

`matfile` only supports partial loading and saving for MAT-files in Version 7.3 format (described in *MAT-File Versions*). If you index into a variable in a Version 7 (the current default) or earlier MAT-file, MATLAB warns and temporarily loads the entire contents of the variable.

### **'Writable'**

Parameter to use with the `isWritable` argument.

## **isWritable**

Logical value that specifies whether to allow saving to the file.  
Possible values:

- |                           |                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------|
| <code>true</code><br>(1)  | Enable saving. If the file is read only, change the system permissions with <code>fileattrib</code> . |
| <code>false</code><br>(0) | Disable saving with <code>matfile</code> . MATLAB does not change the system permissions.             |

**Default:** `true` for new files, `false` for existing files

## **Properties**

### **Properties.Source**

String that contains the fully qualified path to the file. Read only.

### **Properties.Writable**

Logical value that specifies whether to allow saving to the file.  
Possible values:

- |                           |                                                                                                       |
|---------------------------|-------------------------------------------------------------------------------------------------------|
| <code>true</code><br>(1)  | Enable saving. If the file is read only, change the system permissions with <code>fileattrib</code> . |
| <code>false</code><br>(0) | Disable saving with <code>matfile</code> . MATLAB does not change the system permissions.             |

**Default:** `true` for new files, `false` for existing files

## **Methods**

<code>size</code>	Array dimensions
<code>who</code>	Names of variables in MAT-file
<code>whos</code>	Names, sizes, and types of variables in MAT-file

You cannot access help for these methods using the `help` command. Find help on the methods from the command line using the `doc` command, such as `doc matlab.io.MatFile/size`.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Create `myFile.mat` in a temporary folder and save data to part of variable `savedVar`:

```
filename = fullfile(tempdir,'myFile.mat');
matObj = matfile(filename);
matObj.savedVar(81:100,81:100) = magic(20);
```

Load part of the data into variable `loadVar`:

```
loadVar = matObj.savedVar(85:94,85:94);
```

---

Load or save an entire variable by omitting the indices. For example, load variable `topo` from `topography.mat`:

```
filename = 'topography.mat';
matObj = matfile(filename);
topo = matObj.topo;
```

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows, ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
```

# matlab.io.MatFile

---

```
 avgs(idx) = mean(matObj.stocks(:,idx));
end
```

---

By default, `matfile` only supports loading data from existing files. To enable saving, set `Writable` to `true` either during construction of the object,

```
filename = 'myFile.mat';
matObj = matfile(filename, 'Writable', true);
```

or in a separate step, by setting `Properties.Writable`:

```
filename = 'myFile.mat';
matObj = matfile(filename);
matObj.Properties.Writable = true;
```

## See Also

[load](#) | [save](#) | [size](#) | [whos](#)

**Purpose** Close FITS file

**Syntax** `closeFile(fptr)`

**Description** `closeFile(fptr)` closes an open FITS file.

This function corresponds to the `fits_close_file` (`ffclos`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits','READONLY');
fits.closeFile(fptr);
```

**See Also** [createFile](#) | [openFile](#)

# matlab.io.fits.createFile

---

**Purpose** Create FITS file

**Syntax** `fptr = createFile(filename)`

**Description** `fptr = createFile(filename)` creates a FITS file. An error will be returned if the specified file already exists, unless the filename is prefixed with an exclamation point (!). In that case CFITSIO will overwrite (delete) any existing file with the same name.

This function corresponds to the `fits_create_file` (`ffinit`) function in the CFITSIO library C API.

**Examples** Create a new FITS file, overwriting any existing file by the same name.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[256 512]);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

**See Also** [openFile](#) | [closeFile](#) | [createImg](#) | [createTbl](#)

**Purpose** Delete FITS file

**Syntax** deleteFile(fptr)

**Description** deleteFile(fptr) closes and deletes an open FITS file. This can be useful if a FITS file cannot be properly closed.

This function corresponds to the fits\_delete\_file (ffdel) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.deleteFile(fptr);
fptrs = fits.getOpenFiles()
```

**See Also** createFile | closeFile

# matlab.io.fits.fileName

---

**Purpose** Name of FITS file

**Syntax** name = fileName(fpPtr)

**Description** name = fileName(fpPtr) returns the name of the FITS file associated with the file handle.

This function corresponds to the fits\_file\_name (ffflnm) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits','READONLY');
name = fits.fileName(fpPtr);
fits.closeFile(fpPtr);
```

**See Also** createFile | openFile

**Purpose** I/O mode of FITS file

**Syntax** `mode = fileMode(fptr)`

**Description** `mode = fileMode(fptr)` returns the I/O mode of the opened FITS file. Possible values returned for mode are 'READONLY' or 'READWRITE'.  
This function corresponds to the `fits_file_mode (ffflmd)` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
mode = fits.fileMode(fptr);
fits.closeFile(fptr);
```

**See Also** `createFile` | `openFile`

# matlab.io.fits.openFile

---

**Purpose** Open FITS file

**Syntax**  
fptr = openFile(filename)  
fptr = openFile(filename,mode)

**Description** fptr = openFile(filename) opens an existing FITS file in read-only mode and returns a file pointer, fptr, which references the primary array (first header data unit, or "HDU").

fptr = openFile(filename,mode) opens an existing FITS file according to the mode, which describes the type of access. mode may be either 'READONLY' or 'READWRITE'.

This function corresponds to the fits\_open\_file (ffopen) function in the CFITSIO library C API.

**Examples** Open a file in read-only mode and read image data from the primary array.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
imagedata = fits.readImg(fptr);
fits.closeFile(fptr);
```

---

Open a file in read-write mode and add a comment to the primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fptr = fits.openFile('myfile.fits','readwrite');
fits.writeComment(fptr,'This is just a comment.');
```

**See Also** createFile | closeFile

**Purpose** Create FITS image

**Syntax** `createImg(fptr,bitpix,naxes)`

**Description** `createImg(fptr,bitpix,naxes)` creates a new primary image or image extension with a specified datatype `bitpix` and size `naxes`. If the FITS file is currently empty then a primary array is created, otherwise a new image extension is appended to the file.

The first two elements of `naxes` correspond to the NAXIS2 and NAXIS1 keywords, while any additional elements correspond to the NAXIS3, NAXIS4 ... NAXISn keywords.

The datatype `bitpix` may be given as either a CFITSIO name or as the corresponding MATLAB datatype.

'byte_img'	'uint8'
'short_img'	'int16'
'long_img'	'int32'
'longlong_img'	'int64'
'float_img'	'single'
'double_img'	'double'

This function corresponds to the `fits_create_img11` (`ffcrim11`) function in the CFITSIO library C API.

## Examples

Create two images in a new FITS file. There are 100 rows (NAXIS2 keyword) and 200 columns (NAXIS1 keyword) in the first image, and 256 rows (NAXIS2 keyword), 512 columns (NAXIS1 keyword), and 3 planes (NAXIS3 keyword) in the second image.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'int16',[100 200]);
fits.createImg(fptr,'byte_img',[256 512 3]);
fits.closeFile(fptr);
```

# matlab.io.fits.createImg

---

```
fitsdisp('myfile.fits');
```

## See Also

[insertImg](#) | [createTbl](#) | [readImg](#) | [writeImg](#) | [setCompressionType](#)

**Purpose**

Size of image

**Syntax**

```
imagesize = getImgSize(fptr)
```

**Description**

`imagesize = getImgSize(fptr)` returns the number of rows and columns of an image. This function corresponds to the `fits_get_img_size` (`ffgisz`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*;
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
 htype = fits.movAbsHDU(fptr,j);
 sz = fits.getImgSize(fptr);
 fprintf('HDU %d: "%s", [' , j, htype);
 for k = 1:numel(sz)
 fprintf(' %d ', sz(k));
 end
 fprintf(']\n');
end
fits.closeFile(fptr);
```

**See Also**

[createImg](#) | [getImgType](#)

# matlab.io.fits.getImgType

---

**Purpose** Data type of image

**Syntax** `datatype = getImgType(fptr)`

**Description** `datatype = getImgType(fptr)` gets the data type of an image. `datatype` can be one of the following strings:

```
'BYTE_IMG'
'SHORT_IMG'
'LONG_IMG'
'LONGLONG_IMG'
'FLOAT_IMG'
'DOUBLE_IMG'
```

This function corresponds to the `fits_get_img_type` (`ffgidt`) function in the CFITSIO library C API.

## Examples

```
fptr = fits.openFile('tst0012.fits');
hdus = [1 3 4];
for j = hdus;
 htype = fits.movAbsHDU(fptr,j);
 dtype = fits.getImgType(fptr);
 fprintf('HDU %d: "%s", "%s"\n', j, htype, dtype);
end
fits.closeFile(fptr);
```

**See Also** `getImgSize`

**Purpose** Insert FITS image after current image

**Syntax** `insertImage(fptr,bitpix,naxes)`

**Description** `insertImage(fptr,bitpix,naxes)` inserts a new image extension immediately following the current HDU. If the file has just been created, a new primary array is inserted at the beginning of the file. Any following extensions in the file will be shifted down to make room for the new extension. If the current HDU is the last HDU in the file, then the new image extension will be appended to the end of the file.

This function corresponds to the `fits_insert_img11` (`ffiimg11`) function in the CFITSIO library C API.

**Examples** Create a 150x300 image between the 1st and 2nd images in a FITS file.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.createImg(fptr,'byte_img',[200 400]);
fits.movAbsHDU(fptr,1);
fits.insertImg(fptr,'byte_img',[150 300]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

**See Also** `createImg`

# matlab.io.fits.readImg

---

**Purpose** Read image data

**Syntax**

```
imgdata = readImg(fpPtr)
imgdata = readImg(fpPtr,fpixel,lpixel)
imgdata = readImg(fpPtr,fpixel,lpixel,inc)
```

**Description** `imgdata = readImg(fpPtr)` reads the entire current image. The number of rows in `imgdata` will correspond to the value of the NAXIS2 keyword, while the number of columns will correspond to the value of the NAXIS1 keyword. Any further dimensions of `imgdata` will correspond to NAXIS3, NAXIS4, and so on.

`imgdata = readImg(fpPtr,fpixel,lpixel)` reads the subimage defined by pixel coordinates `fpixel` and `lpixel`. The `fpixel` argument is the coordinate of the first pixel and `lpixel` is the coordinate of the last pixel. `fpixel` and `lpixel` are one-based.

`imgdata = readImg(fpPtr,fpixel,lpixel,inc)` reads the subimage defined by `fpixel`, `lpixel`, and `inc`. The `inc` argument denotes the inter- element spacing along each extent.

This function corresponds to the `fits_read_subset (ffgsV)` function in the CFITSIO library C API.

**Examples** Read an entire image.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
data = fits.readImg(fpPtr);
fits.closeFile(fpPtr);
```

---

Read a 70x80 image subset.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
img = fits.readImg(fpPtr,[11 11],[80 90]);
fits.closeFile(fpPtr);
```

**See Also**     `createImg` | `writeImg`

# matlab.io.fits.setBscale

---

**Purpose**            Reset image scaling

**Syntax**            `setBscale(fptr,BSCALE,BZERO)`

**Description**        `setBscale(fptr,BSCALE,BZERO)` resets the scaling factors in the primary array or image extension according to the equation

`output = (FITS array) * BSCALE + BZERO`

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the BSCALE and BZERO keyword values.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.setBscale(fptr,2.0,0.5);
data = fits.readImg(fptr);
fits.closeFile(fptr);
```

**See Also**            `readImg`

**Purpose** Write to FITS image

**Syntax** `writeImg(fptr,data)`  
`writeImg(fptr,data,fpixel)`

**Description** `writeImg(fptr,data)` writes an entire image to the FITS data array. The number of rows and columns in `data` must equal the values of the `NAXIS2` and `NAXIS1` keywords, respectively. Any further extents must correspond to the `NAXIS3`, `NAXIS4` ... `NAXISn` keywords respectively.

`writeImg(fptr,data,fpixel)` writes a subset of an image to the FITS data array. `fpixel` gives the coordinate of the first pixel in the image region.

This function corresponds to the `fits_write_subset` (`ffpss`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fptr,data);
fits.closeFile(fptr);
```

---

Create an 80x40 `uint8` image and set all but the outermost pixels to 1.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'uint8',[80 40]);
data = ones(78,38);
fits.writeImg(fptr,data,[1 1]);
fits.closeFile(fptr);
```

**See Also** `readImg` | `createImg`

# matlab.io.fits.deleteKey

---

**Purpose** Delete key by name

**Syntax** deleteKey(fpPtr,keyname)

**Description** deleteKey(fpPtr,keyname) deletes a keyword by name.  
This function corresponds to the fits\_delete\_key (ffdrec) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before key deletion...\n');
fitsdisp('myfile.fits','index',1);
fpPtr = fits.openFile('myfile.fits','readwrite');
fits.deleteKey(fpPtr,'DATE');
fits.closeFile(fpPtr);
fprintf('\n\n\nAfter key deletion...\n');
fitsdisp('myfile.fits','index',1);
```

**See Also** deleteRecord | writeKey

**Purpose** Delete key by record number

**Syntax** `deleteRecord(fpPtr,keynum)`

**Description** `deleteRecord(fpPtr,keynum)` deletes a keyword by record number. This function corresponds to the `fits_delete_record` (`ffdrec`) function in the CFITSIO library C API.

**Examples** Delete the 18th keyword ("ORIGIN") in a primary array.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fpPtr = fits.openFile('myfile.fits','readwrite');
card = fits.readRecord(fpPtr,18);
fits.deleteRecord(fpPtr,18);
fits.closeFile(fpPtr);
```

**See Also** `readRecord` | `deleteKey`

# matlab.io.fits.getHdrSpace

---

**Purpose**            Number of keywords in header

**Syntax**            `[nkeys,morekeys] = fits.getHdrSpace(fpPtr)`

**Description**        `[nkeys,morekeys] = fits.getHdrSpace(fpPtr)` returns the number of existing keywords (not counting the END keyword) and the amount of space currently available for more keywords. It returns `morekeys = -1` if the header has not yet been closed. Note that the CFITSIO library will dynamically add space if required when writing new keywords to a header so in practice there is no limit to the number of keywords that can be added to a header.

This function corresponds to the `fits_get_hdrspace (ffghsp)` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
[nkeys,morekeys] = fits.getHdrSpace(fpPtr);
fits.closeFile(fpPtr);
```

**Purpose** Header record of keyword

**Syntax** `card = readCard(fpPtr,keyname)`

**Description** `card = readCard(fpPtr,keyname)` returns the entire 80-character header record of the keyword, with any trailing blank characters stripped off.

This function corresponds to the `fits_read_card` (`ffgcrd`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 fits.movAbsHDU(fpPtr,j);
 card = fits.readCard(fpPtr,'NAXIS');
 fprintf('HDU %d: '%s'\n', j, card);
end
fits.closeFile(fpPtr);
```

**See Also** [readRecord](#) | [readKey](#)

# matlab.io.fits.readKey

---

**Purpose** Keyword

**Syntax** [value,comment] = readKey(fpPtr,keyname)

**Description** [value,comment] = readKey(fpPtr,keyname) returns the specified key and comment. value is returned as a string.

This function corresponds to the fits\_read\_key\_str (ffgkys) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 fits.movAbsHDU(fpPtr,j);
 [key,comment] = fits.readKey(fpPtr,'NAXIS');
 fprintf('HDU %d: NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fpPtr);
```

**See Also** readKeyCmplx | readKeyDb1 | readKeyLongLong

**Purpose** Keyword as complex scalar value

**Syntax** [value,comment] = readKeyCmplx(fptr,keyname)

**Description** [value,comment] = readKeyCmplx(fptr,keyname) returns the specified key and comment. value is returned as a double precision complex scalar value.

This function corresponds to the fits\_read\_key\_dblcmp" (ffgkym) function in the CFITSIO library C API.

**See Also** readKey | readKeyDb1 | readKeyLongLong

# matlab.io.fits.readKeyDbl

---

**Purpose** Keyword as double precision value

**Syntax** [value,comment] = readKeyDbl(fpPtr,keyname)

**Description** [value,comment] = readKeyDbl(fpPtr,keyname) returns the specified key and comment.

This function corresponds to the fits\_read\_key\_dbl (ffgkyd) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 fits.movAbsHDU(fpPtr,j);
 [key,comment] = fits.readKeyDbl(fpPtr,'NAXIS');
 fprintf('HDU %d: NAXIS %s, "%s"\n', j, key, comment);
end
fits.closeFile(fpPtr);
```

**See Also** readKey | readKeyCmplx | readKeyLongLong

**Purpose** Keyword as int64

**Syntax** [value,comment] = readKeyLongLong(fpPtr,keyname)

**Description** [value,comment] = readKeyLongLong(fpPtr,keyname) returns the specified key and comment. value is returned an int64 scalar value. This function corresponds to the fits\_read\_key\_lnglng (ffgkyjj) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 fits.movAbsHDU(fpPtr,j);
 [key,comment] = fits.readKeyLongLong(fpPtr,'NAXIS');
 fprintf('HDU %d: NAXIS %d, "%s"\n', j, key, comment);
end
fits.closeFile(fpPtr);
```

**See Also** readKey | readKeyCmplx | readKeyDb1

# matlab.io.fits.readKeyLongStr

---

**Purpose** Long string value

**Syntax** [value,comment] = readKeyLongStr(fptr,keyname)

**Description** [value,comment] = readKeyLongStr(fptr,keyname) returns the specified long string value and comment.

This function corresponds to the fits\_read\_key\_longstr (ffgk1s) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
idata = repmat(char(97:106),1,10);
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeKey(fptr,'mykey',idata);
odata1 = fits.readKey(fptr,'mykey');
odata2 = fits.readKeyLongStr(fptr,'mykey');
fits.closeFile(fptr);
```

**See Also** readKey

**Purpose** Physical units string from keyword

**Syntax** `units = readKeyUnit(fpPtr,keyname)`

**Description** `units = readKeyUnit(fpPtr,keyname)` returns the physical units string from an existing keyword. If no units are defined, `units` is returned as an empty string.

This function corresponds to the `fits_read_key_unit` (ffgunt) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'long_img',[10 20]);
fits.writeKey(fpPtr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fpPtr,'VELOCITY','km/s');
units = fits.readKeyUnit(fpPtr,'VELOCITY');
fits.closeFile(fpPtr);
```

**See Also** `readKey` | `writeKeyUnit`

# matlab.io.fits.readRecord

---

**Purpose** Header record specified by number

**Syntax** `card = readRecord(fpPtr,keynum)`

**Description** `card = readRecord(fpPtr,keynum)` returns the entire 80-character header record identified by the numeric `keynum`. Trailing blanks are truncated.

This function corresponds to the `fits_read_record` (`ffgrec`) function in the CFITSIO library C API.

**Examples** Read the second record in each HDU.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getHdrSpace(fpPtr);
for j = 1:n
 card = fits.readRecord(fpPtr,j);
 fprintf('record %d: "%s"\n', j, card);
end
fits.closeFile(fpPtr);
```

**See Also** `deleteRecord` | `readKey` | `readCard`

**Purpose** Write or append COMMENT keyword to CHU

**Syntax** `writeComment(fpPtr,comment)`

**Description** `writeComment(fpPtr,comment)` writes (appends) a COMMENT keyword to the CHU. The comment string will be continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the `fits_write_comment` (`ffpcom`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'byte_img',[100 200]);
fits.writeComment(fpPtr,'this is a comment');
fits.writeComment(fpPtr,'this is another comment');
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** [writeHistory](#) | [writeDate](#)

# matlab.io.fits.writeDate

---

**Purpose** Write DATE keyword to CHU

**Syntax** writeDate(FPTR)

**Description** writeDate(FPTR) writes the DATE keyword to the CHU.

This function corresponds to the `fits_write_date` (`ffpdat`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr,'byte_img',[100 200]);
fits.writeDate(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** writeComment | writeHistory

**Purpose**

Update or add new keyword into current HDU

**Syntax**

```
writeKey(fpPtr, keyname, value, comment)
writeKey(fpPtr, keyname, value, comment, decimals)
```

**Description**

`writeKey(fpPtr, keyname, value, comment)` adds a new record in the current HDU, or updates it if it already exists. `comment` is optional.

`writeKey(fpPtr, keyname, value, comment, decimals)` adds a new floating point keyword in the current HDU, or updates it if it already exists. You must use this syntax to write a keyword with imaginary components. `decimals` is ignored otherwise.

If a character `value` exceeds 68 characters in length, the LONGWARN convention is automatically employed.

This function corresponds to the `fits_write_key` (`ffpky`) and `fits_update_key` (`ffuky`) family of functions in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr, 'byte_img', [100 200]);
fits.writeKey(fpPtr, 'mykey1', 'a char value', 'with a comment');
fits.writeKey(fpPtr, 'mykey2', int32(1));
fits.writeKey(fpPtr, 'mykey3', 5+7*j, 'with another comment');
fits.writeKey(fpPtr, 'mykey4', 4/3, 'with yet another comment', 2);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'mode', 'full');
```

**See Also**

[readKey](#) | [deleteKey](#) | [readRecord](#)

# matlab.io.fits.writeKeyUnit

---

**Purpose** Write physical units string

**Syntax** writeKeyUnit(fpPtr,keyname,unit)

**Description** writeKeyUnit(fpPtr,keyname,unit) writes a physical units string into an existing keyword.

This function corresponds to the fits\_write\_key\_unit (ffpunit) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myFitsFile.fits');
fits.createImg(fpPtr,'long_img',[10 20]);
fits.writeKey(fpPtr,'VELOCITY',12.3,'orbital speed');
fits.writeKeyUnit(fpPtr,'VELOCITY','km/s');
fits.closeFile(fpPtr);
```

**See Also** readKeyUnit

**Purpose** Write or append HISTORY keyword to CHU

**Syntax** writeHistory(fpPtr,history)

**Description** writeHistory(fpPtr,history) writes (appends) a HISTORY keyword to the CHU. The history string is continued over multiple keywords if it is longer than 70 characters.

This function corresponds to the fits\_write\_history (ffphis) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr,'byte_img',[100 200]);
fits.writeHistory(fpPtr,'this is a history keyword');
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** writeComment | writeDate

# matlab.io.fits.copyHDU

---

**Purpose** Copy current HDU from one file to another

**Syntax** `copyHDU(infptr,outfptr)`

**Description** `copyHDU(infptr,outfptr)` copies the current HDU from the FITS file associated with `infptr` and appends it to the end of the FITS file associated with `outfptr`.

This function corresponds to the `fits_copy_hdu` (`ffcopy`) function in the CFITSIO library C API.

**Examples** Copy the first, third, and fifth HDUs from one file to another.

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,3);
fits.copyHDU(infptr,outfptr);
fits.movAbsHDU(infptr,5);
fits.copyHDU(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
fitsdisp('tst0012.fits','mode','min','index',[1 3 5]);
fitsdisp('myfile.fits','mode','min');
```

**See Also** `deleteHDU`

**Purpose** Delete current HDU in FITS file

**Syntax** HDU\_TYPE = deleteHDU(fptr)

**Description** HDU\_TYPE = deleteHDU(fptr) deletes the current HDU in the FITS file. Any following HDUs will be shifted forward in the file, filling the gap created by the deleted HDU. In the case of deleting the primary array (the first HDU in the file) then the current primary array will be replaced by a null primary array containing the minimum set of required keywords and no data. If there are more HDUs in the file following the HDU being deleted, then the current HDU will be redefined to point to the following HDU. If there are no following HDUs then the current HDU will be redefined to point to the previous HDU. HDU\_TYPE returns the type of the new current HDU.

This function corresponds to the fits\_delete\_hdu (ffdhdu) function in the CFITSIO library C API.

**Examples** Delete the second HDU in a FITS file.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fitsdisp('myfile.fits','mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
new_current_hdu = fits.deleteHDU(fptr);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

**See Also** copyHDU

# matlab.io.fits.getHDUnum

---

**Purpose**            Number of current HDU in FITS file

**Syntax**            `N = getHDUnum(fptr)`

**Description**      `N = getHDUnum(fptr)` returns the number of the current HDU in the FITS file. The primary array has HDU number 1.

This function corresponds to the `fits_get_hdu_num` (`ffghdn`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getHDUnum(fptr);
fits.closeFile(fptr);
```

**See Also**            `getNumHDUs` | `getHDUtype`

**Purpose** Type of current HDU

**Syntax** `htype = getHDUtype(fptr)`

**Description** `htype = getHDUtype(fptr)` returns the type of the current HDU in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_get_hdu_type` (`ffghdt`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 fits.getHDUtype(fptr);
end
fits.closeFile(fptr);
```

**See Also** `getHDUnum`

# matlab.io.fits.getNumHDUs

---

**Purpose** Total number of HDUs in FITS file

**Syntax** N = getNumHDUs(fpPtr)

**Description** N = getNumHDUs(fpPtr) returns the number of completely defined HDUs in a FITS file. If a new HDU has just been added to the FITS file, then that last HDU will only be counted if it has been closed, or if data has been written to the HDU. The current HDU remains unchanged by this routine.

This function corresponds to the fits\_get\_num\_hdus (ffthdu) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
fits.closeFile(fpPtr);
```

**See Also** getHDUenum

**Purpose** Move to absolute HDU number

**Syntax** `htype = fits.movAbsHDU(fptr,HDUNUM)`

**Description** `htype = fits.movAbsHDU(fptr,HDUNUM)` moves to a specified absolute HDU number (starting with 1 for the primary array) in the FITS file. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_move_abs_hdu` function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fptr);
for j = 1:n
 htype = fits.movAbsHDU(fptr,j);
 fprintf('HDU %d: "%s"\n',j,htype);
end
fits.closeFile(fptr);
```

## See Also

`getNumHDUs` | `movRelHDU` | `movNamHDU`

# matlab.io.fits.movNamHDU

---

**Purpose** Move to first HDU having specific type and keyword values

**Syntax** `movNamHDU(fptr,hdutype,EXTNAME,EXTVER)`

**Description** `movNamHDU(fptr,hdutype,EXTNAME,EXTVER)` moves to the first HDU which has the specified extension type and EXTNAME and EXTVER keyword values (or HDUNAME and HDUVER keywords).

The `hdutype` parameter may have a value of:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
'ANY_HDU'
```

If `hdutype` is 'ANY\_HDU', only the EXTNAME and EXTVER values are used to locate the correct extension. If the input value of EXTVER is 0, then the EXTVER keyword is ignored and the first HDU with a matching EXTNAME (or HDUNAME) keyword will be found.

This function corresponds to the `fits_movnam_hdu` (`ffmnhd`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movNamHDU(fptr,'IMAGE_HDU','quality',1);
fits.closeFile(fptr);
```

**See Also** `movAbsHDU` | `movRelHDU`

**Purpose** Move relative number of HDUs from current HDU

**Syntax** `htype = moveRelHDU(fpPtr,nmove)`

**Description** `htype = moveRelHDU(fpPtr,nmove)` moves a relative number of HDUs forward or backward from the current HDU and returns the HDU type, `htype`, of the resulting HDU. The possible values for `htype` are:

```
'IMAGE_HDU'
'ASCII_TBL'
'BINARY_TBL'
```

This function corresponds to the `fits_movrel_hdu` (`ffmrhd`) function in the CFITSIO library C API.

**Examples** Move through each HDU in succession, then move backwards twice by two HDUs.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
n = fits.getNumHDUs(fpPtr);
for j = 1:n
 htype = fits.movAbsHDU(fpPtr,j);
 fprintf('HDU %d: "%s"\n',j,htype);
end
htype = fits.movRelHDU(fpPtr,-2);
n = fits.getHDUnum(fpPtr);
fprintf('HDU %d: "%s"\n',n,htype);
htype = fits.movRelHDU(fpPtr,-2);
n = fits.getHDUnum(fpPtr);
fprintf('HDU %d: "%s"\n',n,htype);
fits.closeFile(fpPtr);
```

**See Also** `movAbsHDU` | `movNamHDU`

# matlab.io.fits.writeChecksum

---

**Purpose** Compute and write checksum for current HDU

**Syntax** writeChecksum(fpPtr)

**Description** writeChecksum(fpPtr) computes and writes the DATASUM and CHECKSUM keyword values for the current HDU into the current header. If the keywords already exist, their values are updated only if necessary (for example, if the file has been modified since the original keyword values were computed).

This function corresponds to the fits\_write\_chksum (ffpcks) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.createImg(fpPtr, 'long_img', [10 20]);
fits.writeChecksum(fpPtr)
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'mode', 'full');
```

**See Also** fitsdisp

**Purpose** Compress HDU from one file into another

**Syntax** `imgCompress(infptr,outfptr)`

**Description** `imgCompress(infptr,outfptr)` initializes the output HDU, copies all the keywords, and loops through the input image, compressing the data and writing the compressed data to the output HDU.

This function corresponds to the `fits_img_compress` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
infptr = fits.openFile('tst0012.fits');
outfptr = fits.createFile('myfile.fits');
fits.setCompressionType(outfptr,'rice');
fits.imgCompress(infptr,outfptr);
fits.closeFile(infptr);
fits.closeFile(outfptr);
```

**See Also** `setCompressionType`

# matlab.io.fits.isCompressedImg

---

**Purpose** Determine if current image is compressed

**Syntax** TF = isCompressedImg(fptr)

**Description** TF = isCompressedImg(fptr) returns true if the image in the current HDU is compressed.

This function corresponds to the `fits_is_compressed_image` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
bool = fits.isCompressedImg(fptr);
fits.closeFile(fptr);
```

**See Also** setCompressionType

**Purpose** Set image compression type

**Syntax** `setCompressionType(fpPtr,comptype)`

**Description** `setCompressionType(fpPtr,comptype)` specifies the image compression algorithm that should be used when writing a FITS image.

Supported values for `comptype` include:

```
'GZIP'
'GZIP2'
'RICE'
'PLIO'
'HCOMPRESS'
'NOCOMPRESS'
```

This function corresponds to the `fits_set_compression_type` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.setCompressionType(fpPtr,'GZIP2');
fits.createImg(fpPtr,'long_img',[256 512]);
data = reshape(1:256*512,[256 512]);
data = int32(data);
fits.writeImg(fpPtr,data);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** `setTileDim` | `createImg`

# matlab.io.fits.setHCompScale

---

**Purpose** Set scale parameter for HCOMPRESS algorithm

**Syntax** `setHCompScale(fptr, scale)`

**Description** `setHCompScale(fptr, scale)` sets the scale parameter to be used with the HCOMPRESS compression algorithm. Setting the scale parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_scale` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
data = 50*ones(256,512,'double') + 10 * rand([256 512]);
fptr = fits.createFile('myfile.fits');
fits.setCompressionType(fptr, 'HCOMPRESS_1');
fits.setHCompScale(fptr, 2.5);
fits.createImg(fptr, 'double_img', [256 512]);
fits.writeImg(fptr, data);
fits.closeFile(fptr);
fitsdisp('myfile.fits', 'mode', 'full');
```

**See Also** `setHCompSmooth` | `setCompressionType`

**Purpose** Set smoothing for images compressed with HCOMPRESS

**Syntax** `setHCompSmooth(fpPtr,smooth)`

**Description** `setHCompSmooth(fpPtr,smooth)` sets the smoothing to be used when compressing an image with the HCOMPRESS algorithm. Setting either the scale or smoothing parameter causes the algorithm to operate in lossy mode.

This function corresponds to the `fits_set_hcomp_smooth` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
data = int32(50*ones(256,512,'double') + 10 * rand([256 512]));
fpPtr = fits.createFile('myfile.fits');
fits.setCompressionType(fpPtr,'HCOMPRESS');
fits.setHCompSmooth(fpPtr,1);
fits.createImg(fpPtr,'long_img',[256 512]);
fits.writeImg(fpPtr,data);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** `setHCompScale` | `setCompressionType`

# matlab.io.fits.setTileDim

---

**Purpose** Set tile dimensions

**Syntax** `fits.setTileDim(fpPtr,tiledims)`

**Description** `fits.setTileDim(fpPtr,tiledims)` specifies the size of the image compression tiles to be used when creating a compressed image.  
This function corresponds to the `fits_set_tile_dim` function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
fits.setCompressionType(fpPtr,'RICE_1');
fits.setTileDim(fpPtr,[64 128]);
fits.createImg(fpPtr,'byte_img',[256 512]);
data = ones(256,512,'uint8');
fits.writeImg(fpPtr,data);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','mode','full');
```

**See Also** `setCompressionType`

**Purpose**

Create new ASCII or binary table extension

**Syntax**

```
fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)
```

**Description**

`fptr = createTbl(fptr,tbltype,nrows,ttype,tform,tunit,extname)` creates a new ASCII or bintable table extension. `ttype` must be either 'binary' or 'ascii'. The `nrows` argument gives the initial number of rows to be created in the table and should normally be zero. `tunit` specifies the units for each column, but can be an empty cell array if no units are desired. `extname` specifies the extension name, but can be omitted.

`tform` specifies the format of the column. For binary tables, the values should be in the form of 'rt', where 'r' is the repeat count and 't' is one of the following letters.

'A'	ASCII character
'B'	Byte or uint8
'C'	Complex (single precision)
'D'	Double precision
'E'	Single precision
'I'	int16
'J'	int32
'K'	int64
'L'	Logical
'M'	Complex (double precision)
'X'	Bit (int8 zeros and ones)

A column can also be specified as having variable-width if the `tform` value has the form '1Pt' or '1Qt', where 't' specifies the data type as above.

For ASCII tables, the `tform` values take the form:

<code>Iw</code>	int16 column with width 'w'
<code>Aw</code>	ASCII column with width 'w'
<code>Fww.dd</code>	Fixed point
<code>Eww.dd</code>	Single precision with width 'ww' and precision 'dd'
<code>Dww.dd</code>	Double precision with width 'ww' and precision 'dd'

This function corresponds to the `fits_create_tbl` (`ffcrtb`) function in the CFITSIO library C API.

## Examples

Create a binary table. The first column contains strings of nine characters each. The second column contains four-element sequences of bits. The third column contains three-element sequences of `uint8` values. The fourth column contains double-precision scalars.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1', 'Col2', 'Col3', 'Col4'};
tform = {'9A', '4X', '3B', '1D'};
tunit = {'m/s', 'kg', 'kg/m^3', 'candela'};
fits.createTbl(fptr, 'binary', 10, ttype, tform, tunit, 'my-table');
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

---

Create a two-column table where the first column has a single double-precision value, but the second column has a variable-length double-precision value.

```
import matlab.io.*
fptr = fits.createFile('myfile2.fits');
ttype = {'Col1', 'Col2'};
```

```
tform = {'1D','1PD'};
fits.createTbl(fptr,'binary',0,ttype,tform);
fits.closeFile(fptr);
fitsdisp('myfile2.fits');
```

## See Also

[insertATbl](#) | [insertBTbl](#) | [readCol](#) | [writeCol](#) | [createImg](#)

# matlab.io.fits.deleteCol

---

**Purpose** Delete column from table

**Syntax** deleteCol(fptr,colnum)

**Description** deleteCol(fptr,colnum) deletes the column from an ASCII or binary table.

This function corresponds to the fits\_delete\_col (ffdcoll) function in the CFITSIO library C API.

**Examples** Delete the second column in a binary table.

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
fits.deleteCol(fptr,2);
fits.closeFile(fptr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

**See Also** deleteRows

**Purpose**

Delete rows from table

**Syntax**

```
deleteRows(fptr,firstrow,nrows)
```

**Description**

`deleteRows(fptr,firstrow,nrows)` deletes rows from an ASCII or binary table.

This function corresponds to the `fits_delete_rows` (`ffdraw`) function in the CFITSIO library C API.

**Examples**

Delete the second, third, and fourth rows in a binary table (second HDU).

```
import matlab.io.*
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','tst0012.fits');
copyfile(srcFile,'myfile.fits');
fileattrib('myfile.fits','+w');
fprintf('Before: '); fitsdisp('myfile.fits','index',2,'mode','min');
fptr = fits.openFile('myfile.fits','readwrite');
fits.movAbsHDU(fptr,2);
fits.deleteRows(fptr,2,2);
fits.closeFile(fptr);
fprintf('After : '); fitsdisp('myfile.fits','index',2,'mode','min');
```

**See Also**

[deleteCol](#) | [insertRows](#)

# matlab.io.fits.insertRows

---

**Purpose** Insert rows into table

**Syntax** `insertRows(fptr,firstrow,nrows)`

**Description** `insertRows(fptr,firstrow,nrows)` inserts rows into an ASCII or binary table. `firstrow` is a one-based number.

This function corresponds to the `fits_insert_rows` (`ffrow`) function in the CFITSIO library C API.

**Examples** Insert five rows into an empty table.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertRows(fptr,1,5);
fits.closeFile(fptr);
fitsdisp('myfile.fits','index',2);
```

**See Also** `insertCol` | `deleteRows`

**Purpose**

ASCII table information

**Syntax**

```
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = getAColParms(fptr,
 colnum)
```

**Description**

[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = getAColParms(fptr, colnum) gets information about an existing ASCII table column.

This function corresponds to the fits\_get\_acolparms (fffac1) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[ttype,tbcol,tunit,tform,scale,zero,nulstr,tdisp] = fits.getAColParms
fits.closeFile(fptr);
```

**See Also**

getBColParms

# matlab.io.fits.getBColParms

---

**Purpose** Binary table information

**Syntax** [ttype,tunit,typechar,repeat,scale,zero,nulval,  
tdisp] = getBColParms(fptr,colnum)

**Description** [ttype,tunit,typechar,repeat,scale,zero,nulval, tdisp] =  
getBColParms(fptr,colnum) gets information about an existing binary  
table column.

This function corresponds to the fits\_get\_bcolparms (ffgbcl)  
function in the CFITSIO library C API.

**Examples** Get information about the second column in a binary table.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[ttype,tunit,typechar,repeat,scale,zero,nulval,tdisp]= fits.getBColParms(
fits.closeFile(fptr);
```

**See Also** getAColParms

**Purpose** Table column name

**Syntax** [colnum,colname] = getColNum(fptr,templt,casesen)

**Description** [colnum,colname] = getColNum(fptr,templt,casesen) gets the table column numbers and names of the columns whose names match an input template name. If casesen is true, then the column name match is case-sensitive. casesen defaults to false.

The input column name template may be either the exact name of the column to be searched for, or it may contain wildcard characters (\*, ?, or #), or it may contain the integer number of the desired column (with the first column = 1). The '\*' wildcard character matches any sequence of characters (including zero characters) and the '?' character matches any single character. The # wildcard matches any consecutive string of decimal digits (0-9).

**Examples** Return all the columns starting with the letter 'C'.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nums,names] = fits.getColName(fptr,'C*');
fits.closeFile(fptr);
```

**See Also** getAColParms | getBColParms

# matlab.io.fits.getColType

---

**Purpose** Scaled column data type, repeat value, width

**Syntax** [dtype,repeat,width] = getColType(fptr,colnum)

**Description** [dtype,repeat,width] = getColType(fptr,colnum) returns the data type, vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the fits\_get\_coltype11 (ffgtc111) function in the CFITSIO library C API.

**Examples** Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getColType(fptr,5);
fits.closeFile(fptr);
```

**See Also** getEqColType

**Purpose** Column data type, repeat value, width

**Syntax** [dtype,repeat,width] = getColType(fptr,colnum)

**Description** [dtype,repeat,width] = getColType(fptr,colnum) returns the scaled data type needed to store the scaled column data type, the vector repeat value, and the width in bytes of a column in an ASCII or binary table.

This function corresponds to the fits\_get\_eqcoltypell (ffeqtyll) function in the CFITSIO library C API.

**Examples** Get information about the 'FLUX' column in the second HDU.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[dtype,repeat,width] = fits.getEqColType(fptr,5);
fits.closeFile(fptr);
```

**See Also** getColType

# matlab.io.fits.getNumCols

---

**Purpose**            Number of columns in table

**Syntax**            `ncols = getNumCols(fptr)`

**Description**      `ncols = getNumCols(fptr)` gets the number of columns in the current FITS table. This function corresponds to the `fits_get_num_cols` (`ffgncl`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
ncols = fits.getNumCols(fptr);
nrows = fits.getNumRows(fptr);
fits.closeFile(fptr);
```

**See Also**            `getNumRows`

**Purpose**            Number of rows in table

**Syntax**            `nrows = getNumRows(fpPtr)`

**Description**        `nrows = getNumRows(fpPtr)` gets the number of rows in the current FITS table. This function corresponds to the `fits_get_num_rows11` (`ffgnrwl1`) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
nCols = fits.getNumCols(fpPtr);
nRows = fits.getNumRows(fpPtr);
fits.closeFile(fpPtr);
```

**See Also**            `getNumCols`

# matlab.io.fits.insertCol

---

**Purpose** Insert column into table

**Syntax** `insertCol(fpPtr,colnum,ttype,tform)`

**Description** `insertCol(fpPtr,colnum,ttype,tform)` inserts a column into an ASCII or binary table.

This function corresponds to the `fits_insert_col` (`fficol`) function in the CFITSIO library C API.

## Examples

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'3A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fpPtr,'binary',0,ttype,tform,tunit,'my-table');
fits.insertCol(fpPtr,3,'Col3','3D');
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','index',2);
```

**See Also** `insertRows`

## Purpose

Insert ASCII table after current HDU

## Syntax

```
insertATbl(fptr, rowlen, nrows, ttype, tbc, tform, tunit, extname)
```

## Description

`insertATbl(fptr, rowlen, nrows, ttype, tbc, tform, tunit, extname)` inserts a new ASCII table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions, then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the current HDU. If `rowlen` is 0, then CFITSIO calculates the default `rowlen` based on the `tbc` and `ttype` values.

`tform` can take the following forms. In each case, 'w' and 'ww' represent the widths of the ASCII columns.

Iw	int16 column
Aw	ASCII column
Fww.dd	Fixed point with 'dd' digits after the decimal point
Eww.dd	Single precision with 'dd' digits of precision
Dww.dd	Double precision with 'dd' digits of precision

Binary tables are recommended instead of ASCII tables.

This function corresponds to the `fits_insert_atbl` (`ffitab`) function in the CFITSIO library C API.

## Examples

Create an ASCII table between two images.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
fits.createImg(fptr, 'uint8', [20 30]);
```

# matlab.io.fits.insertATbl

---

```
fits.createImg(fptr,'int16',[30 40]);
fits.movRelHDU(fptr,-1);
ttype = {'Name','Short','Fix','Double'};
tbcol = [1 17 28 43];
tform = {'A15','I10','F14.2','D12.4'};
tunit = {'','m**2','cm','km/s'};
fits.insertATbl(fptr,0,0,ttype,tbcol,tform,tunit,'my-table');
fits.writeCol(fptr,1,1,char('abracadabra','hocus-pocus'));
fits.writeCol(fptr,2,1,int16([0; 1]));
fits.writeCol(fptr,3,1,[12.4; 4/3]);
fits.writeCol(fptr,4,1,[12.4; 4e8/3]);
fits.closeFile(fptr);
fitsdisp('myfile.fits','mode','min');
```

## See Also

[createTbl](#) | [insertBTbl](#)

**Purpose** Insert binary table after current HDU

**Syntax** `insertBTbl(fptr,nrows,ttype,tform,tunit,extname,pcount)`

**Description** `insertBTbl(fptr,nrows,ttype,tform,tunit,extname,pcount)` inserts a new binary table extension immediately following the current HDU. Any following extensions are shifted down to make room for the new extension. If there are no other following extensions then the new table extension is simply appended to the end of the file. If the FITS file is currently empty then this routine creates a dummy primary array before appending the table to it. The new extension becomes the CHDU. If there are following extensions in the file and if the table contains variable-length array columns then `pcount` must specify the expected final size of the data heap. Otherwise, `pcount` must be zero.

This function corresponds to the `fits_insert_btbl` (`ffibin`) function in the CFITSIO library C API.

**Examples** Create a table following the primary array. Then, insert a new table just before it.

```
import matlab.io.*
fptr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2'};
tform = {'9A','1D'};
tunit = {'m/s','candela'};
fits.createTbl(fptr,'binary',10,ttype,tform,tunit,'my-table');
fits.movRelHDU(fptr,-1);
fits.insertBTbl(fptr,5,ttype,tform,tunit,'my-new-table',0);
fits.closeFile(fptr);
fitsdisp('myfile.fits');
```

**See Also** `createTbl` | `insertATbl`

# matlab.io.fits.readATblHdr

---

**Purpose** Read header information from current ASCII table

**Syntax** [rowlen,nrows,ttype,tbcol,tform,tunit,extname] = readATblHdr(fptr)

**Description** [rowlen,nrows,ttype,tbcol,tform,tunit,extname] = readATblHdr(fptr) reads header information for the current ASCII table.

This function corresponds to the fits\_read\_atblhdr11 (ffghtb11) function in the CFITSIO library C API.

**Examples**

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,5);
[rowlen,nrows,ttype,tbcol,tform,tunit,extname] = fits.readATblHdr(fptr);
fits.closeFile(fptr);
```

**See Also** readBTblHdr

- Purpose** Read header information from current binary table
- Syntax** [nrows,ttype,tform,tunit,exname,pcount] = readBTblHdr(fptr)
- Description** [nrows,ttype,tform,tunit,exname,pcount] = readBTblHdr(fptr) reads header information for the current binary table.
- This function corresponds to the fits\_read\_btblhdr11 (ffghbn11) function in the CFITSIO library C API.
- Examples**
- ```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
[nrows,ttype,tform,tunit,exname,pcount] = fits.readBTblHdr(fptr);
fits.closeFile(fptr);
```
- See Also** readATblHdr

matlab.io.fits.readCol

Purpose Read rows of ASCII or binary table column

Syntax `[coldata,nullval] = readCol(fpPtr,colnum)`
`[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)`

Description `[coldata,nullval] = readCol(fpPtr,colnum)` reads an entire column from an ASCII or binary table column. `nullval` is a logical array specifying if a particular element of `coldata` should be treated as undefined. It is the same size as `coldata`.

`[coldata,nullval] = readCol(fpPtr,colnum,firstrow,numrows)` reads a subsection of rows from an ASCII or binary table column.

The MATLAB data type returned by `readCol` corresponds to the data type returned by `getEqColType`.

This function corresponds to the `fits_read_col (ffgcv)` function in the CFITSIO library C API.

Examples Read an entire column.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
colnum = fits.getColName(fpPtr,'flux');
fluxdata = fits.readCol(fpPtr,colnum);
fits.closeFile(fpPtr);
```

Read the first five rows in a column.

```
import matlab.io.*
fpPtr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fpPtr,2);
colnum = fits.getColName(fpPtr,'flux');
fluxdata = fits.readCol(fpPtr,colnum,1,5);
fits.closeFile(fpPtr);
```

See Also `writeCol`

matlab.io.fits.setTscale

Purpose Reset image scaling

Syntax `setTscale(fptr,colnum,tscale,tzero)`

Description `setTscale(fptr,colnum,tscale,tzero)` resets the scaling factors for a table column according to the equation:

$$\text{output} = (\text{FITS array}) * \text{tscale} + \text{tzero}$$

The inverse formula is used when writing data values to the FITS file.

This only affects the automatic scaling performed when the data elements are read. It does not change the `tscale` and `tzero` keyword values.

Examples Turn off automatic scaling in a table column where the `tscale` and `tzero` keywords are present.

```
import matlab.io.*
fptr = fits.openFile('tst0012.fits');
fits.movAbsHDU(fptr,2);
scaled_data = fits.readCol(fptr,3);
fits.setTscale(fptr,3,1.0,0.0);
unscaled_data = fits.readCol(fptr,3);
fits.closeFile(fptr);
```

See Also `readImg`

| | |
|--------------------|---|
| Purpose | Write elements into ASCII or binary table column |
| Syntax | <code>writeCol(fpPtr,colnum,firstrow,coldata)</code> |
| Description | <p><code>writeCol(fpPtr,colnum,firstrow,coldata)</code> writes elements into an ASCII or binary table extension column.</p> <p>When writing rows of data to a variable length field, <code>coldata</code> must be a cell array.</p> <p>This function corresponds to the <code>fits_write_col</code> (ffpcol) function in the CFITSIO library C API.</p> |

Examples

Write to a table with ASCII, uint8, double-precision, and variable-length double-precision columns.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'3A','3B','1D','1PD'};
tunit = {'m/s','kg/m^3','candela','parsec'};
fits.createTbl(fpPtr,'binary',0,ttype,tform,tunit,'my-table');
fits.writeCol(fpPtr,1,1,['dog'; 'cat']);
fits.writeCol(fpPtr,2,1,[0 1 2; 3 4 5; 6 7 8; 9 10 11]);
fits.writeCol(fpPtr,3,1,[1; 2; 3; 4]);
fits.writeCol(fpPtr,4,1,{1;[1 2];[1 2 3];[1 2 3 4]});
fits.closeFile(fpPtr);
fitsdisp('myfile.fits','index',2,'mode','full');
```

Write to a table with logical, bit, double precision, and variable-length complex single-precision columns.

```
import matlab.io.*
fpPtr = fits.createFile('myfile.fits');
ttype = {'Col1','Col2','Col3','Col4'};
tform = {'2L','3X','1D','1PC'};
```

matlab.io.fits.writeCol

```
tunit = {'', 'kg/m^3', 'candela', 'parsec'};
fits.createTbl(fpPtr, 'binary', 0, ttype, tform, tunit, 'my-table');
fits.writeCol(fpPtr, 1, 1, [false false; true false]);
fits.writeCol(fpPtr, 2, 1, int8([0 1 1; 1 1 1; 1 1 1; 1 0 1]));
fits.writeCol(fpPtr, 3, 1, [1; 2; 3; 4]);
data = cell(4, 1);
data{1} = single(1);
data{2} = single(1+2j);
data{3} = single([1j 2 3+j]);
data{4} = single([1 2+3j 3 4]);
fits.writeCol(fpPtr, 4, 1, data);
fits.closeFile(fpPtr);
fitsdisp('myfile.fits', 'index', 2, 'mode', 'full');
```

See Also

[createTbl](#) | [readCol](#)

Purpose Numeric value of named constant

Syntax N = getConstantValue(name)

Description N = getConstantValue(name) returns the numeric value corresponding to the named CFITSIO constant.

Examples

```
import matlab.io.*  
n = fits.getConstantValue('BYTE_IMG');
```

matlab.io.fits.getVersion

Purpose Revision number of the CFITSIO library

Syntax `V = getVersion()`

Description `V = getVersion()` returns the revision number of the CFITSIO library. This function corresponds to the `fits_get_version` (`ffvers`) function in the CFITSIO library C API.

Examples

```
import matlab.io.*  
v = fits.getVersion();
```

| | |
|--------------------|---|
| Purpose | List of open FITS files |
| Syntax | <code>fptrs = getOpenFiles()</code> |
| Description | <code>fptrs = getOpenFiles()</code> returns a list of file pointers of all open FITS files. |
| Examples | <pre>import matlab.io.* fptr = fits.openFile('tst0012.fits'); clear fptr; fptr = fits.getOpenFiles(); fits.closeFile(fptr);</pre> |
| See Also | <code>openFile</code> <code>closeFile</code> |

Purpose Interact directly with HDF4 multfile scientific data set (SD) interface

Description To use these MATLAB functions, you should be familiar with the HDF SD C API. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF library function. The functions are implemented as the package `matlab.io.hdf4.sd`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','read');
```

Access

| | |
|--|---|
| <code>matlab.io.hdf4.sd.close</code> | Terminate access to SD interface |
| <code>matlab.io.hdf4.sd.endAccess</code> | Terminate access to data set |
| <code>matlab.io.hdf4.sd.getFilename</code> | Name of file |
| <code>matlab.io.hdf4.sd.select</code> | Identifier of data set with specified index |
| <code>matlab.io.hdf4.sd.setExternalFile</code> | Store data in external file |
| <code>matlab.io.hdf4.sd.start</code> | Open HDF file and initialize SD interface |

Read/Write

| | |
|--|-------------------------------|
| <code>matlab.io.hdf4.sd.create</code> | Create new data set |
| <code>matlab.io.hdf4.sd.readData</code> | Read subsample of data |
| <code>matlab.io.hdf4.sd.setFillMode</code> | Set current fill mode of file |
| <code>matlab.io.hdf4.sd.writeData</code> | Write to data set |

Inquiry

| | |
|--|---|
| <code>matlab.io.hdf4.sd.fileInfo</code> | Number of data sets and global attributes in file |
| <code>matlab.io.hdf4.sd.getCompInfo</code> | Information about data set compression |
| <code>matlab.io.hdf4.sd.getFillValue</code> | Fill value for data set |
| <code>matlab.io.hdf4.sd.getInfo</code> | Information about data set |
| <code>matlab.io.hdf4.sd.idToRef</code> | Reference number corresponding to data set identifier |
| <code>matlab.io.hdf4.sd.idType</code> | Type of object |
| <code>matlab.io.hdf4.sd.isCoordVar</code> | Determine if data set is a coordinate variable |
| <code>matlab.io.hdf4.sd.isRecord</code> | Determine if data set is appendable |
| <code>matlab.io.hdf4.sd.nameToIndex</code> | Index value of named data set |
| <code>matlab.io.hdf4.sd.nameToIndices</code> | List of data sets with same name |
| <code>matlab.io.hdf4.sd.refToIndex</code> | Index of data set corresponding to reference number |

Dimensions

| | |
|--|--------------------------------|
| <code>matlab.io.hdf4.sd.dimInfo</code> | Information about dimension |
| <code>matlab.io.hdf4.sd.getDimID</code> | Dimension identifier |
| <code>matlab.io.hdf4.sd.getDimScale</code> | Scale data for dimension |
| <code>matlab.io.hdf4.sd.setDimName</code> | Associate name with dimension |
| <code>matlab.io.hdf4.sd.setDimScale</code> | Set scale values for dimension |

User-defined Attributes

| | |
|----------------------------|------------------------------|
| matlab.io.hdf4.sd.attrInfo | Information about attribute |
| matlab.io.hdf4.sd.findAttr | Index of specified attribute |
| matlab.io.hdf4.sd.readAttr | Read attribute value |
| matlab.io.hdf4.sd.setAttr | Write attribute value |

Predefined Attributes

| | |
|--------------------------------|--|
| matlab.io.hdf4.sd.getCal | Data set calibration information |
| matlab.io.hdf4.sd.getDataStrs | Predefined attribute strings for data set |
| matlab.io.hdf4.sd.getDimStrs | Predefined attribute strings for dimension |
| matlab.io.hdf4.sd.getFillValue | Fill value for data set |
| matlab.io.hdf4.sd.getRange | Maximum and minimum range values |
| matlab.io.hdf4.sd.setCal | Set data set calibration information |
| matlab.io.hdf4.sd.setDataStrs | Set predefined attributes for data set |
| matlab.io.hdf4.sd.setDimStrs | Set label, unit, and format attribute strings |
| matlab.io.hdf4.sd.setFillValue | Set fill value for data set |
| matlab.io.hdf4.sd.setRange | Set maximum and minimum range value for data set |

Chunking/Tiling Operations

| | |
|--------------------------------|---|
| matlab.io.hdf4.sd.getChunkInfo | Chunk size for data set |
| matlab.io.hdf4.sd.readChunk | Read chunk from data set |
| matlab.io.hdf4.sd.setChunk | Set chunk size and compression method of data set |
| matlab.io.hdf4.sd.writeChunk | Write chunk to data set |

Compression

| | |
|----------------------------------|--|
| matlab.io.hdf4.sd.setCompress | Set compression method of data set |
| matlab.io.hdf4.sd.setNBitDataSet | Specify nonstandard bit length for data set values |

matlab.io.hdf4.sd.attrInfo

Purpose Information about attribute

Syntax [name,datatype,nelts] = attrInfo(objID,idx)

Description [name,datatype,nelts] = attrInfo(objID,idx) returns the name, data type, and number of elements in the specified attribute. The attribute is specified by its zero-based index value. objID can be either an SD interface identifier, a data set identifier, or a dimension identifier.

This function corresponds to the SDattrinfo function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
[name,datatype,nelts] = sd.attrInfo(sdID,idx);
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

See Also sd.findAttr

Purpose Terminate access to SD interface

Syntax `sd.close(sdID)`

Description `sd.close(sdID)` closes the file identified by `sdID`.
This function corresponds to the `SDend` function in the HDF C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.start`

matlab.io.hdf4.sd.create

Purpose Create new data set

Syntax `sdsID = create(sdID,name,datatype,dims)`

Description `sdsID = create(sdID,name,datatype,dims)` creates a data set with the given name `name`, data type `datatype`, and dimension sizes `dims`.

To create a data set with an unlimited dimension, the last value in `dims` should be set to 0.

This function corresponds to the `SDcreate` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

Examples Create a 3D data set with an unlimited dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20 0]);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.endAccess`

Purpose Information about dimension

Syntax [name,dimlen,datatype,nattrs] = dimInfo(dimID)

Description [name,dimlen,datatype,nattrs] = dimInfo(dimID) returns the name, length, data type, and number of attributes of the specified dimension.

This function corresponds to the SDdiminfo function in the HDF library C API.

Examples Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'latitude');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[name,dimlen,datatype,nattrs] = sd.dimInfo(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also sd.getDimID

matlab.io.hdf4.sd.endAccess

Purpose Terminate access to data set

Syntax `sd.endAccess(sdsID)`

Description `sd.endAccess(sdsID)` terminates access to the data set identified by `sdsID`. Failing to call this function after all operations on the specified data set are complete may result in loss of data.

This function corresponds to the `SDendaccess` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.select` | `sd.close`

Purpose Number of data sets and global attributes in file

Syntax `[ndatasets,ngatts] = fileInfo(sdID)`

Description `[ndatasets,ngatts] = fileInfo(sdID)` returns the number of data sets `ndatasets` and the number of global attributes `ngatts` in the file identified by `sdID`.

`ndatasets` includes the number of coordinate variable data sets.

This function corresponds to the `SDfileinfo` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
[ndatasets,ngatts] = sd.fileInfo(sdID);
sd.close(sdID);
```

See Also `sd.getInfo`

matlab.io.hdf4.sd.findAttr

Purpose Index of specified attribute

Syntax `idx = findAttr(objID,attrname)`

Description `idx = findAttr(objID,attrname)` returns the index of the attribute specified by `attrname`. The `objID` input can be either an SD interface identifier, a data set identifier, or a dimension identifier.

The function corresponds to the `SDfindattr` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

See Also `sd.start` | `sd.select` | `sd.getDimID` | `sd.readAttr`

Purpose Data set calibration information

Syntax [cal,calErr,offset,offsetErr,datatype] = getCal(sdsID)

Description [cal,calErr,offset,offsetErr,datatype] = getCal(sdsID) retrieves the calibration information associated with a data set.

This function corresponds to the SDgetcal function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[cal,calErr,offset,offsetErr,dtype] = sd.getCal(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also sd.setCal

matlab.io.hdf4.sd.getChunkInfo

Purpose Chunk size for data set

Syntax chunkDims = getChunkInfo(sdsID)

Description chunkDims = getChunkInfo(sdsID) returns the chunk size for the data set specified by sdsID. If a data set is chunked, the dimensions of the chunks is returned in chunkDims. Otherwise chunkDims is [].

This function corresponds to the SDgetchunkinfo function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the chunkDims parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
cdims = sd.getChunkInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also sd.setChunk | sd.getCompInfo

Purpose Information about data set compression

Syntax [comptype,compparms] = getCompType(sdsID)

Description [comptype,compparms] = getCompType(sdsID) retrieves the compression type and compression information for a data set. `comptype` can be one of the following strings.

| | |
|-----------|------------------------------|
| 'none' | No compression |
| 'rle' | Run-length encoding |
| 'nbit' | NBIT compression |
| 'skphuff' | Skipping Huffman compression |
| 'deflate' | GZIP compression |
| 'szip' | SZIP compression |

If `comptype` is 'none' or 'rle', then `compparms` is [].

If `comptype` is 'nbit', then `compparms` is a 4-element array.

| | |
|--------------------------|------------------------|
| <code>compparm(1)</code> | <code>sign_ext</code> |
| <code>compparm(2)</code> | <code>fill_one</code> |
| <code>compparm(3)</code> | <code>start_bit</code> |
| <code>compparm(4)</code> | <code>bit_len</code> |

If `comptype` is 'deflate', then `compparms` contains the deflation value, a number between 0 and 9.

If `comptype` is 'szip', then `compparms` is a 5-element array. Consult the HDF Reference Manual for details on SZIP compression.

This function corresponds to the `SDgetcompinfo` function in the HDF library C API.

matlab.io.hdf4.sd.getCompInfo

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setCompress(sdsID,'deflate',5);
[comptype,compparm] = sd.getCompInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

[sd.setCompress](#) | [sd.setNBitDataSet](#)

Purpose

Predefined attribute strings for data set

Syntax

```
[label,unit,format,coordsys] = getDataStrs(sdsID)
[label,unit,format,coordsys] = getDataStrs(sdsID,maxlen)
```

Description

[label,unit,format,coordsys] = getDataStrs(sdsID) returns the label, unit, format, and coordsys attributes for the data set identified by sdsID.

[label,unit,format,coordsys] = getDataStrs(sdsID,maxlen) returns the label, unit, format, and coordsys attributes for the data set identified by sdsID. The maxlen input is the maximum length of any of the attribute strings. It defaults to 1000 if not specified.

This function corresponds to the SDgetdatastrs function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[label,unit,fmt,coordsys] = sd.getDataStrs(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

sd.setDataStrs

matlab.io.hdf4.sd.getDimID

Purpose Dimension identifier

Syntax `dimID = getDimID(sdsID,dimnumber)`

Description `dimID = getDimID(sdsID,dimnumber)` returns the identifier of the dimension given its index.

Note Note: MATLAB uses Fortran-style indexing while the HDF library uses C-style indexing. The order of the dimension identifiers retrieved with `sd.getDimID` are reversed from what would be retrieved via the C API.

This function corresponds to the `SDgetdimid` function in the HDF library C API.

Examples Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID0 = sd.getDimID(sdsID,0);
dimID1 = sd.getDimID(sdsID,1);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.setDimName`

Purpose Scale data for dimension

Syntax `scale = getDimScale(dimID)`

Description `scale = getDimScale(dimID)` returns the scale values of the dimension identified by `dimID`.

This function corresponds to the `SDgetdimscale` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimScale(dimID,0:5:95);
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
scale = sd.getDimScale(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.dimInfo` | `sd.setDimScale`

matlab.io.hdf4.sd.getDimStrs

Purpose Predefined attribute strings for dimension

Syntax [label,unit,format] = getDimStrs(dimID)

Description [label,unit,format] = getDimStrs(dimID) returns the label, unit, and format attributes for the dimension identified by dimID.

This function corresponds to the SDgetdimstrs function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',20);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'x');
sd.setDimStrs(dimID,'xdim','none','%d');
sd.endAccess(sdsID);
sd.close(sdID);
sdID = sd.start('myfile.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dimID = sd.getDimID(sdsID,0);
[label,unit,fmt] = sd.getDimStrs(dimID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also sd.setDimStrs

Purpose Name of file

Syntax filename = getFilename(sdID)

Description filename = getFilename(sdID) retrieves the name of a file previously opened with the sd package with identifier sdID.

This function corresponds to the SDgetfilename function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
filename = sd.getFilename(sdID);
sd.close(sdID);
```

See Also sd.start | sd.getInfo

matlab.io.hdf4.sd.getFillValue

Purpose Fill value for data set

Syntax `fillvalue = getFillValue(sdsID)`

Description `fillvalue = getFillValue(sdsID)` returns the fill value for a data set.

This function corresponds to the `SDgetfillvalue` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID, 'temperature');
sdsID = sd.select(sdID, idx);
fillvalue = sd.getFillValue(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.setFillValue`

Purpose Information about data set

Syntax [name,dims,datatype,nattrs] = getInfo(sdsID)

Description [name,dims,datatype,nattrs] = getInfo(sdsID) returns the name, extents, and number of attributes of the data set identified by sdsID.

This function corresponds to the `SDgetinfo` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dims` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
[name,dims,datatype,nattrs] = sd.getInfo(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also [sd.dimInfo](#) | [sd.attrInfo](#) | [sd.fileInfo](#)

matlab.io.hdf4.sd.getRange

| | |
|--------------------|---|
| Purpose | Maximum and minimum range values |
| Syntax | <code>[maxval,minval] = getRange(sdsID)</code> |
| Description | <code>[maxval,minval] = getRange(sdsID)</code> retrieves the "valid_range" two-element attribute value.

This function corresponds to the SDgetrange function in the HDF library C API. |
| Examples | <pre>import matlab.io.hdf4.* sdID = sd.start('sd.hdf'); idx = sd.nameToIndex(sdID,'temperature'); sdsID = sd.select(sdID,idx); [maxval,minval] = sd.getRange(sdsID); sd.endAccess(sdsID); sd.close(sdID);</pre> |
| See Also | <code>sd.setRange</code> |

Purpose Reference number corresponding to data set identifier

Syntax `ref = idToRef(sdsID)`

Description `ref = idToRef(sdsID)` returns the reference number corresponding to the data set.

This function corresponds to the `SDidtoRef` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
ref = sd.idToRef(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.refToIndex` |

matlab.io.hdf4.sd.idType

Purpose Type of object

Syntax `objtype = idType(objID)`

Description `objtype = idType(objID)` returns the type of object that `objID` represents. Possible values for `objtype` are:

| | |
|----------------|--|
| 'NOT_SDAPI_ID' | The object is not an HDF SD identifier. |
| 'SD_ID' | The object is an SD identifier (file handle) . |
| 'SDS_ID' | The object is a data set identifier. |
| 'DIM_ID' | The object is a dimension identifier. |

This function corresponds to the `SDidtype` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
objType = sd.idType(sdID);
sd.close(sdID);
```

Purpose Determine if data set is a coordinate variable

Syntax TF = isCoordVar(sdsID)

Description TF = isCoordVar(sdsID) returns true if a data set is a coordinate variable and returns false otherwise.

This function corresponds to the SDisoordvar function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
    sdsID = sd.select(sdID,idx);
    sdsName = sd.getInfo(sdsID);
    fprintf('%s (index %d) ', sdsName, idx);
    if ( sd.isCoordVar(sdsID) )
        fprintf('is a coordinate variable.\n');
    else
        fprintf('is not a coordinate variable.\n');
    end
    sd.endAccess(sdsID);
end
sd.close(sdID);
```

See Also sd.isRecord

matlab.io.hdf4.sd.isRecord

Purpose Determine if data set is appendable

Syntax TF = isRecord(sdsID)

Description TF = isRecord(sdsID) determines if the data set specified by sdsID is appendable, meaning that the slowest changing dimension is unlimited. This function corresponds to the SDisrecord function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
ndataset = sd.fileInfo(sdID);
for idx = 0:ndataset-1
    sdsID = sd.select(sdID,idx);
    sdsName = sd.getInfo(sdsID);
    if sd.isRecord(sdsID)
        fprintf('%s is a record variable.\n',sdsName);
    else
        fprintf('%s is not a record variable.\n',sdsName);
    end
    sd.endAccess(sdsID);
end
sd.close(sdID);
```

See Also sd.isCoordVar

Purpose Index value of named data set

Syntax `idx = nameToIndex(sdID,sdsname)`

Description `idx = nameToIndex(sdID,sdsname)` returns the index of the data set with the name specified by `sdsname`. If there is more than one data set with the same name, the routine returns the index of the first one.

This function corresponds to the `SDnametoindex` function in the HDF C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sd.close(sdID);
```

See Also `sd.select`

matlab.io.hdf4.sd.nameToIndices

Purpose List of data sets with same name

Syntax `varstruct = nameToIndices(sdID,sdsname)`

Description `varstruct = nameToIndices(sdID,sdsname)` returns a structure array for all data sets with the same name. Each element of `varstruct` has two fields.

| | |
|----------------------|---|
| <code>'index'</code> | Index of data set |
| <code>'type'</code> | Type of data set, either 'SDSVAR', 'COORDVAR', or 'UNKNOWN' |

This function corresponds to the `SDnametoindices` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
varlist = sd.nameToIndices(sdID,'latitude');
sd.close(sdID);
```

See Also `sd.setDimScale` | `sd.isCoordVar`

Purpose Read attribute value

Syntax `data = readAttr(objID,idx)`

Description `data = readAttr(objID,idx)` reads the value of the attribute specified by index `idx`. The `objID` input can be an SD interface identifier, a data set identifier, or a dimension identifier. `idx` is a zero-based index.

This function corresponds to the `SDreadattr` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.findAttr(sdID,'creation_date');
data = sd.readAttr(sdID,idx);
sd.close(sdID);
```

See Also `sd.findAttr` | `sd.setAttr`

matlab.io.hdf4.sd.readChunk

Purpose Read chunk from data set

Syntax datachunk = readChunk(sdsID,origin)

Description datachunk = readChunk(sdsID,origin) reads an entire chunk of data from the data set identified by sdsID. The origin input specifies the location of the chunk in zero-based chunking coordinates, not in data set coordinates.

This function corresponds to the SDreadchunk function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the origin parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
dataChunk = sd.readChunk(sdsID,[0 1]);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also sd.writeChunk | sd.writeData

Purpose

Read subsample of data

Syntax

```
data = readData(sdsID)
data = readData(sdsID,start,count)
data = readData(sdsID,start,count,stride)
```

Description

`data = readData(sdsID)` reads all of the data for the data set identified by `sdsID`.

`data = readData(sdsID,start,count)` reads a contiguous hyperslab of data from the data set identified by `sdsID`. The `start` input specifies the starting position from where the hyperslab is read. `count` specifies the number of values to read along each data set dimension.

`data = readData(sdsID,start,count,stride)` reads a strided hyperslab of data from the data set identified by `sdsID`.

`start`, `count`, and `stride` use zero-based indexing.

This function corresponds to the `SDreaddata` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

Examples

Read an entire data set.

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
data = sd.readData(sdsID);
sd.endAccess(sdsID);
sd.close(sdID);
```

Read a 2-by-3 portion of a data set.

```
import matlab.io.hdf4.*
```

matlab.io.hdf4.sd.readData

```
sdID = sd.start('sd.hdf');  
idx = sd.nameToIndex(sdID,'temperature');  
sdsID = sd.select(sdID,idx);  
data = sd.readData(sdsID,[0 0],[2 3]);  
sd.endAccess(sdsID);  
sd.close(sdID);
```

See Also

`sd.writeData`

Purpose Index of data set corresponding to reference number

Syntax `idx = refToIndex(sdID,ref)`

Description `idx = refToIndex(sdID,ref)` returns the index of the data set identified by its reference number `ref`. The `idx` output can then be passed to `sd.select`, to obtain a data set identifier.

This function corresponds to the `SDrefToIndex` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
ref = sd.idToRef(sdsID);
idx2 = sd.refToIndex(sdID,ref);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.idToRef` | `sd.select`

matlab.io.hdf4.sd.select

Purpose Identifier of data set with specified index

Syntax `sdsID = select(sdID,IDX)`

Description `sdsID = select(sdID,IDX)` returns the identifier of the data set specified by its index.

This function corresponds to the `SDselect` function in the HDF C library.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf','read');
idx = sd.nameToIndex(sdID,'temperature');
sdsID = sd.select(sdID,idx);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.endAccess` | `sd.nameToIndex`

Purpose Write attribute value

Syntax `setAttr(objID,name,value)`

Description `setAttr(objID,name,value)` attaches an attribute to the object specified by `objID`. If `objID` is the SD interface identifier, then a global attribute is created. If a data identifier is specified, then the attribute is attached to the data set. If a dimension identifier is specified, then the attribute is attached to the dimension.

This function corresponds to the `SDsetattr` function in the HDF library C API.

Examples Attach attributes to a file, a data set, and to a dimension.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setAttr(sdID,'creation_date',datestr(now));
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setAttr(sdsID,'long_name','Temperature in sunlight.');
```

```
dimID0 = sd.getDimID(sdsID,0);
sd.setAttr(dimID0,'long_name','latitude');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.readAttr` | `sd.findAttr`

matlab.io.hdf4.sd.setCal

Purpose Set data set calibration information

Syntax `setCal(sdsID,cal,calErr,offset,offsetErr,datatype)`

Description `setCal(sdsID,cal,calErr,offset,offsetErr,datatype)` sets the calibration information for a data set.

This function corresponds to the `SDsetcal` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_kelvin','%.3f','spherical');
sd.setCal(sdsID,1,0,273,0,'double');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.getCal`

Purpose Set chunk size and compression method of data set

Syntax `setChunk(sdsID, chunkSize, comptype, compparm)`

Description `setChunk(sdsID, chunkSize, comptype, compparm)` makes the data set specified by `sdsID` a chunked data set with chunk size given by `chunkSize` and compression specified by `comptype` and `compparm`. The `comptype` input can be one of the following strings.

| | |
|-----------|------------------------------|
| 'none' | No compression |
| 'skphuff' | Skipping Huffman compression |
| 'deflate' | GZIP compression |
| 'rle' | Run-length encoding |

- If `comptype` is 'none' or 'rle', then `compparm` need not be specified.
- If `comptype` is 'skphuff', then `compparm` is the skipping size.
- If `comptype` is 'deflate', then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `chunkSize` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf', 'create');
sdsID = sd.create(sdID, 'temperature', 'double', [200 100]);
sd.setChunk(sdsID, [20 10], 'skphuff', 16);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.readChunk` | `sd.writeChunk`

matlab.io.hdf4.sd.setCompress

Purpose Set compression method of data set

Syntax `setCompress(sdsID,comptype,compparm)`

Description `setCompress(sdsID,comptype,compparm)` sets the compression scheme for the specified data set. The compression must be done before writing the data set. `comptype` can be one of the following strings.

| | |
|-----------|------------------------------|
| 'none' | No compression |
| 'skphuff' | Skipping Huffman compression |
| 'deflate' | GZIP compression |
| 'rle' | Run-length encoding |

- If `comptype` is 'none' or 'rle', then `compparm` need not be specified.
- If `comptype` is 'skphuff', then `compparm` is the skipping size.
- If `comptype` is 'deflate', then `compparm` is the deflate level, which must be between 0 and 9.

This function corresponds to the `SDsetcompress` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[200 100]);
sd.setCompress(sdsID,'deflate',5);
data = rand(200,100);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.setChunk`

Purpose Set predefined attributes for data set

Syntax `setDataStrs(sdsID,label,unit,format,coordsys)`

Description `setDataStrs(sdsID,label,unit,format,coordsys)` sets the predefined attributes 'long_name', 'units', 'format', and 'coordsys' for a data set.

This function corresponds to the `SDsetdatastrs` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'degrees_celsius','degrees_east','','geo');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.getDataStrs` | `sd.setDimStrs`

matlab.io.hdf4.sd.setDimName

Purpose Associate name with dimension

Syntax `setDimName(dimID,dimname)`

Description `setDimName(dimID,dimname)` sets the name of the dimension identified by `dimID` to `dimname`.

This function corresponds to the `SDsetdimname` function in the HDF library C API.

Examples Create a 2D data set with dimensions 'lat' and 'lon'.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.dimInfo`

Purpose Set scale values for dimension

Syntax `setDimScale(dimID,scaledata)`

Description `setDimScale(dimID,scaledata)` sets the scale values for a dimension. This function corresponds to the `SDsetdimscale` function in the HDF library C API.

Examples Create a 2D data set with dimensions 'lat' and 'lon'.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
sd.setDimScale(dimID,0:10:90);
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimScale(dimID, -180:18:179);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.getDimScale`

matlab.io.hdf4.sd.setDimStrs

Purpose Set label, unit, and format attribute strings

Syntax `setDimStrs(dimID,label,unit,format)`

Description `setDimStrs(dimID,label,unit,format)` sets the label, unit, and format attributes for the dimension identified by `dimID`.

This function corresponds to the `SDsetdimstrs` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
dimID = sd.getDimID(sdsID,0);
sd.setDimName(dimID,'lat');
dimID = sd.getDimID(sdsID,1);
sd.setDimName(dimID,'lon');
sd.setDimStrs(dimID,'Degrees of Longitude','degrees_east','%.2f');
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.getDimStrs`

Purpose

Store data in external file

Syntax

```
setExternalFile(sdsID,extfile,offset)
```

Description

`setExternalFile(sdsID,extfile,offset)` moves data values (not metadata) into the external data file `extfile` starting at the byte `offset`.

Data can only be moved once for any given data set. The external file should be kept with the main file.

This function corresponds to the `SDsetexternalfile` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setExternalFile(sdsID,'myExternalFile.dat',0);
sd.writeData(sdsID,[0 0],rand(10,20));
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.create` | `sd.writeData`

matlab.io.hdf4.sd.setFillMode

Purpose Set current fill mode of file

Syntax `prevmode = setFillMode(sdID,fillmode)`

Description `prevmode = setFillMode(sdID,fillmode)` returns the previous fill mode of a file and resets it to `fillmode`. This setting applies to all data sets contained in the file identified by `sdID`.

Possible values of `fillmode` are 'fill', and 'nofill'. 'fill' is the default mode and indicates that fill values will be written when the data set is created. 'nofill' indicates that the fill values will not be written.

When a fixed-size data set is created, the first call to `sd.writeData` will fill the entire data set with the default or user-defined fill value if `fillmode` is 'fill'. In data sets with an unlimited dimension, if a new write operation takes place along the unlimited dimension beyond the last location of the previous write operation, the array locations between these written areas will be initialized to the user-defined fill value, or the default fill value if a user-defined fill value has not been specified.

If it is certain that all data set values will be written before any read operation takes place, there is no need to write the fill values. Calling `sd.setFillMode` with 'nofill' can improve performance in this case.

This function corresponds to the `SDsetfillmode` function in the HDF library C API.

Examples

Write two partial records. Write the first in 'nofill' mode, and the second with 'fill' mode.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sd.setFillMode(sdID,'nofill');
sdsID = sd.create(sdID,'temperature','double',[10 10 0]);
sd.writeData(sdsID,[0 0 0], rand(5,5));
sd.setFillMode(sdID,'fill');
sd.setFillValue(sdsID,-999);
sd.writeData(sdsID,[0 0 1], rand(5,5));
sd.endAccess(sdsID);
```

```
sd.close(sdID);
```

See Also

```
sd.setFillValue | sd.getFillValue
```

matlab.io.hdf4.sd.setFillValue

Purpose Set fill value for data set

Syntax `setFillValue(sdsID,fillValue)`

Description `setFillValue(sdsID,fillValue)` sets the fill value for a data set. The fill value must have the same data type as the data set.

This function corresponds to the `SDsetfillvalue` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setFillValue(sdsID,-999);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.getFillValue`

Purpose

Specify nonstandard bit length for data set values

Syntax

`setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)`

Description

`setNBitDataSet(sdsID,startBit,bitlen,ext,fillone)` specifies that the integer data set identified by `sdsID` contains data of a non-standard length defined by `startBit` and `bitlen`.

Any length between 1 and 32 bits can be specified. After `setNBitDataset` has been called for the data set array, any read or write operation will involve conversion between the new data length of the data set array and the data length of the read or write buffer.

Bit lengths of all data types are counted from the right of the bit field starting with 0. In a bit field containing the values 01111011, bits 2 and 7 are set to 0 and all the other bits are set to 1. The least significant bit is bit 0.

The `startBit` parameter specifies the left-most position of the variable-length bit field to be written. For example, in the bit field described in the preceding paragraph a `startBit` parameter set to 4 would correspond to the fourth bit value of 1 from the right.

The parameter `bitlen` specifies the number of bits of the variable-length bit field to be written. This number includes the starting bit and the count proceeds toward the right end of the bit field - toward the lower-bit numbers. For example, starting at bit 5 and writing 4 bits of the bit field described in the preceding paragraph would result in the bit field 1110 being written to the data set. This would correspond to a `startBit` value of 5 and a `bitlen` value of 4.

The parameter `ext` specifies whether to use the left-most bit of the variable-length bit field to sign-extend to the left-most bit of the data set data. For example, if 9-bit signed integer data is extracted from bits 17-25 and the bit in position 25 is 1, then when the data is read back from disk, bits 26-31 will be set to 1. Otherwise bit 25 will be 0 and bits 26-31 will be set to 0. The `ext` parameter can be set to `true` (or 1) or `false` (or 0); specify `true` to sign-extend.

matlab.io.hdf4.sd.setNBitDataSet

The parameter `fillone` specifies whether to fill the "background" bits with the value 1 or 0. This parameter is also set to either `true` (or 1) or `false` (or 0).

The "background" bits of a non-standard length data set are the bits that fall outside of the non-standard length bit field stored on disk. For example, if five bits of an unsigned 16-bit integer data set located in bits 5 to 9 are written to disk with the parameter `fillone` set to `true` (or 1), then when the data is reread into memory bits 0 to 4 and 10 to 15 would be set to 1. If the same 5-bit data was written with a `fillone` value of `false` (or 0), then bits 0 to 4 and 10 to 15 would be set to 0.

The operation on `fillone` is performed before the operation on `ext`. For example, using the `ext` example above, bits 0 to 16 and 26 to 31 will first be set to the background bit value, and then bits 26 to 31 will be set to 1 or 0 based on the value of the 25th bit.

This function corresponds to the `SDsetnbitdataset` in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','int32',[10 20]);
sd.setNBitDataSet(sdsID,6,4,0,0);
data = int32([1:200]);
data = reshape(data,10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

```
sd.setCompress
```

Purpose Set maximum and minimum range value for data set

Syntax `setRange(sdsID,maxval,minval)`

Description `setRange(sdsID,maxval,minval)` sets the maximum and minimum range values of the data set identified by `sdsID`. These values form the "valid_range" attribute for `sdsID`.

The actual maximum and minimum values of the data set are not computed. The "valid_range" attribute is for informational purposes only.

This function corresponds to the `SDsetrange` function in the HDF library C interface.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
sd.setDataStrs(sdsID,'Temperature','degrees_celsius','%.2f','');
sd.setRange(sdsID,1000,-273.15);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also `sd.getRange`

matlab.io.hdf4.sd.start

Purpose Open HDF file and initialize SD interface

Syntax `sdID = start(filename)`
`sdID = start(filename,access)`

Description `sdID = start(filename)` opens the file `filename` in read-only mode. This routine must be called for each file before any other `sd` calls can be made on that file.

`sdID = start(filename,access)` opens the file `filename` with the access mode specified by `access`. This routine must be called before any other SD interface operations can be made on that file. `access` can be one of the following strings:

- 'read'
- 'write'
- 'create'

`access` defaults to 'read' if not supplied.

This function corresponds to the `SDstart` function in the HDF library C API.

Examples

```
import matlab.io.hdf4.*
sdID = sd.start('sd.hdf');
sd.close(sdID);
```

See Also `sd.close`

Purpose

Write chunk to data set

Syntax

```
writeChunk(sdsID,origin,dataChunk)
```

Description

`writeChunk(sdsID,origin,dataChunk)` writes an entire chunk of data to the data set identified by `sdsID`. The `origin` input specifies the location of the chunk in chunking coordinates, not in data set coordinates.

This function corresponds to the `SDwritechunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `origin` parameter is reversed with respect to the C library API.

Examples

Write to a 2D chunked and compressed data set. The chunked layout constitutes a 10-by-5 grid.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[100 50]);
sd.setChunk(sdsID,[10 10],'deflate',5);
for j = 0:9
    for k = 0:4
        origin = [j k];
        data = (1:100) + k*1000 + j*10000;
        data = reshape(data,10,10);
        sd.writeChunk(sdsID,origin,data);
    end
end
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.readChunk` | `sd.writeData`

matlab.io.hdf4.sd.writeData

Purpose Write to data set

Syntax `writeData(sdsID,data)`
`writeData(sdsID,start,data)`
`writeData(sdsID,start,stride,data)`

Description `writeData(sdsID,data)` writes all the data to the data set identified by `sdsID`.

`writeData(sdsID,start,data)` writes a contiguous hyperslab to the data set. `start` specifies the zero-based starting index. The number of values along each dimension is inferred from the size of `data`.

`writeData(sdsID,start,stride,data)` writes a strided hyperslab of data to a grid datafield. The number of elements to write along each dimension is inferred either from the size of `data` or from the data set itself.

`start` and `stride` use zero-based indexing.

This function corresponds to the `SDreadchunk` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

Examples Write to a 2D data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 20]);
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

Write to a 2D unlimited data set.

```
import matlab.io.hdf4.*
sdID = sd.start('myfile.hdf','create');
sdsID = sd.create(sdID,'temperature','double',[10 0]);
data = rand(10,20);
sd.writeData(sdsID,[0 0],data);
data = rand(10,30);
sd.writeData(sdsID,[0 20],data);
sd.endAccess(sdsID);
sd.close(sdID);
```

See Also

`sd.readData`

Purpose Low-level access to HDF-EOS grid data

Description To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfeos.gd`. To use this package, prefix the function name with a package path, or use the import function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfeos.*  
gfid = gd.open(filename, 'read');
```

Access

| | |
|---|---------------------------|
| <code>matlab.io.hdfeos.gd.attach</code> | Attach to existing grid |
| <code>matlab.io.hdfeos.gd.close</code> | Close HDF-EOS grid file |
| <code>matlab.io.hdfeos.gd.detach</code> | Detach from existing grid |
| <code>matlab.io.hdfeos.gd.open</code> | Open grid file |

Definition

| | |
|---|---------------------------------------|
| <code>matlab.io.hdfeos.gd.create</code> | Create new grid structure |
| <code>matlab.io.hdfeos.gd.defComp</code> | Set grid field compression |
| <code>matlab.io.hdfeos.gd.defDim</code> | Define new dimension within grid |
| <code>matlab.io.hdfeos.gd.defField</code> | Define new data field within grid |
| <code>matlab.io.hdfeos.gd.defOrigin</code> | Define origin of pixels in grid |
| <code>matlab.io.hdfeos.gd.defPixReg</code> | Define pixel registration within grid |
| <code>matlab.io.hdfeos.gd.defProj</code> | Define grid projection |
| <code>matlab.io.hdfeos.gd.writeBlkSomOff</code> | Write Block SOM offset |

Basic I/O

| | |
|----------------------------------|------------------------------------|
| matlab.io.hdfEOS.gd.getFillValue | Fill value for specified field |
| matlab.io.hdfEOS.gd.readAttr | Read grid attribute |
| matlab.io.hdfEOS.gd.readField | Read data from grid field |
| matlab.io.hdfEOS.gd.setFillValue | Set fill value for specified field |
| matlab.io.hdfEOS.gd.writeAttr | Write grid attribute |
| matlab.io.hdfEOS.gd.writeField | Write data to grid field |

Inquiry

| | |
|--------------------------------------|---|
| matlab.io.hdfEOS.gd.compInfo | Compression information for field |
| matlab.io.hdfEOS.gd.dimInfo | Length of dimension |
| matlab.io.hdfEOS.gd.fieldInfo | Information about data field |
| matlab.io.hdfEOS.gd.gridInfo | Position and size of grid |
| matlab.io.hdfEOS.gd.inqAttrs | Names of grid attributes |
| matlab.io.hdfEOS.gd.inqDims | Information about dimensions defined in grid |
| matlab.io.hdfEOS.gd.inqFields | Information about data fields defined in grid |
| matlab.io.hdfEOS.gd.inqGrid | Names of grids in file |
| matlab.io.hdfEOS.gd.nEntries | Number of specified objects |
| matlab.io.hdfEOS.gd.originInfo | Origin code |
| matlab.io.hdfEOS.gd.pixRegInfo | Pixel registration code |
| matlab.io.hdfEOS.gd.projInfo | GCTP projection information about grid |
| matlab.io.hdfEOS.gd.readBlkSomOffset | Read Block SOM offset |

Subsetting

| | |
|-----------------------------------|---|
| matlab.io.hdfEOS.gd.defBoxRegion | Define region of interest by latitude and longitude |
| matlab.io.hdfEOS.gd.defVrtRegion | Define vertical subset region |
| matlab.io.hdfEOS.gd.extractRegion | Read region of interest from field |
| matlab.io.hdfEOS.gd.getPixels | Pixel rows and columns for latitude/longitude pairs |
| matlab.io.hdfEOS.gd.getPixValues | Read data values for specified pixels |
| matlab.io.hdfEOS.gd.regionInfo | Information about subsetted region |

Tiling

| | |
|---------------------------------|--|
| matlab.io.hdfEOS.gd.defTile | Define tiling parameters |
| matlab.io.hdfEOS.gd.readTile | Read single tile of data from field |
| matlab.io.hdfEOS.gd.setTileComp | Set tiling and compression for field with fill value |

| matlab.io.hdfEOS.gd.ij2ll | Convert row and column space to latitude and longitude |
| matlab.io.hdfEOS.gd.ll2ij | Convert latitude and longitude to row and column space |

matlab.io.hdfEOS.gd.sphereCodeToName Name corresponding to GCTP
sphere code

matlab.io.hdfEOS.gd.sphereNameToCode Numeric GCTP code
corresponding to sphere name

matlab.io.hdfeos.gd.attach

Purpose Attach to existing grid

Syntax `gridID = attach(gfID,gridName)`

Description `gridID = attach(gfID,gridName)` attaches to the grid dataset identified by `gridName` in the file identified by `gfID`. The `gridID` output is the identifier for the grid dataset.

This function corresponds to the `GDattach` function in the HDF-EOS library C API.

Examples Attach to the grid named 'PolarGrid' in the file 'grid.hdf'.

```
import matlab.io.hdfeos.*
gfID = gd.open('grid.hdf');
gridID = gd.attach(gfID,'PolarGrid');
gd.detach(gridID);
gd.close(gfID);
```

See Also `gd.detach` | `gd.readField` | `gd.inqGrid`

Purpose Close HDF-EOS grid file

Syntax `close(gfID)`

Description `close(gfID)` closes an HDF-EOS grid file identified by `gfID`.
This function corresponds to the `GDClose` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*  
gfID = gd.open('grid.hdf');  
gd.close(gfID);
```

See Also `gd.open` | `gd.create`

matlab.io.hdfEOS.gd.compInfo

Purpose Compression information for field

Syntax `[compCode,parms] = compInfo(gridID,fieldname)`

Description `[compCode,parms] = compInfo(gridID,fieldname)` returns the compression code and compression parameters for a given field. Refer to `gd.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `GDcompinfo` function in the HDF-EOS library C API.

Examples Define a 'Pressure' field with run-length encoding compression and an 'Opacity' field with gzip compression.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
[compCode,compParms] = gd.compInfo(gridID, 'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defComp`

Purpose

Create new grid structure

Syntax

```
gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)
```

Description

`gridID = create(gfID,gridName,xdim,ydim,upLeft,lowRight)` creates a new grid structure where `gfID` is the grid file identifier. `gridName` is the name of the new grid. `xdim` and `ydim` define the size of the grid. `upLeft` is a two-element vector containing the location of the upper left pixel, and `lowRight` is a two-element vector containing the location of the lower right pixel.

Note `upLeft` and `lowRight` are in units of meters for all GCTP projections other than the geographic and bcea projections, which should have units of packed degrees.

Note For certain projections, `upLeft` and `lowRight` can be given as `[]`.

- Polar Stereographic projection of an entire hemisphere.
 - Goode Homolosine projection of the entire globe.
 - Lambert Azimuthal entire polar or equatorial projection.
-

Note MATLAB uses Fortran-style ordering, but the HDF-EOS library uses C-style ordering.

This function corresponds to the `GDcreate` function in the HDF-EOS library C API.

matlab.io.hdfEOS.gd.create

Examples

Create a polar stereographic grid of the northern hemisphere.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid, 'PolarGrid', 100, 100, [], []);
gd.detach(gridID);
gd.close(gfid);
```

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude. Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid, 'UTMGrid', 120, 200, uplft, lowrgt);
gd.detach(gridID);
gd.close(gfid);
```

See Also

[gd.detach](#) | [gd.defProj](#) | [gd.gridInfo](#)

Purpose

Define region of interest by latitude and longitude

Syntax

```
regionID = defBoxRegion(gridID,cornerLat,cornerLon)
```

Description

`regionID = defBoxRegion(gridID,cornerLat,cornerLon)` defines a latitude-longitude box region as a subset region for a grid. `regionID` can be used to read all the entries of a data field within the region.

This function corresponds to the `GDdefboxregion` function in the HDF-EOS library C API.

Examples

Define a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon);
data = gd.extractRegion(gridID,regionID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.extractRegion`

Purpose Set grid field compression

Syntax `defComp(gridID,compscheme,compparm)`

Description `defComp(gridID,compscheme,compparm)` sets the HDF field compression for subsequent field definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

| | |
|-----------|---------------------|
| 'rle' | Run-length encoding |
| 'skphuff' | Skipping Huffman |
| 'deflate' | Gzip deflate |
| 'none' | No compression |

When the compression scheme is 'deflate', `compparm` is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

If a field is defined with compression, it must be written with a single call to `gd.writeField`. If this is not possible, you should consider using tiling.

This function corresponds to the `GDdefcomp` function in the HDF-EOS library C API.

Examples Create a grid with a polar stereographic Pressure field using run-length encoding, and then an Opacity field with deflate compression.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
dims = { 'XDim', 'YDim' };
gd.defComp(gridID,'rle');
```

```
gd.defField(gridID, 'Pressure', dims, 'float');  
gd.defComp(gridID, 'deflate', 5);  
gd.defField(gridID, 'Opacity', dims, 'float');  
gd.detach(gridID);  
gd.close(gfid);
```

See Also

[gd.defField](#) | [gd.defTile](#)

matlab.io.hdfEOS.gd.defDim

Purpose Define new dimension within grid

Syntax `defDim(gridID,dimname,dimlen)`

Description `defDim(gridID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the grid structure identified by `gridID`.
To specify an unlimited dimension, you can use either 0 or 'unlimited' for `dimlen`.

This function corresponds to the `GDdefdim` function in the HDF-EOS library C API.

Examples Define a dimension 'Band' with length of 15 and an unlimited dimension 'Time'.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
gd.defDim(gridID,'Band',15);
gd.defDim(gridID,'Time',0);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defField` | `gd.dimInfo`

Purpose

Define new data field within grid

Syntax

```
defField(gridID,fieldname,dimlist,dtype)
defField(gridID,fieldname,dimlist,dtype,mergeCode)
```

Description

`defField(gridID,fieldname,dimlist,dtype)` defines data fields for a grid specified by `gridID`. The `fieldname` input is the name of the new field. `dimlist` is a cell array of geolocation dimensions and should be listed in FORTRAN-style order, that is, the fastest varying dimension should be listed first. `dimlist` can also be a string if there is only one dimension. `dtype` is the data type of the field.

`defField(gridID,fieldname,dimlist,dtype,mergeCode)` defines a data field with a specific merge code. `mergeCode` can be either 'nomerge' or 'automerge'. The `mergeCode` input defaults to 'nomerge' if not provided.

This function corresponds to the `GDdeffield` function in the HDF library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

Define a single precision grid field 'Temperature' with dimensions 'XDim' and 'YDim'. Then define a single precision field 'Spectra' with dimensions 'XDim', 'YDim', and 'Bands'.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
xdim = 120; ydim = 200;
gridID = gd.create(gfid,'geo',xdim,ydim,[],[]);
gd.defProj(gridID,'geo',[],[],[]);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Temperature',dimlist,'single');
gd.defDim(gridID,'Bands',3);
dimlist = {'XDim','YDim','Bands'};
gd.defField(gridID,'Spectra',dimlist,'uint8');
gd.detach(gridID);
gd.close(gfid);
```

See Also

[gd.create](#) | [gd.defDim](#)

Purpose Define origin of pixels in grid

Syntax `defOrigin(gridID,originCode)`

Description `defOrigin(gridID,originCode)` defines the origin of pixels in a grid. `gridID` is the identifier of the grid, and `originCode` can be one of the following four strings.

| | |
|------|-------------|
| 'ul' | Upper-left |
| 'ur' | Upper-right |
| 'll' | Lower-left |
| 'lr' | Lower-right |

You can select any corner of the grid pixel as the origin. If this routine is not invoked, the grid defaults to using the upper-left corner for the origin.

This function corresponds to the `GDdeforigin` function in the HDF-EOS library C API.

Examples Create a polar stereographic grid with the origin of the grid pixel in the lower right corner.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.defOrigin(gridID,'lr');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.originInfo` | `gd.defPixReg`

Purpose Define pixel registration within grid

Syntax `defPixReg(gridID,pixRegCode)`

Description `defPixReg(gridID,pixRegCode)` defines whether the pixel center or pixel corner is used when requesting the location (longitude and latitude) of a given pixel. `pixRegCode` can be one of the following strings.

| | |
|----------|----------------------|
| 'center' | Center of pixel cell |
| 'corner' | Corner of pixel cell |

If this routine is not invoked, the pixel registration is 'center'.

This function corresponds to the `GDdefpixreg` function in the HDF-EOS library.

Examples Define a grid with pixel registration in the center.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.defPixReg(gridID,'corner');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defOrigin` | `gd.pixRegInfo`

Purpose Define grid projection

Syntax `defProj(gridID,projCode,zoneCode,sphereCode,projParm)`

Description `defProj(gridID,projCode,zoneCode,sphereCode,projParm)` defines a GCTP projection on the grid specified by `gridID`. The `projCode` argument can be one of the following strings.

| | |
|-----------------------|---------------------------------|
| <code>'geo'</code> | Geographic |
| <code>'utm'</code> | Universal Transverse Mercator |
| <code>'albers'</code> | Albers Canonical Equal Area |
| <code>'lamcc'</code> | Lambert Conformal Conic |
| <code>'ps'</code> | Polar Stereographic |
| <code>'polyc'</code> | Polyconic |
| <code>'tm'</code> | Transverse Mercator |
| <code>'lamaz'</code> | Lambert Azimuthal Equal Area |
| <code>'snsoid'</code> | Sinusoidal |
| <code>'hom'</code> | Hotine Oblique Mercator |
| <code>'som'</code> | Space Oblique Mercator |
| <code>'good'</code> | Interrupted Goode Homolosine |
| <code>'cea'</code> | Cylindrical Equal Area |
| <code>'bcea'</code> | Behrmann Cylindrical Equal Area |
| <code>'isinus'</code> | Integerized Sinusoidal |

If `projCode` is `'geo'`, then `zoneCode`, `sphereCode`, and `projParm` should be specified as `[]`. Any other values for these parameters are ignored.

`zoneCode` is the Universal Transverse Mercator zone code. It should be specified as `-1` for other projections.

sphereCode is the name of the GCTP spheroid or the corresponding numeric code.

projParm is a vector of up to 13 elements containing projection-specific parameters. For more details about projCode, zoneCode, sphereCode, and projParm, see Chapter 6 of HDF-EOS Library Users Guide for the ECS Project, Volume 1: Overview and Examples.

This function corresponds to the GDdefproj function in the HDF library C API.

Examples

Create a UTM grid bounded by 54 E to 60 E longitude and 20 N to 30 N latitude (zone 40). Divide the grid into 120 bins along the x-axis and 200 bins along the y-axis.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
uplft = [210584.50041 3322395.95445];
lowrgt = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,uplft,lowrgt);
gd.defProj(gridID,'utm',40,'Clarke 1866',[]);
gd.detach(gridID);
gd.close(gfid);
```

Add a polar stereographic projection of the northern hemisphere with true scale at 90 N, 0 longitude below the pole using the WGS 84 spheroid.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'PolarGrid',100,100,[],[]);
projparm = zeros(1,13);
projparm(6) = 90000000;
gd.defProj(gridID,'ps',[],'WGS 84',projparm);
gd.detach(gridID);
gd.close(gfid);
```

See Also

[gd.projInfo](#) | [gd.create](#) | [gd.sphereCodeToName](#)

matlab.io.hdfEOS.gd.defTile

Purpose Define tiling parameters

Syntax `defTile(gridID,tileDims)`

Description `defTile(gridID,tileDims)` defines tiling dimensions for subsequent field definitions. If `tileDims` is `[]`, then subsequently defined fields will have no tiling.

This function corresponds to the `GDdefTile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileDims` parameter is reversed with respect to the C library API.

Examples Define a field with tiling, then a subsequent field with no tiling.

```
import matlab.io.hdfEOS.*
gfid = gd.open('myfile.hdf','create');
gridID = gd.create(gfid,'GeoGrid',120,200,[],[]);
gd.defDim(gridID,'Bands',3);
gd.defProj(gridID,'geo',[],[],[]);
gd.defTile(gridID,[30 50 1]);
dimlist = {'XDim','YDim','Bands'};
gd.defField(gridID,'Spectra',dimlist,'float');
gd.defTile(gridID,[]);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Temperature',dimlist,'int32');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.tileInfo` | `gd.defField`

Purpose

Define vertical subset region

Syntax

```
out_RID = defVrtRegion(gridID,regionID,vobj,vRange)
```

Description

`out_RID = defVrtRegion(gridID,regionID,vobj,vRange)` defines a vertical subset region and can be used on either a monotonic field or contiguous elements of a dimension.

`regionID` should be 'noprevious' if no prior subsetting has occurred. Otherwise it should be a value as returned from a previous subsetting routine.

`vobj` is the name of either the dimension or field to subset. If `vobj` is a dimension, it should be prefixed with 'DIM:'.

`vRange` is the minimum and maximum range for the vertical subset.

This function corresponds to the `GDdefvrtregion` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
range = [333 667];
regionID = gd.defVrtRegion(gridID,'noprevious','Height',range);
data = gd.extractRegion(gridID,regionID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
range = [3 5];
regionID = gd.defVrtRegion(gridID,'noprevious','DIM:Height',range);
data = gd.extractRegion(gridID,regionID,'pressure');
gd.detach(gridID);
gd.close(gfid);
```

matlab.io.hdfeos.gd.defVrtRegion

See Also

`gd.extractRegion`

| | |
|--------------------|---|
| Purpose | Detach from existing grid |
| Syntax | <code>detach(gridID)</code> |
| Description | <code>detach(gridID)</code> detaches from the grid identified by <code>gridID</code> .
This function corresponds to the <code>GDdetach</code> function in the HDF-EOS library C API. |
| Examples | <pre>import matlab.io.hdfeos.* gfID = gd.open('grid.hdf'); gridID = gd.attach(gfID, 'PolarGrid'); gd.detach(gridID); gd.close(gfID);</pre> |
| See Also | <code>gd.attach</code> |

matlab.io.hdfEOS.gd.dimInfo

Purpose Length of dimension

Syntax `dimlen = diminfo(gridID,dimname)`

Description `dimlen = diminfo(gridID,dimname)` retrieves the length of the specified user-defined dimension.

Please note that the two extents used to create the grid are not considered user-defined dimensions. To retrieve the length of XDim and YDim, use `gd.gridInfo`. This function corresponds to the `GDdiminfo` function in the HDF-EOS library C API.

Examples Inquire about a 'Bands' dimension.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
dimlen = gd.dimInfo(gridID,'Height');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defDim` | `gd.gridInfo`

| | |
|--------------------|--|
| Purpose | Read region of interest from field |
| Syntax | <code>data = extractRegion(gridID,regionID,fieldname)</code> |
| Description | <p><code>data = extractRegion(gridID,regionID,fieldname)</code> extract data from a subsetted region.</p> <p>This routine corresponds to the <code>Gdextractregion</code> function in the HDF-EOS library C API.</p> |
| Examples | <p>Define and extract a region of interest between 20 and 50 degrees latitude and between -90 and -60 degrees longitude.</p> <pre>import matlab.io.hdfeos.* gfid = gd.open('grid.hdf','read'); gridID = gd.attach(gfid,'PolarGrid'); cornerlat = [20 50]; cornerlon = [-90 -60]; regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon); data = gd.extractRegion(gridID,regionID,'ice_temp'); gd.detach(gridID); gd.close(gfid);</pre> |
| See Also | <code>gd.defBoxRegion</code> <code>gd.defVrtRegion</code> |

matlab.io.hdfeos.gd.fieldInfo

Purpose Information about data field

Syntax `[dims,ntype,dimlist] = fieldInfo(gridID,fieldname)`

Description `[dims,ntype,dimlist] = fieldInfo(gridID,fieldname)` returns information about a specific geolocation or data field in the grid. `dims` is a vector containing the dimension sizes of the field. `ntype` is a string containing the HDF number type of the field. `dimlist` is a cell array of strings containing the list of dimension names.

This function corresponds to the `Gdfieldinfo` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
[dims,ntype,dimlist] = gd.fieldInfo(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defField`

Purpose Fill value for specified field

Syntax `fillvalue = getFillValue(gridID,fieldname)`

Description `fillvalue = getFillValue(gridID,fieldname)` retrieves the fill value for the specified field.

This function corresponds to the `GDgetfillvalue` function in the HDF-EOS library C API.

Examples Return the fill value for the 'ice_temp' field in the 'PolarGrid' grid.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
fillvalue = gd.getFillValue(gridID, 'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.setFillValue`

matlab.io.hdfeos.gd.getPixels

Purpose Pixel rows and columns for latitude/longitude pairs

Syntax `[row,col] = getPixels(gridID,lat,lon)`

Description `[row,col] = getPixels(gridID,lat,lon)` converts latitude/longitude pairs into zero-based pixel row and column coordinates. The origin is the upper left-hand corner of the grid pixel. If the latitude/longitude pairs are outside the grid, then row and col are -1.

This function corresponds to the GDgetpixels function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
cornerlat = [20 50];
cornerlon = [-90 -60];
[row,col] = gd.getPixels(gridID,cornerlat,cornerlon);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.getPixValues`

Purpose

Read data values for specified pixels

Syntax

```
data = getPixValues(gridID,rows,cols,fieldname)
```

Description

`data = getPixValues(gridID,rows,cols,fieldname)` reads data values for the pixels specified by the zero-based `rows` and `cols` coordinates. All entries along the non-geographic dimensions, i.e. NOT `XDim` and `YDim`, are returned.

This function corresponds to the `GDgetpixvalues` function in the HDF-EOS library C API.

Examples

Read the grid field's corner values.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
rows = [0 99 99 0];
cols = [0 0 99 99];
data = gd.getPixValues(gridID,rows,cols,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

See Also

[gd.getPixels](#) | [gd.readField](#) | [gd.defBoxRegion](#) | [gd.extractRegion](#)

matlab.io.hdfeos.gd.gridInfo

Purpose Position and size of grid

Syntax `[xDim,yDim,upLeft,lowRight] = gridInfo(gridID)`

Description `[xDim,yDim,upLeft,lowRight] = gridInfo(gridID)` returns the size of a grid as well as the upper left and lower right corners of the grid.

Note `upLeft` and `lowRight` are in units of meters for all GCTP projections other than the geographic and bcea projections, which will have units of packed degrees.

This function corresponds to the `GDgridinfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[xdimsize,ydimsize,upleft,lowright] = gd.gridInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.create`

| | |
|--------------------|---|
| Purpose | Convert row and column space to latitude and longitude |
| Syntax | <code>[lat,lon] = ij2ll(gridID,row,col)</code> |
| Description | <p><code>[lat,lon] = ij2ll(gridID,row,col)</code> converts a grid's row and column coordinates to latitude and longitude in decimal degrees.</p> <p>row and col are zero-based and defined such that col increases monotonically with the XDim dimension and row increases monotonically with the YDim dimension in the HD-EOS library.</p> <p>This routine corresponds to the GDij2ll function in the HDF-EOS C API.</p> |
| Examples | <pre>import matlab.io.hdfeos.* gfid = gd.open('grid.hdf'); gridID = gd.attach(gfid,'PolarGrid'); [xdim,ydim] = gd.gridInfo(gridID); r = 0:(xdim-1); c = 0:(ydim-1); [Col,Row] = meshgrid(c,r); [lat,lon] = gd.ij2ll(gridID,Row,Col); gd.detach(gridID); gd.close(gfid);</pre> |
| See Also | <code>gd.ll2ij</code> <code>gd.readField</code> |

matlab.io.hdfEOS.gd.inqAttrs

| | |
|--------------------|--|
| Purpose | Names of grid attributes |
| Syntax | <code>attrList = inqAttrs(gridID)</code> |
| Description | <code>attrList = inqAttrs(gridID)</code> returns the list of grid attribute names. <code>attrList</code> is a cell array.

This function corresponds to the <code>GDinqattrs</code> function in the HDF-EOS library C API. |
| Examples | <pre>import matlab.io.hdfEOS.* gfid = gd.open('grid.hdf'); gridID = gd.attach(gfid,'PolarGrid'); attrList = gd.inqAttrs(gridID); gd.detach(gridID); gd.close(gfid);</pre> |
| See Also | <code>gd.readAttr</code> <code>gd.writeAttr</code> |

| | |
|--------------------|---|
| Purpose | Information about dimensions defined in grid |
| Syntax | <code>[dimnames,dimlens] = inqDims(gridID)</code> |
| Description | <p><code>[dimnames,dimlens] = inqDims(gridID)</code> returns the names of the dimensions <code>dimnames</code> in a cell array and their respective lengths <code>dimlens</code>. This does not include the grid extent dimensions <code>XDim</code> and <code>YDim</code>.</p> <p>This function corresponds to the <code>GDinqdims</code> function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the <code>dimnames</code> and <code>dimlens</code> parameters are reversed with respect to the C library API.</p> |
| Examples | <pre>import matlab.io.hdfEOS.* gfid = gd.open('grid.hdf','read'); gridID = gd.attach(gfid,'PolarGrid'); [dims,dimlens] = gd.inqDims(gridID); gd.detach(gridID); gd.close(gfid);</pre> |
| See Also | <code>gd.defDim</code> |

matlab.io.hdfEOS.gd.inqFields

Purpose Information about data fields defined in grid

Syntax [fldList,fldRank,fldType] = inqFields(gridID)

Description [fldList,fldRank,fldType] = inqFields(gridID) returns the list of fields fldList as a cell array. fldRank contains the rank of each data field. fldType is a cell array containing the data type of each data field.

This function corresponds to the GDinqfields function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[fldlist,fldranks,fldtypes] = gd.inqFields(gridID);
gd.detach(gridID);
gd.close(gfid);
for j = 1:numel(fldranks)
    fprintf('%s: Rank %d, datatype %s\n', fldlist{j},fldranks(j),fldtypes{j})
end
```

See Also gd.defField

Purpose Names of grids in file

Syntax `grids = inqGrid(filename)`

Description `grids = inqGrid(filename)` returns the names of all grids in the given file. `grids` is a cell array.

This function corresponds to the `GDinqgrid` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
grids = gd.inqGrid('grid.hdf');
```

See Also `gd.create` | `sw.inqSwath`

matlab.io.hdfEOS.gd.ll2ij

Purpose Convert latitude and longitude to row and column space

Syntax `[row,col] = ll2ij(gridID,lat,lon)`

Description `[row,col] = ll2ij(gridID,lat,lon)` converts latitude and longitude coordinates to a pre-defined grid's row and column coordinates.

`row` and `col` are zero-based and defined such that `col` increases monotonically with the XDim dimension and `row` increases monotonically with the YDim dimension in the HD-EOS library.

This routine corresponds to the GD112ij function in the HDF-EOS C API.

Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
lat = [46 46 42 42];
lon = [-71 -67 -67 -71];
[row,col] = gd.ll2ij(gridID,lat,lon);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.ij2ll`

Purpose Number of specified objects

Syntax `nentries = nEntries(gridID,entType)`

Description `nentries = nEntries(gridID,entType)` returns the number of specified objects in a grid. `entType` can be either `'dims'` or `'fields'`.

This function corresponds to the `GDnentries` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
ndims = gd.nEntries(gridID,'dims');
nfls = gd.nEntries(gridID,'fields');
gd.detach(gridID);
gd.close(fid);
fprintf('The number of dimensions is %d.\n', ndims);
fprintf('The number of fields is %d.\n', nfls);
```

See Also `gd.inqGrid`

matlab.io.hdfeos.gd.open

Purpose Open grid file

Syntax `gfid = open(filename,access)`

Description `gfid = open(filename,access)` opens or creates an HDF-EOS grid file identified by `filename` and returns a file ID. `access` can be one of the following string values:

| | |
|-----------------------|--|
| <code>'read'</code> | Read-only |
| <code>'rdwr'</code> | Read-write |
| <code>'create'</code> | Creates a file, deleting it if it already exists |

If `access` is not provided, it defaults to `'read'`.

This function corresponds to the `GDopen` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gd.close(gfid);
```

See Also `gd.attach` | `gd.close`

Purpose Origin code

Syntax `originCode = originInfo(gridID)`

Description `originCode = originInfo(gridID)` retrieves the origin code for the grid specified by `gridID`. The `originCode` output is one of the following four string values.

| | |
|------|-------------|
| 'ul' | Upper-left |
| 'ur' | Upper-right |
| 'll' | Lower-left |
| 'lr' | Lower-right |

This function corresponds to the `GDorigininfo` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
origin = gd.originInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defOrigin`

matlab.io.hdfEOS.gd.pixRegInfo

Purpose Pixel registration code

Syntax `pixRegCode = pixRegInfo(gridID)`

Description `pixRegCode = pixRegInfo(gridID)` retrieve the pixel registration code for the grid identified by `gridID`. The `pixRegCode` output can be one of the following strings.

| | |
|----------|----------------------|
| 'center' | Center of pixel cell |
| 'corner' | Corner of pixel cell |

This function corresponds to the `GDpixreginfo` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
code = gd.pixRegInfo(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.defPixReg`

Purpose

GCTP projection information about grid

Syntax

```
[projCode,zoneCode,sphereName,projParm] = projInfo(gridID)
```

Description

[projCode,zoneCode,sphereName,projParm] = projInfo(gridID) returns the GCTP projection code, zone code, spheroid, and projection parameters for the grid identified by gridID.

zoneCode is -1 if projCode is anything other than 'UTM'.

This function corresponds to the GDprojinfo function in the HDF-EOS library C API.

For details about the GCTP projection code, zone code, spheroid code, and projection parameters, please consult the HDF-EOS User's Guide.

Examples

```
import matlab.io.hdfEOS.*
fid = gd.open('grid.hdf');
gridID = gd.attach(fid,'PolarGrid');
[projCode,zoneCode,sphereCode,projParm] = gd.projInfo(gridID);
gd.detach(gridID);
gd.close(fid);
```

See Also

gd.defProj | gd.sphereNameToCode | gd.sphereCodeToName

matlab.io.hdfEOS.gd.readAttr

Purpose Read grid attribute

Syntax data = readAttr(gridID,attrname)

Description data = readAttr(gridID,attrname) reads a grid attribute.
This function corresponds to the GDreadattr function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
data = gd.readAttr(gridID,'creation_date');
gd.detach(gridID);
gd.close(gfid);
```

See Also gd.writeAttr

Purpose

Read Block SOM offset

Syntax

```
offset = readBlkSomOffset(GID)
```

Description

`offset = readBlkSomOffset(GID)` reads the block SOM offset values, in pixels, from a standard SOM (Space Oblique Mercator) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection.

This function corresponds to the `GDbkSOMoffset` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360; % 98.161 in DDDMMMSSSS
projparm(5) = 87069061; % 87.112 in DDDMMMSSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID,'som',[],[],projparm);
gd.writeBlkSomOffset(gridID,[5 10 12 8 2]);
gd.detach(gridID);
gd.close(gfid);
gfid = gd.open('myfile.hdf');
gridID = gd.attach(gfid,'SOM');
blk = gd.readBlkSomOffset(gridID);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.writeBlkSomOffset`

matlab.io.hdfEOS.gd.readField

Purpose Read data from grid field

Syntax

```
data = readField(gridID,fieldname)
data = readField(gridID,fieldname,start,count)
data = readField(gridID,fieldname,start,count,stride)
[data,lat,lon] = readField( ___ )
```

Description

`data = readField(gridID,fieldname)` reads the entire grid field identified by `fieldname` in the grid identified by `gridID`.

`data = readField(gridID,fieldname,start,count)` reads a contiguous hyperslab of data from the field. `start` specifies the zero-based starting index of the hyperslab. `count` specifies the number of values to read along each dimension.

`data = readField(gridID,fieldname,start,count,stride)` reads a strided hyperslab of data from the field. `stride` specifies the inter-element spacing along each dimension.

`[data,lat,lon] = readField(___)` reads the data and the associated geo-coordinates from the grid field. This syntax is only allowed when the leading two dimensions of the grid are 'XDim' and 'YDim'.

This function corresponds to the `GDreadfield` function in the HDF-EOS library C API.

Examples Read the data, latitude, and longitude for the 'ice_temp' field.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid,'PolarGrid');
[data,lat,lon] = gd.readField(gridID,'ice_temp');
gd.detach(gridID);
gd.close(gfid);
```

Read only the first 4x4 hyperslab of data, latitude, and longitude for the 'ice_temp' field.

```
import matlab.io.hdfEOS.*
gfid = gd.open('grid.hdf');
gridID = gd.attach(gfid, 'PolarGrid');
[data2,lat2,lon2] = gd.readField(gridID, 'ice_temp', [0 0], [4 4]);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.writeField`

matlab.io.hdfeos.gd.readTile

Purpose Read single tile of data from field

Syntax `data = readTile(gridID,fieldname,tileCoords)`

Description `data = readTile(gridID,fieldname,tileCoords)` reads a single of data from a field. If the data is to be read tile by tile, this routine is more efficient than `gd.readField`. In all other cases, use `gd.readField`. The `tileCoords` argument has the form `[rownum colnum]` and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the `GDreadtile` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tileCoords` parameter is reversed with respect to the C library API.

Examples Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfeos.*
gfid = gd.open('grid.hdf','read');
gridID = gd.attach(gfid,'PolarGrid');
for h = 0:9
    data = gd.readTile(gridID,'pressure',[0 0 h]);
end
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.writeTile` | `gd.tileInfo`

| | |
|--------------------|---|
| Purpose | Information about subsetted region |
| Syntax | <code>[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)</code> |
| Description | <p><code>[dims,upLeft,lowRight] = regionInfo(gridID,regionID,fieldname)</code> returns the dimensions and corner points for the specified field of a subsetted region identified by <code>regionID</code> in the grid identified by <code>gridID</code>.</p> <p>This function corresponds to the <code>GDregioninfo</code> function in the HDF-EOS library C API.</p> |
| Examples | <pre>import matlab.io.hdfeos.* gfid = gd.open('grid.hdf','read'); gridID = gd.attach(gfid,'PolarGrid'); cornerlat = [20 50]; cornerlon = [-90 -60]; regionID = gd.defBoxRegion(gridID,cornerlat,cornerlon); [dims,upleft,lowright] = gd.regionInfo(gridID,regionID,'ice_temp'); data = gd.extractRegion(gridID,regionID,'ice_temp'); gd.detach(gridID); gd.close(gfid);</pre> |
| See Also | <code>gd.defBoxRegion</code> <code>gd.defVrtRegion</code> |

matlab.io.hdfEOS.gd.setFillValue

Purpose Set fill value for specified field

Syntax `setFillValue(gridID,fieldname,fillvalue)`

Description `setFillValue(gridID,fieldname,fillvalue)` sets the fill value for the specified field. The fill value should have the same data type as the field.

This function corresponds to the `GDsetfillvalue` function in the HDF-EOS library C API.

Examples Create a new double-precision field with a fill value of -1.

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.defComp(gridID,'none');
gd.defField(gridID,'newfield',{'XDim','YDim'},'double');
gd.setFillValue(gridID,'newfield',-1);
gd.detach(gridID);
gd.close(gfid);
```

See Also `gd.getFillValue`

Purpose

Set tiling and compression for field with fill value

Syntax

```
setTileComp(gridID,fieldname,tilesize,compCode,compParm)
```

Description

`setTileComp(gridID,fieldname,tilesize,compCode,compParm)` sets the tiling and compression for a field that had a fill value. This function must be applied after `gd.defField` and `gd.setFillValue`. The `compCode` argument can be one of the following strings.

| | |
|-----------|---------------------|
| 'rle' | Run-length encoding |
| 'skphuff' | Skipping Huffman |
| 'deflate' | Deflate |
| 'none' | No compression |

`compParm` need only be specified when the compression scheme is 'deflate', and then must be an integer between 0 and 9.

This function corresponds to the `GDsettilecomp` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `tilesize` parameter is reversed with respect to the C library API.

Examples

Define a temperature field with a 2-by-2 tiling scheme, a fill value of -999, and deflate compression.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
upleft = [210584.50041 3322395.95445];
lowright = [813931.10959 2214162.53278];
gridID = gd.create(gfid,'UTMGrid',120,200,upleft,lowright);
spherecode = 0; zonecode = 40;
projparm = zeros(1,13);
gd.defProj(gridID,'utm',zonecode,spherecode,projparm);
gd.defDim(gridID,'Time',10);
gd.defField(gridID,'Pollution',{ 'XDim','YDim','Time'},'float');
gd.setFillValue(gridID,'Pollution',single(7));
```

matlab.io.hdfEOS.gd.setTileComp

```
gd.setTileComp(gridID, 'Pollution', [40 20 1], 'deflate', 5);  
gd.detach(gridID);  
gd.close(gfid);
```

| | |
|--------------------|--|
| Purpose | Tile size of grid field |
| Syntax | <code>tileDims = tileInfo(gridID,fieldname)</code> |
| Description | <p><code>tileDims = tileInfo(gridID,fieldname)</code> returns the tile dimensions of the field specified by <code>fieldname</code> in the grid specified by <code>gridID</code>. If the field is not tiled, then <code>tileDims</code> is <code>[]</code>.</p> <p>This function corresponds to the <code>GDtileinfo</code> function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the <code>tileDims</code> parameter is reversed with respect to the C library API.</p> |
| Examples | <pre>import matlab.io.hdfeos.* gfid = gd.open('grid.hdf'); gridID = gd.attach(gfid,'PolarGrid'); tileDims = gd.tileInfo(gridID,'pressure'); gd.detach(gridID); gd.close(gfid);</pre> |
| See Also | <code>gd.defTile</code> |

matlab.io.hdfEOS.gd.writeAttr

Purpose Write grid attribute

Syntax writeAttr(gridID,attrname,data)

Description writeAttr(gridID,attrname,data) writes an attribute to a grid. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the GDwriteattr function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
gd.writeAttr(gridID,'modification_date',datestr(now));
gd.detach(gridID);
gd.close(gfid);
```

See Also gd.readAttr

Purpose

Write Block SOM offset

Syntax

```
writeBlkSomOffset(gridID,offset)
```

Description

`writeBlkSomOffset(gridID,offset)` writes the block SOM offset values `n` pixels for a standard Solar Oblique Mercator (SOM) projection. `offset` is a vector of offset values for SOM projection data. This routine can only be used with grids that use the SOM projection. You must take care to use this function properly in conjunction with `gd.defProj`. The 12th element of the projection parameters must be set to the total number of blocks to be defined. `offset` starts by listing the offset to the second block, so the 12th element of the projection parameters is always one more than the length of `offset`.

All fields defined after writing the block SOM offset values will automatically include "SOMBlockDim" as the slowest varying dimension.

This function corresponds to the `GDbkSOMoffset` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
lowright = [30521379.68485 1152027.64253];
upleft = [-11119487.42844 8673539.24806];
gridID = gd.create(gfid,'SOM',120,60,upleft,lowright);
projparm(1) = 6378137;
projparm(2) = 0.006694348;
projparm(4) = 98096360; % 98.161 in DDDMMMSSS
projparm(5) = 87069061; % 87.112 in DDDMMMSSS
projparm(9) = 0.068585416*1440;
projparm(10) = 0.0;
projparm(12) = 6;
gd.defProj(gridID,'som',[],[],projparm);
gd.writeBlkSomOffset(gridID,[5 10 12 8 2]);
gd.detach(gridID);
gd.close(gfid);
```

matlab.io.hdfEOS.gd.writeBlkSomOffset

See Also

`gd.readBlkSomOffset`

Purpose

Write data to grid field

Syntax

```
writeField(gridID,fieldname,data)
writeField(gridID,fieldname,start,data)
writeField(gridID,fieldname,start,stride,data)
```

Description

`writeField(gridID,fieldname,data)` writes all the data to a grid field. The field is identified by `fieldname` and the grid is identified by `gridID`.

`writeField(gridID,fieldname,start,data)` writes a contiguous hyperslab to the grid field. `start` specifies the zero-based starting index.

`writeField(gridID,fieldname,start,stride,data)` writes a strided hyperslab of data to a grid data field. `stride` specifies the inter-element spacing along each dimension. The number of elements to write along each dimension is inferred from the size of `data`.

This function corresponds to the `GDwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

Examples

Write all the data to a grid field.

```
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','grid.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
gfid = gd.open('myfile.hdf','rdwr');
gridID = gd.attach(gfid,'PolarGrid');
data = zeros(100,100,'uint16');
gd.writeField(gridID,'ice_temp',data);
gd.detach(gridID);
gd.close(gfid);
```

See Also

`gd.readField`

matlab.io.hdfeos.gd.writeTile

Purpose Write tile to field

Syntax writeTile(gridID,fieldname,tileCoords,data)

Description writeTile(gridID,fieldname,tileCoords,data) writes a single tile of data to a field. If the field data can be arranged tile by tile, this routine is more efficient than gd.writeField. In all other cases, use gd.writeField. The tileCoords argument has the form [rownum colnum] and is defined in terms of the tile coordinates, not the data elements.

This function corresponds to the GDwritetile function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the tileCoords parameter is reversed with respect to the C library API.

Examples Define a field with a 2-by-3 tiling scheme.

```
import matlab.io.hdfeos.*
gfid = gd.open('myfile.hdf','create');
xdim = 200; ydim = 180;
gridID = gd.create(gfid,'PolarGrid',xdim,ydim,[],[]);
zonecode = 40;
spherecode = 0;
projParm = zeros(1,13);
projParm(6) = 90000000;
gd.defProj(gridID,'ps',[],spherecode,projParm);
tileSize = [100 60];
gd.defTile(gridID,tileSize);
dimlist = {'XDim','YDim'};
gd.defField(gridID,'Pressure',dimlist,'int32');
for c = 0:2
    for r = 0:1
        data = (r+c)*ones(tileSize,'int32');
        gd.writeTile(gridID,'Pressure',[r c],data);
    end
end
gd.detach(gridID);
```

```
gd.close(gfid);
```

```
gd.readTile
```

Purpose Low-level access to HDF-EOS swath files

Description To use these MATLAB functions, you must be familiar with the HDF-EOS library C interface. In most cases, the syntax of the MATLAB function is similar to the syntax of the corresponding HDF-EOS library function. The functions are implemented as the package `matlab.io.hdfeos.sw`. To use this package, prefix the function name with a package path, or use the `import` function to add the package to the current import list, prior to calling the function, for example,

```
import matlab.io.hdfeos.*  
fileId = sw.open(filename);
```

Access

| | |
|---|----------------------------|
| <code>matlab.io.hdfeos.sw.attach</code> | Attach to swath data set |
| <code>matlab.io.hdfeos.sw.close</code> | Close swath file |
| <code>matlab.io.hdfeos.sw.create</code> | Create new swath structure |
| <code>matlab.io.hdfeos.sw.detach</code> | Detach from swath |
| <code>matlab.io.hdfeos.sw.open</code> | Open swath file |

Definition

| | |
|---|------------------------------------|
| <code>matlab.io.hdfeos.sw.defComp</code> | Set grid field compression |
| <code>matlab.io.hdfeos.sw.defDataField</code> | Define new data field within swath |
| <code>matlab.io.hdfeos.sw.defDim</code> | Define new dimension within swath |

| | |
|---------------------------------|--|
| matlab.io.hdfEOS.sw.defDimMap | Define mapping between geolocation and data dimensions |
| matlab.io.hdfEOS.sw.defGeoField | Define new data field within swath |

Basic I/O

| | |
|----------------------------------|--|
| matlab.io.hdfEOS.sw.getFillValue | Fill value for specified field |
| matlab.io.hdfEOS.sw.readAttr | Read swath attribute |
| matlab.io.hdfEOS.sw.readField | Read data from swath field |
| matlab.io.hdfEOS.sw.setFillValue | Set fill value for the specified field |
| matlab.io.hdfEOS.sw.writeAttr | Write swath attribute |
| matlab.io.hdfEOS.sw.writeField | Write data to swath field |

Inquiry

| | |
|-----------------------------------|---|
| matlab.io.hdfEOS.sw.compInfo | Compression information for field |
| matlab.io.hdfEOS.sw.dimInfo | Size of dimension |
| matlab.io.hdfEOS.sw.fieldInfo | Information about swath field |
| matlab.io.hdfEOS.sw.geoMapInfo | Type of dimension mapping for named dimension |
| matlab.io.hdfEOS.sw.idxMapInfo | Indexed array of geolocation mapping |

Purpose Attach to swath data set

Syntax `swathID = attach(swfid,swathname)`

Description `swathID = attach(swfid,swathname)` attaches to the swath identified by `swathname` in the file identified by `swfid`. The `swathID` output is the identifier for the named swath.

This function corresponds to the `SWattach` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.detach`

matlab.io.hdfEOS.sw.close

Purpose Close swath file

Syntax `close(swfid)`

Description `close(swfid)` closes an HDF-EOS swath file identified by `swfid`. This function corresponds to the `SWclose` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.open` | `sw.create`

Purpose

Compression information for field

Syntax

```
[code,parms] = compInfo(swathID,fieldname)
```

Description

[code,parms] = compInfo(swathID,fieldname) returns the compression code and compression parameters for a given field. Refer to `sw.defComp` for a description of various compression schemes and parameters.

This function corresponds to the `SWcompinfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*  
swfid = sw.open('swath.hdf');  
swathID = sw.attach(swfid,'Example Swath');  
[compCode,parms] = sw.compInfo(swathID,'Spectra');  
sw.detach(swathID);  
sw.close(swfid);
```

See Also

`sw.defComp`

matlab.io.hdfEOS.sw.create

Purpose Create new swath structure

Syntax `swathID = create(swfID,swathname)`

Description `swathID = create(swfID,swathname)` creates a new swath structure where `swfID` is the swath file identifier and `swathname` is the name of the new swath. The swath is created as a Vgroup with the HDF file with the name `swathname` and HDF Vgroup class 'SWATH'.

This function corresponds to the `SWcreate` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'ExampleSwath');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.detach`

Purpose

Define latitude-longitude region for swath

Syntax

```
regionID = defBoxRegion(swathID,lat,lon,mode)
```

Description

`regionID = defBoxRegion(swathID,lat,lon,mode)` defines a latitude-longitude box region for a swath. `lat` and `lon` are two-element arrays containing the latitude and longitude in decimal degrees of the box corners. A cross track is determined to be within the box if a condition is met according to the value of `mode`:

| | |
|-------------|---|
| 'MIDPOINT' | The cross track midpoint is within the box. |
| 'ENDPOINT' | Either endpoint is within the box. |
| 'ANYPPOINT' | Any point of the cross track is within the box. |

All elements of a cross track are within the region if the condition is met. The swath must have both Longitude and Latitude (or Colatitude) defined.

`regionID` is an identifier to be used by `sw.extractRegion` to read all the entries of a data field within the region.

This function corresponds to the `SWdefboxregion` and `SWregionindex` functions in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
data = sw.extractRegion(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfEOS.sw.defBoxRegion

See Also

`sw.extractRegion`

Purpose

Set grid field compression

Syntax

```
defComp(swathID,compscheme,compparm)
```

Description

`defComp(swathID,compscheme,compparm)` sets the field compression for subsequent definitions. The compression scheme does not apply to one-dimensional fields. `compscheme` can be one of the following strings.

| | |
|-----------|---------------------|
| 'rle' | Run-length encoding |
| 'skphuff' | Skipping Huffman |
| 'deflate' | Gzip compression |
| 'none' | No compression |

When the compression scheme is 'deflate', the `compparm` input is the deflate compression level, an integer between 0 and 9. `compparm` can be omitted for the other compression schemes.

Fields defined with compression must be written with a single call to `sw.writeField`.

This function corresponds to the `SWdefcomp` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',4000);
sw.defDim(swathID,'Xtrack',2000);
sw.defDim(swathID,'Bands',3);
sw.defComp(swathID,'rle');
dims = {'Xtrack','Track'};
sw.defDataField(swathID,'Pressure',dims,'float');
sw.defComp(swathID,'deflate',5);
sw.defDataField(swathID,'Opacity',dims,'float');
sw.defComp(swathID,'skphuff');
dims = {'Xtrack','Track','Bands'};
```

```
sw.defDataField(swathID, 'Spectra', dims, 'float');  
sw.defComp(swathID, 'none');  
dims = {'Xtrack', 'Track'};  
sw.defDataField(swathID, 'Temperature', dims, 'float');  
sw.detach(swathID);  
sw.close(swfid);
```

See Also

`sw.compInfo`

Purpose

Define new data field within swath

Syntax

```
defDataField(swathID,fieldname,dimlist,dtype)
defDataField(swathID,fieldname,dimlist,dtype,mergeCode)
```

Description

`defDataField(swathID,fieldname,dimlist,dtype)` defines a data field to be stored in the swath identified by `swathID`. The `dimlist` input can be a cell array of dimension names, or a single char if there is only one dimension. `dtype` is the data type of the field and can be one of the following strings.

- 'double'
- 'single'
- 'int32'
- 'uint32'
- 'int16'
- 'uint16'
- 'int8'
- 'uint8'
- 'char'

`dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defDataField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a data field that can be merged with other data fields according to the value of `mergeCode`. The `mergeCode` input can be one of two strings, 'automerge' and 'nomerge'. If `mergeCode` is 'automerge', then the HDF-EOS library will attempt to merge swath fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is 'nomerge'.

Note To assure that the fields defined by `sw.defDataField` are properly established in the file, the swath should be detached and then reattached before writing to any fields.

This function corresponds to the `SWdefdatafield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDim(swathID,'Bands',3);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
sw.defGeoField(swathID,'Longitude',dims,'float');
sw.defGeoField(swathID,'Latitude',dims,'float');
dims = {'DataXtrack','DataTrack','Bands'};
sw.defDataField(swathID,'Spectra',dims,'float');
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.defGeoField` | `sw.inqDataFields`

Purpose Define new dimension within swath

Syntax `defDim(swathID,dimname,dimlen)`

Description `defDim(swathID,dimname,dimlen)` defines a new dimension named `dimname` with length `dimlen` in the swath structure identified by `swathID`.

To specify an unlimited dimension, use either 0 or 'unlimited' for `dimlen`.

This function corresponds to the `SWdefdim` function in the HDF-EOS library.

Examples Define a dimension 'Band' with length of 15 and an unlimited dimension 'Time'.

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.dimInfo`

matlab.io.hdfEOS.sw.defDimMap

Purpose Define mapping between geolocation and data dimensions

Syntax `defDimMap(swathID,geoDim,dataDim,offset,increment)`

Description `defDimMap(swathID,geoDim,dataDim,offset,increment)` defines a monotonic mapping between the geolocation and data dimensions, which usually have differing lengths. `offset` gives the index of the data element corresponding to the first geolocation element, and `increment` gives the number of data elements to skip for each geolocation element. If the geolocation dimension begins "before" the data dimension, then `offset` is negative. Similarly, if the geolocation dimension has higher resolution than the data dimension, then `increment` is negative.

This function corresponds to the `SWdefdimmap` function in the HDF-EOS library.

Examples Create a dimension mapping such that the first element of the GeoTrack dimension corresponds to the first element of the DataTrack Dimension and such that the data dimension has twice the resolution as the geolocation dimension. Also create a dimension mapping such that the first element of the GeoXtrack dimension corresponds to the second element of the DataXtrack dimensions and such that the data dimension has twice the resolution as the geolocation dimension.

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defDim` | `sw.mapInfo`

Purpose

Define new data field within swath

Syntax

```
defGeoField(swathID,fieldname,dimlist,dtype)
defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)
```

Description

`defGeoField(swathID,fieldname,dimlist,dtype)` defines a geolocation field to be stored in the swath identified by `swathID`. The `dimlist` argument can be a cell array of dimension names or a single char if there is only one dimension. `dtype` is the data type of the field. `dimlist` should be ordered such that the fastest varying dimension is listed first. This is opposite from the order in which the dimensions are listed in the C API.

`defGeoField(swathID,fieldname,dimlist,dtype,mergeCode)` defines a geolocation field that may be merged with other geolocation fields according to the value of `mergeCode`. The `mergeCode` argument can be one of two strings, 'automerge' and 'nomerge'. If `mergeCode` is 'automerge', then the HDF-EOS library will attempt to merge swath fields into a single object. This should not be done if you wish to access the swath fields individually with the another interface. By default, `mergeCode` is 'nomerge'.

This function corresponds to the `SWdefgeofield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `dimlist` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
dims = {'GeoXtrack','GeoTrack'};
```

matlab.io.hdfEOS.sw.defGeoField

```
sw.defGeoField(swathID, 'Longitude', dims, 'float');  
sw.defGeoField(swathID, 'Latitude', dims, 'float');  
sw.detach(swathID);  
sw.close(swfid);
```

See Also

[sw.defDataField](#) | [sw.inqGeoFields](#)

Purpose Define time period of interest

Syntax `outpID = defTimePeriod(swathID,start,stop,mode)`

Description `outpID = defTimePeriod(swathID,start,stop,mode)` defines a time period for a swath. `outpID` is a swath period ID that can be used to read all the entries of a data field within the time period. The swath structure must have the 'Time' field defined. A cross track is within a time period if a condition is met according to the value of mode:

| | |
|------------|--|
| 'MIDPOINT' | The midpoint is within the time period. |
| 'ENDPOINT' | Either endpoint is within the time period. |

This function corresponds to the `SWdeftimeperiod` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defBoxRegion` | `sw.defVrtRegion` | `sw.extractPeriod`

matlab.io.hdfeos.sw.defVrtRegion

Purpose Subset on monotonic field or dimension

Syntax `regionID_out = defVrtRegion(swathID,regionID,vertObj,range)`

Description `regionID_out = defVrtRegion(swathID,regionID,vertObj,range)` subsets on a monotonic field or contiguous elements of a dimension. Whereas `defBoxRegion` and `defTimePeriod` subset along the 'Track' dimension, this routine allows the user to subset along any dimension. `regionID` specifies the subsetted region from a previous call. `vertObj` specifies the dimension by which to subset. `range` specifies the minimum and maximum values for `vertObj`.

If there is no current subsetted region, `regionID` should be 'noprevsub'.

`vertObj` can be either a dimension or a field. If it is a dimension, then `range` should consist of dimension indices. If `vertObj` corresponds to a field, then `range` should consist of the minimum and maximum field values. `vertObj` must be one-dimensional in this case, and the its values must be monotonic.

This function corresponds to the `SWdefvrtregion` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
regionID = sw.defVrtRegion(swathID,'noprevsub','Bands',[450 600]);
data = sw.extractRegion(swathID,regionID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defBoxRegion` | `sw.defTimePeriod`

Purpose Detach from swath

Syntax `detach(swathID)`

Description `detach(swathID)` detaches from the swath identified by `swathID`. This function corresponds to the `SWdetach` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid, 'Example Swath');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.attach` | `sw.create`

matlab.io.hdfEOS.sw.dimInfo

Purpose Size of dimension

Syntax `dimlen = dimInfo(swathID,dimname)`

Description `dimlen = dimInfo(swathID,dimname)` returns the length of the specified dimension.

This function corresponds to the `SWdiminfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
dimlen = sw.dimInfo(swathID,'GeoTrack');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defDim`

Purpose Read data from subsetted time period

Syntax `data = extractPeriod(swathID,periodID,fieldname)`

Description `data = extractPeriod(swathID,periodID,fieldname)` reads data for the given field for the time period specified by `periodID`.

This routine corresponds to the `SWextractperiod` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
starttime = 25;
stoptime = 425;
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');
data = sw.extractPeriod(swathID,periodID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defTimePeriod`

matlab.io.hdfEOS.sw.extractRegion

Purpose Read subsetted region

Syntax `data = extractRegion(swathID,regionID,fieldname)`

Description `data = extractRegion(swathID,regionID,fieldname)` reads data for a specified field from a subsetted region identified by `regionID`.

This function corresponds to the `SWextractregion` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
data = sw.extractRegion(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defBoxRegion` | `sw.defVrtRegion`

| | |
|--------------------|---|
| Purpose | Information about swath field |
| Syntax | <code>[dimsizes, ntype, dimlist] = fieldInfo(swathID, fieldname)</code> |
| Description | <p><code>[dimsizes, ntype, dimlist] = fieldInfo(swathID, fieldname)</code> returns the size, data type, and list of named dimensions for the specified swath geolocation or data field.</p> <p>This function corresponds to the <code>SWfieldinfo</code> function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the <code>dimlist</code> parameter is reversed with respect to the C library API.</p> |
| Examples | <pre>import matlab.io.hdfEOS.* swfid = sw.open('swath.hdf'); swathID = sw.attach(swfid, 'Example Swath'); [fieldSize, ntype, dimlist] = sw.fieldInfo(swathID, 'Spectra'); sw.detach(swathID); sw.close(swfid);</pre> |
| See Also | <code>sw.inqGeoFields</code> <code>sw.inqDataFields</code> |

matlab.io.hdfEOS.sw.geoMapInfo

Purpose Type of dimension mapping for named dimension

Syntax `mappingType = geoMapInfo(swathID,dimname)`

Description `mappingType = geoMapInfo(swathID,dimname)` returns the type of dimension mapping for the named dimension. `mappingType` is one of 'indexed', 'regular', or 'unmapped'.

This routine corresponds to the `SWgeomapinfo` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
maptype = sw.geoMapInfo(swathID,'GeoTrack');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defDimMap`

Purpose Fill value for specified field

Syntax `fillvalue = getFillValue(swathID,fieldname)`

Description `fillvalue = getFillValue(swathID,fieldname)` returns the fill value for the specified field.

This function corresponds to the `SWgetfillvalue` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
fv = sw.getFillValue(swathID,'Spectra');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.setFillValue`

matlab.io.hdfEOS.sw.idxMapInfo

Purpose Indexed array of geolocation mapping

Syntax `idx = idxMapInfo(swathID,geodim,datadim)`

Description `idx = idxMapInfo(swathID,geodim,datadim)` retrieves the indexed elements of the geolocation mapping between `geodim` and `datadim`.

This function corresponds to the `SWidxmapinfo` function in the HDF-EOS C library API.

See Also `sw.geoMapInfo`

Purpose Names of swath attributes

Syntax `attrlist = inqAttrs(swathID)`

Description `attrlist = inqAttrs(swathID)` returns the list of swath attribute names. `attrlist` is a cell array.

This function corresponds to the `SWinqattrs` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid, 'Example Swath');
attrList = sw.inqAttrs(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.readAttr` | `sw.writeAttr`

matlab.io.hdfeos.sw.inqDataFields

Purpose Information about geolocation fields

Syntax [fields,rank,datatype] = inqDataFields(swathID)

Description [fields,rank,datatype] = inqDataFields(swathID) returns the list of geolocation field names, the rank of each field, and the data type of each field.

This function corresponds to the SWinqdatafields function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the fields parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[fields,rank,datatype] = sw.inqDataFields(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also sw.defDataField | sw.inqGeoFields

Purpose Information about dimensions defined in swath

Syntax [dimnames,dimlens] = inqDims(swathID)

Description [dimnames,dimlens] = inqDims(swathID) returns the names of the dimensions dimnames as a cell array. The length of each respective dimension is returned in dimlens.

This function corresponds to the SWinqdims routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[dimnames,dimlens] = sw.inqDims(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also sw.defDim

matlab.io.hdfeos.sw.inqGeoFields

Purpose Information about geolocation fields

Syntax `[fields,rank,datatype] = inqGeoFields(swathID)`

Description `[fields,rank,datatype] = inqGeoFields(swathID)` returns the list of geolocation fields `fields`, the rank of each field, and the data type of each field.

This function corresponds to the `SWinqgeofields` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `fields` parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[fields,rank,datatypes] = sw.inqGeoFields(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.defGeoField` | `sw.inqDataFields`

- Purpose** Information about swath indexed geolocation mapping
- Syntax** `[idxMap,idxSize] = inqIdxMaps(swathID)`
- Description** `[idxMap,idxSize] = inqIdxMaps(swathID)` retrieves all indexed geolocation/data mappings defined in the swath. `idxMap` is a cell array with each element consisting of the names of the dimensions of a mapping, separated by a `'/'`. `idxSize` contains the size of the index arrays corresponding to each mapping.
- This function corresponds to the `SWinqidxmaps` routine in the HDF-EOS library.
- See Also** `sw.inqMaps`

matlab.io.hdfEOS.sw.inqMaps

Purpose Information about swath geolocation relations

Syntax `[map,offset,increment] = inqMaps(swathID)`

Description `[map,offset,increment] = inqMaps(swathID)` returns the dimension mapping list, the offset of each geolocation relation, and the increment of each geolocation relation. These mappings are not indexed. `map` is a cell array where each element contains the names of the dimensions for each mapping, separated by a slash. `offset` and `increment` contain the offset and increment of each geolocation relation.

This function corresponds to the `SWinqmaps` routine in the HDF-EOS library.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
[dimmap,offset,increment] = sw.inqMaps(swathID);
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.inqDims` | `sw.defDimMap` | `sw.inqIdxMaps`

Purpose

Names of swaths in file

Syntax

```
swaths = inqSwath(filename)
```

Description

`swaths = inqSwath(filename)` returns a cell array containing the names of all the swaths in a file.

This function corresponds to the `SWinqswath` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfeos.*  
swaths = sw.inqSwath('swath.hdf');
```

See Also

`gd.inqGrid`

matlab.io.hdfEOS.sw.mapInfo

Purpose Offset and increment of specific geolocation mapping

Syntax [offset,increment] = mapInfo(swathID,geodim,datadim)

Description [offset,increment] = mapInfo(swathID,geodim,datadim) retrieves the offset and increment of the geolocation mapping between the specified geolocation dimension and the specified data dimension.

This function corresponds to the SWmapinfo function in the HDF-EOS C library API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'GeoTrack',2000);
sw.defDim(swathID,'GeoXtrack',1000);
sw.defDim(swathID,'DataTrack',4000);
sw.defDim(swathID,'DataXtrack',2000);
sw.defDimMap(swathID,'GeoTrack','DataTrack',0,2);
sw.defDimMap(swathID,'GeoXtrack','DataXtrack',1,2);
sw.detach(swathID);
sw.close(swfid);
swfid = sw.open('myfile.hdf','read');
swathID = sw.attach(swfid,'MySwath');
[offset,increment] = sw.mapInfo(swathID,'GeoTrack','DataTrack');
sw.detach(swathID);
sw.close(swfid);
```

See Also

sw.defDimMap

Purpose

Number of entries for specific type

Syntax

```
nEnts = nEntries(swathID,type)
```

Description

`nEnts = nEntries(swathID,type)` returns the number of entries in a swath. Valid inputs for type include:

| | |
|--------------|--------------------|
| 'dims' | or 'HDFE_NENTDIM' |
| 'maps' | or 'HDFE_NENTMAP' |
| 'imaps' | or 'HDFE_NENTIMAP' |
| 'geofields' | or 'HDFE_NENTGFLD' |
| 'datafields' | or 'HDFE_NENTFLD' |

This function corresponds to the `SWnentries` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*  
swfid = sw.open('myfile.hdf','create');  
swathID = sw.create(swfid,'MySwath');  
sw.defDim(swathID,'GeoTrack',2000);  
sw.defDim(swathID,'GeoXtrack',1000);  
sw.defDim(swathID,'DataTrack',4000);  
sw.defDim(swathID,'DataXtrack',2000);  
ndims = sw.nEntries(swathID,'dims');  
sw.detach(swathID);  
sw.close(swfid);
```

matlab.io.hdfEOS.sw.open

Purpose Open swath file

Syntax
`swfID = open(filename)`
`swfID = open(filename,access)`

Description `swfID = open(filename)` opens an HDF-EOS swath file for read-only access.

`swfID = open(filename,access)` opens or creates an HDF-EOS swath file identified by `filename` and returns a file ID. `access` can be one of the following string values.

| | |
|-------------------------------|--|
| <code>'read'</code> (default) | Read-only |
| <code>'rdwr'</code> | Read-write |
| <code>'create'</code> | Creates a file, deleting it if it already exists |

This routine corresponds to the `SWopen` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*  
swfid = sw.open('swath.hdf');  
sw.close(swfid);
```

See Also `sw.close`

Purpose

Information about subsetted period

Syntax

```
[datatype,dims] = periodInfo(swathID,periodID,fieldname)
```

Description

[datatype,dims] = periodInfo(swathID,periodID,fieldname) retrieves information about the period defined for the given field. datatype is the data type of the field. dims is the dimensions of the subsetted region.

This function corresponds to the SWperiodinfo function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the dims parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfEOS.*  
swfid = sw.open('swath.hdf');  
swathID = sw.attach(swfid,'Example Swath');  
starttime = 25;  
stoptime = 425;  
periodID = sw.defTimePeriod(swathID,starttime,stoptime,'MIDPOINT');  
[ntype,dims] = sw.periodInfo(swathID,periodID,'Temperature');  
sw.detach(swathID);  
sw.close(swfid);
```

See Also

sw.defTimePeriod | sw.extractPeriod

matlab.io.hdfEOS.sw.readAttr

Purpose Read swath attribute

Syntax `data = readAttr(swathID,attrname)`

Description `data = readAttr(swathID,attrname)` reads a swath attribute. This function corresponds to the `SWreadAttr` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
value = sw.readAttr(swathID,'creation_date');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.writeAttr`

Purpose Read data from swath field

Syntax

```
data = readField(swathID,fieldname)
data = readField(swathID,fieldname,start,count)
data = readField(swathID,fieldname,start,count,stride)
```

Description

`data = readField(swathID,fieldname)` reads an entire swath field.

`data = readField(swathID,fieldname,start,count)` reads a contiguous hyperslab of data from the swath field `fieldname`. The `start` input specifies the zero-based index of the first element to be read. `count` specifies the number of elements along each dimension to read.

`data = readField(swathID,fieldname,start,count,stride)` reads a strided hyperslab of data from the swath field `fieldname`. The `stride` input specifies the inter-element spacing along each dimension.

This function corresponds to the `SWreadfield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start`, `count`, and `stride` parameters are reversed with respect to the C library API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
data = sw.readField(swathID,'Longitude');
sw.detach(swathID);
sw.close(swfid);
```

See Also `sw.writeField`

matlab.io.hdfeos.sw.regionInfo

Purpose Information about subsetted region

Syntax [datatype,extent] = regionInfo(swathID,regionID,fieldname)

Description [datatype,extent] = regionInfo(swathID,regionID,fieldname) returns the data type and extent of a subsetted region of a field. regionID is the identifier for the subsetted region.

This function corresponds to the SWregioninfo function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the extent parameter is reversed with respect to the C library API.

Examples

```
import matlab.io.hdfeos.*
swfid = sw.open('swath.hdf');
swathID = sw.attach(swfid,'Example Swath');
lat = [34 44];
lon = [16 24];
regionID = sw.defBoxRegion(swathID,lat,lon,'MIDPOINT');
[ntype,dims] = sw.regionInfo(swathID,regionID,'Temperature');
sw.detach(swathID);
sw.close(swfid);
```

See Also sw.defBoxRegion | sw.defVrtRegion

Purpose

Set fill value for the specified field

Syntax

```
setFillValue(swathID,fieldname,fillvalue)
```

Description

`setFillValue(swathID,fieldname,fillvalue)` sets the fill value for the specified field. The field must have more than two dimensions.

This function corresponds to the `SWsetfillvalue` function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.defDim(swathID,'Track',400);
sw.defDim(swathID,'Xtrack',200);
dims = {'Track','Xtrack'};
sw.defDataField(swathID,'Temperature',dims,'float');
sw.setFillValue(swathID,'Temperature',single(-999));
sw.detach(swathID);
sw.close(swfid);
```

See Also

`sw.setFillValue`

matlab.io.hdfEOS.sw.writeAttr

Purpose Write swath attribute

Syntax writeAttr(swathID,attrname,data)

Description writeAttr(swathID,attrname,data) writes an attribute to a swath. If the attribute does not exist, it is created. If the attribute exists, it can be modified in place, but it cannot be recreated with a different data type or length.

This function corresponds to the SWwriteattr function in the HDF-EOS library C API.

Examples

```
import matlab.io.hdfEOS.*
swfid = sw.open('myfile.hdf','create');
swathID = sw.create(swfid,'MySwath');
sw.writeAttr(swathID,'creation_date', datestr(now));
sw.detach(swathID);
sw.close(swfid);
```

See Also sw.readAttr

Purpose

Write data to swath field

Syntax

```
writeField(swathID,fieldname,data)
writeField(swathID,fieldname,start,data)
writeField(swathID,fieldname,start,stride,data)
```

Description

`writeField(swathID,fieldname,data)` writes an entire swath data field.

`writeField(swathID,fieldname,start,data)` writes a contiguous hyperslab to a swath field. `start` specifies the index of the first element to write. The number of elements along each dimension is inferred from either the size of `data` or from the swath field itself.

`writeField(swathID,fieldname,start,stride,data)` writes a strided hyperslab to a swath field. `stride` specifies the inter-element spacing along each dimension.

This function corresponds to the `SWwritefield` function in the HDF-EOS library C API, but because MATLAB uses FORTRAN-style ordering, the `start` and `stride` parameters are reversed with respect to the C library API.

Examples

Write data to a geolocation field 'Longitude'.

```
lon = [-50:49];
data = repmat(lon(:),1,100);
data = single(data);
import matlab.io.hdfEOS.*
srcFile = fullfile(matlabroot,'toolbox','matlab','imagesci','swath.hdf');
copyfile(srcFile,'myfile.hdf');
fileattrib('myfile.hdf','+w');
swfid = sw.open('myfile.hdf','rdwr');
swathID = sw.attach(swfid,'Example Swath');
sw.writeField(swathID,'Longitude',data);
sw.detach(swathID);
sw.close(swfid);
```

matlab.io.hdfEOS.sw.writeField

See Also

`sw.readField`

Purpose

Save workspace variables to MATLAB script

Syntax

```
matlab.io.saveVariablesToScript(filename)
matlab.io.saveVariablesToScript(filename,varnames)
matlab.io.saveVariablesToScript(filename,Name,Value)
[r1,r2] = matlab.io.saveVariablesToScript(filename)
```

Description

`matlab.io.saveVariablesToScript(filename)` saves variables in the current workspace to a MATLAB script named `filename.m`. The `filename` can include the `.m` suffix. If you do not include it, the function adds it when it creates the file.

Variables that MATLAB cannot generate code for are saved to a MAT-file named `filename.mat`.

If a file with the same name already exists, it is overwritten.

`matlab.io.saveVariablesToScript(filename,varnames)` saves only workspace variables specified by `varnames` to the MATLAB script.

`matlab.io.saveVariablesToScript(filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[r1,r2] = matlab.io.saveVariablesToScript(filename)` additionally returns two cell arrays:

- `r1` for variables that were saved to the MATLAB script
- `r2` for variables that were saved to a MAT-file

Input Arguments

filename - Name of MATLAB script for saving variables

`filename` | variable

Name of MATLAB script for saving variables, specified as a string giving a file name or a variable containing the file name.

Example: `matlab.io.saveVariablesToScript('myVariables.m')`

matlab.io.saveVariablesToScript

varnames - Name of variables to save

string | cell array

Name of variables to save, specified as a string or a cell array.

Example: {'X','Y','Z'}

Data Types

char | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'MaximumArraySize',500,'MATFileVersion','v4'` specifies that the maximum number of array elements to save is 500 using MATLAB version 4 syntax.

'MATFileVersion' - MATLAB version whose syntax to use

'v7.3' (default) | 'v4' | 'v6' | 'v7'

MATLAB version whose syntax to use for saving MAT-files, specified as the comma-separated pair consisting of `'MATFileVersion'` and one of the following version numbers:

- 'v4'
- 'v6'
- 'v7'
- 'v7.3'

Example: `'MATFileVersion','v6'`

Data Types

char

'MaximumArraySize' - Maximum array elements to save

1000 (default) | integer

Maximum array elements to save, specified as the comma-separated pair consisting of 'MaximumArraySize' and an integer in the range of 1 to 10,000.

Example: 'MaximumArraySize',1050

'MaximumNestingLevel' - Maximum number of object levels or array hierarchies to save

20 (default) | integer

Maximum number of object levels or array hierarchies to save, specified as the comma-separated pair consisting of 'MaximumNestingLevel' and an integer in the range of 1 to 200.

Example: 'MaximumNestingLevel',67

'MaximumTextWidth' - Text wrap width during save

76 (default) | integer

Text wrap width during save, specified as the comma-separated pair consisting of 'MaximumTextWidth' and an integer in the range of 32 to 256.

Example: 'MaximumTextWidth',82

'MultidimensionalFormat' - Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data

'rowvector' (default) | integer cell array

Dimensions of 2-D slices that represent n-D arrays of char, logic, or numeric data, specified as the comma-separated pair consisting of 'MultidimensionalFormat' and one of these values:

- 'rowvector' — Save multidimensional variables as a single row vector.
- integer cell array — Save a 2-D slice of multidimensional variables, where the dimensions satisfy all the following criteria:
 - Two positive integers represent dimensions.

matlab.io.saveVariablesToScript

- The two integers are less than or equal to the dimensions of the n-D array.
- The second integer is greater than the first.

Example: `'MultidimensionalFormat',[1,3]`

'RegExp' - Regular expression for matching

string

Regular expression for matching, specified as the comma-separated pair consisting of 'RegExp' and one or more expressions given as a string.

Example: `'RegExp','level*'`

Data Types

char

'SaveMode' - Mode to save MATLAB script

`'create'` (default) | `'update'` | `'append'`

Mode to save MATLAB script, specified as the comma-separated pair consisting of SaveMode and one of these values:

- `'create'` — Save variables to a new MATLAB script.
- `'update'` — Only update variables that are already present in a MATLAB script.
- `'append'` — Update variables that are already present in a MATLAB script and append new variables to the end of the script.

Example: `'SaveMode','Update'`

Output Arguments

r1 - Variables that were saved to a MATLAB script

cell array

Variables that were saved to a MATLAB script, returned as a cell array of variable names.

r2 - Variables that were saved to a MAT-file

cell array

Variables that were saved to a MAT-file, returned as a cell array of variable names.

Examples

Save Workspace Variables to MATLAB Script

Save variables from a workspace to a MATLAB script, `test.m`.

```
matlab.io.saveVariablesToScript('test.m')
```

Save Specific Workspace Variables to MATLAB Script

Create and save variable `myVar` from a workspace to a MATLAB script, `test.m`.

```
myVar = 55.3;  
matlab.io.saveVariablesToScript('test.m','myVar')
```

Append Specific Variables to Existing MATLAB Script

Create two variables, `a` and `b`, and save them to an existing MATLAB script `abfile.m`.

```
a = 72.3;  
b = pi;  
matlab.io.saveVariablesToScript('abfile.m',{'a','b'},...  
'SaveMode','append')
```

Update Specific Variables in Existing MATLAB Script

Update and save two variables, `y` and `z`, to an existing MATLAB script `yzfile.m`.

```
y = 15.7;  
z = 3 * pi;  
matlab.io.saveVariablesToScript('yzfile.m',{'y','z'},...  
'SaveMode','update')
```

Specify MATLAB Script Configuration for Saving Variable

Update and save variable `resistance` to an existing MATLAB script `designData.m` while specifying the configuration of the script file.

matlab.io.saveVariablesToScript

```
resistance = [10 20.5 11 13.7 15.1 7.7];
matlab.io.saveVariablesToScript('designData.m','resistance',...
    'SaveMode','Update','MaximumArraySize',5,...
    'MaximumNestingLevel',5,'MaximumTextWidth',30)
```

Specify 2-D Slice for Saving 3-D Array in MATLAB Script

Specify a 2-D slice for the output of the 3-D array `my3Dtable`, such that the 2-D slice expands along the first and third dimensions. Save the 2-D slice in the MATLAB script `sliceData.m`.

```
level1 = [1 2; 3 4];
level2 = [5 6; 7 8];
my3Dtable(:, :, 1) = level1;
my3Dtable(:, :, 2) = level2;
matlab.io.saveVariablesToScript('sliceData.m','MultidimensionalFormat',[1,3])
```

The resulting MATLAB code is similar to the following:

```
level1 = ...
    [1 2;
     3 4];

level2 = ...
    [5 6;
     7 8];
my3Dtable = zeros(2, 2, 2);
my3Dtable(:,1,:) = ...
    [1 5;
     3 7];

my3Dtable(:,2,:) = ...
    [2 6;
     4 8];
```

Save Variables Matching a Regular Expression

Save variables that match the expression `autoL*` to a MATLAB script `autoVariables.m`.

```
matlab.io.saveVariablesToScript('autoVariables.m','RegExp','autoL*')
```

Save Variables to Version 7.3 MATLAB Script

Create two variables, p and q, and save them to a version 7.3 MATLAB script version73.m.

```
p = 49;  
q = 35.5;  
matlab.io.saveVariablesToScript('version73.m','p','q',...  
    'MATFileVersion','v7.3')
```

Return Variables Saved to MATLAB Script

Save variables that were saved to a MATLAB script to the variable r1, and those that were saved to a MAT-file to the variable r2.

```
[r1,r2] = matlab.io.saveVariablesToScript('mydata.m')
```

```
r1 =
```

```
    'level1'  
    'level2'  
    'level3'  
    'my3Dtable'
```

```
r2 =
```

```
Empty cell array: 0-by-1
```

Limitations

- `matlab.io.saveVariablesToScript` does not save the following variables to a MATLAB script or a MAT-file.
 - Java objects
 - .NET objects
- `matlab.io.saveVariablesToScript` saves the following variables only to a MAT-file.

matlab.io.saveVariablesToScript

- MATLAB objects
- Function handles
- Anonymous functions

Purpose

Construct unique strings from input strings

Syntax

```
U = matlab.lang.makeUniqueStrings(S)
```

```
U = matlab.lang.makeUniqueStrings(S,excludedStrings)
```

```
U = matlab.lang.makeUniqueStrings(S,whichStrings)
```

```
U = matlab.lang.makeUniqueStrings(S, __ , maxStringLength)
```

```
[U, modified] = matlab.lang.makeUniqueStrings( __ )
```

Description

`U = matlab.lang.makeUniqueStrings(S)` constructs unique strings, `U`, from input strings, `S`, by appending an underscore and a number to duplicate strings.

`U = matlab.lang.makeUniqueStrings(S,excludedStrings)` constructs strings that are unique within `U` and with respect to `excludedStrings`. The `makeUniqueStrings` function does not check `excludedStrings` for uniqueness.

`U = matlab.lang.makeUniqueStrings(S,whichStrings)` specifies the subset of `S` to make unique within the entire set. `makeUniqueStrings` makes the strings in `S(whichStrings)` unique among themselves and with respect to the remaining strings. `makeUniqueStrings` returns the remaining strings unmodified in `U`. Use this syntax when you have an array of strings, and need to check that only some elements of the array are unique.

`U = matlab.lang.makeUniqueStrings(S, __ , maxStringLength)` specifies the maximum length, `maxStringLength`, of strings in `U`. If `makeUniqueStrings` cannot make elements in `S` unique without exceeding `maxStringLength`, it returns an error. You can use this syntax with any of the input arguments of the previous syntaxes.

`[U, modified] = matlab.lang.makeUniqueStrings(__)` returns a logical array, `modified`, indicating modified strings.

matlab.lang.makeUniqueStrings

Input Arguments

S - Input strings

string or cell array of strings

Input strings, specified as a string or cell array of strings.

excludedStrings - Strings to exclude

string or cell array of strings

Strings to exclude from U, specified as a string or cell array of strings.

Example: 'dontDuplicateThisString',
{'excludeS1','excludeS2'}, who

whichStrings - Subset of strings to make unique

range of linear indices or logical array

Subset of strings, S, to make unique within the entire set, specified as a range of linear indices or as a logical array with the same size and shape as S. If there are duplicates in S, the makeUniqueStrings function only modifies those specified by whichStrings.

If whichStrings is a logical array, strings are checked for uniqueness when the array element in the same position has a value of true.

Example: 1:5, logical([1 0 1]), [true false true]

maxStringLength - Maximum length of output strings

integer

Maximum length of output strings in U, specified as an integer. If makeUniqueStrings cannot make elements in S unique without exceeding maxStringLength, it returns an error.

Output Arguments

U - Unique strings

string | cell array of strings

Unique strings, returned as a string or cell array of strings. The output has the same dimension as the input, S.

modified - Indicator of modified strings

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same dimension as the input, S. A value of 1 (true) indicates that `makeUniqueStrings` modified the input string in the corresponding location. A value of 0 (false) indicates that `makeUniqueStrings` did not need to modify the input string in the corresponding location.

Examples

Construct Unique Strings

Create an array of strings and make each element unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};  
U = matlab.lang.makeUniqueStrings(S)
```

```
U =
```

```
    'John'    'Sue'    'Nick'    'John_1'    'Campion'    'John_2'
```

The `makeUniqueStrings` function appends the duplicate strings in elements 3 and 5 with underscores and incrementing numbers.

Construct Unique Strings and Specify Exclusions

Without specifying excluded strings, make the strings in U unique.

```
S = {'John' 'Sue' 'Nick' 'John' 'Campion' 'John' 'Jason'};  
U = matlab.lang.makeUniqueStrings(S)
```

```
U =
```

```
    'John'    'Sue'    'Nick'    'John_1'    'Campion'    'John_2'
```

Specify that the string, 'Nick', should be excluded from the output.

```
U = matlab.lang.makeUniqueStrings(S, 'Nick')
```

matlab.lang.makeUniqueStrings

```
U =  
    'John'    'Sue'    'Nick_1'    'John_1'    'Campion'    'John_2'
```

`makeUniqueStrings` excludes 'Nick' from U and instead modifies the first duplicate string, found in element 3, to be 'Nick_1'.

Exclude workspace variables from the unique string array.

```
Sue = 42;  
U = matlab.lang.makeUniqueStrings(S, who)
```

```
U =  
    'John'    'Sue_1'    'Nick'    'John_1'    'Campion'    'John_2'
```

Since 'Sue' exists in the workspace, `makeUniqueStrings` makes this string unique by appending an underscore and number.

Construct Unique Strings for Specified Array Elements

Create an array of strings and make only the first four elements unique.

```
S = {'quiz' 'quiz' 'quiz' 'exam' 'quiz' 'exam'};  
U = matlab.lang.makeUniqueStrings(S, 1:4)
```

```
U =  
    'quiz_1'    'quiz_2'    'quiz_3'    'exam_1'    'quiz'    'exam'
```

The first four elements in `U` are unique among themselves, and among the remaining strings in elements 5 and 6 ('quiz' and 'exam'). Alternatively, you can use a logical array instead of a range of linear indices to achieve the same results: `U = matlab.lang.makeUniqueStrings(S, [true true true true false false])` or `U = matlab.lang.makeUniqueStrings(S, logical([1 1 1 1 0 0]))`.

Append a duplicate 'quiz' onto the end of `S` and make the first four elements unique.

```
S{end+1} = 'quiz'  
U = matlab.lang.makeUniqueStrings(S, 1:4)
```

```
S =
```

```
    'quiz'    'quiz'    'quiz'    'exam'    'quiz'    'exam'    'quiz'
```

```
U =
```

```
    'quiz_1'    'quiz_2'    'quiz_3'    'exam_1'    'quiz'    'exam'
```

The strings that `makeUniqueStrings` checks are still unique among themselves and among the remaining strings. Since `makeUniqueStrings` does not check any elements after element 4, duplicate strings remain.

Construct Unique Strings with Maximum Length

Create an array from `S` where the first three elements are unique and the maximum length of each string is 5.

```
S = {'sampleData' 'sampleData' 'sampleData' 'sampleData'};  
U = matlab.lang.makeUniqueStrings(S, 1:3, 5)
```

matlab.lang.makeUniqueStrings

```
U =  
    'sampl'    'sam_1'    'sam_2'    'sampleData'
```

The first element is truncated to 5 characters. The second and third elements are truncated to 3 characters to allow `makeUniqueStrings` to append an underscore and number, and still not exceed 5 characters.

Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};  
[N, modified] = matlab.lang.makeValidName(S)
```

```
N =  
    'a_name'    'name_1'    'x2_name'
```

```
modified =  
    1     0     1
```

`makeValidName` did not modify the second element.

Tips

- To ensure strings are valid and unique, use `matlab.lang.makeValidName` before `matlab.lang.makeUniqueStrings`.

```
S = {'my.Name', 'my_Name', 'my_Name'};  
validStrings = matlab.lang.makeValidName(S)  
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings,...  
    {},nameLengthmax)
```

```
validStrings =
```

```
'my_Name'    'my_Name'    'my_Name'
```

```
validUniqueStrings =
```

```
'my_Name'    'my_Name_1'    'my_Name_2'
```

See Also

[matlab.lang.makeValidName](#) | [namelengthmax](#) | [who](#)

matlab.lang.makeValidName

Purpose Construct valid MATLAB identifiers from input strings

Syntax

```
N = matlab.lang.makeValidName(S)  
N = matlab.lang.makeValidName(S,Name,Value)  
[N, modified] = matlab.lang.makeValidName( ___ )
```

Description `N = matlab.lang.makeValidName(S)` constructs valid MATLAB identifiers, `N`, from input strings, `S`. The `makeValidName` function does not guarantee the strings in `N` are unique.

A valid MATLAB identifier is a string of alphanumerics (A–Z, a–z, 0–9) and underscores, such that the first character is a letter and the length of the string is less than or equal to `namelengthmax`.

`makeValidName` deletes any whitespace characters prior to replacing any characters that are not alphanumerics or underscores. If a whitespace character is followed by a lowercase letter, `makeValidName` converts the letter to the corresponding uppercase character.

`N = matlab.lang.makeValidName(S,Name,Value)` includes additional options specified by one or more `Name,Value` pair arguments.

`[N, modified] = matlab.lang.makeValidName(___)` returns a logical array, `modified`, indicating modified strings. You can use this syntax with any of the input arguments of the previous syntaxes.

Input Arguments

S - Input strings
string or cell array of strings

Input strings, specified as a string or cell array of strings. If `S` is a cell array of strings, it must be a 1xN or Nx1 cell array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ReplacementStyle', 'delete'` deletes invalid characters.

'ReplacementStyle' - Replacement style

`'underscore'` (default) | `'delete'` | `'hex'`

Replacement style, specified as a string. The value controls how MATLAB replaces nonalphanumeric characters.

| ReplacementStyle Value | Description |
|-------------------------------------|---|
| <code>'underscore'</code> (default) | Replaces all characters that are not alphanumeric or underscores with underscores. <code>'underscore'</code> deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase. |
| <code>'hex'</code> | Replaces each character that is not an alphanumeric or underscore with its corresponding hexadecimal representation. <code>'hex'</code> deletes whitespace characters and changes a lowercase letter following a whitespace to uppercase. |
| <code>'delete'</code> | Deletes all characters that are not alphanumerics or underscores. <code>'delete'</code> deletes whitespace characters and changes any lowercase letter following a whitespace to uppercase. |

'Prefix' - Character to prefix

`'x'` (default) | string

Character to prefix to input strings that do not begin with a letter after `makeValidName` replaces nonalphanumeric characters, specified as a string. A valid prefix must start with a letter, contain only alphanumeric characters and underscores, and not be longer than the value of `namelengthmax`.

matlab.lang.makeValidName

Output Arguments

N - Valid MATLAB identifiers

string | cell array of strings

Valid MATLAB identifiers, returned as a string or cell array of strings. The output has the same number of dimensions as the input, S.

modified - Indicator of modified strings

logical scalar | logical array

Indicator of modified strings, returned as a logical scalar or array and having the same number of dimensions as the input, S. A value of 1 (true) indicates that makeValidName modified the input string in the corresponding location. A value of 0 (false) indicates that makeValidName did not need to modify the input string in the corresponding location.

Examples

Construct Valid MATLAB Identifiers

```
S = {'Item_#','Price/Unit','1st order','Contact'};  
N = matlab.lang.makeValidName(S)
```

```
N =
```

```
    'Item__'    'Price_Unit'    'x1stOrder'    'Contact'
```

In the first and second strings, makeValidName replaced the invalid characters (# and /), with underscores. In the third string, makeValidName appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Construct Valid MATLAB Identifiers Using Specified Replacement Style

Replace invalid characters with the corresponding hexadecimal representation.

```
S = {'Item_#','Price/Unit','1st order','Contact'};  
N = matlab.lang.makeValidName(S,'ReplacementStyle','hex')
```

```
N =
```

```
    'Item_0x23'    'Price0x2FUnit'    'x1stOrder'    'Contact'
```

In the first and second strings, `makeValidName` replaced the invalid characters (# and /), with their hexadecimal representation. In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Delete invalid characters.

```
N = matlab.lang.makeValidName(S,'ReplacementStyle','delete')
```

```
N =
```

```
    'Item_'    'PriceUnit'    'x1stOrder'    'Contact'
```

`makeValidName` deleted the invalid characters (# and /). In the third string, `makeValidName` appended a prefix because the string doesn't begin with a letter, deleted the empty space, and capitalized the character following the deleted space.

Construct Valid MATLAB Identifiers Using Specified Prefix

```
S = {'1stMeasurement','2ndMeasurement','Control'};  
N = matlab.lang.makeValidName(S,'Prefix','m_')
```

```
N =
```

matlab.lang.makeValidName

```
'm_1stMeasurement'    'm_2ndMeasurement'    'Control'
```

Only the strings that do not start with a letter are prepended with a prefix.

Determine Modified Strings

```
S = {'a%name', 'name_1', '2_name'};  
[N, modified] = matlab.lang.makeValidName(S)
```

```
N =
```

```
'a_name'    'name_1'    'x2_name'
```

```
modified =
```

```
1     0     1
```

makeValidName did not modify the second element.

Tips

- To ensure strings are valid and unique, use `matlab.lang.makeUniqueStrings` after `matlab.lang.makeValidName`.

```
S = {'my.Name', 'my_Name', 'my_Name'};  
validStrings = matlab.lang.makeValidName(S)  
validUniqueStrings = matlab.lang.makeUniqueStrings(validStrings, {}, ...  
    namelengthmax)
```

```
validStrings =
```

```
'my_Name'    'my_Name'    'my_Name'
```

```
validUniqueStrings =  
  
    'my_Name'    'my_Name_1'    'my_Name_2'
```

- To customize an invalid character replacement, first use functions such as `strrep` or `regexprep` to convert to valid characters. For example, convert '@' characters in the string, `S`, to 'At' using `strrep(S, '@', 'At')`. Then, use `matlab.lang.makeValidName` to ensure that all characters in the strings are valid.

Purpose

Startup file for MATLAB program

Description

At startup time, MATLAB automatically executes the file `matlabrc.m`. This function establishes the MATLAB path, sets the default figure size, and sets some uicontrol defaults.

On multiuser or networked systems, system administrators can put messages, definitions, or other code that applies to all users in their `matlabrc.m` file.

The file `matlabrc.m` invokes the `startup.m` file, if it exists on the search path MATLAB uses.

Individual users should use the `startup.m` file to customize MATLAB startup. The `matlabrc.m` file, located in the `matlabroot/toolbox/local` folder, is reserved for system administrators.

Algorithms

MATLAB invokes `matlabrc` at startup. `matlabrc.m` contains the statements

```
if exist('startup') == 2
    startup
end
```

that invokes `startup.m`, if it exists. Extend this process to create additional startup files, if required.

Tips

You can also start MATLAB using options you define at the Command Window prompt or in your Microsoft Windows shortcut for MATLAB.

Examples

Turning Off the Figure Window Toolbar

If you do not want the toolbar to appear in the figure window, remove the comment marks from the following line in the `matlabrc.m` file, or create a similar line in your own `startup.m` file.

```
% set(0,'defaultfiguretoolbar','none')
```

See Also matlabroot | quit | restoredefaultpath | startup

How To • Startup Options

matlabroot

Purpose Root folder

Syntax matlabroot
mr = matlabroot

Description matlabroot returns the name of the folder where the MATLAB software is installed. Use matlabroot to create a path to MATLAB and toolbox folders that does not depend on a specific platform, MATLAB version, or installation location.

mr = matlabroot returns the name of the folder in which the MATLAB software is installed and assigns it to mr.

Tips **matlabroot as Folder Name**

The term *matlabroot* also refers to the folder where MATLAB files are installed. For example, “save to *matlabroot/toolbox/local*” means save to the *toolbox/local* folder in the MATLAB root folder.

Using \$matlabroot as a Literal

In some files, \$matlabroot is literal. In those files, MATLAB interprets \$matlabroot as the full path to the MATLAB root folder. For example, including the line:

```
$matlabroot/toolbox/local/myfile.jar
```

in *javaclasspath.txt*, adds *myfile.jar*, which is located in the *toolbox/local* folder, to the static Java class path.

Sometimes, particularly in older code examples, the term \$matlabroot or \$MATLABROOT is not meant to be interpreted literally but is used to represent the value returned by the *matlabroot* function.

matlabroot on Macintosh Platforms

In R2008b (V7,7) and more recent versions, running *matlabroot* on Apple Macintosh platforms returns

```
/Applications/MATLAB_R2008b.app
```

In versions prior to R2008b (V7.7), such as R2008a (V7.6), running `matlabroot` on Macintosh platforms returns, for example

```
/Applications/MATLAB_R2008a
```

When you use GUIs on Macintosh platforms, you cannot directly view the contents of the MATLAB root folder. For more information, see “Navigating Within the MATLAB Root Folder on Macintosh Platforms”.

Examples

Get the location where MATLAB is installed:

```
matlabroot
```

MATLAB returns:

```
C:\Program Files\MATLAB\R2009a
```

Produce a full path to the `toolbox/matlab/general` folder that is correct for the platform on which it is executed:

```
fullfile(matlabroot,'toolbox','matlab','general')
```

Change the current folder to the MATLAB root folder:

```
cd(matlabroot)
```

To add the folder `myfiles` to the MATLAB search path, run

```
addpath([matlabroot '/toolbox/local/myfiles'])
```

See Also

`fullfile` | `path` | `toolboxdir`

matlab (UNIX)

Purpose Start MATLAB program (UNIX platforms)

Syntax

```
matlab
matlab helpOption
matlab envDispOption
matlab archOption
matlab dispOption
matlab modeOption
matlab -c licensefile
matlab -debug
matlab -Ddebugger options
matlab -jdb portnumber
matlab -logfile filename
matlab -mwvisual visualid
matlab -noFigureWindows
matlab -nosplash
matlab -nouserjavapath
matlab -r "command"
matlab -singleCompThread
```

Note You can enter more than one of these options in the same `matlab` command. If you use `-Ddebugger` to start MATLAB in debug mode, the first option in the command must be `-Ddebugger`.

Description `matlab` is a Bourne shell script that starts the MATLAB executable on UNIX platforms. (In this document, `matlab` refers to this script; MATLAB refers to the application program). Before actually initiating the execution of MATLAB, this script configures the run-time environment by:

- Determining the MATLAB root folder
- Determining the host machine architecture
- Processing any command-line options
- Reading the MATLAB startup file, `.matlab7rc.sh`

- Setting MATLAB environment variables

There are two ways in which you can control the way the `matlab` script works:

- By specifying command-line options
- By assigning values in the MATLAB startup file, `.matlab7rc.sh`

Specifying Options at the Command Line

Note On Apple Macintosh platforms, the `matlab` script is located inside the MATLAB application package:

```
/Applications/MATLAB_R2012b.app/bin/matlab
```

To run the `matlab` script from Terminal, specify the full path, or `cd` to the `bin` folder within the application package and preface the command with `./` characters. For example:

```
./matlab -nojvm -nodisplay -nosplash -r "myfun(10,30)"
```

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified `helpOption` argument without starting MATLAB. `helpOption` can be any one of the keywords shown in the following table. Enter only one `helpOption` keyword in a `matlab` command.

Values for helpOption

| Option | Description |
|--------------------|--|
| <code>-help</code> | Display <code>matlab</code> command usage. |
| <code>-h</code> | The same as <code>-help</code> . |

matlab (UNIX)

`matlab envDispOption` displays the values of environment variables passed to MATLAB or their values when exiting MATLAB. `envDispOption` can be either one of the options shown in the following table.

Values for `envDispOption`

| Option | Description |
|-----------|--|
| -n | Display all the final values of the environment variables and arguments passed to the MATLAB executable as well as other diagnostic information. Does not start MATLAB. |
| -e | Display <i>all</i> environment variables and their values before exiting. This argument must have been parsed before exiting for anything to be displayed. The last possible exiting point is just before the MATLAB image would have been executed and a status of 0 is returned. If the exit status is not 0 on return, then the variables and values might not be correct. Does not start MATLAB. |

`matlab archOption` starts MATLAB and assumes that you are running on the system architecture specified by `arch`, or using the MATLAB version specified by `variant`, or both. The values for the `archOption` argument are shown in the following table. Enter only one of these options in a `matlab` command.

Values for archOption

| Option | Description |
|-----------------------------|---|
| <code>-arch</code> | Run MATLAB assuming this architecture rather than the actual architecture of the machine you are using. Replace the term <i>arch</i> with a string representing a recognized system architecture. For example:

<code>matlab -glnx86</code> |
| <code>v=variant</code> | Execute the version of MATLAB found in the folder <code>bin/\$ARCH/variant</code> instead of <code>bin/\$ARCH</code> . Replace the term <i>variant</i> with a string representing a MATLAB version. |
| <code>v=arch/variant</code> | Execute the version of MATLAB found in the folder <code>bin/arch/variant</code> instead of <code>bin/\$ARCH</code> . Replace the terms <i>arch</i> and <i>variant</i> with strings representing a specific architecture and MATLAB version. |

`matlab dispOption` starts MATLAB using one of the display options shown in the following table. Enter only one of these options in a `matlab` command.

Values for dispOption

| Option | Description |
|-----------------------------|---|
| <code>-display xDisp</code> | Send X commands to X Window Server display <code>xDisp</code> . This option supersedes the value of the <code>DISPLAY</code> environment variable.

On Macintosh platforms, this option is ignored. |
| <code>-nodisplay</code> | Start the Oracle JVM software, but do not start the MATLAB desktop. Do not display |

(Continued)

| Option | Description |
|--------|---|
| | any X commands, and ignore the DISPLAY environment variable.

On Macintosh platforms, start the JVM in headless mode, and prevent all windows from being displayed. |

matlab modeOption starts MATLAB without its usual desktop component. Enter only one of the options shown in the following table.

Values for modeOption

| Option | Description |
|-------------------|---|
| -desktop | Allow the MATLAB desktop to be started by a process without a controlling terminal. This is usually a required command-line argument when attempting to start MATLAB from a window manager menu or desktop icon. |
| -nodesktop | Start MATLAB without bringing up the MATLAB desktop. The JVM software <i>is</i> started. To enter commands, use the current window in the operating system. Use this option to run in batch processing mode. If you pipe to MATLAB using the > constructor, the <code>nodesktop</code> option is used automatically. With <code>nodesktop</code> , MATLAB does not save statements to the Command History. With <code>nodesktop</code> , you can still use most development environment tools by starting them via a function. For example, use <code>preferences</code> to open the Preferences dialog box and <code>doc</code> to open the Help browser. Do not use <code>nodesktop</code> to provide a Command Window-only |

(Continued)

| Option | Description |
|---------------|--|
| | interface; instead, select Desktop > Desktop Layout > Command Window Only . |
| -nojvm | Start MATLAB without the JVM software. To enter commands, use the current window. The MATLAB desktop does not open. Any tools that require Java software, such as the desktop tools, cannot be used. Handle Graphics and related functionality are not supported; MATLAB produces a warning when you use them. |

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host` or it can be a colon-separated list of license filenames. This option causes the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables to be ignored.

`matlab -debug` starts MATLAB and displays debugging information that can be useful, especially for X based problems. Use this option only when working with a Technical Support Representative from The MathWorks, Inc.

`matlab -Ddebugger options` starts MATLAB in debug mode, using the named debugger (for example, `dbx`, `gdb`, `xdb`, `cvd`, `lldb`). A full path can be specified for debugger.

Notes for -Ddebugger Argument

- The options argument can include *only* those options that follow the debugger name in the syntax of the actual debug command. For most debuggers, there is a limited number of such options. Use options that would normally be passed to the MATLAB executable as parameters of a command inside the debugger (like `run`). Do not use options when running the `matlab` script.

matlab (UNIX)

- If any other `matlab` command options are placed before the `-Ddebugger` argument, they will be handled as if they were part of the options after the `-Ddebugger` argument and are treated as illegal options by most debuggers. The `MATLAB_DEBUG` environment variable is set to the filename part of the debugger argument.
- To customize your debugging session, use a startup file. See your debugger documentation for details.
- For certain debuggers like `gdb`, the `SHELL` environment variable is *always* set to `/bin/sh`.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the Command Window in file `log`. The output includes all crash reports.

`matlab -mwvisual visualid` starts MATLAB and uses `visualid` as the default X visual for figure windows. `visualid` is a hexadecimal number that can be found using `xdpyinfo`.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosplash` starts MATLAB but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "command"` starts MATLAB and executes the specified MATLAB command. Include the command in double quotation marks ("*command*"). If `command` is the name of a MATLAB function or script,

do not specify the file extension. To separate multiple statements, use semicolons or commas.

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB uses the multithreading capabilities of the computer on which it is running.

Specifying Options in the MATLAB Startup File

The `.matlab7rc.sh` shell script contains definitions for a number of variables that the `matlab` script uses. These variables are defined within the `matlab` script, but can be redefined in `.matlab7rc.sh`. When invoked, `matlab` looks for the first occurrence of `.matlab7rc.sh` in the current folder, in the home folder (`$HOME`), and in the `matlabroot/bin` folder, where the template version of `.matlab7rc.sh` is located.

You can edit the template file to redefine information used by the `matlab` script. If you do not want your changes applied system-wide, copy the edited version of the script to your current or home folder. Ensure that you edit the section that applies to your machine architecture.

The following table lists the variables defined in the `.matlab7rc.sh` file. See the comments in the `.matlab7rc.sh` file for more information about these variables.

Variable Options for Startup File

| Variable | Definition and Standard Assignment Behavior |
|----------|---|
| ARCH | The machine architecture.

The value ARCH passed with the <code>-arch</code> or <code>-arch/ext</code> argument to the script is tried first, then the value of the environment variable <code>MATLAB_ARCH</code> is tried next, and finally it is computed. The first one that gives a valid architecture is used. |
| DISPLAY | Linux platforms only. The hostname of the X Window display MATLAB uses for output. |

matlab (UNIX)

| Variable | Definition and Standard Assignment Behavior |
|---|--|
| | The value of <code>Xdisplay</code> passed with the <code>-display</code> argument to the script is used; otherwise, the value in the environment is used. MATLAB ignores <code>DISPLAY</code> if the <code>-nodisplay</code> argument is passed. |
| LD_LIBRARY_PATH
on Linux platforms.

DYLD_LIBRARY_PATH
on Macintosh
platforms. | Final Load library path. The name <code>LD_LIBRARY_PATH</code> is platform-dependent.

The final value is normally a colon-separated list of four sublists, each of which could be empty. The first sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_PREFIX</code> . The second sublist is computed in the script and includes folders inside the MATLAB root folder and relevant Java folders. The third sublist contains any nonempty value of <code>LD_LIBRARY_PATH</code> from the environment possibly augmented in <code>.matlab7rc.sh</code> . The final sublist is defined in <code>.matlab7rc.sh</code> as <code>LDPATH_SUFFIX</code> . |
| LM_LICENSE_FILE | The FLEX lm license variable.

The license file value passed with the <code>-c</code> argument to the script is used; otherwise it is the value set in <code>.matlab7rc.sh</code> . In general, the final value is a colon-separated list of license files and/or <code>port@host</code> entries. The shipping <code>.matlab7rc.sh</code> file starts out the value by prepending <code>LM_LICENSE_FILE</code> in the environment to a default <code>license.file</code> .

Later in the <code>matlab</code> script, if the <code>-c</code> option is not used, the <code>matlabroot/etc</code> folder is searched for the files that start with <code>license.dat.DEMO</code> . These files are assumed to contain demo |

| Variable | Definition and Standard Assignment Behavior |
|--------------|--|
| | licenses and are added automatically to the end of the current list. |
| MATLAB | <p>The MATLAB root folder.</p> <p>The default computed by the script is used unless MATLABdefault is reset in .matlab7rc.sh.</p> <p>Currently MATLABdefault is not reset in the shipping .matlab7rc.sh.</p> |
| MATLAB_DEBUG | <p>Normally set to the name of the debugger.</p> <p>The -Ddebugger argument passed to the script sets this variable. Otherwise, a nonempty value in the environment is used.</p> |
| MATLAB_JAVA | <p>The path to the root of the Java Runtime Environment.</p> <p>The default set in the script is used unless MATLAB_JAVA is already set. Any nonempty value from .matlab7rc.sh is used first, then any nonempty value from the environment. Currently there is no value set in the shipping .matlab67rc.sh, so that environment alone is used.</p> |
| MATLABPATH | <p>The MATLAB search path.</p> <p>The final value is a colon-separated list with the MATLABPATH from the environment prepended to a list of computed defaults. You can add subfolders of userpath to the MATLAB search path upon startup. See userpath for details.</p> |

matlab (UNIX)

| Variable | Definition and Standard Assignment Behavior |
|----------|--|
| SHELL | <p>The shell to use when the “!” or unix command is issued in MATLAB. This value is taken from the environment unless SHELL is reset in <code>.matlab7rc.sh</code>.</p> <p>Another environment variable called <code>MATLAB_SHELL</code> takes precedence over <code>SHELL</code>. MATLAB checks internally for <code>MATLAB_SHELL</code> first and, if empty or not defined, then checks <code>SHELL</code>. If <code>SHELL</code> is also empty or not defined, MATLAB uses <code>/bin/sh</code>. Use an absolute path for the value of <code>MATLAB_SHELL</code>, that is, <code>/bin/sh</code>, not simply <code>sh</code>.</p> <p>Currently, the shipping <code>.matlab7rc.sh</code> file does not reset <code>SHELL</code> and also does not reference or set <code>MATLAB_SHELL</code>.</p> |
| TOOLBOX | <p>Path of the toolbox folder.</p> <p>A nonempty value in the environment is used first. Otherwise, <code>matlabroot/toolbox</code>, computed by the script, is used unless <code>TOOLBOX</code> is reset in <code>.matlab7rc.sh</code>. Currently <code>TOOLBOX</code> is not reset in the shipping <code>.matlab7rc.sh</code>.</p> |

| Variable | Definition and Standard Assignment Behavior |
|-------------|--|
| XAPPLRESDIR | <p>The X application resource folder (Linux systems only).</p> <p>A nonempty value in the environment is used first unless XAPPLRESDIR is reset in <code>.matlab7rc.sh</code>.</p> |
| XKEYSYMDB | <p>The X keysym database file (Linux systems only).</p> <p>A nonempty value in the environment is used first unless XKEYSYMDB is reset in <code>.matlab7rc.sh</code>.</p> |

The `matlab` script determines the path of the MATLAB root folder by looking up the folder tree from the `matlabroot/bin` folder (where the `matlab` script is located). The MATLAB variable is then used to locate all files within the MATLAB folder tree.

You can change the definition of MATLAB if, for example, you want to run a different version of MATLAB or if, for some reason, the path determined by the `matlab` script is not correct. (This can happen when your system uses certain types of automounting schemes.)

See Also

`matlab` (Windows) | `mex`

How To

- “Start MATLAB on Linux Platforms”
- “Start MATLAB on Macintosh Platforms”
- “Startup Options”

matlab (Windows)

Purpose Start MATLAB program (Windows platforms)

Syntax

```
matlab
matlab helpOption
matlab -automation
matlab -c licensefile
matlab -jdb portnumber
matlab -logfile filename
matlab -noFigureWindows
matlab -nosplash
matlab -nouserjavapath
matlab -r "statement"
matlab -regserver
matlab -sd "startdir"
matlab shieldOption
matlab -singleCompThread
matlab -unregserver
matlab -wait
```

Note You can enter more than one of these options in the same `matlab` command.

Description `matlab` is a script that runs the MATLAB executable on Microsoft Windows platforms. (In this document, the term `matlab` refers to the script, and MATLAB refers to the executable). Before actually initiating the execution of MATLAB, it configures the run-time environment by:

- Determining the MATLAB root folder.
- Determining the host machine architecture.
- Selectively processing command line options with the rest passed to MATLAB.
- Setting certain MATLAB environment variables.

There are two ways in which you can control the way `matlab` works:

- By specifying command line options.
- By setting environment variables before calling the program.

Specifying Options at the Command Line

Options that you can enter at the command line are as follows:

`matlab helpOption` displays information that matches the specified *helpOption* argument without starting MATLAB. *helpOption* can be any one of the keywords shown in the table below. Enter only one *helpOption* keyword in a `matlab` statement.

Values for helpOption

| Option | Description |
|--------------|--|
| -help | Display <code>matlab</code> command usage. |
| -h | The same as -help . |
| -? | The same as -help . |

`matlab -automation` starts MATLAB as an automation server. The server window is minimized, and the MATLAB splash screen does not display on startup.

`matlab -c licensefile` starts MATLAB using the specified license file. The `licensefile` argument can have the form `port@host`. This option causes MATLAB to ignore the `LM_LICENSE_FILE` and `MLM_LICENSE_FILE` environment variables.

`matlab -jdb portnumber` starts MATLAB, enabling use of the Java debugger. If you specify a port number, the Java debugger uses that port to communicate with MATLAB. You can specify any port number in the range 0-65535 that is not reserved or currently in use by another application on your system. By default, MATLAB uses port 4444. If you are running multiple MATLAB sessions and want to use the Java debugger, be sure to specify a port number.

matlab (Windows)

`matlab -logfile filename` starts MATLAB and makes a copy of any output to the Command Window in `filename`. This includes all crash reports.

`matlab -noFigureWindows` starts MATLAB, but disables the display of any figure windows in MATLAB.

`matlab -nosplash` starts MATLAB, but does not display the splash screen during startup.

`matlab -nouserjavapath` disables `javaclasspath.txt` and `javalibrarypath.txt` files.

`matlab -r "statement"` starts MATLAB and executes the specified MATLAB statement. If `statement` is the name of a MATLAB function or script, do not specify the file extension. Any required file must be on the MATLAB search path or in the startup folder.

`matlab -regserver` registers MATLAB as a Component Object Model (COM) server.

`matlab -sd "startdir"` specifies the startup folder for MATLAB (the current folder in MATLAB after startup). The `-sd` option has been deprecated. For information about alternatives, see “Startup Folder on Windows Platforms”.

`matlab shieldOption` provides the specified level of protection of the address space used by MATLAB during startup on Windows 32-bit platforms. It attempts to help ensure the largest contiguous block of memory available after startup, which is useful for processing large data sets. The *shieldOption* does this by ensuring resources such as DLLs, are loaded into locations that will not fragment the address space. With *shieldOption* set to a value other than none, address space is protected up to or after the processing of `matlabrc`. Use higher levels of protection to secure larger initial blocks of contiguous memory, however a higher level might not always provide a larger size block and might cause startup problems. Therefore, start with a lower level of protection, and if successful, try the next higher level. You can use the `memory` function after startup to see the size of the largest contiguous block of memory; this helps you determine the actual effect of the *shieldOption* setting

you used. If your `matlabrc` (or `startup.m`) requires significant memory, a higher level of protection for `shieldOption` might cause startup to fail; in that event try a lower level. Values for `shieldOption` can be any one of the keywords shown in the table below.

| Option | Description |
|-------------------------------|---|
| <p>-shield minimum</p> | <p>This is the default setting. It protects the range 0x50000000 to 0x70000000 during MATLAB startup until just before startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>Start with this, the default value. To use the default, do not specify a shield option upon startup.</p> <p>If MATLAB fails to start successfully using the default option, -shield minimum, instead use -shield none.</p> <p>If MATLAB starts successfully with the default value for <code>shieldOption</code> and you want to try to ensure an even larger contiguous block after startup, try using the -shield medium option.</p> |
| <p>-shield medium</p> | <p>This protects the same range as for minimum, 0x50000000 to 0x70000000, but protects the range until just after startup processes <code>matlabrc</code>. It ensures there is at least approximately 500 MB of contiguous memory up to this point.</p> <p>If MATLAB fails to start successfully with the -shield medium option, instead use the default option (-shield minimum).</p> |

matlab (Windows)

| Option | Description |
|------------------------|--|
| | If MATLAB starts successfully with the -shield medium option and you want to try to ensure an even larger contiguous block after startup, try using the -shield maximum option. |
| -shield maximum | This protects the maximum possible range, which can be up to approximately 1.5 GB, until just after startup processes <code>matlabrc</code> .

If MATLAB fails to start successfully with the -shield maximum option, instead use the -shield medium option. |
| -shield none | This completely disables address shielding. Use this if MATLAB fails to start successfully with the default (-shield minimum) option. |

`matlab -singleCompThread` limits MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

`matlab -unregserver` removes all MATLAB COM server entries from the registry.

`matlab -wait` MATLAB is started by a separate starter program which normally launches MATLAB and then immediately quits. Using this option tells the starter program not to quit until MATLAB has terminated. This option is useful when you need to process the results from MATLAB in a script. Calling MATLAB with this option blocks the script from continuing until the results are generated.

Setting Environment Variables

You can set the following environment variables before starting MATLAB.

| Variable Name | Description |
|-----------------|---|
| LM_LICENSE_FILE | This variable specifies the License File to use. If you use the -c argument to specify the License File it overrides this variable. The value of this variable can be a list of License Files, separated by semi-colons, or port@host entries. |

How To

- “Start MATLAB on Windows Platforms”
- “Startup Options”

max

Purpose

Largest elements in array

Syntax

```
C = max(A)
C = max(A, [], dim)
[C, I] = max(...)
```

```
C = max(A, B)
```

Description

`C = max(A)` returns the largest elements along different dimensions of an array.

If `A` is a vector, `max(A)` returns the largest element in `A`.

If `A` is a matrix, `max(A)` treats the columns of `A` as vectors, returning a row vector containing the maximum element from each column.

If `A` is a multidimensional array, `max(A)` treats the values along the first non-singleton dimension as vectors, returning the maximum value of each vector.

`C = max(A, [], dim)` returns the largest elements along the dimension of `A` specified by scalar `dim`. For example, `max(A, [], 1)` produces the maximum values along the first dimension of `A`.

`[C, I] = max(...)` finds the indices of the maximum values of `A`, and returns them in output vector `I`. If there are several identical maximum values, the index of the first one found is returned.

`C = max(A, B)` returns an array the same size as `A` and `B` with the largest elements taken from `A` or `B`. The dimensions of `A` and `B` must match, or they may be scalar.

Examples

Return the maximum of a 2-by-3 matrix from each column:

```
X = [2 8 4; 7 3 9];
max(X, [], 1)
ans =
```

```
7     8     9
```

Return the maximum from each row:

```
max(X,[],2)
ans =
```

```
8
9
```

Compare each element of X to a scalar:

```
max(X,5)
ans =
```

```
5     8     5
7     5     9
```

Tips

For complex input A, `max` returns the complex number with the largest complex modulus (magnitude), computed with `max(abs(A))`. Then computes the largest phase angle with `max(angle(x))`, if necessary.

The `max` function ignores NaNs.

MaximizeCommandWindow

Purpose Open Automation server window

Syntax **IDL Method Signature**

```
HRESULT MaximizeCommandWindow(void)
```

Microsoft Visual Basic Client

```
MaximizeCommandWindow
```

MATLAB Client

```
h.MaximizeCommandWindow  
MaximizeCommandWindow(h)
```

Description h.MaximizeCommandWindow displays the window for the server attached to handle h, and makes it the currently active window on the desktop.

MaximizeCommandWindow(h) is an alternate syntax.

MaximizeCommandWindow restores the window to the size it had at the time it was minimized, not to the maximum size on the desktop. If the server window was not previously in a minimized state, MaximizeCommandWindow does nothing.

Examples From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server:

```
Dim Matlab As Object
```

```
Matlab = CreateObject("matlab.application")  
Matlab.MinimizeCommandWindow
```

```
'Now return the server window to its former state on  
'the desktop and make it the currently active window.
```

```
Matlab.MaximizeCommandWindow
```

See Also MinimizeCommandWindow

Purpose Control maximum number of computational threads

Note `maxNumCompThreads` will be removed in a future version. You can set the `-singleCompThread` option when starting MATLAB to limit MATLAB to a single computational thread. By default, MATLAB makes use of the multithreading capabilities of the computer on which it is running.

Syntax

```
N = maxNumCompThreads
LASTN = maxNumCompThreads(N)
LASTN = maxNumCompThreads('automatic')
```

Description

`N = maxNumCompThreads` returns the current maximum number of computational threads `N`.

`LASTN = maxNumCompThreads(N)` sets the maximum number of computational threads to `N`, and returns the previous maximum number of computational threads, `LASTN`.

`LASTN = maxNumCompThreads('automatic')` sets the maximum number of computational threads using what the MATLAB software determines to be the most desirable. It additionally returns the previous maximum number of computational threads, `LASTN`.

Currently, the maximum number of computational threads is equal to the number of computational cores on your machine.

Note Setting the maximum number of computational threads using `maxNumCompThreads` does not propagate to your next MATLAB session.

mean

Purpose Average or mean value of array

Syntax

```
M = mean(A)
M = mean(A,dim)
M = mean( ___, type)
```

Description `M = mean(A)` returns the mean value along the first array dimension of `A` whose size does not equal 1.

- If `A` is a vector, then `mean(A)` returns the mean of the elements.
- If `A` is a nonempty, nonvector matrix, then `mean(A)` treats the columns of `A` as vectors and returns a row vector whose elements are the mean of each column.
- If `A` is an empty 0-by-0 matrix, then `mean(A)` returns NaN.
- If `A` is a multidimensional array, then `mean(A)` treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of row vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`M = mean(A,dim)` returns the mean along dimension `dim`. For example, if `A` is a matrix, then `mean(A,2)` is a column vector containing the mean of each row.

`M = mean(___, type)` returns the mean in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be 'double', 'native', or 'default'.

Input Arguments

A - Input array
vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

If `A` contains NaN, then `M` returns NaN.

Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension dim indicates the dimension whose length reduces to 1. The $size(M,dim)$ is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, A .

- If $dim = 1$, then $mean(A,1)$ returns a row vector containing the mean of the elements in each column.
- If $dim = 2$, then $mean(A,2)$ returns a column vector containing the mean of the elements in each row.

`mean` returns A if dim is greater than $ndims(A)$.

Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |
uint16 | uint32 | uint64

type - Output class

mean

'default' (default) | 'double' | 'native'

Output class, specified as 'default', 'double', or 'native', and which defines the data type of the output, M.

| type | Output data type |
|-----------|--|
| 'default' | double, unless the input data type is single. In which case, the output data type is single. |
| 'double' | double |
| 'native' | same data type as the input array, A |

Examples

Mean of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```
    0     1     1
    2     3     2
    1     3     2
    4     2     2
```

Find the mean value of each column.

```
M = mean(A)
```

```
M =
```

```
    1.7500    2.2500    1.7500
```

Mean of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```
    0    1    1
    2    3    2
```

Find the mean value of each row.

```
M = mean(A,2)
```

```
M =
```

```
    0.6667
    2.3333
```

Mean of 3-D array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =
```

```
    10     8    10
```

```
A(:,:,2) =
```

```
     6     9     5
```

```
A(:,:,3) =
```

```
     9     6     1
```

```
A(:,:,4) =
```

```
     4     9     5
```

mean

Find the mean values of this 3-D array along the second dimension.

```
M = mean(A)
```

```
M(:, :, 1) =
```

```
    9.3333
```

```
M(:, :, 2) =
```

```
    6.6667
```

```
M(:, :, 3) =
```

```
    5.3333
```

```
M(:, :, 4) =
```

```
    6
```

This operation produces a 1-by-1-by-4 array by computing the mean of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the mean along the first dimension of A.

```
M = mean(A, 1);
```

```
isequal(A,M)
```

```
ans =
```

```
    1
```

This operation returns the same array as A because the size of the first dimension is 1.

Mean of 8-bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =
```

```
     1     2     3     4
```

Compute the mean value.

```
M = mean(A),  
class(M)
```

```
M =
```

```
     2.5000
```

```
ans =
```

```
double
```

M is the mean value returned as `double`. This operation returns the same result as `M = mean(A, 'default')`.

Specify type as `'native'` to return the mean value as an 8-bit integer.

```
M = mean(A, 'native'),  
class(M)
```

```
M =
```

```
     3
```

```
ans =
```

mean

positive integer scalar</p> |

median

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M,dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, `A`.

- If `dim = 1`, then `median(A,1)` returns a row vector containing the median of the elements in each column.
- If `dim = 2`, then `median(A,2)` returns a column vector containing the median of the elements in each row.

`median` returns `A` if `dim` is greater than `ndims(A)`.

Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

Definitions

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If `X` is a 1-by-`n` row vector, then the second dimension is the first nonsingleton dimension of `X`.

- If X is a 1-by-0-by- n empty array, then the second dimension is the first nonsingleton dimension of X .
- If X is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of X .

Examples

Median of Matrix Columns

Define a 4-by-3 matrix.

```
A = [0 1 1; 2 3 2; 1 3 2; 4 2 2]
```

```
A =
```

```

0     1     1
2     3     2
1     3     2
4     2     2
```

Find the median value of each column.

```
M = median(A)
```

```
M =
```

```
1.5000    2.5000    2.0000
```

For each column, the median value is the mean of the middle two numbers in sorted order.

Median of Matrix Rows

Define a 2-by-3 matrix.

```
A = [0 1 1; 2 3 2]
```

```
A =
```

```

0     1     1
2     3     2
```

median

```
2     3     2
```

Find the median value of each row.

```
M = median(A,2)
```

```
M =
```

```
1  
2
```

For each row, the median value is the middle number in sorted order.

Median of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
A = gallery('integerdata',10,[1,3,4],1)
```

```
A(:,:,1) =
```

```
10     8     10
```

```
A(:,:,2) =
```

```
6     9     5
```

```
A(:,:,3) =
```

```
9     6     1
```

```
A(:,:,4) =
```

```
4     9     5
```

Find the median values of this 3-D array along the second dimension.

```
M = median(A)
```

```
M(:,:,1) =
```

```
10
```

```
M(:,:,2) =
```

```
6
```

```
M(:,:,3) =
```

```
6
```

```
M(:,:,4) =
```

```
5
```

This operation produces a 1-by-1-by-4 array by computing the median of the three values along the second dimension. The size of the second dimension is reduced to 1.

Compute the median along the first dimension of A.

```
M = median(A,1);
```

```
isequal(A,M)
```

```
ans =
```

```
1
```

This returns the same array as A because the size of the first dimension is 1.

Median of 8-bit Integer Array

Define a 1-by-4 vector of 8-bit integers.

```
A = int8(1:4)
```

```
A =
```

```
    1    2    3    4
```

Compute the median value.

```
M = median(A),  
class(M)
```

```
M =
```

```
    3
```

```
ans =
```

```
int8
```

M is the mean of the middle two numbers in sorted order returned as an 8-bit integer.

Purpose Create memory map to a file

Syntax
`m = memmapfile(filename)`
`m = memmapfile(filename,Name,Value)`

Description `m = memmapfile(filename)` maps an existing file, `filename`, to memory and returns the memory map, `m`.

Memory-mapping is a mechanism that maps a portion of a file, or an entire file, on disk to a range of memory addresses within the MATLAB address space. Then, MATLAB can access files on disk in the same way it accesses dynamic memory, accelerating file reading and writing. Memory-mapping allows you to work with data in a file as if it were a MATLAB array.

`m = memmapfile(filename,Name,Value)` specifies the properties of `m` using one or more name-value pair arguments. For example, you can specify the format of the data in the file.

Input Arguments

filename - Name of file to map

string

Name of the file to map including the file extension, specified as a string. The `filename` argument cannot include any wildcard characters (for example, `*` or `?`).

Example: `'myFile.dat'`

Data Types

char

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

memmapfile

Example: `m = memmapfile('myFile.dat', 'Format', 'int32', 'Offset', 255)`
maps int32 data in the file, myFile.dat, to memory starting from the 256th byte.

'Writable' - Type of access allowed to mapped region

false (default) | true

Type of access allowed to the mapped region, specified as the comma-separated pair consisting of 'Writable' and either true or false. If the Writable property is set to false, the mapped region is read-only. If true, then write access is allowed.

Example: 'Writeable', true

Data Types

logical

'Offset' - Number of bytes from start of file to start of mapped region

0 (default) | nonnegative integer

Number of bytes from the start of the file to the start of the mapped region, specified as the comma-separated pair consisting of 'Offset' and a nonnegative integer. This value is zero-based. That is, an Offset value of 0 represents the start of the file.

Example: 'Offset', 1024

Data Types

double

'Format' - Format of mapped region

'uint8' (default) | string | n-by-3 cell array

Format of the mapped region contents, specified as the comma-separated pair consisting of 'Format' and a single string or an n-by-3 cell array.

- If the file region you are mapping contains data of only one type, specify the Format value as a string identifying that type.

Example: 'int16'

- To specify an array shape to apply to the data read or written to the mapped file, and a field name to reference this array, specify the `Format` value as a 1-by-3 cell array. The first cell contains a string identifying the data type to apply to the mapped region. The second cell contains the array dimensions to apply to the region. The third cell contains a string specifying the field name to use in the `Data` structure array of the memory map.

Example: `{'uint64',[30 4 10],'x'}`

- If the region you are mapping is composed of segments of varying data types or array shapes, you can specify an individual format for each segment using an n-by-3 cell array, where n is the number of segments.

Example: `{'uint64',[30 4 10],'x'; 'uint32',[30 4 6],'y'}`

You can use any of the following data types when you specify a `Format` value:

- `'int8'`
- `'int16'`
- `'int32'`
- `'int64'`
- `'uint8'`
- `'uint16'`
- `'uint32'`
- `'uint64'`
- `'single'`
- `'double'`

Data Types

`char` | `cell`

'Repeat' - Number of times to apply `Format` parameter

`Inf` (default) | positive integer

memmapfile

Number of times to apply the `Format` parameter to the mapped region of the file, specified as the comma-separated pair consisting of `'Repeat'` and a positive integer. If the value of `Repeat` is `Inf`, then `memmapfile` applies the `Format` parameter until the end of the file.

Example: `'Repeat',2000`

Data Types

double

Output Arguments

m - Memory map

`memmapfile` object

Memory map, returned as a `memmapfile` object with the following properties.

| Property | Description |
|----------|--|
| Filename | Path and name of the mapped file |
| Writable | Type of access allowed to the mapped region |
| Offset | Number of bytes from the start of the file to the start of the mapped region |
| Format | Format of the contents of the mapped region, including data type, array size, and field name by which to access the data |
| Repeat | Number of times to apply the pattern specified by the <code>Format</code> property to the mapped region of the file |
| Data | Memory-mapped data from the file. <code>Data</code> can be a numeric array or a structure array with field names specified in the <code>Format</code> property |

The values for any property (except for `Data`) are set at the time you call `memmapfile`, using name-value pair arguments.

Access any property of `m` with dot notation similar to accessing fields of a structure array. For example, to access the memory-mapped data in the `Data` property, do one of the following:

- If `Data` is a numeric array, call `m.Data`.
- If `Data` is a scalar (1-by-1) structure array, call `m.Data.fieldname`, where `fieldname` is the name of a field.
- If `Data` is a nonscalar structure array, call `m.Data(index).fieldname` where `index` is the index for the element in the structure array, and `fieldname` is the name of a field. For example, to access the file data in the `temperature` field of the first element of `Data`, call `m.Data(1).temperature`.

After you create a memory map, `m`, you can change the value of any of its properties, except for `Data`. To assign a new value, use dot notation. For example, to set a new `Offset` value for `m`, type:

```
m.Offset = 2048;
```

Examples

Map Entire File of uint8 Data

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 `uint8` values.

```
myData = uint8(1:10)';  
  
fileID = fopen('records.dat','w');  
fwrite(fileID, myData, 'uint8');  
fclose(fileID);
```

Create a map for `records.dat`. When using `memmapfile`, the default data format is `uint8` so the file name is the only required input argument in this case.

```
m = memmapfile('records.dat')
```

```
m =
```

memmapfile

```
Filename: 'd:\matlab\records.dat'  
Writable: false  
Offset: 0  
Format: 'uint8'  
Repeat: Inf  
Data: 10x1 uint8 array
```

MATLAB maps the entire `records.dat` file to memory, setting all properties of the memory map to their default values. The memory map is assigned to the variable, `m`. In this example, the command maps the entire file as a sequence of unsigned 8-bit integers and gives the caller read-only access to its contents.

View the mapped data by accessing the `Data` property of `m`.

`m.Data`

`ans =`

```
1  
2  
3  
4  
5  
6  
7  
8  
9  
10
```

Map Entire File of Double-Precision Data

Create a memory map for double-precision data. The syntax is similar when specifying other data types.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10 double values.

```
myData = (1:10)';
```

```
fileID = fopen('records.dat','w');  
fwrite(fileID,myData,'double');  
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `'double'`.

```
m = memmapfile('records.dat','Format','double')
```

```
m =
```

```
    Filename: 'd:\matlab\records.dat'  
    Writable: false  
    Offset: 0  
    Format: 'double'  
    Repeat: Inf  
    Data: 10x1 double array
```

The `Data` property contains the 10 double-precision values in `records.dat`.

Map and Change Part of a File

Create a memory map for a large array of `int32` data. Specify write access, and nondefault `Format` and `Offset` values.

At the command prompt, create a sample file in your current folder called `records.dat`, containing 10,000 `int32` values.

```
myData = int32([1:10000]);
```

```
fileID = fopen('records.dat','w');  
fwrite(fileID,myData,'int32');  
fclose(fileID);
```

Create a memory map for `records.dat`, and set the `Format` property for the output to `int32`. Also, set the `Offset` property to disregard the first 9000 bytes in the file, and the `Writable` property to permit write access.

memmapfile

```
m = memmapfile('records.dat',...
               'Offset',9000,...
               'Format','int32',...
               'Writable',true);
```

An `Offset` value of 9000 indicates that the first 9000 bytes of `records.dat` are not mapped.

Type the name of the memory map to see the current settings for all properties.

```
m

m =
  Filename: 'd:\matlab\records.dat'
  Writable: true
  Offset: 9000
  Format: 'int32'
  Repeat: Inf
  Data: 7750x1 int32 array
```

The `Format` property indicates that any read or write operation made via the memory map reads and writes the file contents as a sequence of signed 32-bit integers. The `Data` property contains only 7750 elements because the first 9000 bytes of `records.dat`, representing the first 2250 values in the file, are not mapped.

View the first five elements of the mapped data by accessing the `Data` property of `m`.

```
m.Data(1:5)
```

```
ans =

    2251
    2252
    2253
    2254
```

2255

Map Region of File to Specific Array Shape

Create a memory map for a region of a file containing 100 double-precision values.

At the command prompt, create a sample file in your current folder called `mybinary.bin`, containing 100 double-precision values.

```
randData = gallery('uniformdata',[100,1],0,'double');

fileID = fopen('mybinary.bin','w');
fwrite(fileID,randData,'double');
fclose(fileID);
```

Map the first 75 values in `mybinary.bin` to a 5-by-5-by-3 array of double-precision values that can be referenced in the structure of the memory map using the field name `x`. Specify these parameters with the `Format` name-value pair argument.

```
m = memmapfile('mybinary.bin',...
              'Format',{'double',[5 5 3],'x'})
```

```
m =
```

```
Filename: 'd:\matlab\mybinary.bin'
Writable: false
Offset: 0
Format: {'double' [5 5 3] 'x'}
Repeat: Inf
Data: 1x1 struct array with fields:
      x
```

The `Data` property is a structure array that contains the mapped values in the field, `x`.

Assign the mapped data to a variable, `A`. Because the `Data` property is a structure array, you must index into the field, `x`, to access the data.

```
A = m.Data.x;
```

View information about A.

```
whos A
```

| Name | Size | Bytes | Class | Attributes |
|------|-------|-------|--------|------------|
| A | 5x5x3 | 600 | double | |

Map Segments of File to Multiple Arrays

Map segments of a file with different array shapes and data types to memory.

At the command prompt, create a sample file in your current folder called `mybinary.bin`. Write `uint16` data and double-precision data representing sample pressure, temperature, and volume values into the file. In this case, each of the `uint16` arrays are 50-by-1 and the double-precision arrays are 5-by-10. `k` is a sample scaling factor.

```
k = 8.21;
[pres1,temp1] = gallery('integerdata',[1,300],[50,1],0,'uint16');
vol1 = double(reshape(k*temp1./pres1,5,10));
[pres2,temp2] = gallery('integerdata',[5,500],[50,1],5,'uint16');
vol2 = double(reshape(k*temp2./pres2,5,10));

fileID = fopen('mybinary.bin','w');
fwrite(fileID,pres1,'uint16');
fwrite(fileID,temp1,'uint16');
fwrite(fileID,vol1,'double');
fwrite(fileID,pres2,'uint16');
fwrite(fileID,temp2,'uint16');
fwrite(fileID,vol2,'double');
fclose(fileID);
```

Map the file to arrays accessible by unique names. Define a field, `pressure`, containing a 50-by-1 array of `uint16` values, followed by a field, `temperature`, containing 50-by-1 `uint16` values. Define a field,

`volume`, containing a 5-by-10 array of double-precision values. Use a cell array to define the format of the mapped region and repeat the pattern twice.

```
m = memmapfile('mybinary.bin',...
'Format',{ 'uint16',[50 1], 'pressure';...
'uint16',[50,1], 'temperature';...
'double',[5,10], 'volume'}, 'Repeat',2)

m =

    Filename: 'd:\matlab\mybinary.bin'
    Writable: false
    Offset: 0
    Format: { 'uint16' [50 1] 'pressure'
             'uint16' [50 1] 'temperature'
             'double' [5 10] 'volume' }
    Repeat: 2
    Data: 2x1 struct array with fields:
        pressure
        temperature
        volume
```

The `Data` property of the memory map, `m`, is a 2-by-1 structure array because the `Format` is applied twice.

Copy the `Data` property to a variable, `A`. Then, view the last block of double data, which you can access using the field name, `volume`.

```
A = m.Data;
myVolume = A(2).volume
```

```
myVolume =
```

```
     2     13     32     5     5     16     4     22     3     8
     2     9     53     38     13     19     23     85     2    120
    29     10     6     1     2     5     6     58     20     11
     7     15     4     1     5     18     1     4     14     8
```

memmapfile

9 8 4 2 0 9 8 6 3 3

Tips

- You can map only an existing file. You cannot create a new file and map that file to memory in one operation. Use the MATLAB file I/O functions to create the file before attempting to map it to memory.
- After `memmapfile` locates the file, MATLAB stores the file's absolute pathname internally, and then uses this stored path to locate the file from that point on. As a result, you can work in other directories outside your current work directory and retain access to the mapped file.
- `memmapfile` does not expand or append to a mapped file. Use instead standard file I/O functions like `fopen` and `fwrite`.

Algorithms

The actual mapping of a file to the MATLAB address space does not take place when you construct a `memmapfile` object. A memory map, based on the information currently stored in the mapped object, is generated the first time you reference or modify the `Data` property for that object.

Concepts

- “Overview of Memory-Mapping”

- Purpose** Display memory information
- Syntax**
- ```
memory
userview = memory
[userview systemview] = memory
```
- Limitations**
- The memory function is available only on Microsoft Windows systems. Results are dependant on your computer hardware and the load on your computer.
- Description**
- memory displays information showing how much memory is available and how much the MATLAB software is currently using. The information displayed at your computer screen includes the following items, each of which is described in a section below:
- “Maximum Possible Array” on page 1-4252
  - “Memory Available for All Arrays” on page 1-4253
  - “Memory Used By MATLAB” on page 1-4254
  - “Total Physical Memory (RAM)” on page 1-4254
- userview = memory returns user-focused information on memory use in structure userview. The information returned in userview includes the following items, each of which is described in a section below:
- “Maximum Possible Array” on page 1-4252
  - “Memory Available for All Arrays” on page 1-4253
  - “Memory Used By MATLAB” on page 1-4254
- [userview systemview] = memory returns both user- and system-focused information on memory use in structures userview and systemview, respectively. The userview structure is described in the command syntax above. The information returned in systemview includes the following items, each of which is described in a section below:
- “Virtual Address Space” on page 1-4255

- “System Memory” on page 1-4255
- “Physical Memory” on page 1-4256

## Output Arguments

Each of the sections below describes a value that is displayed or returned by the `memory` function.

### Maximum Possible Array

Maximum Possible Array is the size of the largest contiguous free memory block. As such, it is an upper bound on the largest single array MATLAB can create at this time.

MATLAB derives this number from the smaller of the following two values:

- The largest contiguous memory block found in the MATLAB virtual address space
- The total available system memory

To see how many array elements this number represents, divide by the number of bytes in the array class. For example, for a `double` array, divide by 8. The actual number of elements MATLAB can create is always fewer than this number.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Maximum possible array:
<code>user = memory</code>	Structure field <code>user.MaxPossibleArrayBytes</code>

All values are double-precision and in units of bytes.

### Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems

show either the first or second footnote; 64-bit systems show only the second footnote:

Limited by contiguous virtual address space available.

There is sufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all virtual addresses in the largest available block of the MATLAB process.

## Memory Available for All Arrays

Memory Available for All Arrays is the total amount of memory available to hold data. The amount of memory available is guaranteed to be at least as large as this field.

MATLAB derives this number from the smaller of the following two values:

- The total available MATLAB virtual address space
- The total available system memory

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory available for all arrays:
<code>user = memory</code>	Structure field <code>user.MemAvailableAllArrays</code>

## Footnotes

When you enter the `memory` command without specifying any outputs, MATLAB may also display one of the following footnotes. 32-bit systems

show either the first or second footnote; 64-bit systems show only the latter footnote:

Limited by virtual address space available.

There is sufficient system memory to allow mapping of all available virtual addresses in the MATLAB process virtual address space to system memory. The maximum amount of total MATLAB virtual address space is either 2 GB or 3 GB, depending on whether the /3GB switch is in effect or not.

Limited by System Memory (physical + swap file) available.

There is insufficient system memory to allow mapping of all available virtual addresses in the MATLAB process.

## Memory Used By MATLAB

Memory Used By MATLAB is the total amount of system memory reserved for the MATLAB process. It is the sum of the physical memory and potential swap file usage.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. When you do assign the output, MATLAB returns the information in a structure field. See the table below.

Command	Returned in
<code>memory</code>	String labelled Memory used by MATLAB:
<code>user = memory</code>	Structure field <code>user.MemUsedMATLAB</code>

## Total Physical Memory (RAM)

Physical Memory (RAM) is the total physical memory (or RAM) in the computer.

When you enter the `memory` command without assigning its output, MATLAB displays this information as a string. See the table below.

Command	Returned in
memory	String labelled Physical Memory (RAM):

### Virtual Address Space

Virtual Address Space is the amount of available and total virtual memory for the MATLAB process. MATLAB returns the information in two fields of the return structure: Available and Total.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.VirtualAddressSpace.Available
	Total memory	sys.VirtualAddressSpace.Total

You can monitor the difference:

```
VirtualAddressSpace.Total - VirtualAddressSpace.Available
```

as the Virtual Bytes counter in the WindowsPerformance program. (e.g., Windows XP Control Panel/Administrative Tool/Performance program).

### System Memory

System Memory is the amount of available system memory on your computer system. This number includes the amount of available physical memory and the amount of available swap file space on the computer running MATLAB. MATLAB returns the information in the SystemMemory field of the return structure.

Command	Return Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.SystemMemory

This is the same as the difference:

```
limit - total (in bytes)
```

# memory

---

found in the Windows Task Manager: Performance/Commit Charge.

## Physical Memory

Physical Memory is the available and total amounts of physical memory (RAM) on the computer running MATLAB. MATLAB returns the information in two fields of the return structure: `Available` and `Total`.

Command	Value	Returned in Structure Field
[user,sys] = memory	Available memory	sys.PhysicalMemory.Available
	Total memory	sys.PhysicalMemory.Total

Available physical memory is the same as:

Available (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

The total physical memory is the same as

Total (in bytes)

found in the Windows Task Manager: Performance/Physical Memory

You can use the amount of available physical memory as a measure of how much data you can access quickly.

## Tips

### Details on Memory Used By MATLAB

MATLAB computes the value for Memory Used By MATLAB by walking the MATLAB process memory structures and summing all the sections that have physical storage allocated in memory or in the paging file on disk.

Using the Windows Task Manager, you have for the MATLAB.exe image:

Mem Usage < MemUsedMATLAB < Mem Usage + VM Size (in bytes)

where both of the following are true:

- **Mem Usage** is the working set size in kilobytes.
- **VM Size** is the page file usage, or private bytes, in kilobytes.

The working set size is the portion of the MATLAB virtual address space that is *currently* resident in RAM and can be referenced without a memory page fault. The page file usage gives the portion of the MATLAB virtual address space that requires a backup that doesn't already exist. Another name for page file usage is *private bytes*. It includes all MATLAB variables and workspaces. Since some of the pages in the page file may also be part of the working set, this sum is an overestimate of MemUseMATLAB. Note that there are virtual pages in the MATLAB process space that already have a backup. For example, code loaded from EXEs and DLLs and memory-mapped files. If any part of those files is in memory when the memory builtin is called, that memory will be counted as part of MemUsedMATLAB.

## Reserved Addresses

Reserved addresses are addresses sets aside in the process virtual address space for some specific future use. These reserved addresses reduce the size of MemAvailableAllArrays and can reduce the size of the current or future value of MaxPossibleArrayBytes.

### Example 1 – Java Virtual Machine (JVM)

At MATLAB startup, part of the MATLAB virtual address space is reserved by the Java Virtual Machine (JVM) and cannot be used for storing MATLAB arrays.

### Example 2 – Standard Windows Heap Manager

MATLAB, by default, uses the standard Windows heap manager except for a set of small preselected allocation sizes. One characteristic of this heap manager is that its behavior depends upon whether the requested allocation is less than or greater than the fixed number of 524,280 bytes. For, example, if you create a sequence of MATLAB arrays, each less than 524,280 bytes, and then clear them all, the MemUsedMATLAB value before and after shows little change, and the MemAvailableAllArrays value is now smaller by the total space allocated.

The result is that, instead of globally freeing the extra memory, the memory becomes reserved. It can *only* be reused for arrays less than 524,280 bytes. You cannot reclaim this memory for a larger array except by restarting MATLAB.

## Examples

Display memory statistics on a 32-bit Windows system:

```
memory
```

```
Maximum possible array: 677 MB (7.101e+008 bytes) *
Memory available for all arrays: 1601 MB (1.679e+009 bytes) **
Memory used by MATLAB: 446 MB (4.681e+008 bytes)
Physical Memory (RAM): 3327 MB (3.489e+009 bytes)
```

\* Limited by contiguous virtual address space available.

\*\* Limited by virtual address space available.

Return in the structure `userview`, information on the largest array MATLAB can create at this time, how much memory is available to hold data, and the amount of memory currently being used by your MATLAB process:

```
userview = memory
```

```
userview =
 MaxPossibleArrayBytes: 710127616
 MemAvailableAllArrays: 1.6792e+009
 MemUsedMATLAB: 468127744
```

Assign the output to two structures, `user` and `sys`, to obtain the information shown here:

```
[user sys] = memory;

% --- Largest array MATLAB can create ---
user.MaxPossibleArrayBytes
ans =
 710127616
```

```
% --- Memory available for data ---
user.MemAvailableAllArrays
ans =
 1.6797e+009

% --- Memory used by MATLAB process ---
user.MemUsedMATLAB
ans =
 467603456

% --- Virtual memory for MATLAB process ---
sys.VirtualAddressSpace
ans =
 Available: 1.6797e+009
 Total: 2.1474e+009

% --- Physical memory and paging file ---
sys.SystemMemory
ans =
 Available: 4.4775e+009

% --- Computer's physical memory ---
sys.PhysicalMemory
ans =
 Available: 2.3941e+009
 Total: 3.4889e+009
```

# menu

---

**Purpose** Generate menu of choices for user input

**Syntax**  
`choice = menu('mtitle','opt1','opt2',..., 'optn')`  
`choice = menu('mtitle',options)`

**Description** `choice = menu('mtitle','opt1','opt2',..., 'optn')` displays the menu whose title is in the string variable 'mtitle' and whose choices are string variables 'opt1', 'opt2', and so on. The menu opens in a modal dialog box. `menu` returns the number of the selected menu item, or 0 if the user clicks the close button on the window.

`choice = menu('mtitle',options)` , where `options` is a 1-by-N cell array of strings containing the menu choices.

If the user's terminal provides a graphics capability, `menu` displays the menu items as push buttons in a figure window (Example 1). Otherwise, they will be given as a numbered list in the Command Window (Example 2).

**Tips** To call `menu` from a `uicontrol` or other `ui` object, set that object's `Interruptible` property to 'on'. For more information, see `Uicontrol Properties`.

## **Examples** **Example 1**

On a system with a display, `menu` displays choices as buttons in a dialog box:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following dialog box.

The number entered by the user in response to the prompt is returned as `choice` (i.e., `choice = 2` implies that the user selected Blue).

After input is accepted, the dialog box closes, returning the output in `choice`. You can use `choice` to control the color of a graph:

```
t = 0:.1:60;
s = sin(t);
color = ['r','b','g']
plot(t,s,color(choice))
```

## Example 2

On a system without a display, `menu` displays choices in the Command Window:

```
choice = menu('Choose a color','Red','Blue','Green')
```

displays the following text.

```
----- Choose a color -----
1) Red
2) Blue
3) Green
Select a menu number:
```

# mergecats

---

**Purpose** Merge categories in categorical array

**Syntax**  
B = mergecats(A,oldcats)  
B = mergecats(A,oldcats,newcat)

**Description** B = mergecats(A,oldcats) merges two or more categories in A into the first category, oldcats(1). Any values in A from oldcats become oldcats(1) in B.

B = mergecats(A,oldcats,newcat) merges oldcats into a single new category, newcat. Any values in A from oldcats become newcat in B.

## Input Arguments

**A - Categorical array**  
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**oldcats - Categories to merge**  
cell array of strings

Categories to merge, specified as a cell array of strings. If A is ordinal, the categories to merge must be consecutive.

**newcat - New category**  
oldcats(1) (default) | string

New category, specified as a string.

## Examples

### Merge Two Categories into One

Create a categorical array containing various colors.

```
A = categorical({'red';'blue';'pink';'red';'blue';'red'})
```

```
A =
```

```
 red
```

```
blue
pink
red
blue
red
```

A is a 6-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'blue'
'pink'
'red'
```

The three categories are in alphabetical order.

Merge the categories red and pink into the category red. Specify red first in oldcats to use it as the merged category.

```
oldcats = {'red','pink'};
B = mergecats(A,oldcats)
```

```
B =
```

```
red
blue
red
red
blue
red
```

mergecats replaces the value pink from A(3) with red.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'blue'
 'red'
```

B has two categories instead of three.

## **Merge Alphabetically Listed Categories**

Create a categorical array containing various items.

```
A = categorical({'shirt' 'pants'; 'shoes' 'shirt'; 'dress' 'belt'})
```

```
A =
```

```
 shirt pants
 shoes shirt
 dress belt
```

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
 'belt'
 'dress'
 'pants'
 'shirt'
 'shoes'
```

The five categories are in alphabetical order.

Merge the categories `belt` and `shoes` into a new category called `other`.

```
B = mergocats(A,{'belt' 'shoes'},'other')
```

```
B =
```

```

shirt pants
other shirt
dress other

```

The value `other` replaces all instances of `belt` and `shoes`.

Display the categories of `B`.

```
categories(B)
```

```
ans =
```

```

'other'
'dress'
'pants'
'shirt'

```

`B` has four categories and the order is no longer alphabetical. `other` appears in place of `belt`.

### **Merge Categories of Ordinal Categorical Array**

Create an ordinal categorical array.

```
A = categorical([1 2 3 2 1],1:3,{'poor','fair','good'},'Ordinal',true)
```

```
A =
```

```

poor fair good fair poor

```

Display the categories of `A`.

```
categories(A)
```

```
ans =
```

```

'poor'
'fair'

```

# mergecats

---

```
'good'
```

Since A is ordinal, the categories have the mathematical ordering `poor < fair < good`.

Consider all `fair` or `poor` values to be `bad`. Since A is ordinal, the categories to merge must be consecutive.

```
B = mergecats(A, {'fair' 'poor'}, 'bad')
```

```
B =
```

```
 bad bad good bad bad
```

The value `bad` replaces all instances of `fair` and `poor`.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'bad'
 'good'
```

B has two categories with the mathematical ordering: `bad < good`.

categories | addcats | removecats | iscategory | renamecats
| reordercats
```

**Purpose**

Mesh plot

**Syntax**

```
mesh(X,Y,Z)
mesh(Z)
mesh(...,C)
mesh(...,'PropertyName',PropertyValue,...)
mesh(axes_handles,...)
h = mesh(...)
```

**Description**

`mesh(X,Y,Z)` draws a wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i,j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i,j), Y(i,j), Z(i,j))$  are the intersections of the wireframe grid lines.

`mesh(Z)` draws a wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`mesh(...,C)` draws a wireframe mesh with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`mesh(...,'PropertyName',PropertyValue,...)` sets the value of the specified surface property. Multiple property values can be set with a single statement.

`mesh(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = mesh(...)` returns a handle to a Surfaceplot graphics object.

## Tips

mesh does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The `hidden` command controls the simulation of hidden-surface elimination in the mesh, and the `shading` command controls the shading model.

## Examples

### Create Mesh Plot of Sinc Function

Create a mesh plot of the sinc function,  $z = \sin(r)/r$ .

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
```

```
figure
mesh(Z);
```

### Specify Color for Mesh Plot

Specify a color matrix for a mesh plot.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
C = gradient(Z);
```

```
figure
```

# mesh

---

`mesh(X,Y,Z,C)`

## Change Lighting and Line Width for Mesh Plot

Change the lighting and the line width for a mesh plot using Name,Value pair arguments.

```
[X,Y] = meshgrid(-8:.5:8);
R = sqrt(X.^2 + Y.^2) + eps;
Z = sin(R)./R;
```

```
C = del2(Z);

figure
mesh(X,Y,Z,C,'FaceLighting','gouraud','LineWidth',0.3)
```

# mesh

---

## **How To**

- “Representing Data as a Surface”

**Purpose** Plot a contour graph under mesh graph

**Syntax**

```
meshc(X,Y,Z)
meshc(Z)
meshc(...,C)
meshc(axes_handles,...)
h = meshc(...)
```

**Description** `meshc(X,Y,Z)` draws a wireframe mesh and a contour plot under it with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case,  $(X(j), Y(i), Z(i, j))$  are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices,  $(X(i, j), Y(i, j), Z(i, j))$  are the intersections of the wireframe grid lines.

`meshc(Z)` draws a contour plot under wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshc(...,C)` draws a `meshc` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshc(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshc(...)` returns a handle to a `Surfaceplot` graphics object.

**Tips** `meshc` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background

color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The hidden command controls the simulation of hidden-surface elimination in the mesh, and the shading command controls the shading model.

## Examples

### Display Contour Plot Under Mesh Plot

Use meshc to display a combination of a mesh plot and a contour plot of the peaks function.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshc(Z);
```

## Algorithms

The range of X, Y, and Z, or the current settings of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties, determine the axis limits. `axis` sets these properties.

The range of C, or the current settings of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function), determine the color scaling. The scaled color values are used as indices into the current colormap.

The mesh rendering functions produce color values by mapping the  $z$  data values (or an explicit color array) onto the current colormap. The

# meshc

---

MATLAB default behavior is to compute the color limits automatically using the minimum and maximum data values (also set using `caxis auto`). The minimum data value maps to the first color value in the colormap and the maximum data value maps to the last color value in the colormap. MATLAB performs a linear transformation on the intermediate values to map them to the current colormap.

`meshc` calls `mesh`, turns `hold` on, and then calls `contour` and positions the contour on the  $x$ - $y$  plane. For additional control over the appearance of the contours, issue these commands directly. You can combine other types of graphs in this manner, for example `surf` and `pcolor` plots.

`meshc` assumes that  $X$  and  $Y$  are monotonically increasing. If  $X$  or  $Y$  is irregularly spaced, `contour3` calculates contours using a regularly spaced contour grid, and then it transforms the data to  $X$  or  $Y$ .

**Purpose** Plot a curtain around mesh plot

**Syntax**

```
meshz(X,Y,Z)
meshz(Z)
meshz(...,C)
meshz(axes_handles,...)
h = meshz(...)
```

**Description** `meshz(X,Y,Z)` draws a curtain around the wireframe mesh with color determined by `Z`, so color is proportional to surface height. If `X` and `Y` are vectors, `length(X) = n` and `length(Y) = m`, where `[m,n] = size(Z)`. In this case, `(X(j), Y(i), Z(i,j))` are the intersections of the wireframe grid lines; `X` and `Y` correspond to the columns and rows of `Z`, respectively. If `X` and `Y` are matrices, `(X(i,j), Y(i,j), Z(i,j))` are the intersections of the wireframe grid lines.

`meshz(Z)` draws a curtain around the wireframe mesh using `X = 1:n` and `Y = 1:m`, where `[m,n] = size(Z)`. The height, `Z`, is a single-valued function defined over a rectangular grid. Color is proportional to surface height.

`meshz(...,C)` draws a `meshz` graph with color determined by matrix `C`. MATLAB performs a linear transformation on the data in `C` to obtain colors from the current colormap. If `X`, `Y`, and `Z` are matrices, they must be the same size as `C`.

`meshz(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = meshz(...)` returns a handle to a `Surfaceplot` graphics object.

**Tips** `meshz` does not accept complex inputs.

A mesh is drawn as a `Surfaceplot` graphics object with the viewpoint specified by `view(3)`. The face color is the same as the background

color (to simulate a wireframe with hidden-surface elimination), or none when drawing a standard see-through wireframe. The current colormap determines the edge color. The hidden command controls the simulation of hidden-surface elimination in the mesh, and the shading command controls the shading model.

## Examples

### Curtain Plot of Peaks Function

Generate a curtain plot of the peaks function using meshz.

```
figure
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
meshz(Z);
```

### Specify Color for Curtain Plot

Specify a color matrix for a curtain plot.

```
[X,Y] = meshgrid(-3:.125:3);
Z = peaks(X,Y);
C = gradient(Z);
```

```
figure
meshz(X,Y,Z,C)
```

<b>Purpose</b>	Rectangular grid in 2-D and 3-D space
<b>Syntax</b>	<pre>[X,Y] = meshgrid(xgv,ygv) [X,Y,Z] = meshgrid(xgv,ygv,zgv) [X,Y] = meshgrid(gv) [X,Y,Z] = meshgrid(gv)</pre>
<b>Description</b>	<p><code>[X,Y] = meshgrid(xgv,ygv)</code> replicates the grid vectors <code>xgv</code> and <code>ygv</code> to produce a full grid. This grid is represented by the output coordinate arrays <code>X</code> and <code>Y</code>. The output coordinate arrays <code>X</code> and <code>Y</code> contain copies of the grid vectors <code>xgv</code> and <code>ygv</code> respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors <code>xgv</code> and <code>ygv</code> of length <code>M</code> and <code>N</code> respectively, <code>X</code> and <code>Y</code> will have <code>N</code> rows and <code>M</code> columns.</p> <p><code>[X,Y,Z] = meshgrid(xgv,ygv,zgv)</code> produces three-dimensional coordinate arrays. The output coordinate arrays <code>X</code>, <code>Y</code>, and <code>Z</code> contain copies of the grid vectors <code>xgv</code>, <code>ygv</code>, and <code>zgv</code> respectively. The sizes of the output arrays are determined by the length of the grid vectors. For grid vectors <code>xgv</code>, <code>ygv</code>, and <code>zgv</code> of length <code>M</code>, <code>N</code>, and <code>P</code> respectively, <code>X</code>, <code>Y</code>, and <code>Z</code> will have <code>N</code> rows, <code>M</code> columns, and <code>P</code> pages.</p> <p><code>[X,Y] = meshgrid(gv)</code> is the same as <code>[X,Y] = meshgrid(gv,gv)</code>. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.</p> <p><code>[X,Y,Z] = meshgrid(gv)</code> is the same as <code>[X,Y,Z] = meshgrid(gv,gv,gv)</code>. Again, the dimensionality of the output arrays is determined by the number of output arguments.</p> <p>The output coordinate arrays are typically used to evaluate functions of two or three variables. They are also frequently used to create surface and volumetric plots.</p>
<b>Input Arguments</b>	<p><b>xgv,ygv,zgv</b></p> <p>Grid vectors specifying a series of grid point coordinates in the <code>x</code>, <code>y</code> and <code>z</code> directions, respectively.</p>

# meshgrid

---

## **gv**

Generic grid vector specifying a series of point coordinates.

## **Output Arguments**

### **X,Y,Z**

Output arrays that specify the full grid.

## **Tips**

The `meshgrid` function is similar to `ndgrid`, however `meshgrid` is restricted to 2-D and 3-D while `ndgrid` supports 1-D to N-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors `x1gv`, `x2gv` and `x3gv` of length `M`, `N` and `P` respectively, `meshgrid(x1gv, x2gv)` will output arrays of size `N-by-M` while `ndgrid(x1gv, x2gv)` outputs arrays of size `M-by-N`. Similarly, `meshgrid(x1gv, x2gv, x3gv)` will output arrays of size `N-by-M-by-P` while `ndgrid(x1gv, x2gv, x3gv)` outputs arrays of size `M-by-N-by-P`. See “Grid Representation” in the MATLAB Mathematics documentation for more information.

## **Examples**

### **2-D Grid From Vectors**

Create a full grid from two monotonically increasing grid vectors:

```
[X,Y] = meshgrid(1:3,10:14)
```

```
X =
```

```
 1 2 3
 1 2 3
 1 2 3
 1 2 3
 1 2 3
```

```
Y =
```

```
 10 10 10
 11 11 11
 12 12 12
 13 13 13
 14 14 14
```

**Plot 3-D Functional Surface**

Use meshgrid to create a gridded  $(X,Y)$  domain.

```
[X,Y] = meshgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function  $z(x,y) = xe^{-x^2-y^2}$  over this domain and generate a surface plot of the results.

```
Z = X .* exp(-X.^2 - Y.^2);
surf(X,Y,Z)
```

# meshgrid

## How To

- “Interpolating Gridded Data”

## Purpose

`meta.class` class describes MATLAB classes

## Description

Instances of the `meta.class` class contains information about MATLAB classes. The read/write properties of the `meta.class` class correspond to class attributes and are set only from within class definitions on the `classdef` line. You can query the read-only properties of the `meta.class` object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class).

You cannot instantiate a `meta.class` object directly. You can construct a `meta.class` object from an instance of a class or using the class name:

- `metaclass` — returns a `meta.class` object representing the object passed as an argument.
- `?ClassName` — returns a `meta.class` object representing the named class.
- `fromName` — static method returns a `meta.class` object representing the named class.

For example, the `metaclass` function returns the `meta.class` object representing `MyClass`.

```
ob = MyClass;
obmeta = metaclass(ob);
obmeta.Name
ans =
MyClass
```

You can use the class name to obtain the `meta.class` object:

```
obmeta = ?MyClass;
```

You can also use the `fromName` static method:

```
obmeta = meta.class.fromName('MyClass');
```

# meta.class

---

## Properties

Property	Purpose
Abstract attribute, default = false	If true, this class is an abstract class (cannot be instantiated).  See “Defining Abstract Classes” for more information.
AllowedSubclasses attribute, write only from <code>classdef</code> statement	List classes that can subclass this class. Specify subclasses as <code>meta.class</code> objects in the form: <ul style="list-style-type: none"><li>• A single <code>meta.class</code> object</li><li>• A cell array of <code>meta.class</code> objects</li></ul> Specify <code>meta.class</code> objects using the <code>?ClassName</code> syntax only.
ConstructOnLoad attribute, default = false	If true, MATLAB calls the class constructor automatically when loading an object from a MAT-file. Therefore, the construction must be implemented so that calling it with no arguments does not produce an error.  See “Tips for Saving and Loading”
ContainingPackage read only	A <code>meta.package</code> object describing the package within which this class is contained, or an empty object if this class is not in a package.  See “Packages Create Namespaces”.
Description read only	Currently not used
DetailedDescription read only	Currently not used

<b>Property</b>	<b>Purpose</b>
Enumeration attribute, default = false	If true, this class is an enumeration class. See “Working with Enumerations”.
EventList read only	An array of meta.event objects describing each event defined by this class, including all inherited events.  See “Events”.
Events read only Use EventList instead	A cell array of meta.event objects describing each event defined by this class, including all inherited events.
EnumerationMemberList	An array of meta.EnumeratedValue objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
EnumeratedValues read only Use EnumeratedMemberList instead	A cell array of meta.EnumeratedValue objects describing the member names defined by an enumeration class.  See “Enumerations” for more information on enumeration classes.
Hidden attribute, default = false	If set to true, the class does not appear in the output of MATLAB commands or tools that display class names.
InferiorClasses attribute, default = {}	A cell array of meta.class objects defining the precedence of classes represented by the list as inferior to this class.  See “Class Precedence”

# meta.class

---

Property	Purpose
MethodList read only	An array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods. See “How to Use Methods”.
Methods read only Use MethodList instead	A cell array of <code>meta.method</code> objects describing each method defined by this class, including all inherited public and protected methods.
Name read only	Name of the class associated with this <code>meta.class</code> object (char array)
PropertyList read only	An array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties. See “Properties”.
Properties read only Use PropertyList instead	A cell array of <code>meta.property</code> objects describing each property defined by this class, including all inherited public and protected properties. See “Properties”.
Sealed attribute, default = false	If true, the class cannot be subclassed.
SuperClassList read only	An array of <code>meta.class</code> objects describing each direct superclass from which this class is derived. See “Creating Subclasses — Syntax and Techniques”.
SuperClasses read only Use SuperClassList instead	A cell array of <code>meta.class</code> objects describing each direct superclass from which this class is derived.

## Methods

Method	Purpose
<code>fromName</code>	Returns the <code>meta.class</code> object associated with the specified class name.
<code>tf = eq(Cls)</code>	Equality function ( <code>a == b</code> ). Use to test if two variables refer to equal classes (classes that contain exactly the same list of elements).
<code>tf = ne(Cls)</code>	Not equal function ( <code>a ~= b</code> ). Use to test if two variables refer to different meta-classes.
<code>tf = lt(ClsA, ClsB)</code>	Less than function ( <code>ClsA &lt; ClsB</code> ). Use to determine if <code>ClsA</code> is a strict subclass of <code>ClsB</code> (i.e., a strict subclass means <code>ClsX &lt; ClsX</code> is false).
<code>tf = le(ClsA, ClsB)</code>	Less than or equal to function ( <code>ClsA &lt;= ClsB</code> ). Use to determine if <code>ClsA</code> is a subclass of <code>ClsB</code> .
<code>tf = gt(ClsA, ClsB)</code>	Greater than function ( <code>ClsB &gt; ClsA</code> ). Use to determine if <code>ClsB</code> is a strict superclass of <code>ClsA</code> (i.e., a strict superclass means <code>ClsX &gt; ClsX</code> is false).
<code>tf = ge(ClsA, ClsB)</code>	Greater than or equal to function ( <code>ClsB &gt;= ClsA</code> ). Use to determine if <code>ClsB</code> is a superclass of <code>ClsA</code> .

# meta.class

---

## Events

Event	Purpose
InstanceCreated	If the class is a handle class, this event occurs every time a new instance of this handle class is created, including new instances of any subclasses. The event occurs immediately after all constructor functions finish executing.
InstanceDestroyed	If the class is a handle class, this event occurs every time an instance of this handle class is destroyed, including all subclasses. The event occurs immediately before any destructor functions execute.

## Examples

Find property attributes using the `handle class findobj` method and the `audioplayer meta.class` object. Determine if a class defines the property named `SampleRate` and does it have public set access.

```
mc = ?audioplayer;
mp = findobj(mc.PropertyList, 'Name', 'SampleRate');
strcmp(mp.SetAccess, 'public')
...
```

## See Also

[fromName](#) | [meta.property](#) | [meta.method](#) | [meta.event](#) | [meta.package](#)

## How To

- “Getting Information About Classes and Objects”

**Purpose** Return meta.class object associated with named class

**Syntax** `mcls = meta.class.fromName('ClassName')`

**Description** `mcls = meta.class.fromName('ClassName')` is a static method that returns the meta.class object associated with the class *ClassName*. Note that you can also use the ? operator to obtain the meta.class object for a class name:

```
mcls = ?ClassName;
```

The equivalent call to `meta.class.fromName` is:

```
mcls = meta.class.fromName('ClassName');
```

Use `meta.class.fromName` when using a char variable for the class name:

```
function mcls = getMetaClass(cname)
 % Do error checking
 mcls = meta.class.fromName(cname);
 ...
end
```

**See Also** `meta.class`

# meta.DynamicProperty

---

## Purpose

`meta.DynamicProperty` class describes dynamic property of MATLAB object

## Description

The `meta.DynamicProperty` class contains descriptive information about dynamic properties that you have added to an instance of a MATLAB classes. The MATLAB class must be a subclass of `dynamicprops`. The properties of the `meta.DynamicProperty` class correspond to property attributes that you specify from within class definitions. Dynamic properties are not defined in `classdef` blocks, but you can set their attributes by setting the `meta.DynamicProperty` object properties.

You add a dynamic property to an object using the `addprop` method of the `dynamicprops` class. The `addprop` method returns a `meta.DynamicProperty` instance representing the new dynamic property. You can modify the properties of the `meta.DynamicProperty` object to set the attributes of the dynamic property or to add set and get access methods, which would be defined in the `classdef` for regular properties.

You cannot instantiate the `meta.DynamicProperty` class. You must use `addprop` to obtain a `meta.DynamicProperty` object.

To remove the dynamic property, call the `delete` handle class method on the `meta.DynamicProperty` object.

Obtain a `meta.DynamicProperty` object from the `addprops` method, which returns an array of `meta.DynamicProperty` objects, one for each dynamic property.

See “Dynamic Properties — Adding Properties to an Instance” for more information.

## Properties

Property	Purpose
Name	Name of the property.
Description	Currently not used

Property	Purpose
DetailedDescription	Currently not used
AbortSet	If true, and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This approach prevents the triggering of property PreSet and PostSet events.
Abstract attribute, default = false	If true, the property has no implementation, but a concrete subclass must redefine this property without Abstract being set to true. <ul style="list-style-type: none"><li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li><li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li><li>• All subclasses must specify the same values as the superclass for the property SetAccess and GetAccess attributes.</li><li>• Abstract=true should be used with the class attribute Sealed=false (the default).</li></ul>

# meta.DynamicProperty

Property	Purpose
Access	<p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"><li>• A single <code>meta.class</code> object</li><li>• A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li></ul> <p>Use <code>Access</code> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <code>Access</code>).</p>
Constant attribute, default = false	<p>Set to <code>true</code> if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"><li>• Subclasses inherit constant properties, but cannot change them.</li><li>• Constant properties cannot be <code>Dependent</code></li><li>• <code>SetAccess</code> is ignored.</li></ul> <p>See “Properties with Constant Values”</p>
DefaultValue	<p>Querying this property returns an error because dynamic properties cannot define default values.</p>

Property	Purpose
DefiningClass	The meta.class object representing the class that defines this property.
GetAccess attribute, default = public	public – unrestricted access protected – access from class or subclasses private – access by class members only
SetAccess attribute, default = public	public – unrestricted access protected – access from class or subclasses private – access by class members only
Dependent attribute, default = false	If false, property value is stored in object. If true, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.  See “Property Get Methods”
Transient attribute, default = false	If true, property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.
Hidden attribute, default = false	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to properties, etc.).
GetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”

# meta.DynamicProperty

---

Property	Purpose
SetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”
GetMethod	Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”
SetMethod	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
HasDefault	Always false. Dynamic properties cannot define default values.

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified
ObjectBeingDestroyed	Inherited from handle

## See Also

addprop | handle

## Purpose

Describes enumeration members of MATLAB class

## Description

The `meta.EnumeratedValue` class contains information about enumeration members defined by MATLAB classes. The properties of a `meta.EnumeratedValue` object correspond to the attributes of the enumeration member being described.

All `meta.EnumeratedValue` properties are read-only. Query the `meta.EnumeratedValue` object to obtain information about the enumeration member it describes.

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object. `EnumerationMemberList` is an array of `Meta.EnumeratedValue` instances, one per enumeration member.

The `meta.EnumeratedValue` class is a subclass of the `handle` class.

## Example

To access the `meta.EnumeratedValue` objects for a class, first create a `meta.class` object for that class. For example, give the following `OnOff` class definition:

```
classdef OnOff < logical
 enumeration
 On (true)
 Off (false)
 end
end
```

Obtain a `meta.EnumeratedValue` object from the `EnumerationMemberList` property of the `meta.class` object:

```
% Obtain the meta.class instance for the OnOff class
mc = ?OnOff;
% Get the array of EnumerateValue objects
enumList = mc.EnumerationMemberList;
% Access the Name property of the first object in the array
enumList(1).Name =
```

# meta.EnumeratedValue

---

```
ans =
On
```

## Properties

Property	Purpose
Name read only	Name of the enumeration member associated with this meta.EnumeratedValue object
Description read only	This property is not used
DetailedDescription read only	This property is not used

## Methods

See the handle superclass for inherited methods.

## Events

See the handle superclass for inherited events.

## See Also

[meta.class](#) | [meta.property](#) | [meta.method](#) | [meta.event](#)

## How To

- “Working with Enumerations”
- “Getting Information About Classes and Objects”

**Purpose**

meta.event class describes MATLAB class events

**Description**

The meta.event class provides information about MATLAB class events. The read/write properties of the meta.event class correspond to event attributes and are specified only from within class definitions.

You can query the read-only properties of the meta.event object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining the event).

You cannot instantiate a meta.event object directly. Obtain a meta.event object from the meta.class EventList property, which contains an array of meta.event objects, one for each event defined by the class. For example, replace *ClassName* with the name of the class whose events you want to query:

```
mco = ?ClassName;
elist = mco.EventList;
elist(1).Name; % name of first event in list
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

**Properties**

Property	Purpose
Name read only	Name of the event.
Description read only	Currently not used
DetailedDescription read only	Currently not used

# meta.event

---

Property	Purpose
Hidden	If true, the event does not appear in the list of events returned by the <code>events</code> function (or other event listing functions or viewers)
ListenAccess	<p>Determines where you can create listeners for the event.</p> <ul style="list-style-type: none"><li>• <code>public</code> — unrestricted access</li><li>• <code>protected</code> — access from methods in class or subclasses</li><li>• <code>private</code> — access by class methods only (not from subclasses)</li><li>• List classes that have listen access to this event. Specify classes as <code>meta.class</code> objects in the form:<ul style="list-style-type: none"><li>▪ A single <code>meta.class</code> object</li><li>▪ A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li></ul></li></ul> <p>See “Controlling Access to Class Members”</p>

Property	Purpose
NotifyAccess	<p>Determines where code can trigger the event.</p> <ul style="list-style-type: none"> <li>• <code>public</code> — any code can trigger event</li> <li>• <code>protected</code> — can trigger event from methods in class or subclasses</li> <li>• <code>private</code> — can trigger event by class methods only (not from subclasses)</li> <li>• List classes that have notify access to this event. Specify classes as <code>meta.class</code> objects in the form: <ul style="list-style-type: none"> <li>▪ A single <code>meta.class</code> object</li> <li>▪ A cell array of <code>meta.class</code> objects. An empty cell array, <code>{}</code>, is the same as <code>private</code> access.</li> </ul> </li> </ul> <p>See “Controlling Access to Class Members”</p>
DefiningClass	<p>The <code>meta.class</code> object representing the class that defines this event.</p>

# meta.MetaData

---

<b>Superclasses</b>	Heterogeneous
<b>Purpose</b>	Superclass for MATLAB object metadata
<b>Description</b>	<p>The <code>meta.MetaData</code> class of objects represent MATLAB class definitions and the constituent parts of those definitions, such as properties and methods. Metadata enable a program to get information about a class definition.</p> <p>The <code>meta.MetaData</code> class forms the root of the metadata class hierarchy, which enables the formation of arrays of metadata objects belonging to different specific classes.</p> <p>MATLAB uses instances of the <code>meta.MetaData</code> class as the default object to fill in missing array elements.</p> <p><code>findobj</code> and <code>findprop</code>, can search the metadata hierarchy and return an array of different metadata objects. These function require the ability to form heterogeneous arrays containing various metaclass objects.</p> <p>See the <code>matlab.mixin.Heterogeneous</code> class for more information on heterogeneous hierarchies.</p>
<b>Construction</b>	You cannot create an instance of the <code>meta.MetaData</code> class directly. MATLAB constructs instances of this class as required.
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.
<b>Examples</b>	<p>This example shows how the <code>meta.MetaData</code> class facilitates working with metaclasses.</p> <p>Create a <code>meta.class</code> instance representing the MATLAB <code>timeseries</code> class:</p> <pre>&gt;&gt; mc = ?timeseries;</pre> <p>MATLAB uses <code>meta.MetaData</code> objects to fill empty array elements:</p>

```
>> m(2) = mc
>> class(m(1))
```

```
ans =
```

```
meta.MetaData
>> class(m(2))
```

```
ans =
```

```
meta.class
```

Use `findobj` to find all properties and methods that have protected access:

```
>> protectedMembers = findobj(mc,{'Access','protected'},...
'-or',{'SetAccess','protected'},...
'-or',{'GetAccess','protected'}});
```

The `timeseries` class defines both properties and methods that have protected access. Therefore, `findobj` returns a heterogeneous array of class `meta.MetaData`. This array contains both `meta.property` and `meta.method` objects.

```
>> protectedMembers
```

```
protectedMembers =
```

```
11x1 heterogeneous meta.MetaData (meta.property, meta.method)
```

```
handle with no properties.
```

```
Package: meta
```

```
>> class(protectedMembers(1))
```

```
ans =
```

```
meta.property
```

```
>> protectedMembers(1).Name
```

```
ans =

Length
>> protectedMembers(1).SetAccess

ans =

protected
>> protectedMembers(1).GetAccess

ans =

public
```

## How To

- [Class Attributes](#)
- [Property Attributes](#)
- [“Getting Information About Classes and Objects”](#)

## Purpose

meta.method class describes MATLAB class methods

## Description

The meta.method class provides information about the methods of MATLAB classes. The read/write properties of the meta.method class correspond to method attributes and are specified only from within class definitions.

You can query the read-only properties of the meta.method object to obtain information that is specified syntactically by the class (for example, to obtain the name of the class defining a method).

You cannot instantiate a meta.method object directly. Obtain a meta.method object from the meta.class MethodList property, which contains an array of meta.method objects, one for each class method. For example, replace *ClassName* with the name of the class whose methods you want to query:

```
mco = ?ClassName;
mlist = mco.MethodList;
mlist(1).Name; % name of first method in the list
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

## Properties

Property	Purpose
Abstract	<p>If true, the method has no implementation. The method has a syntax line that can include arguments, which subclasses use when implementing the method.</p> <ul style="list-style-type: none"> <li>Subclasses are not required to define the same number of input and output arguments.</li> </ul>

# meta.method

---

Property	Purpose
	<ul style="list-style-type: none"><li>• The method can have comments after the function line</li><li>• Does not contain function or end keywords, only the function syntax (e.g., <code>[a,b] = myMethod(x,y)</code>)</li></ul>
Access attribute, default = public	Determines what code can call this method. <ul style="list-style-type: none"><li>• <code>public</code> — unrestricted access</li><li>• <code>protected</code> — access from methods in class</li></ul>
DefiningClass	The <code>meta.class</code> object representing the class that defines this method.
Description read only	Currently not used
DetailedDescription read only	Currently not used
Hidden attribute, default = false	When <code>false</code> , the method name shows in the list of methods displayed using the <code>methods</code> or <code>methodsview</code> commands. If set to <code>true</code> , the method name is not included in these listings.
Name read only	Name of the method.

Property	Purpose
Sealed attribute, default = false	If true, the method cannot be redefined in a subclass. Attempting to define a method with the same name in a subclass causes an error.
Static attribute, default = false	Set to true to define a method that does not depend on an object of the class and does not require an object argument. Call static methods using the class name in place of the object:  <code>classname.methodname()</code>  Or with an instance of the class, like any method:  <code>o.methodname()</code>  See “Static Methods”

# meta.package

---

**Purpose** meta.package class describes MATLAB packages

**Description** The meta.package class contains information about MATLAB packages. You cannot instantiate a meta.package object directly. Obtain a meta.package object from the meta.class ContainingPackage property, which contains a meta.package object, or an empty object, if the class is not in a package.

## Properties

Property	Purpose
Name read only	Name of the package associated with this meta.package object
ClassList read only	List of classes that are scoped to this package. An object array of meta.class objects.
Classes read only Use ClassList instead	List of classes that are scoped to this package. A cell array of meta.class objects.
FunctionList read only	List of functions that are scoped to this package. An object array of function handles.
Functions read only Use FunctionList instead	List of functions that are scoped to this package. A cell array of function handles.
PackageList read only	List of packages that are scoped to this package. An object array of meta.package objects.
Packages read only Use PackageList instead	List of packages that are scoped to this package. A cell array of meta.package objects.
ContainingPackage read only	A meta.package object describing the package within which this package is contained, or an empty object if this package is not nested.

## Methods

Method	Purpose
<code>fromName</code>	Static method returns a <code>meta.package</code> object for a specified package name.
<code>getAllPackages</code>	Static method returns a cell array of <code>meta.package</code> objects representing all top-level packages.

## How To

- “Getting Information About Classes and Objects”

# meta.abstractDetails

---

**Purpose** Find abstract methods and properties

**Syntax**

```
meta.abstractDetails(ClassName)
meta.abstractDetails(mc)
absMembers = meta.abstractDetails(___)
```

**Description** `meta.abstractDetails(ClassName)` displays a list of abstract methods and properties for the class with name `ClassName`. Use the fully specified name for classes in packages. MATLAB displays all public and protected abstract methods and properties, including those declared `Hidden`.

`meta.abstractDetails(mc)` displays a list of abstract methods and properties for the class represented by the `meta.class` object `mc`.

`absMembers = meta.abstractDetails( ___ )` returns an array of the metaclass objects corresponding to the abstract members of the class, and can include any of the input arguments in previous syntaxes. If the class has both abstract methods and abstract properties, `absMembers` is a heterogeneous array of class `meta.MetaData` containing `meta.method` and `meta.property` objects.

A class can be abstract without defining any abstract methods or properties if it declares the `Abstract` class attribute. In this case, `meta.abstractDetails` returns no abstract members for that class, but the class is abstract. See “Determine If a Class Is Abstract” for more information.

## Input Arguments

### **ClassName**

Name of the class specified as a character string (for example, 'MyClass')

### **mc**

`meta.class` object representing the class (for example, ?MyClass)

## Output Arguments

### **absMembers**

Array of metaclass objects representing abstract class members

## Examples

### **Display Abstract Member Names**

Define the class, `AbsBase`, with an abstract property:

```
classdef AbsBase
 properties (Abstract)
 Prop1
 end
 methods(AbsBase)
 result = methodOne(obj)
 output = methodTwo(obj)
 end
end
```

Pass the class name (`AbsBase`) as a string:

```
meta.abstractDetails('AbsBase')
```

`meta.abstractDetails` displays the names of the abstract properties and methods defined in the class `AbsBase`.

```
Abstract methods for class AbsBase:
 methodTwo % defined in AbsBase
 methodOne % defined in AbsBase
```

```
Abstract properties for class AbsBase:
 Prop1 % defined in AbsBase
```

### **Return Abstract Member Metaclass Objects**

Pass a `meta.class` object representing the `AbsBase` class and return the metaclass objects for the abstract members. Use the definition of the `AbsBase` class from the previous example.

```
mc = ?AbsBase;
```

# meta.abstractDetails

---

```
absMembers = meta.abstractDetails(mc);
```

absMembers is a heterogeneous array containing a meta.property object for the Prop1 abstract property and meta.method objects for the methodOne and methodTwo abstract methods.

List the names of the metaclass objects.

```
for k=1:length(absMembers)
 disp(absMembers(k).Name)
end
```

```
methodTwo
methodOne
Prop1
```

## Find Inherited Abstract Members

Derive the SubAbsBase class from AbsBase, which is defined in a previous example.

```
classdef SubAbsBase < AbsBase
 properties
 SubProp = 1;
 end
 methods
 function result = methodOne(obj)
 result = obj.SubProp + 1;
 end
 end
end
```

Display the names of the abstract members inherited by SubAbsBase.

```
meta.abstractDetails('SubAbsBase')
```

```
Abstract methods for class SubAbsBase:
 methodTwo % defined in AbsBase
```

```
Abstract properties for class SubAbsBase:
 Prop1 % defined in AbsBase
```

To make SubAbsBase a concrete class, you need to implement concrete versions of methodTwo and Prop1 in the subclass.

`meta.class` | `meta.class.forName`

## Concepts

- “Defining Abstract Classes”
- “Getting Information About Classes and Objects”

# meta.package.fromName

---

**Purpose** Return meta.package object for specified package

**Syntax** `mpkg = meta.package.fromName('pkgname')`

**Description** `mpkg = meta.package.fromName('pkgname')` is a static method that returns the meta.package object associated with the named package. If `pkgname` is a nested package, then you must provide the fully qualified name (e.g., 'pkgname1.pkgname2').

**Examples** List the classes in the event package:

```
mev = meta.package.fromName('event');
for k=1:length(mev.Classes)
 disp(mev.Classes{k}.Name)
end
event.EventData
event.PropertyEvent
event.listener
event.propListener
```

**See Also** `meta.package` | `meta.package.getAllPackages`

**Purpose** Get all top-level packages

**Syntax** `P = meta.package.getAllPackages`

**Description** `P = meta.package.getAllPackages` is a static method that returns a cell array of `meta.package` objects representing all the top-level packages that are visible on the MATLAB path or defined as top-level built-in packages. You can access subpackages using the `Packages` property of each `meta.package` object.

Note that the time required to find all the packages on the path might be excessively long in some cases. You should therefore avoid using this method in any code where execution time is a consideration. `getAllPackages` is generally intended for interactive use only.

**See Also** `meta.package` | `meta.package.fromName`

# meta.property

---

**Purpose** meta.property class describes MATLAB class properties

**Description** The meta.property class provides information about the properties of MATLAB classes. The read/write properties of the meta.property class correspond to property attributes and are specified only from within your class definitions.

You can query the read-only properties of the meta.property object to obtain information that is specified syntactically by the class (for example, to obtain the function handle of a property's set access method).

You cannot instantiate a meta.property object directly. Obtain a meta.property object from the meta.class PropertyList property, which contains an array of meta.property objects, one for each class property. For example, replace *ClassName* with the name of the class whose properties you want to query:

```
mco = ?ClassName;
plist = mco.PropertyList;
plist(1).Name; % name of first property
```

Use the metaclass function to obtain a meta.class object from a class instance:

```
mco = metaclass(obj);
```

## Properties

Property	Purpose
Name read only	Name of the property.
Description read only	Currently not used
DetailedDescription read only	Currently not used

Property	Purpose
AbortSet attribute, default = false	<p>If true, and this property belongs to a handle class, then MATLAB does not set the property value if the new value is the same as the current value. This prevents the triggering of property PreSet and PostSet events.</p> <p>See “Listen for Changes to Property Values”</p>
Abstract attribute, default = false	<p>If true, the property has no implementation, but a concrete subclass must redefine this property without Abstract being set to true.</p> <ul style="list-style-type: none"> <li>• Abstract properties cannot define set or get access methods. See “Property Access Methods”</li> <li>• Abstract properties cannot define initial values. “Assigning a Default Value”</li> <li>• All subclasses must specify the same values as the superclass for the property SetAccess and GetAccess attributes.</li> <li>• Abstract=true should be used with the class attribute Sealed=false (the default).</li> </ul>
Access	<p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only (not subclasses)</p> <p>List of classes that have get and set access to this property. Specify classes as meta.class objects in the form:</p> <ul style="list-style-type: none"> <li>• A single meta.class object</li> </ul>

# meta.property

---

Property	Purpose
	<ul style="list-style-type: none"><li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as <code>private</code> access.</li></ul> <p>Use <code>Access</code> to set both <code>SetAccess</code> and <code>GetAccess</code> to the same value. Query the values of <code>SetAccess</code> and <code>GetAccess</code> directly (not <code>Access</code>).</p>
Constant attribute, default = false	<p>Set to true if you want only one value for this property in all instances of the class.</p> <ul style="list-style-type: none"><li>• Subclasses inherit constant properties, but cannot change them.</li><li>• Constant properties cannot be <code>Dependent</code></li><li>• <code>SetAccess</code> is ignored.</li></ul> <p>See “Properties with Constant Values”</p>
DefaultValue	<p>Property default value (if specified in class definition). See also <code>HasDefault</code> property. Abstract, dependent and dynamic properties cannot specify default values.</p>
DefiningClass	<p>The <code>meta.class</code> object representing the class that defines this property.</p>

<b>Property</b>	<b>Purpose</b>
<p>GetAccess attribute, default = public</p>	<p>public – unrestricted access protected – access from class or subclasses private – access by class members only</p> <p>List classes that have get access to this property. Specify classes as <code>meta.class</code> objects in the form:</p> <ul style="list-style-type: none"> <li>• A single <code>meta.class</code> object</li> <li>• A cell array of <code>meta.class</code> objects. An empty cell array, {}, is the same as private access.</li> </ul> <p>See “Controlling Access to Class Members”</p>
<p>Dependent attribute, default = false</p>	<p>If false, property value is stored in object. If true, property value is not stored in object and the set and get functions cannot access the property by indexing into the object using the property name.</p> <p>See “Property Get Methods”</p>
<p>Transient attribute, default = false</p>	<p>If true, property value is not saved when object is saved to a file. See “Understanding the Save and Load Process” for more about saving objects.</p>
<p>GetMethod read only</p>	<p>Function handle of the get method associated with this property. Empty if there is no get method specified. See “Get Method Syntax”</p>

# meta.property

Property	Purpose
GetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are queried. See “Property-Set and Query Events”
HasDefault	Property contains a boolean value indicating if the property defines a default value. Test HasDefault before querying the DefaultValue property to avoid a MATLAB: class:NoDefaultDefined error.
Hidden attribute, default = false	Determines whether the property should be shown in a property list (e.g., Property Inspector, call to properties, etc.).
SetAccess attribute, default = public	<p>public – unrestricted access</p> <p>protected – access from class or subclasses</p> <p>private – access by class members only</p> <p>immutable — property can be set only in the constructor.</p> <p>See “Mutable and Immutable Properties”</p> <p>List classes that have set access to this property. Specify classes as meta.class objects in the form:</p> <ul style="list-style-type: none"><li>• A single meta.class object</li><li>• A cell array of meta.class objects. An empty cell array, {}, is the same as private access.</li></ul> <p>See “Controlling Access to Class Members”</p>

Property	Purpose
SetMethod read only	Function handle of the set method associated with this property. Empty if there is no set method specified. See “Property Set Methods”
SetObservable attribute, default = false	If true, and it is a handle class property, then listeners can be created for access to this property. The listeners are called whenever property values are modified. See “Property-Set and Query Events”

## Events

See “Listen for Changes to Property Values” for information on using property events.

Event Name	Purpose
PreGet	Event occurs just before property is queried.
PostGet	Event occurs just after property has been queried
PreSet	Event occurs just before this property is modified
PostSet	Event occurs just after this property has been modified

## See Also

## How To

- “Properties”
- “Getting Information About Classes and Objects”

# metaclass

---

**Purpose** Obtain `meta.class` object

**Syntax** `mc = metaclass(object)`  
`mc = ?ClassName`

**Description** `mc = metaclass(object)` returns the `meta.class` object for the class of `object`. The `object` input argument can be a scalar or an array of objects. However, `metaclass` always returns a scalar `meta.class` object.

`mc = ?ClassName` returns the `meta.class` object for the class with name, *ClassName*. The `?` operator works only with a class name, not an object.

If you pass a class name as a string to the `metaclass` function, it returns the `meta.class` object for the `char` class. Use the `?` operator or the `meta.class.fromName` method to obtain the `meta.class` object from a class name. Use this method if you want to pass the class name in a string variable.

**Examples** Return the `meta.class` object for an instance of the `MException` class:

```
obj = MException('Msg:ID', 'MsgTxt');
mc = metaclass(obj);
```

Use the `?` operator to get the `meta.class` object for the `hgsetget` class:

```
mc = ?hgsetget;
```

**See Also** `meta.class` | `meta.class.fromName`

**Tutorials** • “Class Metadata”

## Purpose

Class method names

## Syntax

```
methods('classname')
methods(..., '-full')
m = methods(...)
```

## Description

`methods('classname')` displays the names of the methods for the class *classname*. If *classname* is a MATLAB or Java class, then `methods` displays only public methods, including those methods inherited from superclasses.

`methods(..., '-full')` displays a full description of the methods, including inheritance information and, for MATLAB and Java methods, method attributes and signatures. `methods` does not remove duplicate method names with different signatures. Do not use this option with classes defined before MATLAB 7.6.

`m = methods(...)` returns the method names in a cell array of strings.

`methods` is also a MATLAB class-definition keyword. See `classdef` for more information on class-definition keywords.

This function does not show generic methods from classes based on the Microsoft .NET Framework. Use your product documentation to get information on generic methods.

## Examples

Retrieve the names of the static methods in class `MException`:

```
methods('MException')
```

```
Methods for class MException:
```

```
addCause getReport ne throw
eq isequal rethrow throwAsCaller
```

```
Static methods:
```

```
last
```

# methods

---

## **See Also**

[methodsview](#) | [properties](#) | [events](#) | [what](#) | [which](#)

## **Tutorials**

- [“Methods”](#)

**Purpose**

View class methods

**Syntax**

```
methodsview packagename.classname
methodsview classname
methodsview(object)
```

**Description**

`methodsview packagename.classname` displays information about the methods in the class, `classname`. If the class is in a package, include `packagename`. If `classname` is a MATLAB or Java class, `methodsview` lists only public methods, including those methods inherited from superclasses.

`methodsview classname` displays information describing the class `classname`.

`methodsview(object)` displays information about the methods of the class of `object`.

`methodsview` creates a window that displays the methods defined in the specified class. `methodsview` provides additional information like arguments, returned values, and superclasses. It also includes method qualifiers (for example, `abstract` or `synchronized`) and possible exceptions thrown.

**Examples**

List information on all methods in the `java.awt.MenuItem` class:

```
methodsview java.awt.MenuItem
```

MATLAB displays this information in a new window.

**See Also**

[methods](#) | [import](#) | [class](#) | [javaArray](#)

**Purpose** Build MEX-function from C/C++ or Fortran source code

**Syntax**

```
mex -setup

mex filenames
mex option1 ... optionN filenames

mex -setup lang
```

**Description** `mex filenames` compiles and links one or more C, C++, or Fortran source files into a binary MEX-file, callable from MATLAB. `filenames` specify the source files. Also builds executable files for standalone MATLAB engine and MAT-file applications.

MATLAB automatically selects a compiler, if installed, based on the language of the `filenames` arguments.

`mex option1 ... optionN filenames` builds with the specified build options. The `option1 ... optionN` arguments supplement or override the default mex build configuration.

`mex -setup lang` selects a compiler for the given `lang`. Use this option when you want to change the default compiler for the given language.

## Input Arguments

### **filenames - One or more file names**

string

One or more file names, including name and file extension, specified as a string. If the file is not in the current folder, specify the full path to the file. File names can be any combination of:

- C, C++, or Fortran language source files
- Simulink S-function files
- object files
- library files

The first file listed in `filenames` is the name of the binary MEX-file. To override this naming convention, use the `'-output'` option.

**Data Types**

char

**option1 ... optionN - One or more build options**

strings corresponding to valid option flags

One or more build options, specified as one of these values. Options can appear in any order on any platform, except where indicated.

Option	Description
<code>@rspfile</code>	Uses Windows RSP file. An RSP file is a text file containing command-line options.
<code>-c</code>	Compiles an object file only. Does not build a binary MEX-file.
<code>-client engine</code>	Build engine application.
<code>-compatibleArrayDims</code> (default) <code>-largeArrayDims</code>	Links with the specified MATLAB array-handling API. <ul style="list-style-type: none"> <li>• <code>-compatibleArrayDims</code> — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li>• <code>-largeArrayDims</code> — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> In verbose mode ( <code>-v</code> option), if you do not specify either the <code>-compatibleArrayDims</code> or the <code>-largeArrayDims</code> option, MATLAB displays a message showing the default option.

(Continued)

Option	Description
<p>-D<i>symbolname</i>                      -D<i>symbolname</i>=<i>symbolvalue</i>                      -U<i>symbolname</i></p>	<p>The -D options define C preprocessor macros. Equivalent to the following in the source file:</p> <ul style="list-style-type: none"> <li>• #define <i>symbolname</i></li> <li>• #define <i>symbolname symbolvalue</i></li> </ul> <p>The -U option removes any initial definition of the C preprocessor macro, <i>symbolname</i>. Inverse of the -D option.</p> <p>Do not add a space between <b>D</b> or <b>U</b> and <i>symbolname</i>. Do not add spaces around the = sign.</p> <p>Example: “Define Directive” on page 1-4337</p>
<p>-f <i>filepath</i></p>	<p>To build engine applications, use the -client engine option.</p> <p>Specifies name and location of the mex configuration file. Overrides the default compiler selection. For information about using a non-default compiler, see “Changing Default Compiler”. <i>filepath</i> is the name and full path of the configuration file, specified as a string.</p>
<p>-g</p>	<p>Adds symbolic information and disables optimizing built object code. Use for debugging. To debug with optimization, add the -O option.</p>
<p>-h[elp]</p>	<p>Displays help for mex. Use from an operating system prompt.</p>

(Continued)

Option	Description
-I <i>pathname</i>	<p>Adds <i>pathname</i> to the list of folders to search for #include files.</p> <p>Do not add a space between <b>I</b> and <i>pathname</i>.</p> <p>Example: “Specify Path to Include File” on page 1-4335</p>
-llibname -Llibfolder -llibname	<p>Links with object library <i>libname</i> in (optional) <i>libfolder</i>.</p> <p>MATLAB expands <i>libname</i> to:</p> <ul style="list-style-type: none"> <li>• <i>libname.lib</i> or <i>liblibname.lib</i> — Windows systems</li> <li>• <i>liblibname.dylib</i> — Mac systems</li> <li>• <i>liblibname.so</i> — Linux systems</li> </ul> <p>If used, the -L option must precede the -l option. When using the -L option on Linux or Mac systems, you also must set the runtime library path, as explained in “Setting Run-Time Library Path”.</p> <p>Do not add a space between <b>l</b> and <i>libname</i> or between <b>L</b> and <i>libfolder</i>.</p> <p>Specify the -l option with the lowercase letter <b>L</b>.</p> <p>Example: “Specify Path to Library File” on page 1-4336</p>

**(Continued)**

<b>Option</b>	<b>Description</b>
<p>-largeArrayDims -compatibleArrayDims (default)</p>	<p>Links with the specified MATLAB array-handling API.</p> <ul style="list-style-type: none"> <li>-compatibleArrayDims — Uses the MATLAB Version 7.2 array-handling API, which limits arrays to <math>2^{31}-1</math> elements. Default option.</li> <li>-largeArrayDims — Uses the MATLAB large-array-handling API. This API handles arrays with more than <math>2^{31}-1</math> elements. Must use this option when calling LAPACK or BLAS functions.</li> </ul> <p>In verbose mode (-v option), if you do not specify either the -compatibleArrayDims or the -largeArrayDims option, MATLAB displays a message showing the default option.</p>
<p>-n</p>	<p>Displays, but does not execute, commands that mex would execute.</p> <p>Example: “Preview Build Commands” on page 1-4334</p>
<p>-O</p>	<p>Optimizes the object code. Use this option to compile with optimization.</p> <p>Optimization is enabled by default. Optimization is disabled when the -g option appears without the -O option.</p> <p>Specify this option with the capital letter <b>O</b>.</p>

(Continued)

Option	Description
-outdir <i>dirname</i>	Places all output files in folder <i>dirname</i> .  Example: “Create and Link to Separate Object Files” on page 1-4334
-output <i>mexname</i>	Overrides the default MEX-file naming mechanism. Creates binary MEX-file named <i>mexname</i> with the appropriate MEX-file extension.
-setup <i>lang</i>	Change the default compiler to build <i>lang</i> language MEX-files. When you use this option, all other command-line options are ignored.
-silent	Suppresses informational messages. The <code>mex</code> function still reports errors and warnings, even when you specify <code>-silent</code> .
-U <i>symbolname</i>	Removes any initial definition of the C preprocessor macro <i>symbolname</i> . (Inverse of the <code>-D</code> option.)  Do not add a space between <b>U</b> and <i>symbolname</i> .
-v	Builds in verbose mode. Displays values for internal variables after all command-line arguments are considered. Displays each compile and link step fully evaluated.  Example: “Display Detailed Build and Troubleshooting Information” on page 1-4334
<i>varname=varvalue</i>	Overrides default setting for variable <i>varname</i> . This option is processed after all command-line arguments are considered.

**(Continued)**

Option	Description
	Example: “Override Default Compiler Switch Option” on page 1-4337.

**lang - Language**

C (default) | C++ | CPP | Fortran

Language, specified as one of these values.

C	C compilers, including C++.
C++ or CPP	C++ compilers.
Fortran	Fortran compilers.

## Examples

### Build C MEX-File

Build a single C program, `yprime.c`, into a MEX-file.

Each example is based on MEX examples in the `matlabroot/extern/examples` subfolders. To build the example code, copy the source file to a writable folder on your path, such as `c:\work`. Set the current folder to `c:\work`.

```
[s,msg,msgid] = mkdir('c:\work');
if (isempty(msgid))
 mkdir('c:\work')
end
cd c:\work
```

Copy the source code, `yprime.c`.

```
copyfile(fullfile(matlabroot,'extern','examples','mex',...
 'yprime.c'),'.','f');
```

Build the MEX-file.

```
mex yprime.c
```

```
Building with 'Microsoft Visual C++ 2010 (C)'.
MEX completed successfully.
```

The output displays information specific to your compiler.

Test.

```
T=1; Y=1:4;
yprime(T,Y)
```

```
ans =
 2.0000 8.9685 4.0000 -1.0947
```

### **Build MEX-File from Multiple Source Files**

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the source files to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'loadsparse.F'),'.','f');
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'fulltosparse.F'),'.','f');
```

Build the `fulltosparse` MEX-file.

```
mex -largeArrayDims fulltosparse.F loadsparse.F
```

The MEX-file name is `fulltosparse` because `fulltosparse.F` is the first file on the command line.

Test.

```
full = eye(5);
```

```
spar = fulltosparse(full)
```

```
spar =
 (1,1) 1
 (2,2) 1
 (3,3) 1
 (4,4) 1
 (5,5) 1
```

## Preview Build Commands

To preview the build command details without executing the commands, use the `-n` option.

```
mex -n yprime.c
```

The output displays information specific to your platform and compiler.

## Display Detailed Build and Troubleshooting Information

To display the compile and link commands and other information useful for troubleshooting, use verbose mode.

```
mex -v -compatibleArrayDims yprime.c
```

The output displays information specific to your platform and compiler.

## Create and Link to Separate Object Files

You can link to object files that you compile separately from your source MEX-files.

The MEX-file example, `fulltosparse`, consists of two Fortran source files, `loadsparse.F` and `fulltosparse.F`. The `fulltosparse` file is the gateway routine (contains the `mexFunction` subroutine) and `loadsparse` contains the computational routine.

To run this example, you need a supported Fortran compiler installed on your system.

Copy the computational subroutine to your current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'loadsparse.F'),'.','f');
```

Compile the subroutine and place the object file in a separate folder, c:\objfiles.

```
mkdir c:\objfiles
mex -largeArrayDims -c -outdir c:\objfiles loadsparse.F
```

Copy the gateway subroutine to your current folder. Compile and link with the loadsparse object file.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'fulltosparse.F'),'.','f');
mex -largeArrayDims fulltosparse.F c:\objfiles\loadsparse.obj
```

### Specify Path to Include File

Use the `-I` option to specify the path to include the MATLAB LAPACK library subroutines for handling complex number routines. To use these subroutines, your MEX-file must access the header file, `fort.h`.

Copy the `matrixDivideComplex.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'matrixDivideComplex.c'),'.','f');
```

Create the `-I` argument by concatenating `'-I'` with the path to `fort.h` file.

```
ipath = ['-I' fullfile(matlabroot,'extern','examples','refbook')];
```

Create variables for the names and paths to the LAPACK library file and the file, `fort.c`, containing the complex number handling routines.

```
lapacklib = fullfile(matlabroot, ...
 'extern','lib',computer('arch'),'microsoft','libmwlapack.lib');
fortfile = fullfile(matlabroot,'extern','examples',...)
```

```
'refbook','fort.c');
```

Build the MEX-file.

```
mex('-v','-largeArrayDims',ipath, ...
 'matrixDivideComplex.c',fortfile,lapacklib)
```

## Specify Path to Library File

Build the `matrixDivide.c` example on a Windows platform.

Use the `-L` and `-l` options to specify the `libmwlapack.lib` library, located in the folder, `matlabroot\extern\lib\arch\microsoft`.

Copy the `matrixDivide.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','refbook',...
 'matrixDivide.c'),'.','f');
```

Capture the value of `matlabroot`.

```
matlabroot
```

```
ans =
```

```
C:\Program Files\MATLAB\R2014a
```

Capture the value of `arch`.

```
arch
```

```
ans =
```

```
win64
```

To build the MEX-file, copy the values of `matlabroot` and `arch` into the `mex` command, as shown in the following statement.

```
mex -largeArrayDims '-LC:\Program Files\MATLAB\R2014a\extern\lib\win64\mi
```

You must use the ' characters because \Program Files in the path includes a space.

### Define Directive

Define the character to use between strings in a matrix.

The MATLAB example, `mxcreatecharmatrixfromstr.c`, uses a `#define` symbol, `SPACE_PADDING`, to determine what character to use between strings in a matrix. To set the value, build the MEX-file with the `-D` option.

Copy the `mxcreatecharmatrixfromstr.c` example to the current folder.

```
copyfile(fullfile(matlabroot,'extern','examples','mx',...
 'mxcreatecharmatrixfromstr.c'),'.','f');
```

Set the `SPACE_PADDING` directive to add a space between strings.

```
mex mxcreatecharmatrixfromstr.c -DSPACE_PADDING
```

### Override Default Compiler Switch Option

Build the `yprime.c` MEX-file by appending the value `-Wall` to the existing compiler flag. Because the value includes a space character, you must delineate the string; the character you use depends on the platform.

At the MATLAB prompt, use MATLAB single quotes (').

```
mex -v COMPFLAGS='$COMPFLAGS -Wall' yprime.c
```

At the Windows Command Prompt, use double quotes (").

```
mex -v COMPFLAGS="$COMPFLAGS -Wall" yprime.c
```

At the shell command line on Mac and Linux, use single quotes (').

```
mex -v CFLAGS='$CFLAGS -Wall' yprime.c
```

## Build Engine Application

Copy the `engwindemo.c` engine example to the current folder.

```
copyfile(fullfile(matlabroot,...
 'extern','examples','eng_mat','engwindemo.c'),'.','f');
```

```
mex -client engine engwindemo.c
```

Run the example.

```
!engwindemo
```

## Select C Compiler

```
mex -setup
```

MATLAB displays the options for your version and system based on the list of Supported and Compatible Compilers.

## Tips

- You can run `mex` from:
  - MATLAB Command Window
  - Windows system prompt
  - Mac Terminal
  - Linux shell

For command-line usage outside of MATLAB, the `mex` program is located in the folder specified by `[matlabroot 'bin']`.

- The MEX-file has a platform-dependent extension. You can place binary MEX-files for different platforms in the same folder.

Platform	Binary MEX-File Extension
Linux (64-bit)	<code>mexa64</code>
Apple Mac (64-bit)	<code>mexmaci64</code>

(Continued)

Platform	Binary MEX-File Extension
Microsoft Windows (32-bit)	mexw32
Windows (64-bit)	mexw64

To identify the MEX-file extension, use the `mexext` function.

- To use `mex` to build executable files for standalone MATLAB engine and MAT-file applications, use the `-client` engine option.

# mex.getCompilerConfigurations

---

**Purpose** Get compiler configuration information for building MEX-files

**Syntax**

```
cc = mex.getCompilerConfigurations
cc = mex.getCompilerConfigurations(lang)
cc = mex.getCompilerConfigurations(lang,list)
```

**Description** `cc = mex.getCompilerConfigurations` returns an object `cc` containing information about the default compiler configurations used by the `mex` command. There is one configuration for each supported language.

`cc = mex.getCompilerConfigurations(lang)` returns an array of objects for the given language, `lang`.

`cc = mex.getCompilerConfigurations(lang,list)` returns information about the set of configurations, `list`.

## Input Arguments

### **lang - Language**

'Any' (default) | 'C' | 'C++' | 'CPP' | 'Fortran'

Language, specified as one of these values.

'Any'	All supported languages. This is the default value.
'C'	All C compiler configurations, including C++ configurations.
'C++' or 'CPP'	All C++ compiler configurations.
'Fortran'	All Fortran compiler configurations.

### **list - Set of configurations**

'Selected' (default) | 'Installed' | 'Supported'

Set of configurations, specified as one of these values.

'Selected'	The default compiler for each language.
'Installed'	All supported compilers mex finds installed on your system.
'Supported'	All compilers supported in the current release.

## Output Arguments

### cc - Compiler information

mex.CompilerConfiguration object or array of objects

Compiler information, specified as a mex.CompilerConfiguration object or array of mex.CompilerConfiguration objects. The mex.CompilerConfiguration class contains the following read-only properties.

Property	Purpose
Name	Compiler name.
ShortName	Character string used to identify options file for the compiler.
Manufacturer	Name of the manufacturer of the compiler.
Language	Compiler language.
Version	(Windows platforms only) Version of the compiler.
Location	(Windows platforms only) Folder where compiler is installed.
Details	More read-only properties about the compiler configuration. These properties might differ across compilers, platforms, and releases of MATLAB.
LinkerName	Linker name.
LinkerVersion	(Windows platforms only) Version of the linker.

# mex.getCompilerConfigurations

---

Property	Purpose
MexOpt	Name and full path to options file.
Priority	The priority of this compiler.

## Examples

### Display Information for C Compiler

```
myCCompiler = mex.getCompilerConfigurations('C','Selected')
```

```
myCCompiler =
```

```
 CompilerConfiguration with properties:
```

```
 Name: 'Microsoft Visual C++ 2010 (C)'
 Manufacturer: 'Microsoft'
 Language: 'C'
 Version: '10.0'
 Location: 'c:\Program Files (x86)\Microsoft Visual Studio 10.0'
 ShortName: 'MSVC100'
 Priority: 'A'
 Details: [1x1 mex.CompilerConfigurationDetails]
 LinkerName: 'link'
 LinkerVersion: ''
 MexOpt: 'C:\Users\user\AppData\Roaming\MathWorks\MATLAB\R2014
```

MATLAB displays information depending on your architecture and your version of MATLAB.

### Display Number of Supported C Compilers

```
cLanguageCC = mex.getCompilerConfigurations('C','Supported');
length(cLanguageCC)
```

```
ans =
 10
```

The number of compilers for your version of MATLAB might be different.

# MException

---

<b>Purpose</b>	Capture error information
<b>Syntax</b>	<code>exception = MException(msgIdent, msgString, v<sub>1</sub>, v<sub>2</sub>, ..., v<sub>N</sub>)</code>
<b>Description</b>	<p><code>exception = MException(msgIdent, msgString, v<sub>1</sub>, v<sub>2</sub>, ..., v<sub>N</sub>)</code> captures information about a specific error and stores it in MException object, <i>exception</i>. Information stored in the object includes a message identifier <i>msgIdent</i> and an error message string <i>msgString</i>. Optional arguments <i>v<sub>1</sub></i>, <i>v<sub>2</sub></i>, ... represent text or numeric values that replace conversion specifiers in <i>msgString</i> at run time.</p> <p>Message identifier <i>msgIdent</i> is a character string composed of at least two substrings, the <i>component</i> and the <i>mnemonic</i>, separated by a colon (e.g., <i>component:mnemonic</i>). The purpose of the identifier is to better identify the source of the error. See the documentation on “Message Identifiers” for more information.</p> <p>Message string <i>msgString</i> is a character string that informs the user about the cause of the error and can also suggest how to correct the faulty condition. The <i>msgString</i> string can include escape sequences such as <code>\t</code> or <code>\n</code>, as well as any of the format specifiers supported by the <code>sprintf</code> function (such as <code>%s</code> or <code>%d</code>). Additional arguments <i>v<sub>1</sub></i>, <i>v<sub>2</sub></i>, ..., <i>v<sub>N</sub></i> provide values that correspond to and replace the conversion specifiers.</p> <p>For example, if <i>msgString</i> is “Error on line %d, command %s”, then <i>v<sub>1</sub></i> is the line number at which the error was detected, and <i>v<sub>2</sub></i> is the command that failed. See “Formatting Strings” in the MATLAB Programming Fundamentals documentation for more detailed information on using string formatting commands.</p> <p>The <i>exception</i> output is an object of the MException class. MException is the constructor for this class. In addition to calling the constructor directly, you can also create an object of MException with any of the following functions: <code>error</code> and <code>assert</code>. See the documentation and figure in the section “The MException Class” for more information on this class.</p>

## Properties

The MException object has four properties: `identifier`, `message`, `stack`, and `cause`. Click any of the links below to find out more about MException properties:

Property	Description
<code>identifier</code>	Identifies the error.
<code>message</code>	Formatted error message that is displayed.
<code>stack</code>	Structure containing stack trace information such as file name, function name, and line number where the MException was thrown.
<code>cause</code>	Cell array of MException that caused this exception to be created.

## Methods

The MException class has the following methods. Click any of the links below to find out more about MException methods:

Method	Description
<code>addCause</code>	Appends an MException to the <code>cause</code> field of another MException.
<code>eq</code>	Tests scalar MException objects for equality.
<code>getReport</code>	Returns a formatted message string that uses the same format as errors thrown by internal MATLAB code.
<code>isequal</code>	Tests scalar MException objects for equality.
<code>last</code>	Returns an MException object for the most recently thrown exception.
<code>ne</code>	Tests scalar MException objects for inequality.

# MException

---

Method	Description
rethrow	Reissues an exception that has been caught, causing the program to stop.
throw	Issues an exception from the currently running function.
throwAsCaller	Issues an exception from the currently running function, also omitting the current stack frame from the <code>stack</code> field of the <code>MException</code> .

## Tips

Valid escape sequences for the `msgString` argument are `\b`, `\f`, `\n`, `\r`, `\t`, and `\x` or `\` when followed by a valid hexadecimal or octal number, respectively. Following a backslash in the `msgString` with any other character causes MATLAB to issue a warning. Conversion specifiers are similar to those used in the C programming language and in the `sprintf` function.

All string input arguments must be enclosed in single quotation marks.

## Examples

### Example 1 – Formatted Messages

If your message string requires formatting specifications like those used with the `sprintf` function, you can use this syntax to compose the error message string:

```
exception = MException(msgIdent, msgString, v1, v2, ...)
```

For example,

```
exception = MException('AcctError:Incomplete', ...
 'Field ''%.%.s'' is not defined.', ...
 'Accounts', 'ClientName');
```

```
exception.message
ans =
 Field 'Accounts.ClientName' is not defined.
```

## Example 2

The catch block in this example checks to see if the specified file could not be found. If this is the case, the program allows for the possibility that a common variation of the filename extension (e.g., jpeg instead of jpg) was used by retrying the operation with a modified extension. This is done using a try/catch statement that is nested within the original try/catch.

```
function d_in = read_image(filename)
[path name ext] = fileparts(filename);
try
 fid = fopen(filename, 'r');
 d_in = fread(fid);
catch exception

 % Did the read fail because the file could not be found?
 if ~exist(filename, 'file')

 % Yes. Try modifying the filename extension.
 switch ext
 case '.jpg' % Change jpg to jpeg
 altFilename = strrep(filename, '.jpg', '.jpeg')
 case '.jpeg' % Change jpeg to jpg
 altFilename = strrep(filename, '.jpeg', '.jpg')
 case '.tif' % Change tif to tiff
 altFilename = strrep(filename, '.tif', '.tiff')
 case '.tiff' % Change tiff to tif
 altFilename = strrep(filename, '.tiff', '.tif')
 otherwise
 rethrow(exception);
 end

 % Try again, with modified filename.
 try
 fid = fopen(altFilename, 'r');
 d_in = fread(fid);
 catch
```

```
 rethrow(exception)
 end
end
end
```

### Example 3 – Nested try/catch

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second:

```
function data = read_it(filename);
try
 % Attempt to open and read from a file.
 fid = fopen(filename, 'r');
 data = fread(fid);
catch exception1
 % If the error was caused by an invalid file ID, try
 % reading from another location.
 if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
 msg = sprintf(...
 '\nCannot open file %s. Try another location? ', ...
 filename);
 reply = input(msg, 's')
 if reply(1) == 'y'
 newFolder = input('Enter folder name: ', 's');
 else
 throw(exception1);
 end
 oldpath = addpath(newFolder);
 try
 fid = fopen(filename, 'r');
 data = fread(fid);
 catch exception2
 exception3 = addCause(exception2, exception1)
 path(oldpath);
 throw(exception3);
 end
 end
end
```

```
 end
 path(oldpath);
 end
end
fclose(fid);
```

If you run this function in a try-catch block at the command line, you can look at the MException object by assigning it to a variable (e) with the catch command.

# mexext

---

**Purpose** Binary MEX-file-name extension

**Syntax**  
`ext = mexext`  
`extlist = mexext('all')`

**Description** `ext = mexext` returns the file-name extension for the current platform.

`extlist = mexext('all')` returns the extensions for all platforms.

**Output Arguments**  
**ext - File-name extension**  
`mexa64` | `mexmaci64` | `mexw32` | `mexw64`

File-name extension for MEX-file, returned as one of these values.

Platform	Binary MEX-File Extension
Linux (64-bit)	<code>mexa64</code>
Apple Mac (64-bit)	<code>mexmaci64</code>
Microsoft Windows (32-bit)	<code>mexw32</code>
Windows (64-bit)	<code>mexw64</code>

**extlist - All file-name extensions**

structure

All file-name extensions, returned as a structure with these fields:

**arch - Platform**

string

Platform, specified as a string. The name of the platform is the output of the `computer('arch')` command.

**ext - File extension**

string

File extension, specified as a string.

## Examples

### Display File Extension for Your Computer

Find the MEX-file extension for the system you are currently working on.

```
ext = mexext
```

```
ext =
 mexw32
```

Your results reflect your system.

### Find File Extension for Specific Platform

Find the MEX-file extension for the Apple Macintosh systems.

Get the list for supported platforms.

```
extlist = mexext('all');
```

The mex function identifies a platform by its arch value, which is the output of the computer('arch') command. For Macintosh platforms, the value is maci64.

Search the arch field in the results, extlist, for 'maci64', and display the corresponding ext field.

```
for k=1:length(extlist)
 if strcmp(extlist(k).arch, 'maci64')
 disp(sprintf('Arch: %s Ext: %s', ...
 extlist(k).arch, extlist(k).ext))
 end, end
```

```
Arch: maci64 Ext: mexmaci64
```

The file extension is mexmaci64.

## Tips

- To use the MEX-file-name extension in makefiles or scripts outside MATLAB, type one of the following from the system command prompt. The script is located in the *matlabroot*\bin folder.
  - `mexext.bat`—Windows platform.
  - `mexext.sh`—UNIX platform.

For example, the following commands are in a GNU® makefile.

```
ext = $(shell mexext)
yprime.$(ext) : yprime.c
 mex yprime.c
```

- MATLAB continues to execute a MEX-file with a `.dll` extension, but future versions of MATLAB will not support this extension.

## See Also

`mex` | `computer`

**Purpose** File name of currently running function

**Syntax**

```
mfilename
p = mfilename('fullpath')
c = mfilename('class')
```

**Description** `mfilename` returns a string containing the file name of the most recently invoked function. When called from within the file, it returns the name of that file. This allows a function to determine its name, even if the file name has been changed.

`p = mfilename('fullpath')` returns the full path and name of the file in which the call occurs, not including the filename extension.

`c = mfilename('class')` in a method, returns the class of the method, not including the leading @ sign. If called from a nonmethod, it yields the empty string.

**Tips** If `mfilename` is called with any argument other than the above two, it behaves as if it were called with no argument.

When called from the command line, `mfilename` returns an empty string.

To get the names of the callers of a MATLAB function file, use `dbstack` with an output argument.

**See Also** `dbstack` | `function` | `nargin` | `nargout` | `inputname`

# FTP.mget

---

<b>Purpose</b>	Download files from FTP server
<b>Syntax</b>	<code>mget(ftpobj, contents)</code> <code>mget(ftpobj, contents, target)</code>
<b>Description</b>	<code>mget(ftpobj, contents)</code> retrieves the file or folder specified by <code>contents</code> from an FTP server into the MATLAB current folder. <code>mget(ftpobj, contents, target)</code> retrieves the file or folder into the local folder specified by <code>target</code> , which includes an absolute or relative path.
<b>Input Arguments</b>	<b>ftpobj</b> FTP object created by <code>ftp</code> . <b>contents</b> String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (*). <b>target</b> String enclosed in single quotation marks that specifies the absolute or relative path of the local folder to contain the downloaded contents.
<b>Examples</b>	Connect to an FTP server and retrieve the file README into the current MATLAB folder: <pre>mw = ftp('ftp.mathworks.com'); mget(mw, 'README'); close(mw);</pre>
<b>See Also</b>	<code>cd</code>   <code>ftp</code>   <code>mput</code>

**Purpose**

Smallest elements in array

**Syntax**

```
C = min(A)
C = min(A,[],dim)
[C,I] = min(...)
```

```
C = min(A,B)
```

**Description**

`C = min(A)` returns the smallest elements along different dimensions of an array.

If `A` is a vector, `min(A)` returns the smallest element in `A`.

If `A` is a matrix, `min(A)` treats the columns of `A` as vectors, returning a row vector containing the minimum element from each column.

If `A` is a multidimensional array, `min` operates along the first nonsingleton dimension.

`C = min(A,[],dim)` returns the smallest elements along the dimension of `A` specified by scalar `dim`. For example, `min(A,[],1)` produces the minimum values along the first dimension of `A`.

`[C,I] = min(...)` finds the indices of the minimum values of `A`, and returns them in output vector `I`. If there are several identical minimum values, the index of the first one found is returned.

`C = min(A,B)` returns an array the same size as `A` and `B` with the smallest elements taken from `A` or `B`. The dimensions of `A` and `B` must match, or they may be scalar.

**Examples**

Return the minimum of a 2-by-3 matrix from each column:

```
X = [2 8 4; 7 3 9];
min(X,[],1)
ans =
```

# min

---

```
2 3 4
```

Return the minimum from each row:

```
min(X,[],2)
ans =
```

```
2
3
```

Compare each element of X to a scalar:

```
min(X,5)
ans =
```

```
2 5 4
5 3 5
```

## Tips

For complex input A, `min` returns the complex number with the smallest complex modulus (magnitude), computed with `min(abs(A))`. Then computes the smallest phase angle with `min(angle(x))`, if necessary.

The `min` function ignores NaNs.

## See Also

**Purpose** Minimize size of Automation server window

**Syntax** **IDL Method Signature**

```
HRESULT MinimizeCommandWindow(void)
```

**Microsoft Visual Basic Client**

```
MinimizeCommandWindow
```

**MATLAB Client**

```
h.MinimizeCommandWindow
MinimizeCommandWindow(h)
```

**Description** h.MinimizeCommandWindow minimizes the window for the server attached to handle h, and makes it inactive.

MinimizeCommandWindow(h) is an alternate syntax.

If the server window was already in a minimized state, MinimizeCommandWindow does nothing.

**Examples** From a Visual Basic .NET client, modify the size of the command window in a MATLAB Automation server:

```
Dim Matlab As Object
```

```
Matlab = CreateObject("matlab.application")
Matlab.MinimizeCommandWindow
```

```
'Now return the server window to its former state on
'the desktop and make it the currently active window.
```

```
Matlab.MaximizeCommandWindow
```

**See Also** MaximizeCommandWindow

# minres

---

## Purpose

Minimum residual method

## Syntax

```
x = minres(A,b)
minres(A,b,tol)
minres(A,b,tol,maxit)
minres(A,b,tol,maxit,M)
minres(A,b,tol,maxit,M1,M2)
minres(A,b,tol,maxit,M1,M2,x0)
[x,flag] = minres(A,b,...)
[x,flag,relres] = minres(A,b,...)
[x,flag,relres,iter] = minres(A,b,...)
[x,flag,relres,iter,resvec] = minres(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = minres(A,b,...)
```

## Description

`x = minres(A,b)` attempts to find a minimum norm residual solution  $x$  to the system of linear equations  $A*x=b$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `minres` converges, a message to that effect is displayed. If `minres` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual norm  $\|b-A*x\|/\|b\|$  and the iteration number at which the method stopped or failed.

`minres(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `minres` uses the default,  $1e-6$ .

`minres(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `minres` uses the default,  $\min(n,20)$ .

`minres(A,b,tol,maxit,M)` and `minres(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M))*A*\text{inv}(\text{sqrt}(M))*y =$

$\text{inv}(\text{sqrt}(M))*b$  for  $y$  and then return  $x = \text{inv}(\text{sqrt}(M))*y$ . If  $M$  is  $[]$  then `minres` applies no preconditioner.  $M$  can be a function handle `mfun`, such that `mfun(x)` returns  $M \backslash x$ .

`minres(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is  $[]$ , then `minres` uses the default, an all-zero vector.

`[x,flag] = minres(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	minres converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	minres iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	minres stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>minres</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = minres(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = minres(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = minres(A,b,...)` also returns a vector of estimates of the `minres` residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

`[x,flag,relres,iter,resvec,resvecg] = minres(A,b,...)` also returns a vector of estimates of the Conjugate Gradients residual norms at each iteration.

## Examples

### Using minres with a Matrix Input

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M1 = spdiags(4*on,0,n,n);

x = minres(A,b,tol,maxit,M1);
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_minres` that

- Calls `minres` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_minres` are available to `afun`.

The following shows the code for `run_minres`:

```
function x1 = run_minres
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50;
M = spdiags(4*on,0,n,n);
x1 = minres(@afun,b,tol,maxit,M);

function y = afun(x)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - 2 * x(2:n);
```

```

 end
 end

```

When you enter

```
x1=run_minres;
```

MATLAB software displays the message

```
minres converged at iteration 49 to a solution with relative
residual 4.7e-014
```

### Using minres instead of pcg

Use a symmetric indefinite matrix that fails with pcg.

```
A = diag([20:-1:1, -1:-1:-20]);
b = sum(A,2); % The true solution is the vector of all ones.
x = pcg(A,b); % Errors out at the first iteration.
```

displays the following message:

```
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1
```

However, minres can handle the indefinite matrix A.

```
x = minres(A,b,1e-6,40);
minres converged at iteration 39 to a solution with relative
residual 1.3e-007
```

<b>Purpose</b>	Subtraction
<b>Syntax</b>	$C = A - B$ <code>C = minus(A,B)</code>
<b>Description</b>	<p><math>C = A - B</math> subtracts array B from array A and returns the result in C.</p> <p><code>C = minus(A,B)</code> is an alternate way to execute <math>A - B</math>, but is rarely used. It enables operator overloading for classes.</p>
<b>Input Arguments</b>	<p><b>A - Input array</b> scalar   vector   matrix   multidimensional array</p> <p>Input array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char <b>Complex Number Support:</b> Yes</p> <p><b>B - Input array</b> scalar   vector   matrix   multidimensional array</p> <p>Input array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char <b>Complex Number Support:</b> Yes</p>
<b>Examples</b>	<p><b>Subtract Scalar from Array</b></p> <p>Create an array, A, and subtract a scalar value from it.</p>

## minus, -

---

```
A = [2 1; 3 5];
C = A - 2
```

```
C =
```

```
 0 -1
 1 3
```

The scalar is subtracted from each entry of A.

### Subtract Two Arrays

Create two arrays, A and B, and subtract the second, B, from the first, A.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
C = A - B
```

```
C =
```

```
 -4 -9
 0 3
```

The elements of B are subtracted from the corresponding elements of A.

Use the syntax `-C` to negate the elements of C.

```
-C
```

```
ans =
```

```
 4 9
 0 -3
```

**Purpose** Determine if function is locked in memory

**Syntax** `mislocked`  
`mislocked(fun)`

**Description** `mislocked` by itself returns logical 1 (`true`) if the currently running function is locked in memory, and logical 0 (`false`) otherwise. Functions that are locked cannot be removed with the `clear` function unless you first unlock them using the `munlock` function. You can use locking on functions that reside in MATLAB `.m` files or `.mex` files.

`mislocked(fun)` returns logical 1 (`true`) if the function named *fun* is locked in memory, and logical 0 (`false`) otherwise.

**See Also** `mlock` | `munlock` | `inmem`

# mkdir

---

## Purpose

Make new folder

## Syntax

```
mkdir('folderName')
mkdir('parentFolder','folderName')
status = mkdir(___)
[status,message,messageid] = mkdir(___)
```

## Description

`mkdir('folderName')` creates the folder `folderName`, where `folderName` can be an absolute or a relative path.

`mkdir('parentFolder','folderName')` creates the folder `folderName` in `parentFolder`, where `parentFolder` is an absolute or relative path. If `parentFolder` does not exist, MATLAB attempts to create it. See the Tips section.

`status = mkdir( ___ )` creates the specified folder. When the operation is successful, it returns a `status` of logical 1. When the operation is unsuccessful, it returns logical 0.

`[status,message,messageid] = mkdir( ___ )` creates the specified folder, and returns the `status`, message string, and MATLAB message ID. The value given to `status` is logical 1 for success, and logical 0 for error.

## Tips

If an argument specifies a path that includes one or more nonexistent folders, MATLAB attempts to create the nonexistent folder. For example, for

```
mkdir('myFolder\folder1\folder2\targetFolder')
```

if `folder1` does not exist, MATLAB creates `folder1`, creates `folder2` within `folder1`, and creates `targetFolder` within `folder2`.

## Examples

### Creating a Subfolder in the Current Folder

Create a subfolder called `newdir` in the current folder:

```
mkdir('newdir')
```

### Creating a Subfolder in the Specified Parent Folder

Create a subfolder called `newFolder` in the folder `testdata`, using a relative path, where `newFolder` is at the same level as the current folder:

```
mkdir('../testdata','newFolder')
```

### Returning Status When Creating a Folder

In this example, the first attempt to create `newFolder` succeeds, returning a status of 1, and no error or warning message or message identifier:

```
[s, mess, messid] = mkdir('../testdata', 'newFolder')
s =
 1
mess =
 ''
messid =
 ''
```

Attempt to create the same folder again. `mkdir` again returns a success status, and also a warning and message identifier informing you that the folder exists:

```
[s,mess,messid] = mkdir('../testdata','newFolder')
s =
 1
mess =
 Directory "newFolder" already exists.
messid =
 MATLAB:MKDIR:DirectoryExists
```

### How To

- “Manage Files and Folders”

# FTP.mkdir

---

**Purpose** Create folder on FTP server

**Syntax** `mkdir(ftpobj, folder)`

**Description** `mkdir(ftpobj, folder)` creates the specified folder on the FTP server associated with `ftpobj`.

**Input Arguments**

**ftpobj**  
FTP object created by `ftp`.

**folder**  
String enclosed in single quotation marks that specifies a path relative to the current folder on the FTP server.

**Examples** Suppose that a hypothetical host, `ftp.testsite.com`, contains a folder named `testfolder`. Connect to the server and add a subfolder:

```
test=ftp('ftp.testsite.com');
mkdir(test, 'testfolder/newfolder');
close(test);
```

**See Also** `dir` | `ftp` | `rmdir`

**Purpose** Make piecewise polynomial

**Syntax**  
`pp = mkpp(breaks,coefs)`  
`pp = mkpp(breaks,coefs,d)`

**Description** `pp = mkpp(breaks,coefs)` builds a piecewise polynomial `pp` from its `breaks` and coefficients. `breaks` is a vector of length `L+1` with strictly increasing elements which represent the start and end of each of `L` intervals. `coefs` is an `L`-by-`k` matrix with each row `coefs(i,:)` containing the coefficients of the terms, from highest to lowest exponent, of the order `k` polynomial on the interval `[breaks(i),breaks(i+1)]`.

`pp = mkpp(breaks,coefs,d)` indicates that the piecewise polynomial `pp` is `d`-vector valued, i.e., the value of each of its coefficients is a vector of length `d`. `breaks` is an increasing vector of length `L+1`. `coefs` is a `d`-by-`L`-by-`k` array with `coefs(r,i,:)` containing the `k` coefficients of the `i`th polynomial piece of the `r`th component of the piecewise polynomial.

Use `ppval` to evaluate the piecewise polynomial at specific points. Use `unmkpp` to extract details of the piecewise polynomial.

**Note.** The *order* of a polynomial tells you the number of coefficients used in its description. A *k*th order polynomial has the form

$$c_1x^{k-1} + c_2x^{k-2} + \dots + c_{k-1}x + c_k$$

It has *k* coefficients, some of which can be 0, and maximum exponent *k* - 1. So the order of a polynomial is usually one greater than its degree. For example, a cubic polynomial is of order 4.

## Examples **Construct and Plot Piecewise Polynomial**

The first plot shows the quadratic polynomial

$$1 - \left(\frac{x}{2} - 1\right)^2 = \frac{-x^2}{4} + x$$

shifted to the interval `[-8,-4]`. The second plot shows its negative

$$\left(\frac{x}{2} - 1\right)^2 - 1 = \frac{x^2}{4} - x$$

but shifted to the interval [-4,0].

The last plot shows a piecewise polynomial constructed by alternating these two quadratic pieces over four intervals. It also shows its first derivative, which was constructed after breaking the piecewise polynomial apart using `unmkpp`.

```
subplot(2,2,1)
cc = [-1/4 1 0];
pp1 = mkpp([-8 -4],cc);
xx1 = -8:0.1:-4;
plot(xx1,ppval(pp1,xx1),'k-')

subplot(2,2,2)
pp2 = mkpp([-4 0],-cc);
xx2 = -4:0.1:0;
plot(xx2,ppval(pp2,xx2),'k-')

subplot(2,1,2)
pp = mkpp([-8 -4 0 4 8],[cc;-cc;cc;-cc]);
xx = -8:0.1:8;
plot(xx,ppval(pp,xx),'k-')
[breaks,coefs,l,k,d] = unmkpp(pp);
dpp = mkpp(breaks,repmat(k-1:-1:1,d*1,1).*coefs(:,1:k-1),d);
hold on, plot(xx,ppval(dpp,xx),'r-'), hold off
```

**See Also** [ppval](#) | [spline](#) | [unmkpp](#)

# mldivide, \

---

**Purpose** Solve systems of linear equations  $Ax = B$  for  $x$

**Syntax**  
 $x = A \setminus B$   
 $x = \text{mldivide}(A,B)$

**Description**  $x = A \setminus B$  solves the system of linear equations  $A * x = B$ . The matrices  $A$  and  $B$  must have the same number of rows. MATLAB displays a warning message if  $A$  is badly scaled or nearly singular, but performs the calculation regardless.

- If  $A$  is a scalar, then  $A \setminus B$  is equivalent to  $A . \setminus B$ .
- If  $A$  is a square  $n$ -by- $n$  matrix and  $B$  is a matrix with  $n$  rows, then  $x = A \setminus B$  is a solution to the equation  $A * x = B$ , if it exists.
- If  $A$  is a rectangular  $m$ -by- $n$  matrix with  $m \neq n$ , and  $B$  is a matrix with  $m$  rows, then  $A \setminus B$  returns a least-squares solution to the system of equations  $A * x = B$ .

$x = \text{mldivide}(A,B)$  is an alternative way to execute  $x = A \setminus B$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Coefficient matrix**  
vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If  $A$  has  $m$  rows, then  $B$  must have  $m$  rows.

**Data Types**  
single | double  
**Complex Number Support:** Yes

**B - Right-hand side**  
vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If  $B$  has  $m$  rows, then  $A$  must have  $m$  rows.

**Data Types**

single | double

**Complex Number Support:** Yes**Output Arguments****x - Solution**

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If A is an m-by-n matrix and B is an m-by-p matrix, then x is an n-by-p matrix, including the case when p==1.

If A has full storage, x is also full. If A is sparse, then x has the same storage as B.

**Examples****System of Equations**

Solve a simple system of linear equations,  $A*x = B$ .

```
A = magic(3);
B = [15; 15; 15];
x = A\B
```

```
x =
```

```
 1.0000
 1.0000
 1.0000
```

**Linear System with Singular Matrix**

Solve a linear system of equations  $A*x = b$  involving a singular matrix, A.

```
A = magic(4);
b = [34; 34; 34; 34];
x = A\b
```

```
Warning: Matrix is close to singular or badly scaled. Results may be
1.306145e-17.
```

# mldivide, \

---

```
x =

 1.5000
 2.5000
 -0.5000
 0.5000
```

When `rcond` is between 0 and `eps`, MATLAB issues a nearly singular warning, but proceeds with the calculation. When working with ill-conditioned matrices, an unreliable solution can result even though the residual ( $\mathbf{b} - \mathbf{A}^*\mathbf{x}$ ) is relatively small. In this particular example, the norm of the residual is zero, and an exact solution is obtained, although `rcond` is small.

When `rcond` is equal to 0, the singular warning appears.

```
A = [1 0; 0 0];
b = [1; 1];
x = A\b
```

```
Warning: Matrix is singular to working precision.
```

```
x =

 1
 Inf
```

In this case, division by zero leads to computations with `Inf` and/or `NaN`, making the computed result unreliable.

## Least-Squares Solution of Underdetermined System

Solve a system of linear equations,  $\mathbf{A}^*\mathbf{x} = \mathbf{b}$ .

```
A = [1 2 0; 0 4 3];
b = [8; 18];
x = A\b
```

```
ans =
 0
 4.0000
 0.6667
```

### Linear System with Sparse Matrix

Solve a simple system of linear equations using sparse matrices.

Consider the matrix equation  $A*x = B$ .

```
A = sparse([0 2 0 1 0; 4 -1 -1 0 0; 0 0 0 3 -6; -2 0 0 0 2; 0 0 4 2 0]);
B = sparse([8; -1; -18; 8; 20]);
x = A\B
```

```
x =
 (1,1) 1.0000
 (2,1) 2.0000
 (3,1) 3.0000
 (4,1) 4.0000
 (5,1) 5.0000
```

### Tips

- If  $A$  is a square matrix,  $A\backslash B$  is roughly equal to  $\text{inv}(A)*B$ , but MATLAB processes  $A\backslash B$  differently and more robustly.
- If the rank of  $A$  is less than the number of columns in  $A$ , then  $x = A\backslash B$  is not necessarily the minimum norm solution. The more computationally expensive  $x = \text{pinv}(A)*B$  computes the minimum norm least-squares solution.
- For full singular inputs, you can compute the least-squares solution using the function `linsolve`.

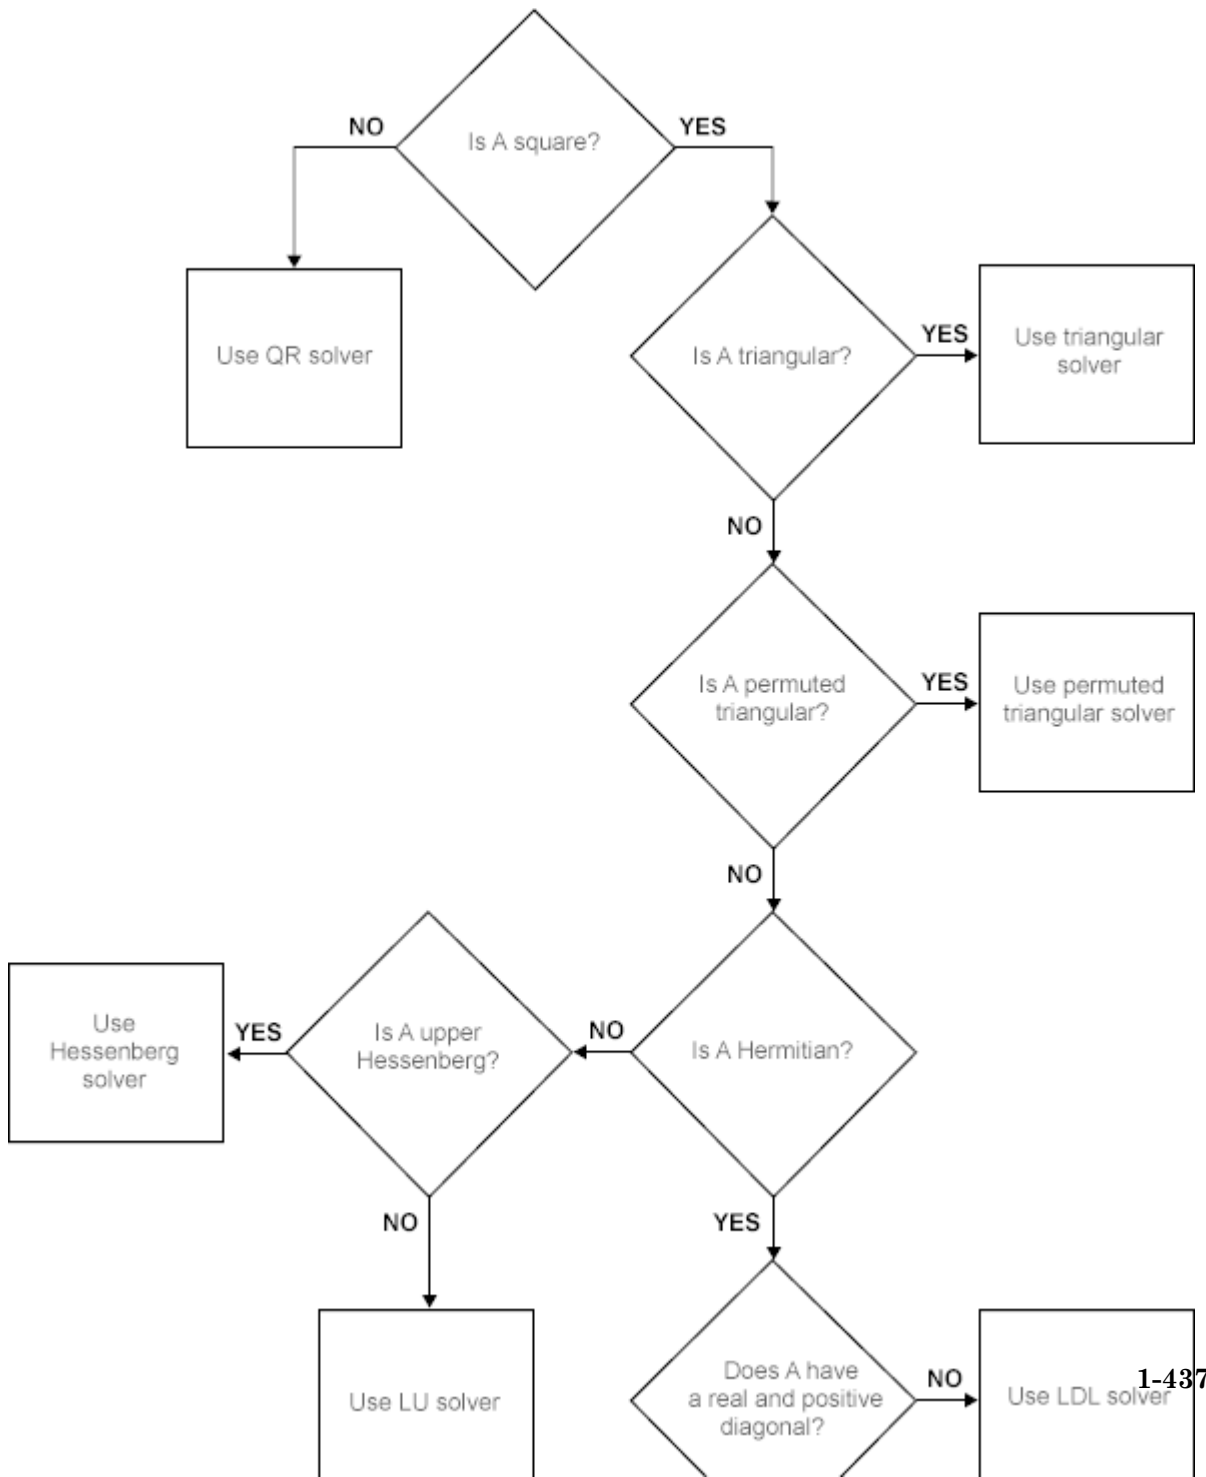

### Algorithms

The versatility of `mldivide` in solving linear systems stems from its ability to take advantage of symmetries in the problem by dispatching to an appropriate solver. This approach aims to minimize computation

time. The first distinction the function makes is between *full* (also called “*dense*”) and *sparse* input arrays.

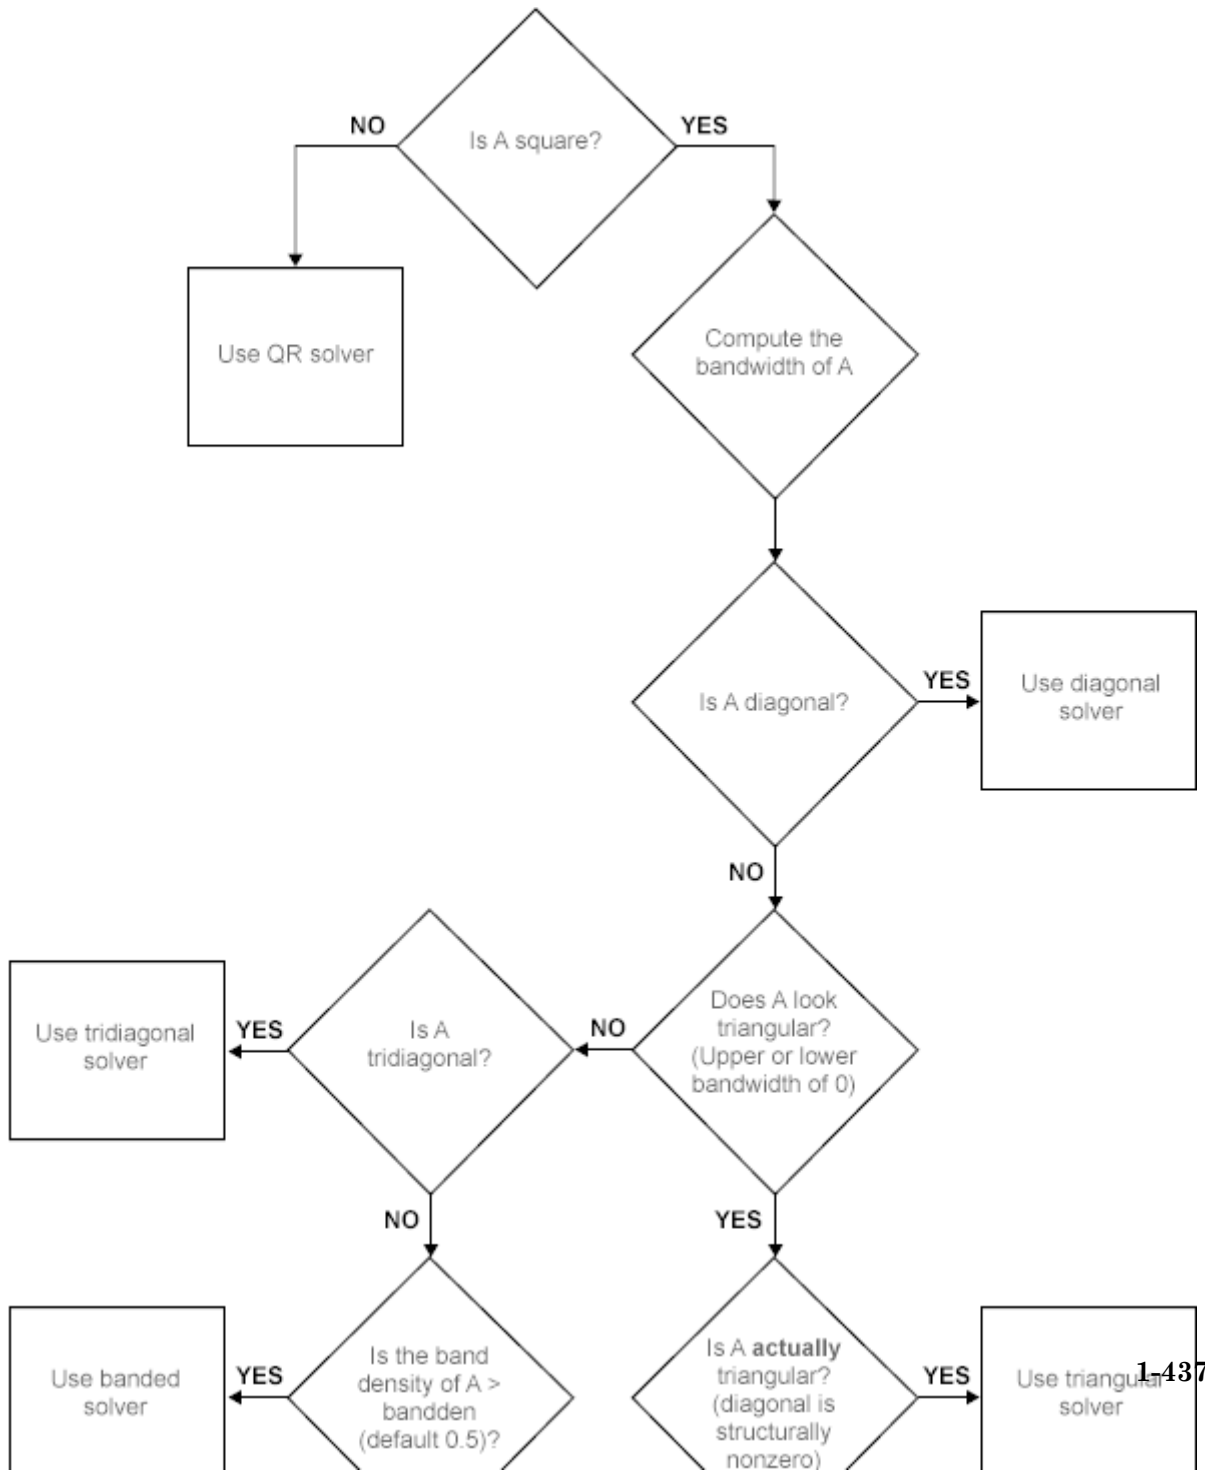

## **Algorithm for Full Inputs**

The flow chart below shows the algorithm path when inputs A and B are **full**.

## **Algorithm for Sparse Inputs**

If  $A$  is full and  $B$  is sparse then `mldivide` converts  $B$  to a full matrix and uses the full algorithm path (above) to compute a solution with full storage. If  $A$  is sparse, the storage of the solution  $x$  is the same as that of  $B$  and `mldivide` follows the algorithm path for **sparse** inputs, shown below.

# **mldivide, \**

---

## **Concepts**

- “Systems of Linear Equations”
- “Implementing Operators for Your Class”

**Purpose** Solve systems of linear equations  $xA = B$  for  $x$

**Syntax**  
 $x = B/A$   
 $x = \text{mrdivide}(B,A)$

**Description**  $x = B/A$  solves the system of linear equations  $x*A = B$  for  $x$ . The matrices **A** and **B** must contain the same number of columns. MATLAB displays a warning message if **A** is badly scaled or nearly singular, but performs the calculation regardless.

- If **A** is a scalar, then  $B/A$  is equivalent to  $B ./ A$ .
- If **A** is a square  $n$ -by- $n$  matrix and **B** is a matrix with  $n$  columns, then  $x = B/A$  is a solution to the equation  $x*A = B$ , if it exists.
- If **A** is a rectangular  $m$ -by- $n$  matrix with  $m \neq n$ , and **B** is a matrix with  $n$  columns, then  $x = B/A$  returns a least-squares solution of the system of equations  $x*A = B$ .

$x = \text{mrdivide}(B,A)$  is an alternative way to execute  $x = B/A$ , but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Coefficient matrix**  
 vector | full matrix | sparse matrix

Coefficient matrix, specified as a vector, full matrix, or sparse matrix. If **A** has  $n$  columns, then **B** must have  $n$  columns.

**Data Types**  
 single | double

**Complex Number Support:** Yes

**B - Right-hand side**  
 vector | full matrix | sparse matrix

Right-hand side, specified as a vector, full matrix, or sparse matrix. If **B** has  $n$  columns, then **A** must have  $n$  columns.

## Data Types

single | double

**Complex Number Support:** Yes

## Output Arguments

### x - Solution

vector | full matrix | sparse matrix

Solution, returned as a vector, full matrix, or sparse matrix. If A is an m-by-n matrix and B is a p-by-n matrix, then x is a p-by-m matrix.

x is sparse only if both A and B are sparse matrices.

## Examples

### System of Equations

Solve a system of equations that has a unique solution,  $x*A = B$ .

```
A = [1 1 3; 2 0 4; -1 6 -1];
```

```
B = [2 19 8];
```

```
x = B/A
```

```
x =
```

```
 1.0000 2.0000 3.0000
```

### Least-Squares on an Underdetermined System

Solve an underdetermined system,  $x*C = D$ .

```
C = [1 0; 2 0; 1 0];
```

```
D = [1 2];
```

```
x = D/C
```

```
Warning: Rank deficient, rank = 1, tol = 6.280370e-16.
```

```
x =
```

```
 0 0.5000 0
```

MATLAB issues a warning but proceeds with calculation.

Verify that  $x$  is not an exact solution.

```
x*C-D
```

```
ans =
```

```
 0 -2
```

**Tips**

- The operators `/` and `\` are related to each other by the equation  $B/A = (A' \setminus B')'$ .
- If  $A$  is a square matrix,  $B/A$  is roughly equal to  $B \cdot \text{inv}(A)$ , but MATLAB processes  $B/A$  differently and more robustly.

**See Also**

**Concepts**

- “Systems of Linear Equations”

# mlint

---

**Purpose** Check MATLAB code files for possible problems

---

**Note** `mlint` is not recommended. Use `checkcode` instead.

---

**Alternatives** For information on using the graphical user interface to the Code Analyzer, see “Check Code for Errors and Warnings”.

**Syntax**

```
mlint('filename')
mlint('filename', '-config=settings.txt')
mlint('filename', '-config=factory')
inform=mlint('filename', '-struct')
msg=mlint('filename', '-string')
[inform, filepaths]=mlint('filename')
inform=mlint('filename', '-id')
inform=mlint('filename', '-fullpath')
inform=mlint('filename', '-notok')
mlint('filename', '-cyc')
mlint('filename', '-codegen')
mlint('filename', '-eml')
```

**Description** `mlint('filename')` displays Code Analyzer messages about `filename`, where the message reports potential problems and opportunities for code improvement. The line number in the message is a hyperlink that opens the file in the Editor, scrolled to that line. If `filename` is a cell array, information is displayed for each file. For `mlint(F1,F2,F3,...)`, where each input is a character array, MATLAB software displays information about each input file name. You cannot combine cell arrays and character arrays of file names. Note that the exact text of the `mlint` messages is subject to some change between versions.

`mlint('filename', '-config=settings.txt')` overrides the default active settings file with the settings that enable or suppress messages as indicated in the specified `settings.txt` file.

---

**Note** If used, you must specify the full path to the `settings.txt` file specified with the `-config` option.

---

For information about creating a `settings.txt` file, see “Save and Reuse Code Analyzer Message Settings”. If you specify an invalid file, `mlint` returns a message indicating that it cannot open or read the file you specified. In that case, `mlint` uses the factory default settings.

`mlint('filename', '-config=factory')` ignores all settings files and uses the factory default preference settings.

`inform=mlint('filename', '-struct')` returns the information in a structure array whose length is the number of messages found. The structure has the fields that follow.

Field	Description
<code>message</code>	Message describing the suspicious construct that code analysis caught.
<code>line</code>	Vector of file line numbers to which the message refers.
<code>column</code>	Two-column array of file columns (column extents) to which the message applies. The first column of the array specifies the column in the Editor where the message begins. The second column of the array specifies the column in the Editor where the message ends. There is one row in the two-column array for each occurrence of a message.

If you specify multiple file names as input, or if you specify a cell array as input, `inform` contains a cell array of structures.

`msg=mlint('filename', '-string')` returns the information as a string to the variable `msg`. If you specify multiple file names as input, or if you specify a cell array as input, `msg` contains a string where each

file's information is separated by 10 equal sign characters (=), a space, the file name, a space, and 10 equal sign characters.

If you omit the **-struct** or **-string** argument and you specify an output argument, the default behavior is **-struct**. If you omit the argument and there are no output arguments, the default behavior is to display the information to the command line.

`[inform,filepath]=mlint('filename')` additionally returns `filepath`, the absolute paths to the file names, in the same order as you specified them.

`inform=mlint('filename','-id')` requests the message ID, where ID is a string of the form ABC... When returned to a structure, the output also has the `id` field, which is the ID associated with the message.

`inform=mlint('filename','-fullpath')` assumes that the input file names are absolute paths, so that `mlint` does not try to locate them.

`inform=mlint('filename','-notok')` runs `mlint` for all lines in `filename`, even those lines that end with the `mlint` suppression directive, `##ok`.

`mlint('filename','-cyc')` displays the McCabe complexity (also referred to as cyclomatic complexity) of each function in the file. Higher McCabe complexity values indicate higher complexity, and there is some evidence to suggest that programs with higher complexity values are more likely to contain errors. Frequently, you can lower the complexity of a function by dividing it into smaller, simpler functions. In general, smaller complexity values indicate programs that are easier to understand and modify. Some people advocate splitting up programs that have a complexity rating over 10.

`mlint('filename','-codegen')` enables code generation messages for display in the Command Window.

`mlint('filename','-eml')` `-eml` is not recommended. Use `-codegen` instead.

## Examples

The following examples use `lengthofline.m`, which is a sample file with MATLAB code that can be improved. You can find it in

*matlabroot/help/techdoc/matlab\_env/examples*. If you want to run the examples, save a copy of *lengthofline.m* to a location on your MATLAB path.

## Running mlint on a File with No Options

To run `mlint` on the example file, *lengthofline.m*, run

```
mlint('lengthofline')
```

MATLAB displays the M-Lint messages for *lengthofline.m* in the Command Window:

```
L 22 (C 1-9): The value assigned here to variable 'nothandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMPI(str1,str2) instead of using LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD.
 Type 'doc struct' for more information.
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop.Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages” in the MATLAB Desktop Tools and Development Environment documentation.

## Running mlint with Options to Show IDs and Return Results to a Structure

To store the results to a structure and include message IDs, run

```
inform=mlint('lengthofline', '-id')
```

MATLAB returns

```
inform =

19x1 struct array with fields:
 message
 line
 column
 id
```

To see values for the first message, run

```
inform(1)
```

MATLAB displays

```
ans =

 message: 'The value assigned here to variable 'nohandle' might never be used.'
 line: 22
 column: [1 9]
 id: 'NASGU'
```

Here, the message is for the value that appears on line 22 that extends from column 1–9 in the file.NASGU is the ID for the message 'The value assigned here to variable 'nohandle' might never be used.'.

## Displaying McCabe Complexity with mlint

To display the McCabe complexity of a MATLAB code file, run `mlint` with the `-cyc` option, as shown in the following example (assuming you have saved `lengthofline.m` to a local folder).

```
mlint lengthofline.m -cyc
```

Results displayed in the Command Window show the McCabe complexity of the file, followed by the M-Lint messages, as shown here:

```
L 1 (C 23-34): The McCabe complexity of 'lengthofline' is 12.
L 22 (C 1-9): The value assigned here to variable 'nohandle' might never be used.
L 23 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 24 (C 5-11): 'notline' might be growing inside a loop. Consider preallocating for speed.
L 24 (C 44-49): Use STRCMP(str1,str2) instead of using UPPER/LOWER in a call to STRCMP.
L 28 (C 12-15): NUMEL(x) is usually faster than PROD(SIZE(x)).
L 34 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 34 (C 24-31): Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for mo
L 38 (C 29): Use || instead of | as the OR operator in (scalar) conditional statements.
L 39 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 40 (C 47): Use || instead of | as the OR operator in (scalar) conditional statements.
L 42 (C 13-16): 'data' might be growing inside a loop. Consider preallocating for speed.
L 43 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 45 (C 13-15): 'dim' might be growing inside a loop. Consider preallocating for speed.
L 48 (C 52): There may be a parenthesis imbalance around here.
L 48 (C 53): There may be a parenthesis imbalance around here.
L 48 (C 54): There may be a parenthesis imbalance around here.
L 48 (C 55): There may be a parenthesis imbalance around here.
L 49 (C 17): Terminate statement with semicolon to suppress output (in functions).
L 49 (C 23): Use of brackets [] is unnecessary. Use parentheses to group, if needed.
```

mlintrpt, profile

## How To

- For information on the suppression directive, `%#ok`, and suppressing messages from within your program, see “Adjust Code Analyzer Message Indicators and Messages”.

# mlintrpt

---

**Purpose** Run checkcode for file or folder, reporting results in browser

**Syntax**

```
mlintrpt
mlintrpt('filename','file')
mlintrpt('dirname','dir')
mlintrpt('filename','file','settings.txt')
mlintrpt('dirname','dir','settings.txt')
```

**Description** `mlintrpt` scans all files with an `.m` file extension in the current folder for Code Analyzer messages and reports the results in a MATLAB Web browser.

`mlintrpt('filename','file')` scans `filename` for Code Analyzer messages and reports results. You can omit `'file'` in this form of the syntax because it is the default.

`mlintrpt('dirname','dir')` scans the specified folder. Here, `dirname` can be in the current folder or can be a full path.

`mlintrpt('filename','file','settings.txt')` applies the Code Analyzer preference settings to enable or suppress messages as indicated in the specified `settings.txt` file.

`mlintrpt('dirname','dir','settings.txt')` applies the settings indicated in the specified `settings.txt` file.

---

**Note** If you specify a `settings.txt` file, you must specify the full path to the file.

---

**Examples** `lengthofline.m` is an example file with code that can be improved. It is found in `matlabroot/matlab/help/techdoc/matlab_env/examples`.

## Run Report for All Files in a Folder

Run

```
mlintrpt(fullfile(matlabroot,'help','techdoc','matlab_env','examples'),'dir')
```

and MATLAB displays a report of potential problems and improvements for all files with an `.m` file extension in the `examples` folder.

For details about these messages and how to improve the code, see “Changing Code Based on Code Analyzer Messages”.

### Run Report Using Code Analyzer Preference Settings

You can save preference settings to a text file by clicking the **Preferences** button in the **Environment** section on the **Home** tab and selecting **Code Analyzer** in the left pane. To save a preferences file, select **Save as** under the  drop-down list. To apply those settings when you run `mlintrpt`, use the `file` option and supply the full path to the settings file name as shown in this example:

```
mlintrpt('lengthofline.m', 'file', ...
'C:\WINNT\Profiles\me\Application Data\MathWorks\MATLAB\R2012b\mymlint.txt')
```

Alternatively, use `fullfile` if the settings file is stored in the preferences folder:

```
mlintrpt('lengthofline.m', 'file', fullfile(prefdir, 'mymlint.txt'))
```

Assuming that in that example `mymlint.txt` file, the setting for **Terminate statement with semicolon to suppress output** has been disabled, the results of `mlintrpt` for `lengthofline` do not show that message for line 49.

When `mlintrpt` cannot locate the settings file, the first message in the report is

```
0: Unable to open or read the configuration file 'mymlint.txt'--using default settings.
```

`checkcode`

## Concepts

- “Check Code for Errors and Warnings”

# mlock

---

**Purpose** Prevent clearing function from memory

**Syntax** `mlock`

**Description** `mlock` locks the currently running function in memory so that subsequent `clear` functions do not remove it. Locking a function in memory also prevents any persistent variables defined in the file from getting reinitialized.

Use the `munlock` function to return the file to its normal, clearable state.

**Examples** The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
.
.
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked('testfun')
ans =
 1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock('testfun')

mislocked('testfun')
ans =
 0
```

**See Also** `mislocked` | `munlock` | `inmem` | `persistent`

**Purpose** Information about multimedia file

**Syntax** `info = mmfileinfo(filename)`

**Description** `info = mmfileinfo(filename)` returns a structure, *info*, with fields containing information about the contents of the multimedia file identified by *filename*. The *filename* input is a string enclosed in single quotation marks.

If *filename* is a URL, `mmfileinfo` might take a long time to return because it must first download the file. For large files, downloading can take several minutes. To avoid blocking the MATLAB command line while this processing takes place, download the file before calling `mmfileinfo`.

The *info* structure contains the following fields, listed in the order they appear in the structure.

Field	Description
Filename	String indicating the name of the file.
Path	String indicating the absolute path to the file.
Duration	Length of the file in seconds.
Audio	Structure containing information about the audio data in the file. See “Audio Data” on page 1-4394 for more information about this data structure.
Video	Structure containing information about the video data in the file. See “Video Data” on page 1-4394 for more information about this data structure.

## Audio Data

The Audio structure contains the following fields, listed in the order they appear in the structure. If the file does not contain audio data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the audio format.
NumberOfChannels	Number of audio channels.

## Video Data

The Video structure contains the following fields, listed in the order they appear in the structure. If the file does not contain video data, the fields in the structure are empty.

Field	Description
Format	Text string, indicating the video format.
Height	Height of the video frame.
Width	Width of the video frame.

## Examples

Display information about the example file `xylophone.mpg`:

```
info = mmfileinfo('xylophone.mpg')
audio = info.Audio
video = info.Video
```

MATLAB returns:

```
info =
 Filename: 'xylophone.mpg'
 Path: 'matlabroot\toolbox\matlab\audiovideo'
 Duration: 4.7020
 Audio: [1x1 struct]
 Video: [1x1 struct]
```

```
audio =
 Format: 'MPEG'
 NumberOfChannels: 2
```

```
video =
 Format: 'MPEG1'
 Height: 240
 Width: 320
```

where Path is system-dependent.

## See Also

[get | VideoReader](#)

# mmreader

---

**Purpose** Create object for reading video files

---

**Note** mmreader has been removed. Use VideoReader instead.

---

**Description** Use mmreader with the read method to read video data from a multimedia file into the MATLAB workspace.

The file formats that mmreader supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	Motion JPEG 2000 (.mj2)
Windows	AVI (.avi), MPEG-1 (.mpg), Windows Media Video (.wmv, .asf, .asx), and any format supported by Microsoft DirectShow.
Macintosh	AVI (.avi), MPEG-1 (.mpg), MPEG-4 (.mp4, .m4v), Apple QuickTime Movie (.mov), and any format supported by QuickTime as listed on <a href="http://support.apple.com/kb/HT3775">http://support.apple.com/kb/HT3775</a> .
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including AVI (.avi) and Ogg Theora (.ogg).

For more information, see “Supported Video File Formats” in the MATLAB Data Import and Export documentation.

**Construction** `obj = mmreader(filename)` constructs `obj` to read video data from the file named `filename`. The mmreader constructor searches for the file on the MATLAB path. If it cannot construct the object for any reason, mmreader generates an error.

```
obj = mmreader(filename, 'PropertyName', PropertyValue)
```

constructs the object using options, specified as property name/value pairs. Property name/value pairs can be in any format that the set method supports: name/value string pairs, structures, or name/value cell array pairs.

## Properties

### **BitsPerPixel**

Bits per pixel of the video data. (Read-only)

### **Duration**

Total length of the file in seconds. (Read-only)

### **FrameRate**

Frame rate of the video in frames per second. (Read-only)

### **Height**

Height of the video frame in pixels. (Read-only)

### **Name**

Name of the file associated with the object. (Read-only)

### **NumberOfFrames**

Total number of frames in the video stream. (Read-only)

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, mmreader cannot determine the number of frames until you read the last frame. When you construct the object, mmreader returns a warning and does not set the NumberOfFrames property.

To count the number of frames in a variable frame rate file, use the read method to read the last frame of the file. For example:

```
vidObj = mmreader('varFrameRateFile.wmv');
lastFrame = read(vidObj, inf);
numFrames = vidObj.NumberOfFrames;
```

# mmreader

---

For more information, see “Read Variable Frame Rate Video” in the MATLAB Data Import and Export documentation.

## **Path**

String containing the full path to the file associated with the reader. (Read-only)

## **Tag**

User-defined string to identify the object.

**Default:** ''

## **Type**

Class name of the object: 'mmreader'. (Read-only)

## **UserData**

Generic field for user-defined data.

**Default:** []

## **VideoFormat**

String indicating the MATLAB representation of the video format, such as 'RGB24'. (Read-only)

## **Width**

Width of the video frame in pixels. (Read-only)

## **Methods**

For backward compatibility, mmreader supports the following VideoReader methods:

get	Query property values for video reader object
getFileFormats	File formats that VideoReader supports

read	Read video frame data from file
set	Set property values for video reader object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB Programming Fundamentals documentation.

## Examples

Construct an mmreader object for the example movie file xylophone.mpg and view its properties:

```
xyloObj = mmreader('xylophone.mpg', 'Tag', 'My reader object');
get(xyloObj)
```

---

Read and play back the movie file xylophone.mpg:

```
xyloObj = mmreader('xylophone.mpg');

nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;

% Preallocate movie structure.
mov(1:nFrames) = ...
 struct('cdata', zeros(vidHeight, vidWidth, 3, 'uint8'),...
 'colormap', []);

% Read one frame at a time.
for k = 1 : nFrames
 mov(k).cdata = read(xyloObj, k);
end

% Size a figure based on the video's width and height.
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])
```

# mmreader

---

```
% Play back the movie once at the video's frame rate.
movie(hf, mov, 1, xyloObj.FrameRate);
```

## How To

- “Read Video Files”

<b>Purpose</b>	Modulus after division
<b>Syntax</b>	$M = \text{mod}(X, Y)$
<b>Description</b>	<p><math>M = \text{mod}(X, Y)</math> returns the modulus after division of <math>X</math> by <math>Y</math>. In general, if <math>Y</math> does not equal 0, <math>M = \text{mod}(X, Y)</math> returns <math>X - n.*Y</math>, where <math>n = \text{floor}(X./Y)</math>. If <math>Y</math> is not an integer and the quotient <math>X./Y</math> is within roundoff error of an integer, then <math>n</math> is that integer. Inputs <math>X</math> and <math>Y</math> must have the same dimensions unless one is a scalar double. If one input has an integer data type, then the other input must be of the same integer data type or be a scalar double.</p> <p>The following are true by convention:</p> <ul style="list-style-type: none"><li>• <math>\text{mod}(X, 0)</math> is <math>X</math>.</li><li>• <math>\text{mod}(X, X)</math> is 0.</li><li>• <math>\text{mod}(X, Y)</math> for <math>X \sim Y</math> and <math>Y \sim 0</math> has the same sign as <math>Y</math>.</li></ul>
<b>Input Arguments</b>	<p><b>X - Dividend</b> scalar   vector   matrix   multidimensional array</p> <p>Dividend, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   char</p> <p><b>Y - Divisor</b> scalar   vector   matrix   multidimensional array</p> <p>Divisor, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   char</p>

## Examples

### Modulus of Two Scalars

Compute 23 modulo 5.

```
X = 23;
Y = 5;
M = mod(X,Y)
```

M =

3

### Modulus of a Vector

Create a vector, then use `mod` to find the modulus after dividing a scalar into each element of the vector.

```
X = 1:5;
Y = 3;
M = mod(X,Y)
```

M =

1 2 0 1 2

When you specify one or more of the inputs as an array, the `mod` function acts on each array element independently.

### Modulus of Two Arrays

Create two 3-by-3 matrices, then use `mod` to find the modulus after dividing `Y` into `X`.

```
X = [1 2 3;4 5 6;7 8 9];
Y = [9 8 7;6 5 4;3 2 1];
M = mod(X,Y)
```

M =

1 2 3

```

4 0 2
1 0 0

```

Inputs  $X$  and  $Y$  must have the same dimensions unless one is a scalar double.

### Forced Rounding in mod

If  $Y$  is not an integer and  $X./Y$  is within roundoff error of an integer, then `mod` rounds to that integer for its calculation. The size of the roundoff error is very small.

```

X = 2;
Y = 2 - eps(2)

```

```

Y =
 2.0000

```

It looks like  $Y$  is trivially equal to 2, but in fact there is an infinitesimal difference.

```

2 - Y
ans =
 4.4409e-16

```

This difference is forced to zero by `mod` if it is small enough.

```

M = mod(X,Y)
M =
 0

```

Make the difference a little larger and the forced rounding disappears.

```

Y = 2 - eps(4);

```

# mod

---

```
M = mod(X,Y)
```

```
M =
```

```
8.8818e-16
```

## Difference Between mod and rem

Define X and Y with different signs.

```
X = 5;
```

```
Y = -2;
```

Compute the modulus after division with `mod`, then compute the remainder after division with `rem`.

```
M = mod(X,Y)
```

```
M =
```

```
-1
```

```
R = rem(X,Y)
```

```
R =
```

```
1
```

`mod(X,Y)` and `rem(X,Y)` are equal if X and Y have the same sign, but differ by Y if X and Y have different signs. Notice that `mod` retains the sign of Y, while `rem` retains the sign of X.

## Tips

- The `mod` function is useful for congruence relationships: *x* and *y* are congruent (mod *m*) if and only if `mod(x,m) == mod(y,m)`. For example, 23 and 13 are congruent (mod 5).

## See Also

`rem`

**Purpose** Most frequent values in array

**Syntax**  
`M = mode(X)`  
`M = mode(X, dim)`

`[M, F] = mode( ___ )`  
`[M, F, C] = mode( ___ )`

**Description** `M = mode(X)` returns the sample mode of `X`, which is the most frequently occurring value in `X`. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, the smallest value is the first value in a sorted list.

- If `X` is a vector, then `mode(X)` returns the most frequent value of `X`.
- If `X` is a nonempty matrix, then `mode(X)` returns a row vector containing the mode of each column of `X`.
- If `X` is an empty 0-by-0 matrix, `mode(X)` returns NaN.
- If `X` is a multidimensional array, then `mode(X)` acts along the first nonsingleton dimension and returns an array of most frequent values. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`M = mode(X, dim)` returns the mode of elements along dimension `dim`. For example, if `X` is a matrix, then `mode(X, 2)` is a column vector containing the most frequent value of each row

`[M, F] = mode( ___ )` also returns a frequency array `F`, using any of the input arguments in the previous syntaxes. `F` is the same size as `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

`[M, F, C] = mode( ___ )` also returns a cell array `C` of the same size as `M` and `F`. Each element of `C` is a sorted vector of all values that have the same frequency as the corresponding element of `M`.

# mode

## Input Arguments

### X - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

NaN values in the input array, X, are ignored.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

### dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension `dim` indicates the dimension whose length reduces to 1. The `size(M,dim)` is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array, X.

- If `dim = 1`, then `mode(X,1)` returns a row vector containing the most frequent value in each column.
- If `dim = 2`, then `mode(X,2)` returns a column vector containing the most frequent value in each row.

`mode` returns X if `dim` is greater than `ndims(X)`.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Output  
Arguments****M - Most frequent values**

scalar | vector | matrix | multidimensional array

Most frequent values returned as a scalar, vector, matrix, or multidimensional array. When there are multiple values occurring equally frequently, `mode` returns the smallest of those values. For complex inputs, this is taken to be the first value in a sorted list of values.

The class of `M` is the same as the class of the input array, `X`.

**F - Frequency array**

scalar | vector | matrix | multidimensional array

Frequency array returned as a scalar, vector, matrix, or multidimensional array. The size of `F` is the same as the size of `M`, and each element of `F` represents the number of occurrences of the corresponding element of `M`.

The class of `F` is always `double`.

**C - Most frequent values with multiplicity**

cell array

Most frequent values with multiplicity returned as a cell array. The size of `C` is the same as the size of `M` and `F`, and each element of `C` is a sorted column vector of all values that have the same frequency as the corresponding element of `M`.

**Definitions****First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

# mode

---

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Tips

- The mode function is most useful with discrete or coarsely rounded data. The mode for a continuous probability distribution is defined as the peak of its density function. Applying the mode function to a sample from that distribution is unlikely to provide a good estimate of the peak; it would be better to compute a histogram or density estimate and calculate the peak of that estimate. Also, the mode function is not suitable for finding peaks in distributions having multiple modes.

## Examples

### Mode of Matrix Columns

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each column.

```
M = mode(X)
```

```
M =
```

```
 0 0 1 4
```

### Mode of Matrix Rows

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each row.

```
M = mode(X,2)
```

```
M =
```

```
 3
 0
 0
```

### Mode of 3-D Array

Create a 1-by-3-by-4 array of integers between 1 and 10.

```
X = gallery('integerdata',10,[1,3,4],1)
```

```
X(:,:,1) =
```

```
 10 8 10
```

```
X(:,:,2) =
```

```
 6 9 5
```

```
X(:,:,3) =
```

# mode

---

```
9 6 1
```

```
X(:,:,4) =
```

```
4 9 5
```

Find the most frequent values of this 3-D array along the second dimension.

```
M = mode(X)
```

```
M(:,:,1) =
```

```
10
```

```
M(:,:,2) =
```

```
5
```

```
M(:,:,3) =
```

```
1
```

```
M(:,:,4) =
```

```
4
```

This operation produces a 1-by-1-by-4 array by finding the most frequent value along the second dimension. The size of the second dimension reduces to 1.

Compute the mode along the first dimension of X.

```
M = mode(X,1);
isequal(X,M)
```

```
ans =
```

```
1
```

This returns the same array as  $X$  because the size of the first dimension is 1.

### Mode of Matrix Columns with Frequency Information

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
3 3 1 4
0 0 1 1
0 1 2 4
```

Find the most frequent value of each column, as well as how often it occurs.

```
[M,F] = mode(X)
```

```
M =
```

```
0 0 1 4
```

```
F =
```

```
2 1 2 2
```

$F(1)$  is 2 since  $M(1)$  occurs twice in the first column.

## Mode of Matrix Rows with Frequency and Multiplicity Information

Define a 3-by-4 matrix.

```
X = [3 3 1 4; 0 0 1 1; 0 1 2 4]
```

```
X =
```

```
 3 3 1 4
 0 0 1 1
 0 1 2 4
```

Find the most frequent value of each row, how often it occurs, and which values in that row occur with the same frequency.

```
[M,F,C] = mode(X,2)
```

```
M =
```

```
 3
 0
 0
```

```
F =
```

```
 2
 2
 1
```

```
C =
```

```
 [3]
 [2x1 double]
 [4x1 double]
```

$C\{2\}$  is the 2-by-1 vector  $[0;1]$  since values 0 and 1 in the second row occur with frequency  $F(2)$ .

$C\{3\}$  is the 4-by-1 vector  $[0;1;2;4]$  since all values in the third row occur with frequency  $F(3)$ .

### Mode of 16-bit Unsigned Integer Array

Define a 1-by-4 vector of 16-bit unsigned integers.

```
X = gallery('integerdata',10,[1,4],3,'uint16')
```

```
X =
```

```
 6 3 2 3
```

Find the most frequent value, as well as the number of times it occurs.

```
[M,F] = mode(X),
class(M)
```

```
M =
```

```
 3
```

```
F =
```

```
 2
```

```
ans =
```

```
uint16
```

$M$  is the same class as the input,  $X$ .

[mean](#) | [median](#) | [hist](#) | [histc](#) | [sort](#)

# more

---

**Purpose** Control paged output for Command Window

**Syntax**

```
more on
more off
more(n)
A = more(state)
```

**Description** `more on` enables paging of the output in the MATLAB Command Window. MATLAB displays output one page at a time. Use the keys defined in the table below to control paging.

`more off` disables paging of the output in the MATLAB Command Window.

`more(n)` defines the length of a page to be `n` lines.

`A = more(state)` returns in `A` the number of lines that are currently defined to be a page. The `state` input can be one of the quoted strings `'on'` or `'off'`, or the number of lines to set as the new page length.

By default, the length of a page is equal to the number of lines available for display in the MATLAB Command Window. Manually changing the size of the command window adjusts the page length accordingly.

If you set the page length to a specific value, MATLAB uses that value for the page size, regardless of the size of the command window. To have MATLAB return to matching page size to window size, type `more off` followed by `more on`.

To see the status of `more`, type `get(0, 'More')`. MATLAB returns either `on` or `off`, indicating the `more` status.

When you have enabled `more` and are examining output, you can do the following.

<b>Press the...</b>	<b>To...</b>
Return key	Advance to the next line of output.
Space bar	Advance to the next page of output.
Q (for quit) key	Terminate display of the text. Do not use <b>Ctrl+C</b> to terminate <b>more</b> or you might generate error messages in the Command Window.

**more** is in the **off** state, by default.

**See Also**

diary

# move

---

**Purpose** Move or resize control in parent window

**Syntax** `V = h.move(position)`  
`V = move(h, position)`

**Description** `V = h.move(position)` moves the control to the position specified by the `position` argument. When you use `move` with only the handle argument, `h`, it returns a four-element vector indicating the current position of the control.

`V = move(h, position)` is an alternate syntax.

The `position` argument is a four-element vector specifying the position and size of the control in the parent figure window. The elements of the vector are:

`[x, y, width, height]`

where `x` and `y` are offsets, in pixels, from the bottom left corner of the figure window to the same corner of the control, and `width` and `height` are the size of the control itself.

**Examples** This example moves the control:

```
f = figure('Position', [100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1', [0 0 200 200], f);
pos = h.move([50 50 200 200])
```

```
pos =
 50 50 200 200
```

The next example resizes the control to always be centered in the figure as you resize the figure window. Start by creating the script `resizectl.m` that contains

```
% Get the new position and size of the figure window
fpos = get(gcbo, 'position');
```

---

```
% Resize the control accordingly
h.move([0 0 fpos(3) fpos(4)]);
```

Now execute the following:

```
f = figure('Position', [100 100 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.1', [0 0 200 200]);
set(f, 'ResizeFcn', 'resizectrl');
```

As you resize the figure window, notice that the circle moves so that it is always positioned in the center of the window.

## See Also

set (COM) | get (COM)

# movefile

---

## Purpose

Move file or folder

## Syntax

```
movefile('source')
movefile('source','destination')
movefile('source','destination','f')
[status,message,messageid] = movefile(___)
```

## Description

`movefile('source')` moves the file or folder named `source` to the current folder, where `source` is the absolute or relative path name for the folder or file. To move multiple files or folders, use one or more wildcard characters (\*) after the last file separator in `source`. The `source` argument permits a wildcard character in a path string. `movefile` does not preserve the archive attribute of `source`.

`movefile('source','destination')` moves the file or folder named `source` to the location `destination`, where `source` and `destination` are the absolute or relative paths for the folder or file. To move multiple files or folders, you can use one or more wildcard characters (\*) after the last file separator in `source`. You cannot use a wildcard character in `destination`. To rename a file or folder when moving it, make `destination` a different name than `source`, and specify only one file for `source`. When `source` and `destination` have the same location, `movefile` renames `source` to `destination`.

`movefile('source','destination','f')` moves the file or folder named `source` to the location `destination`, regardless of the read-only attribute of `destination`.

`[status,message,messageid] = movefile( ___ )` moves the file or folder named `source` to the location `destination`, returning the `status`, a message, and the MATLAB message ID. Here, `status` is logical 1 for success or logical 0 for error. `movefile` requires only one output argument.

## Examples

### Moving a File to the Current Folder

Assuming `myfiles` is a subfolder within the current folder, move the file `myfunction.m` to the current folder:

```
movefile('myfiles/myfunction.m')
```

Assuming `projects/testcases` is the current folder, move `projects/myfiles` and its contents to the current folder:

```
movefile('../myfiles')
```

## Renaming a File in the Current Folder

In the current folder, rename `myfunction.m` to `oldfunction.m`:

```
movefile('myfunction.m','oldfunction.m')
```

## Using a Wildcard to Move All Matching Files

Assuming `myfiles` is a subfolder of the current folder, move all files whose names that begin with `my` from the `myfiles` folder, to the current folder:

```
movefile('myfiles/my*')
```

## Moving a File to a Different Folder

Assuming `projects` and the current folder are at the same level, move the file `myfunction.m` from the current folder to the folder `projects`:

```
movefile('myfunction.m','../projects')
```

## Moving a Folder Down One Level

Assuming `projects` is a subfolder of the current folder, move the folder `projects/testcases` and all its contents down a level in `projects` into `projects/myfiles`:

```
movefile('projects/testcases','projects/myfiles/')
```

## Moving a File to a Read-Only Folder and Renaming the File

Move the file `myfile.m` from the current folder to `d:/work/restricted`, assigning it the name `test1.m`, where `restricted` is a read-only folder:

```
movefile('myfile.m','d:/work/restricted/test1.m','f')
```

# movefile

---

The read-only file `myfile.m` is no longer in the current folder. The file `test1.m` is in `d:/work/restricted` and is read only.

## Returning Status When Moving Files

Move all files in the folder `myfiles` whose names start with `new` to the current folder, when there is an error. You mistype `new*` as `nex*` and no items in the current folder start with `nex*`:

```
[s,mess,messid] = movefile('myfiles/nex*')
```

```
s =
 0
```

```
mess =
```

```
No matching files were found.
```

```
messid =
```

```
MATLAB:MOVEFILE:FileDoesNotExist
```

## See Also

```

## How To

- “Manage Files and Folders”

**Purpose** Move GUI figure to specified location on screen

**Syntax**

```
movegui(h, 'position')
movegui(position)
movegui(h)
movegui
```

**Description** `movegui(h, 'position')` moves the figure identified by handle `h` to the specified screen location, preserving the figure's size. The `position` argument is either a string or a two-element vector, as defined in the tables that follow.

`movegui(position)` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the specified position.

`movegui(h)` moves the figure identified by the handle `h` to the onscreen position.

`movegui` moves the callback figure (`gcbf`) or the current figure (`gcf`) to the onscreen position. You can specify 'movegui' as a `CreateFcn` callback for a figure. Doing so ensures after you save a figure, that figure appears on screen when you reload it, regardless of its saved position. See the following example.

When it is a string, `position` is one of the following descriptors.

Position String	Description
north	Top center edge of screen
south	Bottom center edge of screen
east	Right center edge of screen
west	Left center edge of screen
northeast	Top right corner of screen
northwest	Top left corner of screen
southeast	Bottom right corner of screen

# movegui

---

Position String	Description
southwest	Bottom left corner
center	Centered on screen
onscreen	Nearest location to current location that is entirely on screen

You can also specify the *position* argument as a two-element vector,  $[h, v]$ . Depending on sign,  $h$  specifies the figure's offset from the left or right edge of the screen, and  $v$  specifies the figure's offset from the top or bottom of the screen, in pixels. The following table summarizes the possible values.

$h$ (for $h \geq 0$ )	Offset of left side from left edge of screen
$h$ (for $h < 0$ )	Offset of right side from right edge of screen
$v$ (for $v \geq 0$ )	Offset of bottom edge from bottom of screen
$v$ (for $v < 0$ )	Offset of top edge from top of screen

Applying `movegui` to a maximized figure window moves the window towards the task bar and creates a gap on the opposite side of the screen about as wide as the task bar. The window might shrink in size by a few pixels. If you use the `onscreen` option with a maximized figure window, then `movegui` creates a gap on both the left and upper sides of the screen so that the top-left corner of the figure is visible.

`GUIDE` and `openfig` call `movegui` when loading figures to ensure they are visible.

## Examples

Ensure that a saved GUI appears on screen when you reload it, regardless of the target computer screen size and resolution. Create a

---

figure that is off the screen, assign `movegui` as its `CreateFcn` callback, save the figure, and then reload it.

```
f = figure('Position',[10000,10000,400,300]);
% The figure does not display because
% it is created offscreen.
set(f,'CreateFcn','movegui')
hgsave(f,'onscreenfig')
close(f)
f2 = hgload('onscreenfig');
% The reloaded figure is now visible
```

---

Move a figure to the bottom left corner of the screen.

```
f = figure;
movegui(f,'southwest');
```

---

Move a figure so that it is offset 100 pixels from the bottom and left side of the screen.

```
f = figure;
movegui(f,[100,100]);
```

## How To

- “Positioning Figures”

# movie

---

**Purpose** Play recorded movie frames

**Syntax**

```
movie(M)
movie(M,n)
movie(M,n,fps)
movie(h,...)
movie(h,M,n,fps,loc)
```

**Description** The `movie` function plays the movie defined by a matrix whose columns are movie frames (usually produced by `getframe`).

`movie(M)` plays the movie in matrix `M` once, using the current axes as the default target. If you want to play the movie in the figure instead of the axes, specify the figure handle (or `gcf`) as the first argument: `movie(figure_handle,...)`. `M` must be an array of movie frames (usually from `getframe`).

`movie(M,n)` plays the movie `n` times. If `n` is negative, each cycle is shown forward then backward. If `n` is a vector, the first element is the number of times to play the movie, and the remaining elements make up a list of frames to play in the movie.

For example, if `M` has four frames then `n = [10 4 4 2 1]` plays the movie ten times, and the movie consists of frame 4 followed by frame 4 again, followed by frame 2 and finally frame 1.

`movie(M,n,fps)` plays the movie at `fps` frames per second. The default is 12 frames per second. Computers that cannot achieve the specified speed play as fast as possible.

`movie(h,...)` plays the movie centered in the figure or axes identified by the handle `h`. Specifying the figure or axes enables MATLAB to fit the movie to the available size.

`movie(h,M,n,fps,loc)` specifies `loc`, a four-element location vector, `[x y 0 0]`, where the lower left corner of the movie frame is anchored (only the first two elements in the vector are used). The location is relative to the lower left corner of the figure or axes specified by handle `h` and in units of pixels, regardless of the object's `Units` property.

**Tips**

The `movie` function uses a default figure size of 560-by-420 and does not resize figures to fit movies with larger or smaller frames. To accommodate other frame sizes, you can resize the figure to fit the movie, as shown in the second example below.

`movie` only accepts 8-bit image frames; it does not accept 16-bit grayscale or 24-bit truecolor image frames.

Buffering the movie places all frames in memory. As a result, on Microsoft Windows and perhaps other platforms, a long movie (on the order of several hundred frames) can exhaust memory, depending on system resources. In such cases an error message is issued that says

```
??? Error using ==> movie
Could not create movie frame
```

You can abort a movie by typing **Ctrl-C**.

`movie` is not a built-in function. Therefore, you cannot call `movie` using the `builtin` function.

**Limitations with Renderer on Windows Systems**

Setting the figure `Renderer` property to `zbuffer` or `painters` works around limitations of using `getframe` with the OpenGL renderer on some Windows systems.

**Examples**

Animate the `peaks` function as you scale the values of `Z`:

```
figure('Renderer','zbuffer')
Z = peaks;
surf(Z);
axis tight manual
set(gca,'NextPlot','replaceChildren');
% Preallocate the struct array for the struct returned by getframe
F(20) = struct('cdata',[],'colormap',[]);
% Record the movie
for j = 1:20
 surf(.01+sin(2*pi*j/20)*Z,Z)
 F(j) = getframe;
```

# movie

---

```
end
```

Now play the movie ten times. The twelfth frame looks like the following plot.

```
movie(F,10)
```

---

With larger frames, first adjust the figure's size to fit the movie:

```
figure('Position',[100 100 850 600])
```

```
Z = peaks; surf(Z);
axis tight manual
set(gca,'NextPlot','replacechildren');
% Record the movie
for j = 1:20
 surf(sin(2*pi*j/20)*Z,Z)
 F(j) = getframe;
end
% use 1st frame to get dimensions
[h, w, p] = size(F(1).cdata);
hf = figure;
% resize figure based on frame's w x h, and place at (150, 150)
set(hf,'Position', [150 150 w h]);
axis off
% Place frames at bottom left
movie(hf,F,4,30,[0 0 0 0]);
```

**See Also**

**How To**

- [Example – Visualizing an FFT as a Movie](#)

# movie2avi

---

**Purpose** Create Audio/Video Interleaved (AVI) file from MATLAB movie

**Syntax** `movie2avi(mov, filename)`  
`movie2avi(mov, filename, ParameterName, ParameterValue)`

**Description** `movie2avi(mov, filename)` creates the AVI file `filename` from the MATLAB movie `mov`. The `filename` input is a string. The `mov` input is a 1-by- $n$  structure array, where  $n$  is the number of frames. Each frame is a structure with two fields: `cdata` and `colormap`. For more information, see `getframe`.

`movie2avi(mov, filename, ParameterName, ParameterValue)` accepts one or more comma-separated parameter name/value pairs. The following table lists the available parameters and values.

Parameter Name	Value	Default
'colormap'	An $m$ -by-3 matrix defining the colormap for indexed AVI movies, where $m$ is no more than 256 (236 for Indeo compression).  Valid only when the 'compression' is 'MSVC', 'RLE', or 'None'.	No default
'compression'	A text string specifying the compression codec to use. To create an uncompressed file, specify a value of 'None'.  On UNIX operating systems, the only valid value is 'None'.  On Windows systems, valid values include: <ul style="list-style-type: none"><li>• 'MSVC'</li><li>• 'RLE'</li><li>• 'Cinepak' on 32-bit systems.</li></ul>	'Indeo5' on Windows systems.  'None' on UNIX systems.

Parameter Name	Value	Default
	<ul style="list-style-type: none"> <li>'Indeo3' or 'Indeo5' on 32-bit Windows XP systems.</li> </ul> <p>Alternatively, specify a custom compression codec on Windows systems using the four-character code that identifies the codec (typically included in the codec documentation). If MATLAB cannot find the specified codec, it returns an error.</p>	
'fps'	A scalar value specifying the speed of the AVI movie in frames per second (fps).	15 fps
'keyframe'	For compressors that support temporal compression, the number of key frames per second.	2.1429 key frames per second
'quality'	A number from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.  Valid only for compressed movies.	75
'videoname'	A descriptive name for the video stream, no more than 64 characters.	<i>filename</i>

**Tips**

- On some Windows systems, including all 64-bit systems, the default Indeo 5 codec is not available. MATLAB issues a warning, and creates an uncompressed file.
- On 32-bit Windows XP systems, MATLAB can create AVI files compressed with Indeo 3 and Indeo 5 codecs. However, Microsoft Windows XP Service Pack 3 (SP3) with Security Update 954157 disables playback of Indeo 3 and Indeo 5 codecs in Windows Media Player and Internet Explorer. Consider specifying a compression value of 'None'.

## Examples

Create a movie and write to an uncompressed AVI file, `myPeaks.avi`:

```
nFrames = 20;

% Preallocate movie structure.
mov(1:nFrames) = struct('cdata', [],...
 'colormap', []);

% Create movie.
Z = peaks; surf(Z);
axis tight
set(gca, 'nextplot', 'replacechildren');
for k = 1:nFrames
 surf(sin(2*pi*k/20)*Z, Z)
 mov(k) = getframe(gcf);
end

% Create AVI file.
movie2avi(mov, 'myPeaks.avi', 'compression', 'None');
```

**Purpose** Matrix power

**Syntax**  
 $C = A^B$   
`C = mpower(A,B)`

**Description**  $C = A^B$  computes A to the B power and returns the result in C.

$C = \text{mpower}(A,B)$  is an alternate way to execute  $A^B$ , but is rarely used. It enables operator overloading for classes.

**Input Arguments** **A - Base**  
 scalar | matrix

Base, specified as a scalar or matrix. Inputs A and B must be one of the following:

- Base A is a square matrix and exponent B is a scalar. If B is a positive integer, the power is computed by repeated squaring. For other values of B the calculation involves eigenvalues and eigenvectors.
- Base A is a scalar and exponent B is a square matrix. The calculation uses eigenvalues and eigenvectors.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**B - Exponent**  
 scalar | matrix

Exponent, specified as a scalar or matrix. Inputs A and B must be one of the following:

- Base A is a square matrix and exponent B is a scalar. If B is a positive integer, the power is computed by repeated squaring. For other values of B the calculation involves eigenvalues and eigenvectors.

- Base A is a scalar and exponent B is a square matrix. The calculation uses eigenvalues and eigenvectors.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Square a Matrix

Create a 2-by-2 matrix and square it.

```
A = [1 2; 3 4];
C = A^2
```

```
C =
```

```
 7 10
 15 22
```

The syntax A^2 is equivalent to A\*A.

### Matrix Exponents

Create a 2-by-2 matrix and use it as the exponent for a scalar.

```
B = [0 1; 1 0];
C = 2^B
```

```
C =
```

```
 1.2500 0.7500
 0.7500 1.2500
```

Compute C by first finding the eigenvalues D and eigenvectors V of the matrix B.

```
[V,D] = eig(B)
```

V =

```
-0.7071 0.7071
 0.7071 0.7071
```

D =

```
-1 0
 0 1
```

Next, use the formula  $2^B = V*2^D/V$  to compute the power.

C = V\*2^D/V

C =

```
1.2500 0.7500
 0.7500 1.2500
```

power | mtimes | times

# FTP.mput

---

**Purpose** Upload file or folder to FTP server

**Syntax** `mput(ftpobj,contents)`  
`paths = mput(ftpobj,contents)`

**Description** `mput(ftpobj,contents)` uploads the file or folder specified by `contents` to the current folder on an FTP server.

`paths = mput(ftpobj,contents)` returns a cell array that lists the paths to the uploaded files on the server.

**Input Arguments** **ftpobj**  
FTP object created by `ftp`.

**contents**  
String enclosed in single quotation marks that specifies either a file name or a folder name. Can include a wildcard character (\*).

**Output Arguments** **paths**  
Cell array that includes the paths to the uploaded files on the server.

**Examples** Suppose that your current MATLAB folder contains files `myfile1.m` through `myfile10.m`, and that you want to upload to a hypothetical FTP server, `ftp.testsite.com`. Connect to the server and upload the files:

```
test = ftp('ftp.testsite.com');
mput(test, 'myfile*.m');
close(test);
```

**See Also** `mget` | `ftp` | `mkdir` | `rename`

<b>Purpose</b>	Create and open message dialog box
<b>Syntax</b>	<pre>h = msgbox(Message) h = msgbox(Message,Title) h = msgbox(Message,Title,Icon) h = msgbox(Message,Title,'custom',IconData,IconCMap) h = msgbox( ___,CreateMode)</pre>
<b>Description</b>	<p><code>h = msgbox(Message)</code> creates a message dialog box that automatically wraps <code>Message</code> to fit an appropriately sized figure.</p> <p><code>h = msgbox(Message,Title)</code> specifies the title of the message box.</p> <p><code>h = msgbox(Message,Title,Icon)</code> specifies which built-in icon to display in the message dialog box.</p> <p><code>h = msgbox(Message,Title,'custom',IconData,IconCMap)</code> specifies a custom icon to include in the message dialog box. <code>IconData</code> is the image data that defines the icon. <code>IconCMap</code> is the colormap used for the image. If <code>IconData</code> is a true-color image, you do not need to specify an <code>IconCMap</code>.</p> <p><code>h = msgbox( ___,CreateMode)</code> specifies whether the message box is modal. Additionally, you can specify a TeX interpreter for <code>Message</code> and <code>Title</code>.</p>
<b>Input Arguments</b>	<p><b>Message - Message dialog box text</b> string vector   string matrix   cell array</p> <p>Dialog box text specified as a string vector, string matrix, or cell array.</p> <p><b>Example:</b> 'Operation Completed'</p> <p><b>Example:</b> ['Operation ', 'Completed']</p> <p><b>Example:</b> {'Operation', 'Completed'}</p>

## **Title - Message dialog box title bar text**

string vector

Dialog box title bar text specified as a string vector.

**Example:** 'Success'

## **Icon - Icon to include in message dialog box**

'none' (default) | 'error' | 'help' | 'warn' | 'custom'

Icon to include in message dialog box specified as a string.

Built-in icons appear as follows:

-  Error
-  Help
-  Warn

## **IconData - Image data defining a custom icon**

matrix

Image data defining a custom icon specified as a matrix. Each element of the matrix specifies the color of a rectangular segment in the image. Use `imread` to get the `IconData` value for an image that you want to use as a message dialog box icon.

**Example:** `[1:64]'*[1:64])/64`

## **IconCMap - Colormap for a custom icon that is not true-color**

m-by-3 matrix | built-in colormap

Colormap for a custom icon that is not true-color, specified as a m-by-3 matrix of real numbers between 0.0 and 1.0, or as a MATLAB built-in colormap. Use `imread` to get the `IconCMap` value for an image that you want to use as a message dialog box icon.

**Example:** `[0.5 0.5 0.5]`

**Example:** `hot(64)`

**CreateMode - Message dialog box mode**

structure | 'nonmodal' (default) | 'modal' | 'replace'

Mode in which message dialog box is created, specified as a string or a structure.

- If `CreateMode` is a structure, it can have the fields `WindowStyle` and `Interpreter`. The `WindowStyle` field must be one of the strings listed in the list items that follow this one. The `Interpreter` field must be the string 'tex' or 'none'. If the `Interpreter` value is 'tex', MATLAB interprets the `Message` and `Title` values as TeX. The default value for `Interpreter` is 'none'.
- If `CreateMode` is 'nonmodal', MATLAB creates a new nonmodal message box with the specified parameters. Existing message boxes with the same `Title` remain.
- If `CreateMode` is 'modal', MATLAB replaces the existing message box with the specified `Title` that was last created or clicked on with the specified modal dialog box. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.
- If `CreateMode` is 'replace', MATLAB replaces the message box having the specified `Title` that was last created or clicked on with a nonmodal message box as specified. MATLAB deletes all other message boxes with the same title. The replaced message box can be either modal or nonmodal.

**Example:** `CreateStruct.Interpreter='tex';`

**Output Arguments****h - Message dialog box handle**

scalar

Message dialog box handle returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific message dialog box.

## Tips

- Program execution continues even when a modal dialog box is active. To block MATLAB program execution until the user responds to the modal dialog box, use the `uiwait` function.
- If you open a dialog box with `errordlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a nonmodal dialog box that was created with any of these functions is already present and *has the same title as the modal dialog box*, then the nonmodal dialog box closes when the modal one opens.

## Definitions

### modal dialog box

A modal dialog box prevents a user from interacting with other windows before responding to the modal dialog box.

For more information about modal dialog boxes, see `WindowStyle` in the `Figure Properties` topic.

## Examples

### Simple Message Dialog Box

Specify the text you want displayed in the message dialog box.

```
h = msgbox('Operation Completed');
```

### Message Dialog Box Text with Line Breaks

Specify the message dialog box text using a cell array of strings to insert line breaks between the display of each string in the cell array.

```
h = msgbox({'Operation' 'Completed'});
```

### Message Dialog Box with a Title

Specify the message dialog box text and give the dialog box a title, Success.

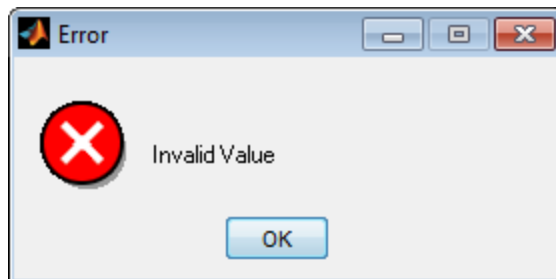

```
h = msgbox('Operation Completed', 'Success');
```

### Message Dialog Box that Uses a Built-in Icon

Include a built-in error icon with an error message in a message dialog box entitled Error.

```
h = msgbox('Invalid Value', 'Error', 'error');
```

## Message Dialog Box that Uses a True-Color Custom Icon

Use a .png file as an icon in your message dialog box. True-color images, such as .png files, do not use colormaps.

Copy a .png file to a folder on your MATLAB search path.

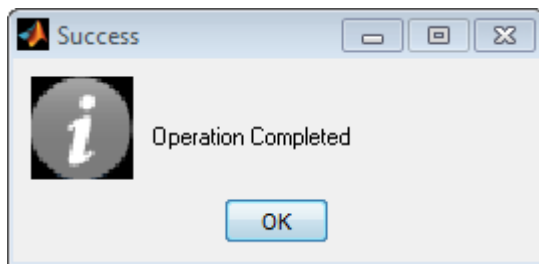

```
copyfile(fullfile(matlabroot,...
 'help','includes','product',...
 'images','global','ico_large_info.png'));
```

Determine the value to specify for `IconData` by passing the image file to `imread`.

```
[cdata] = imread('ico_large_info.png');
```

Create the message dialog box, including the custom icon. Because .png files are true-color, you do not specify a colormap.

```
h=msgbox('Operation Completed',...
 'Success','custom',cdata);
```

## Message Dialog Box that Uses an Indexed Custom Icon

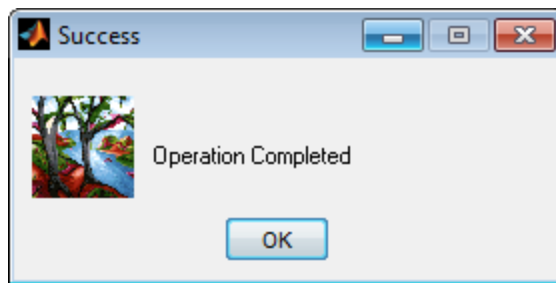

Use `trees.tif` (which is on the MATLAB path) as an icon in your message dialog box. Because .tiff images use a colormap to define the colors, you must specify a colormap. Change the colormap to change the image colors.

Determine the value to specify for `IconData` by passing the image file to `imread`.

```
[cdata,map] = imread('trees.tif');
```

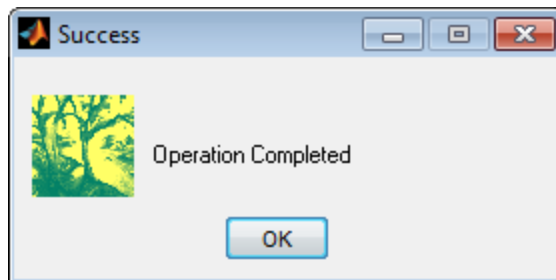

Create the message dialog box, including the custom icon.

```
h=msgbox('Operation Completed',...
 'Success','custom',cdata,map);
```

Adjust the image colors by specifying a different colormap. For instance, specify the MATLAB built-in colormap, `summer`

```
h=msgbox('Operation Completed','Success','custom',...
 cdata,summer);
```

## Modal Message Dialog Box

Create a modal message dialog box, wrapping the call to `msgbox` with `uiwait` to make the message dialog box block MATLAB execution until the user responds to the message dialog box.

```
uiwait(msgbox('Operation Completed','Success','modal'));
```

## Modal Message Dialog Box that Uses a TeX Formatted Message

Create a structure to specify that the user must click OK before interacting with another window and that MATLAB interpret the message text as TeX format.

```
CreateStruct.Interpreter = 'tex';
CreateStruct.WindowStyle = 'modal';
```

Create the message dialog box.

```
h=msgbox('Z = X^2 + Y^2','Value',CreateStruct);
```

**Concepts**

- “Reading Image Data”

# mtimes, \*

---

**Purpose** Matrix Multiplication

**Syntax**  
`C = A*B`  
`C = mtimes(A,B)`

**Description** `C = A*B` is the matrix product of `A` and `B`. If `A` is an `m`-by-`p` and `B` is a `p`-by-`n` matrix, then `C` is an `m`-by-`n` matrix defined by

$$C(i,j) = \sum_{k=1}^p A(i,k)B(k,j).$$

This definition says that `C(i,j)` is the inner product of the `i`th row of `A` with the `j`th column of `B`. You can write this definition using the MATLAB colon operator as

$$C(i,j) = A(i,:) * B(:,j)$$

For nonscalar `A` and `B`, the number of columns of `A` must equal the number of rows of `B`. Matrix multiplication is *not* universally commutative for nonscalar inputs. That is, `A*B` is typically not equal to `B*A`. If at least one input is scalar, then `A*B` is equivalent to `A.*B` and is commutative.

`C = mtimes(A,B)` is an alternative way to execute `A*B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

**A - Left Array**  
scalar | vector | matrix

Left Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in `A` must be equal to the number of rows in `B`.

**Data Types**  
single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**B - Right Array**

scalar | vector | matrix

Right Array, specified as a scalar, vector, or matrix. For nonscalar inputs, the number of columns in A must be equal to the number of rows in B.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**Output Arguments**

**C - Product Array**

scalar | vector | matrix

Product Array, returned as a scalar, vector, or matrix. Array C has the same number of rows as input A and the same number of columns as input B. For example, if A is an m-by-0 empty matrix and B is a 0-by-n empty matrix, then A\*B is an m-by-n matrix of zeros.

**Examples**

**Multiply Two Vectors**

Create a 1-by-4 row vector, A, and a 4-by-1 column vector, B.

```
A = [1 1 0 0];
B = [1; 2; 3; 4];
```

Multiply A times B.

```
C = A*B
```

```
C =
```

```
3
```

The result is a 1-by-1 scalar, also called the *dot product* or *inner product* of the vectors A and B. Alternatively, you can calculate the dot product  $A \cdot B$  with the syntax `dot(A,B)`.

Multiply B times A.

```
C = B*A
```

```
C =
```

```
 1 1 0 0
 2 2 0 0
 3 3 0 0
 4 4 0 0
```

The result is a 4-by-4 matrix, also called the *outer product* of the vectors A and B. The outer product of two vectors,  $A \otimes B$ , returns a matrix.

## Multiply Two Arrays

Create two arrays, A and B.

```
A = [1 3 5; 2 4 7];
```

```
B = [-5 8 11; 3 9 21; 4 0 8];
```

Calculate the product of A and B.

```
C = A*B
```

```
C =
```

```
 24 35 114
 30 52 162
```

Calculate the inner product of the second row of A and the third column of B.

```
A(2,:) * B(:,3)
```

```
ans =
```

```
 162
```

This answer is the same as  $C(2,3)$ .

**See Also**

# mu2lin

---

**Purpose** Convert mu-law audio signal to linear

**Syntax** `y = mu2lin(mu)`

**Description** `y = mu2lin(mu)` converts mu-law encoded 8-bit audio signals, stored as “flints” in the range  $0 \leq \mu \leq 255$ , to linear signal amplitude in the range  $-s < Y < s$  where  $s = 32124/32768 \approx .9803$ . The input `mu` is often obtained using `fread(..., 'uchar')` to read byte-encoded audio files. “Flints” are MATLAB integers — floating-point numbers whose values are integers.

**See Also** `auread` | `lin2mu`

## Purpose

Read band-interleaved data from binary file

## Syntax

```
X = multibandread(filename, size, precision, offset, interleave,
 bytearray)
X = multibandread(...,subset1,subset2,subset3)
```

## Description

`X = multibandread(filename, size, precision, offset, interleave, bytearray)` reads band-sequential (BSQ), band-interleaved-by-line (BIL), or band-interleaved-by-pixel (BIP) data from the binary file `filename`. The `filename` input is a string enclosed in single quotes. This function defines *band* as the third dimension in a 3-D array, as shown in this figure.

You can use the parameters to `multibandread` to specify many aspects of the read operation, such as which bands to read. See “Parameters” on page 1-4450 for more information.

`X` is a 2-D array if only one band is read; otherwise it is 3-D. `X` is returned as an array of data type `double` by default. Use the `precision` parameter to map the data to a different data type.

`X = multibandread(...,subset1,subset2,subset3)` reads a subset of the data in the file. You can use up to three subsetting parameters to specify the data subset along row, column, and band dimensions. See “Subsetting Parameters” on page 1-4451 for more information.

# multibandread

---

---

**Note** In addition to BSQ, BIL, and BIP files, multiband imagery may be stored using the TIFF file format. In that case, use the `imread` function to import the data.

---

## Parameters

This table describes the arguments accepted by `multibandread`.

Argument	Description
<code>filename</code>	String containing the name of the file to be read.
<code>size</code>	Three-element vector of integers consisting of [height, width, N], where <ul style="list-style-type: none"><li>• height is the total number of rows</li><li>• width is the total number of elements in each row</li><li>• N is the total number of bands.</li></ul> This will be the dimensions of the data if it is read in its entirety.
<code>precision</code>	String specifying the format of the data to be read, such as 'uint8', 'double', 'integer*4', or any of the other precisions supported by the <code>fread</code> function.  Note: You can also use the <code>precision</code> parameter to specify the format of the output data. For example, to read <code>uint8</code> data and output a <code>uint8</code> array, specify a precision of 'uint8=>uint8' (or '*uint8'). To read <code>uint8</code> data and output it in the MATLAB software in single precision, specify 'uint8=>single'. See <code>fread</code> for more information.

<b>Argument</b>	<b>Description</b>
offset	Scalar specifying the zero-based location of the first data element in the file. This value represents the number of bytes from the beginning of the file to where the data begins.
interleave	String specifying the format in which the data is stored <ul style="list-style-type: none"> <li>• 'bsq' — Band-Sequential</li> <li>• 'bil' — Band-Interleaved-by-Line</li> <li>• 'bip' — Band-Interleaved-by-Pixel</li> </ul> <p>For more information about these interleave methods, see the <a href="#">multibandwrite</a> reference page.</p>
byteorder	String specifying the byte ordering (machine format) in which the data is stored, such as <ul style="list-style-type: none"> <li>• 'ieee-le' — Little-endian</li> <li>• 'ieee-be' — Big-endian</li> </ul> <p>See <code>fopen</code> for a complete list of supported formats.</p>

## Subsetting Parameters

You can specify up to three subsetting parameters. Each subsetting parameter is a three-element cell array, `{dim, method, index}`, where

<b>Parameter</b>	<b>Description</b>
<i>dim</i>	Text string specifying the dimension to subset along. It can have any of these values: <ul style="list-style-type: none"> <li>• 'Column'</li> <li>• 'Row'</li> </ul>

# multibandread

---

Parameter	Description
<i>method</i>	<ul style="list-style-type: none"><li>• 'Band'</li></ul> Text string specifying the subsetting method. It can have either of these values: <ul style="list-style-type: none"><li>• 'Direct'</li><li>• 'Range'</li></ul>
<i>index</i>	If you leave out this element of the subset cell array, <code>multibandread</code> uses 'Direct' as the default. If method is 'Direct', <i>index</i> is a vector specifying the indices to read along the Band dimension. If method is 'Range', <i>index</i> is a three-element vector of [start, increment, stop] specifying the range and step size to read along the dimension specified in <i>dim</i> . If <i>index</i> is a two-element vector, <code>multibandread</code> assumes that the value of increment is 1.

## Examples

### Example 1

Setup initial parameters for a data set.

```
rows=3; cols=3; bands=5;
filename = tempname;
```

Define the data set.

```
fid = fopen(filename, 'w', 'ieee-le');
fwrite(fid, 1:rows*cols*bands, 'double');
fclose(fid);
```

Read every other band of the data using the Band-Sequential format.

```
im1 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bsq', 'ieee-le', ...
 {'Band', 'Range', [1 2 bands]})
```

Read the first two rows and columns of data using  
Band-Interleaved-by-Pixel format.

```
im2 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bip', 'ieee-le', ...
 {'Row', 'Range', [1 2]}, ...
 {'Column', 'Range', [1 2]})
```

Read the data using Band-Interleaved-by-Line format.

```
im3 = multibandread(filename, [rows cols bands], ...
 'double', 0, 'bil', 'ieee-le')
```

Delete the file created in this example.

```
delete(filename);
```

## Example 2

Read int16 BIL data from the FITS file `tst0012.fits`, starting at  
byte 74880.

```
im4 = multibandread('tst0012.fits', [31 73 5], ...
 'int16', 74880, 'bil', 'ieee-be', ...
 {'Band', 'Range', [1 3]});
im5 = double(im4)/max(max(max(im4)));
imagesc(im5);
```

## See Also

`fread` | `fwrite` | `imread` | `memmapfile` | `multibandwrite`

# multibandwrite

---

**Purpose** Write band-interleaved data to file

**Syntax** `multibandwrite(data,filename,interleave)`  
`multibandwrite(data,filename,interleave,start,totalsize)`  
`multibandwrite(...,param,value...)`

**Description** `multibandwrite(data,filename,interleave)` writes `data`, a two- or three-dimensional numeric or logical array, to the binary file specified by `filename`. The `filename` input is a string enclosed in single quotes. The length of the third dimension of `data` determines the number of bands written to the file. The bands are written to the file in the form specified by `interleave`. See “Interleave Methods” on page 1-4456 for more information about this argument.

If `filename` already exists, `multibandwrite` overwrites it unless you specify the optional `offset` parameter. See the last alternate syntax for `multibandwrite` for information about other optional parameters.

`multibandwrite(data,filename,interleave,start,totalsize)` writes `data` to the binary file `filename` in chunks. In this syntax, `data` is a subset of the complete data set.

`start` is a 1-by-3 array [`firstrow firstcolumn firstband`] that specifies the location to start writing data. `firstrow` and `firstcolumn` specify the location of the upper left image pixel. `firstband` gives the index of the first band to write. For example, `data(I,J,K)` contains the data for the pixel at [`firstrow+I-1, firstcolumn+J-1`] in the (`firstband+K-1`)-th band.

`totalsize` is a 1-by-3 array, [`totalrows,totalcolumns,totalbands`], which specifies the full, three-dimensional size of the data to be written to the file.

---

**Note** In this syntax, you must call `multibandwrite` multiple times to write all the data to the file. The first time it is called, `multibandwrite` writes the complete file, using the fill value for all values outside the data subset. In each subsequent call, `multibandwrite` overwrites these fill values with the data subset in `data`. The parameters `filename`, `interleave`, `offset`, and `totalsize` must remain constant throughout the writing of the file.

---

`multibandwrite(..., param, value...)` writes the multiband data to a file, specifying any of these optional parameter/value pairs.

Parameter	Description
'precision'	String specifying the form and size of each element written to the file. See the help for <code>fwrite</code> for a list of valid values. The default precision is the class of the data.
'offset'	The number of bytes to skip before the first data element. If the file does not already exist, <code>multibandwrite</code> writes ASCII null values to fill the space. To specify a different fill value, use the parameter <code>'fillvalue'</code> .  This option is useful when you are writing a header to the file before or after writing the data. When writing the header to the file after the data is written, open the file with <code>fopen</code> using <code>'r+'</code> permission.

# multibandwrite

Parameter	Description
'machfmt'	String to control the format in which the data is written to the file. Typical values are 'ieee-le' for little endian and 'ieee-be' for big endian. See the help for <code>fopen</code> for a complete list of available formats. The default machine format is the local machine format.
'fillvalue'	A number specifying the value to use in place of missing data. 'fillvalue' can be a single number, specifying the fill value for all missing data, or a 1-by-Number-of-bands vector of numbers specifying the fill value for each band. This value is used to fill space when data is written in chunks.

## Interleave Methods

`interleave` is a string that specifies how `multibandwrite` interleaves the bands as it writes data to the file. If data is two-dimensional, `multibandwrite` ignores the `interleave` argument. The following table lists the supported methods and uses this example multiband file to illustrate each method.

Supported methods of interleaving bands include those listed below.

Method	String	Description	Example
Band-Interleaved-by-Line	'bil'	Write an entire row from each band	AAAAABBBBBCCCCC AAAAABBBBBCCCCC AAAAABBBBBCCCCC
Band-Interleaved-by-Pixel	'bip'	Write a pixel from each band	ABCABCABCABC...
Band-Sequential	'bsq'	Write each band in its entirety	AAAAA AAAAA AAAAA BBBBB BBBBB BBBBB CCCCC CCCCC CCCCC

## Examples

---

**Note** To run these examples successfully, you must be in a writable directory.

---

### Example 1

Write all data (interleaved by line) to the file in one call.

```
data = reshape(uint16(1:600), [10 20 3]);
multibandwrite(data, 'data.bil', 'bil');
```

# multibandwrite

---

## Example 2

Write a single-band tiled image with one call for each tile. This is only useful if a subset of each band is available at each call to `multibandwrite`.

```
numBands = 1;
dataDims = [1024 1024 numBands];
data = reshape(uint32(1:(1024 * 1024 * numBands)), dataDims);

for band = 1:numBands
 for row = 1:2
 for col = 1:2

 subsetRows = ((row - 1) * 512 + 1):(row * 512);
 subsetCols = ((col - 1) * 512 + 1):(col * 512);

 upperLeft = [subsetRows(1), subsetCols(1), band];
 multibandwrite(data(subsetRows, subsetCols, band), ...
 'banddata.bsq', 'bsq', upperLeft, dataDims);

 end
 end
end
```

## See Also

`multibandread` | `fwrite` | `fread`

**Purpose** Allow clearing functions from memory

**Syntax**

```
munlock
munlock fun
munlock('fun')
```

**Description** `munlock` unlocks the currently running `.m` or `.mex` function in memory so that subsequent `clear` functions can remove it.

`munlock fun` unlocks the `.m` or `.mex` file named `fun` from memory. By default, these files are unlocked so that changes to the file are picked up. Calls to `munlock` are needed only to unlock `.m` or `.mex` functions that have been locked with `mlock`.

`munlock('fun')` is the function form of `munlock`.

**Examples** The function `testfun` begins with an `mlock` statement.

```
function testfun
mlock
.
.
```

When you execute this function, it becomes locked in memory. You can check this using the `mislocked` function.

```
testfun

mislocked testfun
ans =
 1
```

Using `munlock`, you unlock the `testfun` function in memory. Checking its status with `mislocked` shows that it is indeed unlocked at this point.

```
munlock testfun

mislocked testfun
ans =
```

# **munlock**

---

0

## **See Also**

`mlock` | `mislocked` | `inmem` | `persistent`

**Purpose** Maximum identifier length

**Syntax** `len = namelengthmax`

**Description** `len = namelengthmax` returns the maximum length allowed for MATLAB identifiers, which include:

- Variable names
- Structure field names
- Script, function, and class names
- Model names

Rather than hard-coding a specific maximum name length into your programs, use the `namelengthmax` function. This saves you the trouble of having to update these limits should the identifier length change in some future MATLAB release.

**Examples** Call `namelengthmax` to get the maximum identifier length:

```
maxid = namelengthmax
maxid =
 63
```

**See Also** `isvarname` | `matlab.lang.makeValidName` | `matlab.lang.makeUniqueStrings`

# NaN

---

## Purpose

Not-a-Number

## Syntax

```
NaN
N = NaN(n)
N = NaN(sz1, ..., szN)
N = NaN(sz)

N = NaN(classname)
N = NaN(n, classname)
N = NaN(sz1, ..., szN, classname)
N = NaN(sz, classname)

N = NaN('like', p)
N = NaN(n, 'like', p)
N = NaN(sz1, ..., szN, 'like', p)
N = NaN(sz, 'like', p)
```

## Description

NaN returns the IEEE arithmetic representation for Not-a-Number (NaN). These values result from operations which have undefined numerical results.

$N = \text{NaN}(n)$  is an  $n$ -by- $n$  matrix of NaN values.

$N = \text{NaN}(sz1, \dots, szN)$  is a  $sz1$ -by-...-by- $szN$  array of NaN values where  $sz1, \dots, szN$  indicates the size of each dimension. For example,  $\text{NaN}(3, 4)$  returns a 3-by-4 array of NaN values.

$N = \text{NaN}(sz)$  is an array of NaN values where the size vector,  $sz$ , defines  $\text{size}(N)$ . For example,  $\text{NaN}([3, 4])$  returns a 3-by-4 array of NaN values.

---

**Note** The size inputs  $sz1, \dots, szN$ , as well as the elements of the size vector  $sz$ , should be nonnegative integers. Negative integers are treated as 0.

---

`N = NaN(classname)` returns a NaN value where the string, `classname`, specifies the data type. `classname` can be either 'single' or 'double'.

`N = NaN(n,classname)` returns an n-by-n array of NaN values of data type `classname`.

`N = NaN(sz1,...szN,classname)` returns a sz1-by-...-by-szN array of NaN values of data type `classname`.

`N = NaN(sz,classname)` returns an array of NaN values where the size vector, `sz`, defines `size(N)` and `classname` defines `class(N)`.

`N = NaN('like',p)` returns a NaN value of the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`N = NaN(n,'like',p)` returns an n-by-n array of NaN values like `p`.

`N = NaN(sz1,...szN,'like',p)` returns a sz1-by-...-by-szN array of NaN values like `p`.

`N = NaN(sz,'like',p)` returns an array of NaN values like `p` where the size vector, `sz`, defines `size(N)`.

## Examples

These operations produce NaN:

- Any arithmetic operation on a NaN, such as `sqrt(NaN)`
- Addition or subtraction, such as magnitude subtraction of infinities as `(+Inf)+(-Inf)`
- Multiplication, such as `0*Inf`
- Division, such as `0/0` and `Inf/Inf`
- Remainder, such as `rem(x,y)` where `y` is zero or `x` is infinity

# NaN

---

## Tips

Because two NaNs are not equal to each other, logical operations involving NaNs always return false, except `~=` (not equal). Consequently,

```
NaN ~= NaN
ans =
 1
NaN == NaN
ans =
 0
```

and the NaNs in a vector are treated as different unique elements.

```
unique([1 1 NaN NaN])
ans =
 1 NaN NaN
```

Use the `isnan` function to detect NaNs in an array.

```
isnan([1 1 NaN NaN])
ans =
 0 0 1 1
```

## Concepts

- “Class Support for Array-Creation Functions”

**Purpose**

Validate number of input arguments

---

**Note** nargchk will be removed in a future version. Use narginchk instead.

---

**Syntax**

```
msgstring = nargchk(minargs, maxargs, numargs)
msgstring = nargchk(minargs, maxargs, numargs, 'string')
msgstruct = nargchk(minargs, maxargs, numargs, 'struct')
```

**Description**

Use nargchk inside a function to check that the desired number of input arguments is specified in the call to that function.

msgstring = nargchk(minargs, maxargs, numargs) returns an error message string msgstring if the number of inputs specified in the call numargs is less than minargs or greater than maxargs. If numargs is between minargs and maxargs (inclusive), nargchk returns an empty matrix.

It is common to use the nargin function to determine the number of input arguments specified in the call.

msgstring = nargchk(minargs, maxargs, numargs, 'string') is essentially the same as the command shown above, as nargchk returns a string by default.

msgstruct = nargchk(minargs, maxargs, numargs, 'struct') returns an error message structure msgstruct instead of a string. The fields of the return structure contain the error message string and a message identifier. If numargs is between minargs and maxargs (inclusive), nargchk returns an empty structure.

When too few inputs are supplied, the message string and identifier are

```
message: 'Not enough input arguments.'
identifier: 'MATLAB:nargchk:notEnoughInputs'
```

When too many inputs are supplied, the message string and identifier are

# nargchk

---

```
message: 'Too many input arguments.'
identifier: 'MATLAB:nargchk:tooManyInputs'
```

## Tips

nargchk is often used together with the error function. The error function accepts either type of return value from nargchk: a message string or message structure. For example, this command provides the error function with a message string and identifier regarding which error was caught:

```
error(nargchk(2, 4, nargin, 'struct'))
```

If nargchk detects no error, it returns an empty string or structure. When nargchk is used with the error function, as shown here, this empty string or structure is passed as an input to error. When error receives an empty string or structure, it simply returns and no error is generated.

## Examples

Given the function CheckInputs,

```
function CheckInputs(x, y, z)
error(nargchk(2, 3, nargin))
```

Then typing CheckInputs(1) produces

```
Not enough input arguments.
```

## See Also

```
narginchk | nargoutchk | nargin | nargout | varargin | varargout
| error
```

**Purpose** Number of function input arguments

**Syntax** nargin  
nargin(fx)

**Description** nargin returns the number of input arguments passed in the call to the currently executing function. Use this nargin syntax only in the body of a function.

nargin(fx) returns the number of input arguments that appear in the definition statement for function fx. If the function includes varargin in its definition, then nargin returns the negative of the number of inputs. For example, if function foo declares inputs a, b, and varargin, then nargin('foo') returns -3.

**Input Arguments** **fx**  
Either a function handle or a string in single quotes that specifies the name of a function.

## **Examples** **Inputs to Current Function**

Create a function in a file named addme.m that accepts up to two inputs, and identify the number of inputs with nargin.

```
function c = addme(a,b)
```

```
switch nargin
 case 2
 c = a + b;
 case 1
 c = a + a;
 otherwise
 c = 0;
end
```

## **Inputs Defined for a Function**

Determine how many inputs a function can accept.

# nargin

---

The function `addme` created in the previous example has two inputs in its declaration statement (`a` and `b`).

```
fx = 'addme';
nargin(fx)
```

```
ans =
 2
```

## Function with varargin Input

Determine how many inputs a function that uses `varargin` can accept.

Define a function in a file named `mynewplot.m` that accepts numeric inputs `x` and `y` and any number of additional plot inputs using `varargin`.

```
function mynewplot(x,y,varargin)
 figure
 plot(x,y,varargin{:})
 title('My New Plot')
```

At the command line, query how many inputs `newplot` can accept.

```
fx = 'mynewplot';
nargin(fx)
```

```
ans =
 -3
```

The minus sign indicates that the third input is `varargin`. The `mynewplot` function can accept an indeterminate number of additional input arguments.

`nargout` | `narginchk` | `nargoutchk` | `varargin` | `varargout` | `inputname`

<b>Purpose</b>	Validate number of input arguments
<b>Syntax</b>	<code>narginchk(minargs, maxargs)</code>
<b>Description</b>	<p><code>narginchk(minargs, maxargs)</code> throws an error if the number of inputs specified in the call to the currently executing function is less than <code>minargs</code> or greater than <code>maxargs</code>. If the number of inputs is between <code>minargs</code> and <code>maxargs</code> (inclusive), <code>narginchk</code> does nothing.</p> <p>When too few inputs are supplied, the message identifier and message are:</p> <pre>identifier: 'MATLAB:narginchk:notEnoughInputs' message: 'Not enough input arguments.'</pre> <p>When too many inputs are supplied, the message identifier and message are:</p> <pre>identifier: 'MATLAB:narginchk:tooManyInputs' message: 'Too many input arguments.'</pre> <ul style="list-style-type: none"><li>• To verify that there are a minimum of <code>N</code> arguments, specify <code>inf</code> as <code>maxargs</code>. For example: <code>narginchk(5,inf)</code> throws an error when there are not at least five inputs.</li></ul>
<b>Examples</b>	<p>This function uses <code>narginchk</code> to verify that a minimum of 2 and maximum of 5 input arguments are received from the calling function:</p> <pre>function check_inputs(A, B, varargin) minargs=2; maxargs=5;  % Number of inputs must be &gt;=minargs and &lt;=maxargs. narginchk(minargs, maxargs)  fprintf('Received 2 required, %d optional inputs.\n\n', ... size(varargin, 2))</pre>

# narginchk

---

Call the example function, passing 1 input argument:

```
check_inputs(23)
Error using check_inputs
Not enough input arguments.
```

Call the function, passing 5 arguments:

```
check_inputs(23, 9, 15, 34, 62)
Received 2 required, 3 optional inputs.
```

Call the function, passing 6 arguments:

```
check_inputs(23, 9, 15, 34, 62, 6)
Error using check_inputs
Too many input arguments.
```

## See Also

nargoutchk | nargin | nargout | varargin | varargout

<b>Purpose</b>	Number of function output arguments
<b>Syntax</b>	nargout nargout(fx)
<b>Description</b>	<p>nargout returns the number of output arguments specified in the call to the currently executing function. Use this nargout syntax only in the body of a function.</p> <p>nargout(fx) returns the number of outputs that appear in the definition statement of function fx. If the function includes varargout in its definition, then nargout returns the negative of the number of outputs. For example, if function foo declares outputs a, b, and varargout, then nargout('foo') returns -3.</p>
<b>Input Arguments</b>	<p><b>fx</b></p> <p>Either a function handle or a string in single quotes that specifies the name of a function.</p>
<b>Examples</b>	<p><b>Outputs for Current Function</b></p> <p>Create a function in a file named <code>subtract.m</code> that calculates a second return value only when requested.</p> <pre>function [dif,absdif] = subtract(y,x) dif = y - x; if nargout &gt; 1     disp('Calculating absolute value')     absdif = abs(dif); end</pre> <p><b>Outputs Defined for a Function</b></p> <p>Determine how many outputs a function can return.</p> <p>The function named <code>subtract</code> created in the previous example has two outputs in its declaration statement (<code>dif</code> and <code>absdif</code>).</p>

```
fx = 'subtract';
nargout(fx)
```

```
ans =
 2
```

## Function with varargout Output

Determine how many outputs a function that uses `varargout` can return.

Define a function in a file named `mysize.m` that returns a vector of dimensions from the `size` function and the individual dimensions using `varargout`.

```
function [sizeVector,varargout] = mysize(x)
 sizeVector = size(x);
 varargout = cell(1,nargout-1);
 for k = 1:length(varargout)
 varargout{k} = sizeVector(k);
 end
```

At the command line, query how many outputs `mysize` can return.

```
fx = 'mysize';
nargout(fx)
```

```
ans =
 -2
```

The minus sign indicates that the second output is `varargout`. The `mysize` function can return an indeterminate number of additional outputs.

## Tips

- When you use a function as part of an expression, MATLAB calls the function with one output argument, so `nargout` within the function returns 1. For example, given the following `if` statement and the `subtract` function defined in the Examples section, the value of `nargout` within the `subtract` function is 1.

```
a = 1; b = 2;
if subtract(a,b) < 0
 disp('Result is negative')
end
```

## See Also

[nargin](#) | [nargoutchk](#) | [narginchk](#) | [varargout](#) | [varargin](#) | [inputname](#)

# nargoutchk

---

**Purpose** Validate number of output arguments

**Syntax** `nargoutchk(minargs, maxargs)`

**Description** `nargoutchk(minargs, maxargs)` throws an error if the number of outputs specified in the call is less than `minargs` or greater than `maxargs`. If the number of outputs is between `minargs` and `maxargs` (inclusive), `nargoutchk` does nothing.

When too few outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:notEnoughOutputs'
message: 'Not enough output arguments.'
```

When too many outputs are supplied, the identifier and message are:

```
identifier: 'MATLAB:nargoutchk:tooManyOutputs'
message: 'Too many output arguments.'
```

**Tips**

- To verify that there are a minimum of `N` arguments, specify `inf` as `maxargs`. For example: `nargoutchk(5,inf)` throws an error when there are not at least five outputs.

**Examples** This function uses `nargoutchk` to verify that a minimum of 2 and maximum of 5 input arguments are passed back to the calling function:

```
function [varargout] = check_outputs(array_in)
minargs=2; maxargs=5;

% Number of outputs must be >=minargs and <=maxargs.
nargoutchk(minargs, maxargs)

for k=1:nargout
 varargout{k} = array_in(k)*3;
end
```

Initialize input array `X` to a vector of 6 elements:

```
X = 5:7:40
X =
 5 12 19 26 33 40
```

Call the example function with 1 output argument. This is less than the minimum (2) that was specified by nargoutchk and results in an error:

```
A = check_outputs(X);
```

```
Error using check_outputs
Not enough output arguments.
```

Call the function with 4 output arguments. This is within the allowable bounds (2 to 5) specified by nargoutchk:

```
[A, B, C, D] = check_outputs(X);
```

```
[A, B, C, D]
ans =
 15 36 57 78
```

Call the function with 6 output arguments. This exceeds the maximum (5) that was specified by nargoutchk and results in an error:

```
[A, B, C, D, E, F] = check_outputs(X);
```

```
Error using check_outputs
Too many output arguments.
```

# native2unicode

---

**Purpose** Convert numeric bytes to Unicode character representation

**Syntax** `unicodestr = native2unicode(bytes)`  
`unicodestr = native2unicode(bytes, encoding)`

**Description** `unicodestr = native2unicode(bytes)` converts a numeric vector, `bytes`, from the user default encoding to Unicode character representation. `bytes` is treated as a stream of 8-bit bytes, and each value must be in the range [0,255]. Return value `unicodestr` is a char vector having the same general array shape as `bytes`.

`unicodestr = native2unicode(bytes, encoding)` converts `bytes` to Unicode representation assuming that the byte stream is in the character encoding scheme specified by the string `encoding`. `encoding` must be the empty string ('') or a name or alias for an encoding scheme. Some examples are 'UTF-8', 'latin1', 'US-ASCII', and 'Shift\_JIS'. If `encoding` is unspecified or is the empty string (''), the default encoding scheme is used.

---

**Note** If `bytes` is a char vector, it is returned unchanged.

---

**Examples** This example begins with a vector of bytes in an unknown character encoding scheme. The user-written function `detect_encoding` determines the encoding scheme. If successful, it returns the encoding scheme name or alias as a string. If unsuccessful, it throws an error represented by an `MException` object, `ME`. The example calls `native2unicode` to convert the bytes to Unicode representation:

```
try
 enc = detect_encoding(bytes);
 str = native2unicode(bytes, enc);
 disp(str);
catch ME
 rethrow(ME);
end
```

Note that the computer must be configured to display text in a language represented by the detected encoding scheme for the output of `disp(str)` to be correct.

`unicode2native`

# nchoosek

---

## Purpose

Binomial coefficient or all combinations

## Syntax

`b = nchoosek(n,k)`  
`C = nchoosek(v,k)`

## Description

`b = nchoosek(n,k)` returns the binomial coefficient, defined as  $n!/((n-k)! k!)$ . This is the number of combinations of  $n$  items taken  $k$  at a time.

`C = nchoosek(v,k)` returns a matrix containing all possible combinations of the elements of vector  $v$  taken  $k$  at a time. Matrix  $C$  has  $k$  columns and  $n!/((n-k)! k!)$  rows, where  $n$  is `length(v)`.

## Input Arguments

### **n - Number of possible choices**

scalar, real, nonnegative value

Number of possible choices, specified as a scalar value of any numeric type that is real and nonnegative.

**Example:** 10

**Example:** `int16(10)`

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### **k - Number of selected choices**

scalar, real, nonnegative value

Number of selected choices, specified as a scalar value that is real and nonnegative.  $k$  can be any numeric type. However, `nchoosek(n,k)` requires that  $n$  and  $k$  be the same type or that at least one of them be of type double.

There are no restrictions on combining inputs of different types for `nchoosek(v,k)`.

**Example:** 3

**Example:** `int16(3)`

**Data Types**

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64`

**v - Set of all choices**

vector of numeric, logical, or char values

Set of all choices, specified as a vector of numeric, logical, or char values.

**Example:** `[1 2 3 4 5]`

**Example:** `[1+1i 2+1i 3+1i 4+1i]`

**Example:** `int16([1 2 3 4 5])`

**Example:** `[true false true false]`

**Example:** `['abcd']`

**Data Types**

`single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char`

**Complex Number Support:** Yes

**Output Arguments**

**b - Binomial coefficient**

nonnegative scalar value

Binomial coefficient, returned as a nonnegative scalar value. `b` is the same type as `n` and `k`. If `n` and `k` are of different types, then `b` is returned as the `nondouble` type.

**C - All combinations of v**

matrix

All combinations of `v`, returned as a matrix of the same type as `v`. Matrix `C` has `k` columns and  $n!/((n-k)! k!)$  rows, where `n` is `length(v)`.

Each row of **C** contains a combination of *k* items chosen from *v*. The elements in each row of **C** are listed in the same order as they appear in *v*.

## Limitations

- When  $b = \text{nchoosek}(n, k)$  is sufficiently large, `nchoosek` displays a warning that the result might not be exact. In this case, the result is only accurate to 15 digits for double-precision inputs, or 8 digits for single-precision inputs.
- $C = \text{nchoosek}(v, k)$  is only practical for situations where  $\text{length}(v)$  is less than about 15.

## Examples

### Binomial Coefficient, "5 Choose 4"

```
b = nchoosek(5,4)
```

```
b =
```

```
5
```

### All Combinations of Five Numbers Taken Four at a Time

```
v = 2:2:10;
```

```
C = nchoosek(v,4)
```

```
C =
```

```
2 4 6 8
2 4 6 10
2 4 8 10
2 6 8 10
4 6 8 10
```

### All Combinations of Three Unsigned Integers Taken Two at a Time

```
v = uint16([10 20 30]);
```

```
C = nchoosek(v,uint16(2))
```

C =

10	20
10	30
20	30

# ndgrid

---

<b>Purpose</b>	Rectangular grid in N-D space
<b>Syntax</b>	$[X1, X2, X3, \dots, Xn] = \text{ndgrid}(x1gv, x2gv, x3gv, \dots, xngv)$ $[X1, X2, \dots, Xn] = \text{ndgrid}(xgv)$
<b>Description</b>	<p><math>[X1, X2, X3, \dots, Xn] = \text{ndgrid}(x1gv, x2gv, x3gv, \dots, xngv)</math> replicates the grid vectors <math>x1gv, x2gv, x3gv, \dots, xngv</math> to produce a full grid. This grid is represented by the output coordinate arrays <math>X1, X2, X3, \dots, Xn</math>. The <math>i</math>th dimension of any output array <math>Xi</math> contains copies of the grid vector <math>xigv</math>.</p> <p><math>[X1, X2, \dots, Xn] = \text{ndgrid}(xgv)</math> is the same as <math>[X1, X2, \dots, Xn] = \text{ndgrid}(xgv, xgv, \dots, xgv)</math>. In other words, you can reuse the same grid vector in each respective dimension. The dimensionality of the output arrays is determined by the number of output arguments.</p> <p>The coordinate arrays <math>[X1, X2, X3, \dots, Xn]</math> are typically used to evaluate functions of several variables and to create surface and volumetric plots.</p>
<b>Input Arguments</b>	<p><b>xigv</b> Grid vector specifying a series of grid point coordinates in the <math>i</math>th dimension.</p> <p><b>xgv</b> Generic grid vector specifying a series of point coordinates.</p>
<b>Output Arguments</b>	<p><b>Xi</b> The <math>i</math>th dimension of the output array <math>Xi</math> are copies of elements of the grid vector <math>xigv</math>. The output arrays specify the full grid.</p>
<b>Tips</b>	The <code>ndgrid</code> function is similar to <code>meshgrid</code> , however <code>ndgrid</code> supports 1-D to N-D while <code>meshgrid</code> is restricted to 2-D and 3-D. The coordinates output by each function are the same, but the shape of the output arrays in the first two dimensions are different. For grid vectors $x1gv$ ,

$x2gv$  and  $x3gv$  of length  $M$ ,  $N$  and  $P$  respectively, `ndgrid(x1gv, x2gv)` will output arrays of size  $M$ -by- $N$  while `meshgrid(x1gv, x2gv)` outputs arrays of size  $N$ -by- $M$ . Similarly, `ndgrid(x1gv, x2gv, x3gv)` will output arrays of size  $M$ -by- $N$ -by- $P$  while `meshgrid(x1gv, x2gv, x3gv)` outputs arrays of size  $N$ -by- $M$ -by- $P$ . See “Grid Representation” in the MATLAB Mathematics documentation for more information.

## Examples

### Evaluate Function Over Gridded Domain

Evaluate the function  $x_1 e^{-x_1^2 - x_2^2}$  over the gridded domain  $-2 < x_1 < 2$  and  $-2 < x_2 < 2$ .

Create a grid of values for the domain.

```
[X1,X2] = ndgrid(-2:.2:2, -2:.2:2);
```

Evaluate the function over the domain.

```
Z = X1 .* exp(-X1.^2 - X2.^2);
```

Generate a mesh plot of the function.

```
mesh(X1,X2,Z)
```

# ndgrid

---

## How To

- “Interpolating Gridded Data”

<b>Purpose</b>	Number of array dimensions
<b>Syntax</b>	<code>N = ndims(A)</code>
<b>Description</b>	<code>N = ndims(A)</code> returns the number of dimensions in the array <code>A</code> . The number of dimensions is always greater than or equal to 2. The function ignores trailing singleton dimensions, for which <code>size(A,dim) = 1</code> .
<b>Input Arguments</b>	<b>A - Input array</b> scalar   vector   matrix   multidimensional array  Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, tables, structure arrays, cell arrays, and object arrays.
<b>Examples</b>	<b>Find Dimensions of Vector</b>  Create a row vector.  <code>A = 1:5;</code>  Find the number of dimensions in the vector.  <code>ndims(A)</code>  <code>ans =</code>  2  The result is 2 because the vector has a size of 1-by-5.  <b>Find Dimensions of Cell Array</b>  Create a cell array of strings.  <code>C{1,1,1} = 'cell_1';</code> <code>C{1,1,2} = 'cell_2';</code> <code>C{1,1,3} = 'cell_3'</code>

# ndims

---

```
C(:,:,1) =
 'cell_1'
```

```
C(:,:,2) =
 'cell_2'
```

```
C(:,:,3) =
 'cell_3'
```

Find the number of dimensions of the cell array.

```
ndims(A)
```

```
ans =
```

```
 3
```

The result is 3 because the cell array has a size of 1-by-1-by-3.

## Algorithms

The number of dimensions in an array is the same as the length of the size vector of the array. In other words, `ndims(A) = length(size(A))`.

## See Also

[size](#) | [length](#)

<b>Purpose</b>	Determine inequality
<b>Syntax</b>	A ~= B ne(A,B)
<b>Description</b>	<p>A ~= B returns a logical array with elements set to logical 1 (true) where arrays A and B are not equal; otherwise, it returns logical 0 (false). The test compares both real and imaginary parts of numeric arrays. ne returns logical 1 (true) where A or B have NaN or undefined categorical elements.</p> <p>ne(A,B) is an alternative way to execute A ~= B, but is rarely used. It enables operator overloading for classes.</p>
<b>Input Arguments</b>	<p><b>A - Left array</b> numeric array   logical array   character array   categorical array</p> <p>Left array, specified as a numeric array, logical array, character array, or categorical array. Inputs A and B must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.</p> <p>If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char</p> <p><b>Complex Number Support:</b> Yes</p> <p><b>B - Right array</b> numeric array   logical array   character array   categorical array</p>

Right array, specified as a numeric array, logical array, character array, or categorical array. Inputs **A** and **B** must be the same size unless one is a scalar. A scalar input expands into an array of the same size as the other input.

If one input is a categorical array, the other input can be a categorical array, a cell array of strings, or a single string. A single string expands into a cell array of strings of the same size as the other input. If both inputs are ordinal categorical arrays, they must have the same sets of categories, including their order. If both inputs are categorical arrays that are not ordinal, they can have different sets of categories. See “Compare Categorical Array Elements” for more details.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**Examples****Inequality of Two Vectors**

Create two vectors containing both real and imaginary numbers.

```
A = [1+i 3 2 4+i];
```

```
B = [1 3+i 2 4+i];
```

Compare the two vectors for inequality.

```
A ~= B
```

```
ans =
```

```
 1 1 0 0
```

The `ne` function tests both real and imaginary parts for inequality, and returns logical 1 (true) where one or both parts are not equal.

**Find Characters in String**

Create a string of characters.

```
M = 'masterpiece';
```

Test the string for the presence of a specific character using ~=.

```
M ~= 'n'
```

```
ans =
```

```
 1 1 1 1 1 1 1 1 1 1 1
```

The value of logical 1 (true) in the vector indicates the absence of the character 'n'. The character is not present in the string.

### Find Values in Categorical Array

Create a categorical array.

```
A = categorical({'heads' 'heads' 'tails'; 'tails' 'heads' 'tails'})
```

```
A =
```

```
 heads heads tails
 tails heads tails
```

The array has two categories: 'heads' and 'tails'.

Find all values not in the 'heads' category.

```
A ~= 'heads'
```

```
ans =
```

```
 0 0 1
 1 0 1
```

A value of logical 1 (true) indicates a value not in the category. Since A only has two categories, A ~= 'heads' returns the same answer as A == 'tails'.

Compare the rows of A for inequality.

```
A(1,:) ~= A(2, :)
```

```
ans =
```

```
 1 0 0
```

The function returns logical 1 (true) where the rows have unequal category values.

### **Compare Floating-Point Numbers**

Some floating-point numbers cannot be represented exactly in binary form. This leads to small differences in results that the ~= operator reflects.

Perform a few subtraction operations on a floating-point number and store the result in **C**.

```
C = 0.5-0.4-0.1
```

```
C =
```

```
-2.7756e-17
```

Intuitively, **C** should be equal to *exactly* 0. Its small value is due to the nature of floating-point arithmetic.

Compare **C** to zero for inequality.

```
C ~= 0
```

```
ans =
```

```
 1
```

The result is logical 1 (true).

Compare floating-point numbers using a tolerance, **tol**, instead of ~=.

```
tol = eps;
```

```
abs(C-0) > tol
```

```
ans =
```

```
0
```

The two numbers, `C` and `0`, are closer to one another than two consecutive floating-point numbers. They are essentially equal.

# DelaunayTri.nearestNeighbor

---

## Purpose

(Will be removed) Point closest to specified location

---

**Note** `nearestNeighbor(DelaunayTri)` will be removed in a future release. Use `nearestNeighbor(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

## Syntax

```
PI = nearestNeighbor(DT,QX)
PI = nearestNeighbor(DT,QX,QY)
PI = nearestNeighbor(DT,QX,QY,QZ)
[PI,D] = nearestNeighbor(DT,QX,...)
```

## Description

`PI = nearestNeighbor(DT,QX)` returns the index of the nearest point in `DT.X` for each query point location in `QX`.

`PI = nearestNeighbor(DT,QX,QY)` and `PI = nearestNeighbor(DT,QX,QY,QZ)` allow the query points to be specified in column vector format when working in 2-D and 3-D.

`[PI,D] = nearestNeighbor(DT,QX,...)` returns the index of the nearest point in `DT.X` for each query point location in `QX`. The corresponding Euclidean distances between the query points and their nearest neighbors are returned in `D`.

---

**Note** Note: `nearestNeighbor` is not supported for 2-D triangulations that have constrained edges.

---

## Input Arguments

DT	Delaunay triangulation.
QX	The matrix <code>QX</code> is of size <code>mpts-by-ndim</code> , <code>mpts</code> being the number of query points and <code>ndim</code> the dimension of the space where the points reside.

## Output Arguments

PI            PI is a column vector of point indices that index into the points DT.X. The length of PI is equal to the number of query points mpts

D            D is a column vector of length mpts.

## Examples

Create a Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
dt = DelaunayTri(x,y);
```

Create query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
```

Find the nearest neighbors to the query points:

```
pid = nearestNeighbor(dt, qrypts)
```

## See Also

[pointLocation](#) | [delaunayTriangulation](#) | [triangulation](#)

## ne (MException)

---

<b>Purpose</b>	Compare scalar MException objects for inequality
<b>Syntax</b>	<code>eObj1 ~= eObj2</code>
<b>Description</b>	<code>eObj1 ~= eObj2</code> tests MException objects <code>eObj1</code> and <code>eObj2</code> for inequality, returning logical 1 (true) if the two objects are not identical, otherwise returning logical 0 (false).
<b>See Also</b>	<code>addCause(MException)   disp(MException)   eq(MException)   isequal(MException)   last(MException)   throwAsCaller(MException)   rethrow(MException)   throw(MException)   getReport(MException)   MException   assert   error   try, catch</code>

**Purpose** (Will be removed) Simplex neighbor information

---

**Note** `neighbors(TriRep)` will be removed in a future release. Use `neighbors(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `SN = neighbors(TR, SI)`

**Description** `SN = neighbors(TR, SI)` returns the simplex neighbor information for the specified simplices `SI`.

**Input Arguments**

<code>TR</code>	Triangulation representation.
<code>SI</code>	<code>SI</code> is a column vector of simplex indices that index into the triangulation matrix <code>TR.Triangulation</code> . If <code>SI</code> is not specified the neighbor information for the entire triangulation is returned, where the neighbors associated with simplex <code>i</code> are defined by the <code>i</code> 'th row of <code>SN</code> .

**Output Arguments**

<code>SN</code>	<code>SN</code> is an <code>m</code> -by- <code>n</code> matrix, where <code>m = length(SI)</code> , the number of specified simplices, and <code>n</code> is the number of neighbors per simplex. Each row <code>SN(i, :)</code> represents the neighbors of the simplex <code>SI(i)</code> .  By convention, the simplex opposite vertex <code>(j)</code> of simplex <code>SI(i)</code> is <code>SN(i, j)</code> . If a simplex has one or more boundary facets, the nonexistent neighbors are represented by <code>NaN</code> .
-----------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

# TriRep.neighbors

---

## Definitions

A *simplex* is a triangle/tetrahedron or higher-dimensional equivalent. A *facet* is an edge of a triangle or a face of a tetrahedron.

## Examples

### Example 1

Load a 3-D triangulation and use `TriRep` to compute the neighbors of all tetrahedra.

```
load tetmesh
trep = TriRep(tet, X)
nbrs = neighbors(trep)
```

### Example 2

Query a 2-D triangulation created using `DelaunayTri`.

```
x = rand(10,1)
y = rand(10,1)
dt = DelaunayTri(x,y)
```

Find the neighbors of the first triangle:

```
n1 = neighbors(dt, 1)
```

**Purpose**

Summary of functions in MATLAB .NET interface

**Description**

Use the following functions to bring assemblies from the Microsoft .NET Framework into the MATLAB environment. The functions are implemented as a package called NET. To use these functions, prefix the function name with package name NET.

BeginInvoke	Initiate asynchronous .NET delegate call
cell	Create cell array
Combine	Convenience function for static .NET System.Delegate Combine method
enableNETfromNetworkDrive	Enable access to .NET commands from network drive
EndInvoke	Retrieve result of asynchronous call initiated by .NET System.Delegate BeginInvoke method
NET.addAssembly	Make .NET assembly visible to MATLAB
NET.Assembly	Members of .NET assembly
NET.convertArray	Convert numeric MATLAB array to .NET array
NET.createArray	Array for nonprimitive .NET types
NET.createGeneric	Create instance of specialized .NET generic type
NET.disableAutoRelease	Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

NET.enableAutoRelease	Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object
NET.GenericClass	Represent parameterized generic type definitions
NET.invokeGenericMethod	Invoke generic method of object
NET.isNETSupported	Check for supported
NET.NetException	Capture error information for .NET exception
NET.setStaticProperty	Static property or field name
Remove	Convenience function for static .NET System.Delegate Remove method
RemoveAll	Convenience function for static .NET System.Delegate RemoveAll method

## How To

- “Call .NET Libraries”

<b>Purpose</b>	Make .NET assembly visible to MATLAB
<b>Syntax</b>	<pre>asmInfo = NET.addAssembly(globalName) asmInfo = NET.addAssembly(privateName)</pre>
<b>Description</b>	<p><code>asmInfo = NET.addAssembly(globalName)</code> loads a global .NET assembly into MATLAB.</p> <p><code>asmInfo = NET.addAssembly(privateName)</code> loads a private .NET assembly.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• MATLAB dynamically loads the <code>mscorlib.dll</code> and <code>system.dll</code> assemblies from the .NET Framework class library the first time you type "NET." or "System.". You do not need to call <code>NET.addAssembly</code> to access classes in these assemblies.</li><li>• Refer to your .NET product documentation for the name of the assembly and its deployment type (global or private).</li></ul>
<b>Limitations</b>	<ul style="list-style-type: none"><li>• <code>NET.addAssembly</code> does not support assemblies generated by the MATLAB Builder NE product.</li></ul>
<b>Input Arguments</b>	<p><b>globalName</b></p> <p>One of the following:</p> <ul style="list-style-type: none"><li>• String representing the name of a global assembly.</li><li>• Instance of <code>System.Reflection.AssemblyName</code> class.</li></ul> <p><b>privateName</b></p> <p>String representing the full path of a private assembly.</p>
<b>Output Arguments</b>	<p><b>asmInfo</b></p> <p><code>NET.Assembly</code> object containing names of the members of the assembly.</p>

# NET.addAssembly

---

## Examples

Display today's date using `System.DateTime` in the `mscorlib` assembly.

```
System.DateTime.Now.ToLongDateString
```

---

Call the `System.Windows.Forms.MessageBox.Show` method in the global assembly `System.Windows.Forms`.

```
asm = NET.addAssembly('System.Windows.Forms');
import System.Windows.Forms.*;
MessageBox.Show('Simple Message Box')
```

---

Display classes in the private assembly `NetSample.dll`.

```
asm = NET.addAssembly('c:\work\NetSample.dll');
asm.Classes
```

## See Also

## How To

- “An Assembly is a Library of .NET Classes”

## Related Links

- [MSDN AssemblyName Class](#)

<b>Purpose</b>	Members of .NET assembly
<b>Description</b>	NET.Assembly object returns names of the members of an assembly.
<b>Construction</b>	The NET.addAssembly function creates an instance of this class.
<b>Properties</b>	<b>AssemblyHandle</b> Instance of System.Reflection.Assembly class of the added assembly.
	<b>Classes</b> nClassx1 cell array of class names of the assembly, where nClass is the number of classes
	<b>Enums</b> nEnumx1 cell array of enums of the assembly, where nEnum is the number of enums
	<b>Structures</b> nStructx1 cell array of structures of the assembly, where nStruct is the number of structures
	<b>GenericTypes</b> nGenTypex1 cell array of generic types of the assembly, where nGenType is the number of generic types
	<b>Interfaces</b> nInterfacex1 cell array of interface names of the assembly, where nInterface is the number of interfaces
	<b>Delegates</b> nDelegatex1 cell array of delegates of the assembly, where nDelegate is the number of delegates
<b>See Also</b>	NET.addAssembly

# NET.Assembly

---

## How To

- “What Classes Are in a .NET Assembly?”

**Purpose** Convert numeric MATLAB array to .NET array

---

**Note** MATLAB automatically converts arrays to .NET types. For information, see “Using Arrays with .NET Applications”.

---

**Syntax** `arrObj = NET.convertArray(V, 'arrType', [m,n])`

**Description** `arrObj = NET.convertArray(V, 'arrType', [m,n])` converts a MATLAB array `V` to a .NET array. Optional value `arrType` is a string representing a namespace-qualified .NET array type. Use optional values `m,n` to convert a MATLAB vector to a two-dimensional .NET array (either 1-by-`n` or `m`-by-1). If `V` is a MATLAB vector and you do not specify the number of dimensions and their sizes, the output `arrObj` is a one-dimensional .NET array.

If you do not specify `arrType`, MATLAB converts the type according to the MATLAB Primitive Type Conversion Table. See “Pass Primitive .NET Types”.

**Examples** Create a list `aList` of random `System.Int32` integers using the `System.Collections.Generic.List` class, and then sort the results:

```
%Create array R of random integers
nInt = 5;
R = randi(100,1,nInt);
%Create .NET array A
A = NET.convertArray(R, 'System.Int32');
%Put A into aList, a generic collections list
aList = NET.createGeneric(...
 'System.Collections.Generic.List',...
 {'System.Int32'},A.Length);
aList.AddRange(A);
%Sort the values in aList
aList.Sort;
```

# NET.convertArray

---

## See Also

[NET.createArray](#)

## Purpose

Array for nonprimitive .NET types

## Syntax

```
array = NET.createArray(typeName,[m,n,p,...])
array = NET.createArray(typeName,m,n,p,...)
```

## Description

`array = NET.createArray(typeName,[m,n,p,...])` creates an m-by-n-by-p-by-... array of type `typeName`, which is either a fully qualified .NET array type name (namespace and array type name) or an instance of the `NET.GenericClass` class, in case of arrays of generic type. `m,n,p,...` are the number of elements in each dimension of the array.

`array = NET.createArray(typeName,m,n,p,...)` alternative syntax for creating an array.

You cannot specify the lower bound of an array.

## Examples

### Create .NET Array of Generic Type

This example creates a .NET array of `List<Int32>` generic type.

```
genType = NET.GenericClass('System.Collections.Generic.List',...
 'System.Int32');
arr = NET.createArray(genType, 5)
```

```
arr =
```

```
List<System*Int32>[] with properties:
```

```
 Length: 5
 LongLength: 5
 Rank: 1
 SyncRoot: [1x1 System.Collections.Generic.List<System*Int32>
 ReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

# NET.createArray

---

## Create and Initialize Jagged Array

This example creates a jagged .NET array of 3 elements.

```
jaggedArray = NET.createArray('System.Double[]', 3)
```

```
jaggedArray =
```

```
 Double[][] with properties
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Double[][]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

Assign values:

```
jaggedArray(1) = [1, 3, 5, 7, 9];
jaggedArray(2) = [0, 2, 4, 6];
jaggedArray(3) = [11, 22];
```

Access first value of 3rd array:

```
jaggedArray(3,1)
```

```
ans =
 11
```

## Create Jagged Array of Generic Type

This example creates a jagged array of List<Double> generic type.

```
genCls = NET.GenericClass('System.Collections.Generic.List[]',...
 'System.Double');
```

Create the array, genArr.

```
genArr = NET.createArray(genCls,3)
```

```
genArr =
```

```
List<System*Double>[[]] with properties:
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Collections.Generic.List`1[[]]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

## Create Nested Jagged Array

This command creates a jagged array of type `System.Double[[][]]`.

```
netArr = NET.createArray('System.Double[[]]', 3)
```

```
netArr =
```

```
Double[[][]] with properties:
```

```
 Length: 3
 LongLength: 3
 Rank: 1
 SyncRoot: [1x1 System.Double[[]]]
 IsReadOnly: 0
 IsFixedSize: 1
 IsSynchronized: 0
```

## See Also

[NET.convertArray](#) | [NET.createGeneric](#)

# NET.createGeneric

---

<b>Purpose</b>	Create instance of specialized .NET generic type
<b>Syntax</b>	<code>genObj = createGeneric(className,paramTypes,varargin ctorArgs)</code>
<b>Description</b>	<code>genObj = createGeneric(className,paramTypes,varargin ctorArgs)</code> creates an instance <code>genObj</code> of generic type <code>className</code> .

<b>Input Arguments</b>	<code>className</code>	Fully qualified string with the generic type name.
	<code>paramTypes</code>	Allowed cell types are: strings with fully qualified parameter type names and instances of the <code>NET.GenericClass</code> class when parameterization with another parameterized type is needed.
	<code>ctorArgs</code>	Optional, variable length (0 to N) list of constructor arguments matching the arguments of the .NET generic class constructor intended to be invoked.

<b>Output Arguments</b>	<code>genObj</code>	Handle to the specialized generic class instance.
-------------------------	---------------------	---------------------------------------------------

## Examples **Create a List of System.Double Objects**

Create a strongly typed list `dblLst` of objects of type `System.Double`:

```
t = NET.createGeneric('System.Collections.Generic.List',...
 {'System.Double'},10);
```

## **Create a List with Key/Value Pairs**

Create the `kvpType` generic association where Key is of `System.Int32` type and Value is a `System.String`:

```
pe = NET.GenericClass('System.Collections.Generic.KeyValuePair',...
 'System.Int32', 'System.String');
```

Create the list `kvpList` with initial storage capacity for 10 key-value pairs:

```
st = NET.createGeneric('System.Collections.Generic.List',...
 {kvpType}, 10);
```

## **Add an Item to the List**

Create a `KeyValuePair` item.

```
kvpItem = NET.createGeneric('System.Collections.Generic.KeyValuePair',...
 {'System.Int32', 'System.String'}, 42, 'myString');
```

Add this item to the list `kvpList`.

```
kvpList.Add(kvpItem);
```

## **See Also**

`NET.GenericClass`

# NET.disableAutoRelease

---

**Purpose** Lock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release COM object

**Syntax** A = NET.disableAutoRelease(obj)

**Description** A = NET.disableAutoRelease(obj) locks a .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB does not release the COM object. obj is a .NET object representing a COM Wrapper.

Before passing a .NET object representing a COM Wrapper to another process, lock the object using this function so that MATLAB does not release it. After using the object, call NET.enableAutoRelease to release the COM object.

**Examples** The following user-defined function, GetComApp.m, has access to a COM object defined in the **pseudo-class** ComNamespace.ComClass. One of its methods is readData, with the signature:

```
System.StringRetVal readData(ComNamespace.ComClass this, System.String strIn)
```

The input argument is defined in the **pseudo-class** NetDocTest.MyClass, which has a property named MyApp.

```
function GetComApp(obj)
comObj = ComNamespace.ComClass;
obj.MyApp = comObj;
% To pass a COM object to another process, lock the object
NET.disableAutoRelease(comObj);
end
```

The example in NET.enableAutoRelease shows how to call the GetComApp function.

**See Also** NET.enableAutoRelease

**How To** • “How MATLAB Handles System.\_\_ComObject”

**Purpose** Unlock .NET object representing a RunTime Callable Wrapper (COM Wrapper) so that MATLAB releases COM object

**Syntax** A = NET.enableAutoRelease(obj)

**Description** A = NET.enableAutoRelease(obj) releases the COM wrapper when the object goes out of scope, where obj is a .NET object representing a COM Wrapper.

Call this function only if the object was locked using NET.disableAutoRelease.

**Examples** The following **pseudo-code** shows how to call a function (GetComApp.m, described in NET.disableAutoRelease) which returns a COM object. The object, mainObj of type NetDocTest.MyClass, has a property, MyApp. Call GetComApp to get a COM object, and use its readData method.

```
mainObj = NetDocTest.MyClass;
GetComApp(mainObj);
app = mainObj.MyApp;
app.readData('hello');
% Unlock the COM object
NET.enableAutoRelease(mainObj.MyApp);
```

**See Also** NET.disableAutoRelease

**How To** • “How MATLAB Handles System.\_\_ComObject”

# NET.GenericClass

---

**Purpose** Represent parameterized generic type definitions

**Description** Instances of this class are used by the `NET.createGeneric` function when creation of generic specialization requires parameterization with another parameterized type.

**Construction** `genType = NET.GenericClass (className, paramTypes)`

## Input Arguments

### className

Fully qualified string containing the generic type name.

### paramTypes

Optional, variable length (1 to N) list of types for the generic class parameterization. Allowed argument types are:

- Fully qualified string containing the generic type name.
- Instance of the `NET.GenericClass` class when deeper nested parameterization with another parameterized type is needed.

## Examples

Create an instance of `System.Collections.Generic.List` of `System.Collections.Generic.KeyValuePair` generic associations where `Key` is of `System.Int32` type and `Value` is a `System.String` class with initial storage capacity for 10 key-value pairs.

```
kvpType = NET.GenericClass(...
 'System.Collections.Generic.KeyValuePair',...
 'System.Int32', 'System.String');
kvpList = NET.createGeneric('System.Collections.Generic.List',...
 { kvpType }, 10);
```

**See Also** `NET.createGeneric` | `NET.createArray` | `NET.invokeGenericMethod`

**How To**

- “.NET Generic Classes”

<b>Purpose</b>	Invoke generic method of object								
<b>Syntax</b>	<pre>[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName',     paramTypes, args, ...)</pre>								
<b>Description</b>	<pre>[varargout] = NET.invokeGenericMethod(obj, 'genericMethodName', paramTypes, args, ...) calls instance or static generic method <i>genericMethodName</i>.</pre>								
<b>Input Arguments</b>	<table><tr><td>obj</td><td>Allowed argument types are:<ul style="list-style-type: none"><li>• Instances of class containing the generic method</li><li>• Strings with fully qualified class name, if calling static generic methods</li><li>• Instances of NET.GenericClass definitions, if calling static generic methods of a generic class</li></ul></td></tr><tr><td><i>genericMethodName</i></td><td>Generic method name to invoke</td></tr><tr><td>paramTypes</td><td>Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are:<ul style="list-style-type: none"><li>• Strings with fully qualified parameter type name.</li><li>• Instances of NET.GenericClass definitions, if using nested parameterization with another parameterized type</li></ul></td></tr><tr><td>args</td><td>Optional, variable length (0 to N) list of method arguments</td></tr></table>	obj	Allowed argument types are: <ul style="list-style-type: none"><li>• Instances of class containing the generic method</li><li>• Strings with fully qualified class name, if calling static generic methods</li><li>• Instances of NET.GenericClass definitions, if calling static generic methods of a generic class</li></ul>	<i>genericMethodName</i>	Generic method name to invoke	paramTypes	Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are: <ul style="list-style-type: none"><li>• Strings with fully qualified parameter type name.</li><li>• Instances of NET.GenericClass definitions, if using nested parameterization with another parameterized type</li></ul>	args	Optional, variable length (0 to N) list of method arguments
obj	Allowed argument types are: <ul style="list-style-type: none"><li>• Instances of class containing the generic method</li><li>• Strings with fully qualified class name, if calling static generic methods</li><li>• Instances of NET.GenericClass definitions, if calling static generic methods of a generic class</li></ul>								
<i>genericMethodName</i>	Generic method name to invoke								
paramTypes	Cell vector (1 to N) with the types for generic method parameterization, where allowed cell types are: <ul style="list-style-type: none"><li>• Strings with fully qualified parameter type name.</li><li>• Instances of NET.GenericClass definitions, if using nested parameterization with another parameterized type</li></ul>								
args	Optional, variable length (0 to N) list of method arguments								

# NET.invokeGenericMethod

---

## Output Arguments

varargout      Variable-length output argument list, varargout, from method *genericMethodName*

## Examples

Use the following syntax to call a generic method that takes two parameterized types and returns a parameterized type:

```
a = NET.invokeGenericMethod(obj, ...
 'myGenericSwapMethod', ...
 {'System.Double', 'System.Double'}, ...
 5, 6);
```

---

To display generic methods in MATLAB, see the example “Display .NET Generic Methods Using Reflection”.

## See Also

NET.GenericClass | NET.createGeneric | varargout

## How To

- “Call .NET Generic Methods”

**Purpose**

Check for supported Microsoft .NET Framework

**Syntax**

```
tf = NET.isNETSupported
```

**Description**

`tf = NET.isNETSupported` returns logical 1 (true) if a supported version of the Microsoft .NET Framework is found. Otherwise, it returns logical 0 (false) and you cannot use the .NET Framework in MATLAB.

# NET.NetException

---

<b>Purpose</b>	Capture error information for .NET exception
<b>Description</b>	Process information from a NET.NetException object to handle .NET errors. This class is derived from MException.
<b>Construction</b>	<code>e = NET.NetException(msgID, errMsg, netObj)</code> constructs instance <code>e</code> of NET.NetException class.
<b>Input Arguments</b>	<b>msgID</b> message identifier <b>errMsg</b> error message string <b>netObj</b> System.Exception object that caused the exception
<b>Properties</b>	<b>ExceptionObject</b> System.Exception class causing the error.
<b>Methods</b>	<b>Inherited Methods</b> See the methods of the base class MException.
<b>Examples</b>	Display error information after trying to load an unknown assembly: <pre>try   NET.addAssembly('C:\Work\invalidfile.dll') catch e   e.message;   if(isa(e, 'NET.NetException'))     eObj = e.ExceptionObject   end end  ans =</pre>

```
Message: Could not load file or assembly
'file:///C:\Work\invalidfile.dll' or
one of its dependencies. The system cannot
find the file specified.
```

```
Source: mscorlib
```

```
HelpLink:
```

```
eObj =
```

```
FileNotFoundException with properties:
```

```

```

## See Also

MException

## How To

- Class Attributes
- Property Attributes

# NET.setStaticProperty

---

**Purpose** Static property or field name

**Syntax** `NET.setStaticProperty('propName', value)`

**Description** `NET.setStaticProperty('propName', value)` sets the static property or field name specified in the string `propName` to the given value.

**Examples** To set the `myStaticProperty` in the given class and namespace, use the syntax:

```
NET.setStaticProperty('MyTestObject.MyClass.myStaticProperty', 5);
```

<b>Purpose</b>	Create variable in NetCDF file
<b>Syntax</b>	<code>nccreate(filename,varname)</code> <code>nccreate(filename,varname,Name,Value)</code>
<b>Description</b>	<p><code>nccreate(filename,varname)</code> creates a scalar double variable named <code>varname</code> in the NetCDF file <code>filename</code>. If <code>filename</code> does not exist, <code>nccreate</code> creates the file using the <code>netcdf4_classic</code> format. To create a nonscalar variable, use the <code>Dimensions</code> argument.</p> <p><code>nccreate(filename,varname,Name,Value)</code> creates a variable named <code>varname</code> with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>filename</b></p> <p>Text string specifying a NetCDF file, or the name you want to assign to a new NetCDF file.</p> <p><b>varname</b></p> <p>Text string specifying the name you want to assign to a variable in a NetCDF file.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>'Dimensions'</b></p> <p>Cell array specifying dimensions for the variable in the NetCDF file. The cell array lists the dimension name as a string followed by its numerical length: <code>{dname1,dlength1,dname2,dlength2,...}</code>. If a dimension exists, specifying its length is optional. Use <code>Inf</code> to specify an unlimited dimension.</p>

All formats other than `netcdf4` format files can have only one unlimited dimension per file and it has to be the last in the list specified. A `netcdf4` format file can have any number of unlimited dimensions in any order.

A single-dimension variable is always treated as a column vector.

## 'Datatype'

Text string specifying a MATLAB data type. When `nccreate` creates the variable in the NetCDF file, it uses a corresponding NetCDF datatype. The following table describes how MATLAB datatypes map to NetCDF datatypes.

<b>MATLAB Data Type</b>	<b>Corresponding NetCDF Variable Type</b>
<code>double</code>	<code>NC_DOUBLE</code>
<code>single</code>	<code>NC_FLOAT</code>
<code>int64</code>	<code>NC_INT64*</code>
<code>uint64</code>	<code>NC_UINT64*</code>
<code>int32</code>	<code>NC_INT</code>
<code>uint32</code>	<code>NC_UINT*</code>
<code>int16</code>	<code>NC_SHORT</code>
<code>uint16</code>	<code>NC_USHORT*</code>
<code>int8</code>	<code>NC_BYTE</code>
<code>uint8</code>	<code>NC_UBYTE*</code>
<code>char</code>	<code>NC_CHAR</code>

\* These data types are only available when the file is a `netcdf4` format file.

## 'Format'

Text string specifying the type of NetCDF file you want to create.

Format String	Description
classic	NetCDF 3
64bit	NetCDF 3, with 64-bit offsets
netcdf4_classic	NetCDF 4 classic model
netcdf4	NetCDF 4 model (Use this to enable group hierarchy)

If varname specifies a group (e.g., '/grid3/temperature'), nccreate sets the value of format to 'netcdf4'.

**Default:** netcdf4\_classic

#### 'FillValue'

A scalar specifying the value to use for missing values. To disable fill values, set FillValue to the text string 'disable'. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Value specified by the NetCDF library

#### 'ChunkSize'

Vector specifying the size of the chunk along each dimension, [num\_rows,num\_cols,..., num\_ndims]. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Set by the NetCDF library

#### 'DeflateLevel'

Numeric value between 0 (least) and 9 (most) specifying the compression setting for the deflate filter, or the text string disable. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** Disabled

## **'Shuffle'**

Boolean flag to turn on the shuffle filter. (Available for netcdf4 or netcdf4\_classic formats only.)

**Default:** False

## **Examples**

Create a new 2-D variable in a classic format file. Write data to this variable

```
nccreate('myncclassic.nc', 'peaks', ...
 'Dimensions', {'r' 200 'c' 200}, ...
 'Format', 'classic');
ncwrite('myncclassic.nc', 'peaks', peaks(200));
ncdisp('myncclassic.nc');
```

## **See Also**

`ncdisp` | `ncwrite` | `ncinfo` | `ncwritescema` | `netcdf`

## **Tutorials**

- “Exporting to NetCDF Files”

**Purpose** Display contents of NetCDF data source in Command Window

**Syntax**  
`ncdisp(source)`  
`ncdisp(source,location)`  
`ncdisp(source,location,dispFormat)`

**Description** `ncdisp(source)` displays all the groups, dimensions, variable definitions, and all attributes in the NetCDF data source, `source`, as text in the Command Window.

`ncdisp(source,location)` displays information about the variable or group specified by `location`.

`ncdisp(source,location,dispFormat)` displays the contents of the NetCDF data source, in the display format specified by `dispFormat`.

## Input Arguments

### **source - Name of NetCDF file**

string

Name of a NetCDF file, specified as a string. `source` also can be the URL of an OPeNDAP NetCDF data source that resolves to a NetCDF file or a variable in a NetCDF file.

**Example:** `'myNetCDFfile.nc'`

### **Data Types**

char

### **location - Location of variable or group**

'/' (default) | string

Location of a variable or group in the NetCDF file, specified as a string. Set `location` to '/' (forward slash) to display the entire contents of the file.

### **Data Types**

char

## dispFormat - Display format

'full' (default) | 'min'

Display format, specified as one of the following strings.

'full'	Display group hierarchy with dimensions, attributes, and variable definitions.
'min'	Display group hierarchy and variable definitions.

## Data Types

char

## Examples

### Display Contents of NetCDF File

Display the contents of the example NetCDF file, `example.nc`.

```
ncdisp('example.nc')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Global Attributes:

```
creation_date = '29-Mar-2010'
```

Dimensions:

```
x = 50
```

```
y = 50
```

```
z = 5
```

Variables:

```
avagadros_number
```

```
Size: 1x1
```

```
Dimensions:
```

```
Datatype: double
```

```
Attributes:
```

```
description = 'this variable has no dimensions'
```

```
temperature
```

```
Size: 50x1
```

```
Dimensions: x
```

```

 Datatype: int16
 Attributes:
 scale_factor = 1.8
 add_offset = 32
 units = 'degrees_fahrenheit'
peaks
 Size: 50x50
 Dimensions: x,y
 Datatype: int16
 Attributes:
 description = 'z = peaks(50);'
Groups:
 /grid1/
 Attributes:
 description = 'This is a group attribute.'
 Dimensions:
 x = 360
 y = 180
 time = 0 (UNLIMITED)
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16

 /grid2/
 Attributes:
 description = 'This is another group attribute.'
 Dimensions:
 x = 360
 y = 180
 time = 0 (UNLIMITED)
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16
```

MATLAB displays all the groups, dimensions, and variable definitions in `example.nc`.

## Display Contents of NetCDF Variable

Display the contents of the variable `peaks` in the file, `example.nc`.

```
ncdisp('example.nc','peaks')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Dimensions:

```
x = 50
```

```
y = 50
```

Variables:

```
peaks
```

```
Size: 50x50
```

```
Dimensions: x,y
```

```
Datatype: int16
```

```
Attributes:
```

```
description = 'z = peaks(50);'
```

## Display Contents of NetCDF File and Hide Attributes

Display only the group hierarchy and variable definitions of the example file, `example.nc`.

```
ncdisp('example.nc','/','min')
```

Source:

```
matlabroot\toolbox\matlab\demos\example.nc
```

Format:

```
netcdf4
```

Variables:

```
avagadros_number
```

```
Size: 1x1
```

```
Dimensions:

 Dimensions: x,y,time
 Datatype: int16
 /grid2/
 Variables:
 temp
 Size: []
 Dimensions: x,y,time
 Datatype: int16
```

**Tips**

- If source is an OPeNDAP URL with string constraints, use the syntax, `ncdisp(source)` with no other input arguments.

**See Also**

`ncwrite` | `ncinfo` | `ncread` | `netcdf` | `ncreadatt`

**Concepts**

- “Importing NetCDF Files and OPeNDAP Data”

# ncinfo

---

**Purpose** Return information about NetCDF data source

**Syntax**

```
finfo = ncinfo(source)
vinfo = ncinfo(source,varname)
ginfo = ncinfo(source,groupname)
```

**Description**

`finfo = ncinfo(source)` returns information in the structure `finfo` about the entire NetCDF data source specified by `source`, where `source` can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

`vinfo = ncinfo(source,varname)` returns information in the structure `vinfo` about the variable `varname` in `source`.

`ginfo = ncinfo(source,groupname)` returns information in the structure `ginfo` about the group `groupname` in `source` (only NetCDF4 data sources).

---

**Note** Use `ncdisp` for visual inspection of a NetCDF source.

---

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **varname**

Text string specifying the name of a variable in a NetCDF file or OPeNDAP data source.

### **groupname**

Text string specifying the name of a group in a NetCDF file or OPeNDAP data source.

## Output Arguments

### finfo

A structure with the following fields.

Field	Description	
Filename	NetCDF file name or OPeNDAP URL	
Name	' / ', indicating the full file	
Dimensions	An array of structures with these fields:	
	Name	Dimension name
	Length	Current length of dimension
	Unlimited	Boolean flag, true for unlimited dimensions
Variables	An array of structures with these fields:	
	Name	Variable name
	Dimensions	Associated dimensions
	Size	Current variable size
	Datatype	MATLAB datatype
	Attributes	Associated variable attributes
	ChunkSize	Chunk size, if defined. [ ] otherwise
	FillValue	Fill value of the variable.
	DeflateLevel	Deflate filter level, if enabled.
	Shuffle	Shuffle filter enabled flag
Attributes	An array of global attributes with these fields:	
	Name	Attribute name
	Value	Attribute value

Field	Description	
Groups	An array of groups present in the file, for netcdf4 files; An empty array ([]) for all other NetCDF file formats.	
Format	The format of the NetCDF file	

## **vinfo**

A structure containing only the variable fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the variable
Dimensions	Dimensions of the variable
Size	Size of the current variable
Datatype	MATLAB datatype
Attributes	Attributes associated with the variable
ChunkSize	Chunk size, if defined. [] otherwise.
FillValue	Fill value used in the variable.
DeflateLevel	Deflate filter level, if enabled.
Shuffle	Shuffle filter enabled flag
Format	The format of the NetCDF file

## **ginfo**

A structure containing only the group fields from `finfo`.

Field	Description
Filename	NetCDF file name
Name	Name of the group

Field	Description
Dimensions	Only dimensions defined in the specified group
Variables	Only variables defined in the specified group
Attributes	Attributes associated with the variable
Groups	Names of groups, if defined. [] otherwise.
Format	The format of the NetCDF file

## Examples

Search for dimensions with names that start with the character x in the file.

```
finfo = ncinfo('example.nc');
disp(finfo);
dimNames = {finfo.Dimensions.Name};
dimMatch = strncmpi(dimNames,'x',1);
disp(finfo.Dimensions(dimMatch));
```

Obtain the size of a variable and check if it has any unlimited dimensions.

```
vinfos = ncinfo('example.nc','peaks');
varSize =vinfos.Size;
disp(vinfos);
hasUnLimDim = any([vinfos.Dimensions.Unlimited]);
```

Find all unlimited dimensions defined in a group.

```
ginfo = ncinfo('example.nc','/grid2/');
unlimDims = [ginfo.Dimensions.Unlimited];
disp(ginfo.Dimensions(unlimDims));
```

# ncinfo

---

## **See Also**

`ncdisp` | `ncwrite` | `ncread` | `ncwritschema` | `netcdf`

## **Tutorials**

- “Importing NetCDF Files and OPeNDAP Data”

**Purpose**

Read data from variable in NetCDF data source

**Syntax**

```
vardata = ncread(source,varname)
vardata = ncread(source,varname,start,count,stride)
```

**Description**

`vardata = ncread(source,varname)` reads data from the variable `varname` in `source`, which can be either the name of a NetCDF file or an OPeNDAP NetCDF data source.

`vardata = ncread(source,varname,start,count,stride)` reads data from the variable `varname` in `source` beginning at the location given by `start`. `count` specifies the number of elements to read along the corresponding dimension. The optional argument `stride` specifies the inter-element spacing along each dimension.

**Input Arguments****source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

**varname**

Text string specifying the name of a variable in the NetCDF file or OPeNDAP NetCDF data source.

**start**

For an  $N$ -dimensional variable, `start` is a vector of length  $N$  of indices specifying the starting location. Indices are 1-based.

**count**

Vector of length  $N$  specifying the number of elements to read along the corresponding dimensions. If a particular element of `count` is `Inf`, `ncread` reads data until the end of the corresponding dimension.

**stride**

Optional argument that specifies the inter-element spacing along each dimension.

**Default:** Vector of 1s (ones)

## Output Arguments

### **vardata**

The data in the variable. `ncread` uses the MATLAB datatype that is the closest type to the corresponding NetCDF datatype, except when at least one of `_FillValue`, `scale_offset`, and `add_offset` variables attribute is present. `ncread` applies the following attribute conventions, in sequence, to `vardata` if the corresponding attribute exists for this variable:

- If the `_FillValue` attribute exists, `ncread` replaces values in `vardata` equal to the value of `_FillValue` with NaNs. If the `_FillValue` attribute does not exist, `ncread` queries the NetCDF library for the variable's fill value.
- If the `scale_factor` attribute exists, `ncread` multiplies `vardata` by the value of the `scale_factor` attribute.
- If the `add_offset` attribute exists, `ncread` adds the value of the `add_offset` attribute to `vardata`.

## Examples

Read and display the data in the `peaks` variable in the example file.

```
ncdisp('example.nc','peaks');
peaksData = ncread('example.nc','peaks');
peaksDesc = ncreadatt('example.nc','peaks','description');
surf(double(peaksData));
title(peaksDesc);
```

---

Subsample the `peaks` data by a factor of 2 (read every other value along each dimension).

```
subsetdata = ncread('example.nc','peaks',...
 [1 1], [Inf Inf], [2 2]);
```

```
surf(double(subsetdata));
```

## Tutorials

- “Importing NetCDF Files and OPeNDAP Data”

# ncreadatt

---

**Purpose** Read attribute value from NetCDF data source

**Syntax** `attvalue = ncreadatt(source,location,attname)`

**Description** `attvalue = ncreadatt(source,location,attname)` reads the attribute `attname` from the group or variable specified by `location` in `source`, where `source` is the name of a NetCDF file or the URL of a NetCDF data source.

## Input Arguments

### **source**

Text string specifying the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source.

### **location**

Text string specifying a group or variable in the NetCDF data source. To read global attributes, set `location` to `'/'` (forward slash).

### **attname**

Text string specifying the name of an attribute that you want to read in the NetCDF data source.

## Output Arguments

### **attvalue**

Data associated with the attribute.

## Examples

Read a global attribute.

```
creation_date = ncreadatt('example.nc','/','creation_date');
disp(creation_date);
```

---

Read an attribute associated with a variable.

```
scale_factor = ncreadatt('example.nc','temperature','scale_factor');
disp(scale_factor);
```

---

Read an attribute associated with a group (netcdf4 format files only).

```
desc_value = ncreadatt('example.nc', '/grid2', 'description');
disp(desc_value);
```

## Tutorials

- “Importing NetCDF Files and OPeNDAP Data”

# ncwrite

---

## Purpose

Write data to NetCDF file

## Syntax

```
ncwrite(filename,varname,vardata)
ncwrite(filename,varname,vardata,start, stride)
```

## Description

`ncwrite(filename,varname,vardata)` writes the numerical or char data in `vardata` to an existing variable `varname` in the NetCDF file `filename`. `ncwrite` writes the data in `vardata` starting at the beginning of the variable and extends unlimited dimensions automatically, if needed.

If the NetCDF file or the variable do not exist, use `nccreate` to create them first.

`ncwrite(filename,varname,vardata,start, stride)` writes `vardata` to an existing variable `varname` in file `filename` beginning at the location given by `start`. `stride` is an optional argument that specifies the inter-element spacing of the data written. Use this syntax to append data to an existing variable or write partial data.

## Tips

- If the variable `varname` already exists, `ncwrite` expects the datatype of `vardata` to match the NetCDF variable data type.
- If the variable `varname` has a `_FillValue`, `scale_factor` or `add_offset` attribute, `ncwrite` expects data in double format and casts `vardata` to the NetCDF data type, after applying the following attribute conventions in sequence:
  - 1 Subtract the value of the `add_offset` attribute from `vardata`.
  - 2 Divide `vardata` by the value of the `scale_factor` attribute.
  - 3 Replace NaNs in `vardata` by the value of the `_FillValue` attribute. If this attribute does not exist, `ncwrite` tries to use the fill value for this variable as reported by the NetCDF library.

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file. If the file does not exist, use `nccreate` to create it first.

**varname**

Text string specifying the name of a variable in a NetCDF file. If the variable does not exist, use `nccreate` to create it first.

**vardata**

Data to write to the variable in the NetCDF file.

**start**

For an  $N$ -dimensional variable, `start` is a vector of indices of length  $N$  specifying the starting location. Indices are 1-based.

**stride**

(Optional) Vector of length  $N$ , specifying the inter-element spacing.

**Default:** Vector of ones

## Examples

Create a new `netcdf4_classic` file, and write a scalar variable with no dimensions. Add the creation time as a global attribute.

```
nccreate('myfile.nc', 'pi');
ncwrite('myfile.nc', 'pi', 3.1);
ncwriteatt('myfile.nc', '/', 'creation_time', datestr(now));
% overwrite existing data
ncwrite('myfile.nc', 'pi', 3.1416);
ncdisp('myfile.nc');
```

Create a `netcdf4_classic` file with a variable defined on an unlimited dimension. Write data incrementally to the variable.

```
nccreate('mynctest.nc', 'vmark', ...
 'Dimensions', {'time', inf, 'cols', 6}, ...
 'ChunkSize', [3 3], ...
 'DeflateLevel', 2);
ncwrite('mynctest.nc', 'vmark', eye(3), [1 1]);
```

# ncwrite

---

```
varData = ncread('myncfile.nc','vmark');
disp(varData);
ncwrite('myncfile.nc','vmark',fliplr(eye(3)),[1 4]);
varData = ncread('myncfile.nc','vmark');
disp(varData);
```

## Tutorials

- “Exporting to NetCDF Files”

---

<b>Purpose</b>	Write attribute to NetCDF file
<b>Syntax</b>	<code>ncwriteatt(filename,location,attname,attvalue)</code>
<b>Description</b>	<code>ncwriteatt(filename,location,attname,attvalue)</code> creates or modifies the attribute specified by <code>attname</code> in the group or variable specified by <code>location</code> , in the NetCDF file specified by <code>filename</code> . <code>attvalue</code> can be a numeric vector or a string.
<b>Input Arguments</b>	<p><b>filename</b> Text string specifying the name of a NetCDF file</p> <p><b>location</b> Text string specifying a group or variable in the NetCDF file. To write global attributes, set <code>location</code> to <code>'/'</code> (forward slash).</p> <p><b>attname</b> Text string specifying the name of an existing attribute in a NetCDF file or the name of the attribute that you want to create.</p> <p><b>attvalue</b> Numeric vector or a string.</p>
<b>Examples</b>	<p>Create a global attribute.</p> <pre>copyfile(which('example.nc'),'myfile.nc'); fileattrib('myfile.nc','+w'); ncdisp('myfile.nc'); ncwriteatt('myfile.nc','/','creation_date',datestr(now)); ncdisp('myfile.nc');</pre> <hr/> <p>Modify an existing attribute.</p>

# ncwriteatt

---

```
copyfile(which('example.nc'),'myfile.nc');
fileattrib('myfile.nc','+w');
ncdisp('myfile.nc','peaks');
ncwriteatt('myfile.nc','peaks','description','Output of PEAKS');
ncdisp('myfile.nc','peaks');
```

## See Also

[ncdisp](#) | [ncreadatt](#) | [ncwrite](#) | [ncread](#) | [ncreate](#) | [netcdf](#)

## Tutorials

- [“Exporting to NetCDF Files”](#)

## Purpose

Add NetCDF schema definitions to NetCDF file

## Syntax

```
ncwritescema(filename,schema)
```

## Description

`ncwritescema(filename,schema)` creates or adds attributes, dimensions, variable definitions and group structure defined in `schema` to the file `filename`.

Use `ncwritescema` in combination with `ncinfo` to create a new NetCDF file based on the schema of an existing file. You can also use `ncwritescema` to add variable definitions, attributes, dimensions, or group structure to an existing file.

---

**Note** `ncwritescema` does not write variable data. Use `ncwrite` to write data to the created variables. Created unlimited dimensions will have an initial size of 0 until you write data.

---

---

**Note** `ncwritescema` cannot change the format of an existing file. It cannot redefine existing variables and dimensions in `filename`. If your schema contains attributes, dimensions, variable definitions, or a group structure that already exist in the file, `writescema` issues a warning but continues processing.

---

## Input Arguments

### **filename**

Text string specifying the name of a NetCDF file. If `filename` does not exist, `ncwritescema` creates a new file using the `netcdf4_classic` format, unless the `Format` field in `schema` specifies another format.

### **schema**

A structure, or array of structures, representing either a dimension, variable, an entire NetCDF file, or a `netcdf4` group. A group or file schema can contain a dimension or variable schema, or both. You can

# ncwritschema

---

use the output returned by `ncinfo` as a schema structure. The following table lists the fields in the various types of schema structures. Optional fields are marked with asterisk (\*).

Schema Type	Structure Field	Description
Group/File Schema	Name	Text string identifying the group name. Use '/' to indicate the entire file.
	Dimensions*	Dimension schema
	Variables*	Variable schema
	Attributes*	Structure array of group/global attributes with Name and Value fields
	Format*	Text string identifying a NetCDF file format
Dimension schema	Name	Text string identifying the dimension
	Length	Length of the dimension. Can be Inf.
	Unlimited*	Boolean flag indicating if the dimension is unlimited
	Format*	Text string identifying a NetCDF file format
Variable schema	Name	Text string identifying a variable name
	Dimensions	Variable's dimension schema
	Datatype	Text string identifying a MATLAB datatype
	Attributes*	Structure array of variable attributes with Name and Value fields

Schema Type	Structure Field	Description
	ChunkSize*	Numeric value specifying chunk size of the variable
	FillValue*	Character or numeric fill value
	DeflateValue*	Deflate compression level
	Shuffle*	Boolean flag to turn on the Shuffle filter
	Format*	Text string identifying a NetCDF file format

## Examples

Create a classic format file with two dimension definitions.

```
mySchema.Name = '/';
mySchema.Format = 'classic';
mySchema.Dimensions(1).Name = 'time';
mySchema.Dimensions(1).Length = Inf;
mySchema.Dimensions(2).Name = 'rows';
mySchema.Dimensions(2).Length = 10;
ncwritescema('emptyFile.nc', mySchema);
ncdisp('emptyFile.nc');
```

Create a netcdf4\_classic format file to store a single variable from an existing file. First use ncinfo to get the schema of the peaks variable from the file. Then use ncwritescema to create a NetCDF file, defining the peaks variable. Use ncread to get the data associated with the peaks variable and then use ncwrite to write the data to the variable in the new NetCDF file.

```
myVarSchema = ncinfo('example.nc', 'peaks');
ncwritescema('peaksFile.nc', myVarSchema);
peaksData = ncread('example.nc', 'peaks');
ncwrite('peaksFile.nc', 'peaks', peaksData);
ncdisp('peaksFile.nc');
```

# ncwritschema

---

`ncdisp` | `ncinfo` | `ncwrite` | `ncread` | `netcdf`

## **Tutorials**

- “Exporting to NetCDF Files”

**Purpose** Summary of MATLAB Network Common Data Form (NetCDF) capabilities

**Description** MATLAB provides both high- and low-level access to NetCDF files:

- High-level access functions make it easy to read a data set from a NetCDF file or write a variable from the MATLAB workspace into a NetCDF file
- Low-level access functions provide interfaces to dozens of functions in the NetCDF library

---

**Note** For information about MATLAB support for the Common Data Format (CDF), which is a completely separate and incompatible format, see `cdflib`.

---

### High-Level Access

These functions provide high-level access to NetCDF files.

<code>nccreate</code>	Create variable in NetCDF file
<code>ncinfo</code>	Return information about NetCDF data source
<code>ncread</code>	Read data from variable in NetCDF data source
<code>ncreadatt</code>	Read attribute value from NetCDF data source
<code>ncwrite</code>	Write data to NetCDF file
<code>ncwriteatt</code>	Write attribute to NetCDF file
<code>ncwritescema</code>	Add NetCDF schema definitions to NetCDF file

## Low-Level Access

The MATLAB low-level functions provide an API that you can use to enable reading data from and writing data to NetCDF files (known as *data sets* in NetCDF terminology). To use these functions, you should be familiar with the information about NetCDF contained in the [NetCDF C Interface Guide](#).

MATLAB supports NetCDF version 4.1.3.

In most cases, the syntax of the MATLAB function matches the syntax of the NetCDF library function. The functions are implemented as a package called `netcdf`. To use these functions, prefix the function name with package name `netcdf`. For example, to call the NetCDF library routine used to open existing NetCDF files, use the following MATLAB syntax:

```
ncid = netcdf.open(ncfile, mode);
```

## Library Functions

<code>netcdf</code>	Summary of MATLAB Network Common Data Form (NetCDF) capabilities
<code>netcdf.getChunkCache</code>	Retrieve chunk cache settings for NetCDF library
<code>netcdf.inqLibVers</code>	Return NetCDF library version information
<code>netcdf.setChunkCache</code>	Set default chunk cache settings for NetCDF library
<code>netcdf.setDefaultFormat</code>	Change default netCDF file format

## File Operations

<code>netcdf.abort</code>	Revert recent netCDF file definitions
<code>netcdf.close</code>	Close netCDF file

---

netcdf.create	Create new NetCDF dataset
netcdf.endDef	End netCDF file define mode
netcdf.inq	Return information about netCDF file
netcdf.inqFormat	Determine format of NetCDF file
netcdf.inqGrps	Retrieve array of child group IDs
netcdf.inqUnlimDims	Return list of unlimited dimensions in group
netcdf.open	Open NetCDF data source
netcdf.reDef	Put open netCDF file into define mode
netcdf.setFill	Set netCDF fill mode
netcdf.sync	Synchronize netCDF file to disk

**Dimensions**

netcdf.defDim	Create netCDF dimension
netcdf.inqDim	Return netCDF dimension name and length
netcdf.inqDimID	Return dimension ID
netcdf.renameDim	Change name of netCDF dimension

**Variables**

netcdf.defVar	Create NetCDF variable
netcdf.defVarChunking	Define chunking behavior for NetCDF variable
netcdf.defVarDeflate	Define compression parameters for NetCDF variable
netcdf.defVarFill	Define fill parameters for NetCDF variable

<code>netcdf.defVarFletcher32</code>	Define checksum parameters for NetCDF variable
<code>netcdf.getVar</code>	Return data from netCDF variable
<code>netcdf.inqVar</code>	Information about variable
<code>netcdf.inqVarChunking</code>	Determine chunking settings for NetCDF variable
<code>netcdf.inqVarDeflate</code>	Determine compression settings for NetCDF variable
<code>netcdf.inqVarFill</code>	Determine values of fill parameters for NetCDF variable
<code>netcdf.inqVarFletcher32</code>	Fletcher32 checksum setting for NetCDF variable
<code>netcdf.inqVarID</code>	Return ID associated with variable name
<code>netcdf.putVar</code>	Write data to netCDF variable
<code>netcdf.renameVar</code>	Change name of netCDF variable
<b>Attributes</b>	
<code>netcdf.copyAtt</code>	Copy attribute to new location
<code>netcdf.delAtt</code>	Delete netCDF attribute
<code>netcdf.getAtt</code>	Return netCDF attribute
<code>netcdf.inqAtt</code>	Return information about netCDF attribute
<code>netcdf.inqAttID</code>	Return ID of netCDF attribute
<code>netcdf.inqAttName</code>	Return name of netCDF attribute
<code>netcdf.putAtt</code>	Write netCDF attribute
<code>netcdf.renameAtt</code>	Change name of attribute

**Utilities**`netcdf.getConstant`

Return numeric value of named constant

`netcdf.getConstantNames`

Return list of constants known to netCDF library

# netcdf.abort

---

**Purpose** Revert recent netCDF file definitions

**Syntax** `netcdf.abort(ncid)`

**Description** `netcdf.abort(ncid)` reverts a netCDF file to its previous state, backing out any definitions made since the file last entered define mode. A file enters define mode when you create it (using `netcdf.create`) or when you explicitly enter define mode (using `netcdf.redef`). Once you leave define mode (using `netcdf.endDef`), you cannot revert the definitions you made while in define mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. A call to `netcdf.abort` closes the file.

This function corresponds to the `nc_abort` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new file, performs an operation on the file, and then reverts the file back to its original state. To run this example, you must have write permission in your current directory.

```
% Create a netCDF file
ncid = netcdf.create('foo.nc','NC_NOCLlobber');

% Perform an operation, such as defining a dimension.
dimid = netcdf.defDim(ncid, 'lat', 50);

% Revert the file back to its previous state.
netcdf.abort(ncid)

% Verify that the file is now closed.
dimid = netcdf.defDim(ncid, 'lat', 50); % should fail
??? Error using ==> netcdf.lib
NetCDF: Not a valid ID

Error in ==> defDim at 22
dimid = netcdf.lib('def_dim', ncid,dimname,dimlen);
```

## See Also

[netcdf.create](#) | [netcdf.endDef](#) | [netcdf.reDef](#)

# netcdf.close

---

**Purpose** Close netCDF file

**Syntax** `netcdf.close(ncid)`

**Description** `netcdf.close(ncid)` terminates access to the netCDF file identified by `ncid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_close` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file, and then closes the file. You must have write permission in your current directory to run this example.

```
ncid = netcdf.open('foo.nc', 'NC_WRITE')
```

```
netcdf.close(ncid)
```

**See Also** `netcdf.create` | `netCDF.open`

<b>Purpose</b>	Copy attribute to new location
<b>Syntax</b>	<code>netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)</code>
<b>Description</b>	<p><code>netcdf.copyAtt(ncid_in,varid_in,attname,ncid_out,varid_out)</code> copies an attribute from one variable to another, possibly across files. <code>ncid_in</code> and <code>ncid_out</code> are netCDF file identifiers returned by <code>netcdf.create</code> or <code>netcdf.open</code>. <code>varid_in</code> identifies the variable with an attribute that you want to copy. <code>varid_out</code> identifies the variable to which you want to associate a copy of the attribute.</p> <p>This function corresponds to the <code>nc_copy_att</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example makes a copy of the attribute associated with the first variable in the netCDF example file, <code>example.nc</code>, in a new file. To run this example, you must have write permission in your current directory.</p> <pre>% Open example file. ncid = netcdf.open('example.nc','NC_NOWRITE');  % Get identifier for a variable in the file. varid = netcdf.inqVarID(ncid,'avagadros_number');  % Create new netCDF file. ncid2 = netcdf.create('foo.nc','NC_NOCLlobber');  % Define a dimension in the new file. dimid2 = netcdf.defDim(ncid2,'x',50);  % Define a variable in the new file. varid2 = netcdf.defVar(ncid2,'myvar','double',dimid2);  % Copy the attribute named 'description' into the new file, % associating the attribute with the new variable. netcdf.copyAtt(ncid,varid,'description',ncid2,varid2);</pre>

# netcdf.copyAtt

---

```
%
% Check the name of the attribute in new file.
attname = netcdf.inqAttName(ncid2,varid2,0)

attname =

description
```

## See Also

```
netcdf.inqAtt | netcdf.inqAttID | netcdf.inqAttName |
netcdf.putAtt | netcdf.renameAtt
```

**Purpose** Create new NetCDF dataset

**Syntax**

```
ncid = netcdf.create(filename,mode)
[chunksize_out,ncid] = netcdf.create(filename,mode,initasz,chunksize)
```

**Description** `ncid = netcdf.create(filename,mode)` creates a new NetCDF file according to the file creation mode. The return value `ncid` is a file ID. The mode parameter is a text string that describes the type of file access, which can have any of the following values.

Value	Description
NOCLOBBER	Prevent overwriting of existing file with the
CLOBBER	Overwrite any existing file with the same name.
SHARE	Allow synchronous file updates.
64BIT_OFFSET	Allow easier creation of files and variables which are larger than two gigabytes.
NETCDF4	Create a NetCDF-4/HDF5 file
CLASSIC_MODEL	Enforce the classic model; has no effect unless used in a bitwise-or with NETCDF4

**Note** You can specify the mode as a numeric value, retrieved using the `netcdf.getConstant` function. To specify more than one mode, use a bitwise-OR of the numeric values of the modes.

`[chunksize_out,ncid] = netcdf.create(filename,mode,initasz,chunksize)` creates a new netCDF file, but with additional performance tuning parameters. `initasz` sets the initial size of the file. `chunksize` can affect I/O performance. The actual value chosen by the NetCDF library might not correspond to the input value.

# netcdf.create

---

This function corresponds to the `nc_create` and `nc__create` functions in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a netCDF dataset named `foo.nc`, only if no other file with the same name exists in the current directory. To run this example, you must have write permission in your current directory.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

---

This example creates a netCDF-4 file that uses the classic model.

```
mode = netcdf.getConstant('NETCDF4');
mode = bitor(mode, netcdf.getConstant('CLASSIC_MODEL'));
ncid = netcdf.create('myfile.nc', mode);
netcdf.close(ncid);
```

## See Also

`netcdf.getConstant` | `netcdf.open`

<b>Purpose</b>	Create netCDF dimension
<b>Syntax</b>	<code>dimid = netcdf.defDim(ncid,dimname,dimlen)</code>
<b>Description</b>	<p><code>dimid = netcdf.defDim(ncid,dimname,dimlen)</code> creates a new dimension in the netCDF file specified by <code>ncid</code>, where <code>dimname</code> is a character string that specifies the name of the dimension and <code>dimlen</code> is a numeric value that specifies its length. To define an unlimited dimension, specify the predefined constant <code>'NC_UNLIMITED'</code> for <code>dimlen</code>, using <code>netcdf.getConstant</code> to retrieve the value.</p> <p><code>netcdf.defDim</code> returns <code>dimid</code>, a numeric ID corresponding to the new dimension.</p> <p>This function corresponds to the <code>nc_def_dim</code> function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>
<b>Examples</b>	<p>Create a new file and define two dimensions in the file. One dimension is an unlimited dimension. To run this example, you must have write permission in your current folder.</p> <pre>% Create a netCDF file. ncid = netcdf.create('foo.nc','NC_NOCLlobber')  % Define a dimension. lat_dimID = netcdf.defDim(ncid,'latitude',360);  % Define an unlimited dimension. long_dimID = netcdf.defDim(ncid,'longitude',...     netcdf.getConstant('NC_UNLIMITED'));</pre>
<b>See Also</b>	<code>netcdf.getConstant</code>

# netcdf.defGrp

---

<b>Purpose</b>	Create group in NetCDF file
<b>Syntax</b>	<code>childGrpID = netcdf.defGrp(parentGroupId,childGroupName)</code>
<b>Description</b>	<code>childGrpID = netcdf.defGrp(parentGroupId,childGroupName)</code> creates a child group with the name specified by <code>childGroupName</code> , that is the child of the parent group specified by <code>parentGroupId</code>
<b>Input Arguments</b>	<b>parentGroupId</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> . <b>childGroupName</b> Text string specifying the name that you want to assign to the group.
<b>Output Arguments</b>	<b>childGrpID</b> Identifier of a NetCDF group.
<b>Examples</b>	This example creates a NetCDF dataset and then defines a group. <pre>ncid = netcdf.create('myfile.nc','netcdf4'); childGroupId = netcdf.defGrp(ncid,'mygroup'); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_def_grp</code> function in the NetCDF library C API. For copyright information, read the files <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> .
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqGrps</code>

<b>Purpose</b>	Create NetCDF variable
<b>Syntax</b>	<code>varid = netcdf.defVar(ncid,varname,xtype,dimids)</code>
<b>Description</b>	<p><code>varid = netcdf.defVar(ncid,varname,xtype,dimids)</code> creates a new variable in the dataset identified by <code>ncid</code>.</p> <p><code>varname</code> is a character string that specifies the name of the variable. <code>xtype</code> can be either a character string specifying the data type of the variable, such as <code>'double'</code>, or it can be the numeric equivalent returned by the <code>netcdf.getConstant</code> function. <code>dimids</code> specifies a list of dimension IDs.</p> <p><code>netcdf.defVar</code> returns <code>varid</code>, a numeric identifier for the new variable.</p> <p>This function corresponds to the <code>nc_def_var</code> function in the NetCDF library C API. Because MATLAB uses FORTRAN-style ordering, the fastest-varying dimension comes first and the slowest comes last. Any unlimited dimension is therefore last in the list of dimension IDs. This ordering is the reverse of that found in the C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>
<b>Examples</b>	<p>This example creates a new netCDF file, defines a dimension in the file, and then defines a variable on that dimension. (In netCDF files, you must create a dimension before you can create a variable.) To run this example, you must have write permission in your current directory.</p> <pre>% Create netCDF file. ncid = netcdf.create('foo.nc','NC_NOCLlobber'); % % Define a dimension in the new file. dimid = netcdf.defDim(ncid,'x',50);  % Define a variable in the new file. varid = netcdf.defVar(ncid,'myvar','double',dimid)</pre>
<b>See Also</b>	<code>netCDF.getConstant</code>   <code>netCDF.inqVar</code>   <code>netCDF.putVar</code>

# netcdf.defVarChunking

---

<b>Purpose</b>	Define chunking behavior for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarChunking(ncid,varid,storage,chunkDims)</code>
<b>Description</b>	<p><code>netcdf.defVarChunking(ncid,varid,storage,chunkDims)</code>. sets the chunk settings for the variable specified by <code>varid</code>. Chunking is a technique to improve performance. <code>storage</code> specifies the type of chunking to use and <code>chunkDims</code> specifies the extents of the chunk size. You must specify the chunk size used with a variable after creating the variable but before you write data to the variable.</p> <p>You cannot specify the chunk size for variables in a NetCDF file created with the netCDF-3 mode (<code>CLASSIC_MODEL</code>).</p>
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>storage</b> Text string specifying whether NetCDF should break the variable into chunks when writing to a file. If set to <code>CHUNKED</code>, NetCDF breaks the variable into chunks; if set to <code>CONTIGUOUS</code>, NetCDF does not break the data into chunks.</p> <p><b>chunkDims</b> Array specifying the dimensions of the chunk. Because MATLAB uses FORTRAN-style ordering, the order of dimensions in <code>chunkdims</code> is reversed relative to what would be in the C API. If <code>storage</code> is <code>CONTIGUOUS</code>, you can omit <code>chunkDims</code>.</p>

**Default:** Chunk size determined by the NetCDF library.

## Examples

This example creates a NetCDF file and specifies the chunking behavior of a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
londimid = netcdf.defDim(ncid, 'col', 3600);
varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]);
netcdf.defVarChunking(ncid, varid, 'CHUNKED', [180 360]);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_chunking` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexncopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarChunking`

# netcdf.defVarDeflate

---

<b>Purpose</b>	Define compression parameters for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)</code>
<b>Description</b>	<code>netcdf.defVarDeflate(ncid, varid, shuffle, deflate, deflateLevel)</code> sets the compression parameters for the NetCDF variable specified by <code>varid</code> in the location specified by <code>ncid</code> .
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>shuffle</b> Boolean value. To turn on the shuffle filter, set this argument to <code>true</code>. The shuffle filter can assist with the compression of integer data by changing the byte order in the data stream.</p> <p><b>deflate</b> Boolean value. To turn on compression, set this argument to <code>true</code> and set the <code>deflateLevel</code> argument to the desired compression level.</p> <p><b>deflateLevel</b> Numeric value between 0 and 9 specifying the amount of compression, where 0 is no compression and 9 is the most compression.</p>

## Examples

This example create a variable with dimensions [1800 3600] and a compression level of 5. This results in a chunked layout that is a 10-by-10 grid.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
latdimid = netcdf.defDim(ncid, 'lat', 1800);
```

```
londimid = netcdf.defDim(ncid,'col',3600);
varid = netcdf.defVar(ncid,'earthgrid','double',[latdimid londimid]);
netcdf.defVarDeflate(ncid,varid,true,true,5);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_deflate` function in the netCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexncopyright.txt` files.

## See Also

`netcdf` | `netcdf.inqVarDeflate`

# netcdf.defVarFill

---

**Purpose** Define fill parameters for NetCDF variable

**Syntax** `netcdf.defVarFill(ncid, varid, noFillMode, fillValue)`

**Description** `netcdf.defVarFill(ncid, varid, noFillMode, fillValue)` sets the fill parameters for the NetCDF variable identified by `varid`. `ncid` specifies the location.

For netCDF-4 files, you can only specify fill values when the NetCDF is in definition mode (before calling `netcdf.endDef`). For NetCDF files in classic and 64-bit offset modes, you can turn no-fill mode on and off at any time.

## Input Arguments

### **ncid**

Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

### **varid**

Identifier of a NetCDF variable, returned by `netcdf.defVar`.

### **noFillMode**

Boolean value. When set to `true`, turns off use of fill values for the variable, which can be helpful in high performance applications. When `true`, `netcdf.defVarFill` ignores the value of the `fillValue` argument. To use the fill value, set this to `false`.

### **fillValue**

Specifies the value to use in the variable when no other value is specified. The data type must be the same data type as the variable.

## Examples

This example creates a NetCDF file and defines a fill value for a variable.

```
ncid = netcdf.create('myfile.nc', 'NETCDF4');
dimid = netcdf.defDim(ncid, 'latitude', 180);
```

```
varid = netcdf.defVar(ncid,'latitude','double',dimid);
netcdf.defVarFill(ncid,varid,false,-999);
netcdf.close(ncid);
```

## References

This function corresponds to the `nc_def_var_fill` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

# netcdf.defVarFletcher32

---

<b>Purpose</b>	Define checksum parameters for NetCDF variable
<b>Syntax</b>	<code>netcdf.defVarFletcher32(ncid,varid,setting)</code>
<b>Description</b>	<code>netcdf.defVarFletcher32(ncid,varid,setting)</code> defines the checksum settings for the NetCDF variable specified by <code>varid</code> in the file specified by <code>ncid</code> .
<b>Input Arguments</b>	<p><b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code>, or of a NetCDF group, returned by <code>netcdf.defGrp</code>.</p> <p><b>varid</b> Identifier of a NetCDF variable, returned by <code>netcdf.defVar</code>.</p> <p><b>setting</b> Text string specifying whether Fletcher32 checksum error detection is used with the variable. To turn on Fletcher32 checksum, specify the value <code>FLETCHER32</code>. To turn off the use of checksum error detection, specify the value <code>NOCHECKSUM</code>.</p>
<b>Examples</b>	<p>This example creates a NetCDF dataset and turns on the Fletcher32 checksum for a variable.</p> <pre>ncid = netcdf.create('myfile.nc', 'NETCDF4'); latdimid = netcdf.defDim(ncid, 'lat', 1800); londimid = netcdf.defDim(ncid, 'col', 3600); varid = netcdf.defVar(ncid, 'earthgrid', 'double', [latdimid londimid]); netcdf.defVarFletcher32(ncid, varid, 'FLETCHER32'); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_def_var_fletcher32</code> function in the NetCDF library C API.

For copyright information, read the files `netcdfcopyright.txt` and `mexnccopyright.txt`.

### **See Also**

`netcdf` | `netcdf.inqVarFletcher32`

# netcdf.delAtt

---

**Purpose** Delete netCDF attribute

**Syntax** `netcdf.delAtt(ncid,varid,attName)`

**Description** `netcdf.delAtt(ncid,varid,attName)` deletes the attribute identified by the text string `attName`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` is a numeric value that identifies the variable. To delete a global attribute, use `netcdf.getConstant('GLOBAL')` for the `varid`. You must be in define mode to delete an attribute.

This function corresponds to the `nc_del_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open a netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Determine number of global attributes in file.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

 1

% Get name of attribute; it is needed for deletion.
attname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0)

% Put file in define mode to delete an attribute.
netcdf.reDef(ncid);

% Delete the global attribute in the netCDF file.
```

```
netcdf.delAtt(ncid,netcdf.getConstant('GLOBAL'),attname);

% Verify that the global attribute was deleted.
[numdims numvars numatts unlimdimID] = netcdf.inq(ncid);

numatts =

 0
```

## See Also

[netcdf.getConstant](#) | [netcdf.inqAttName](#)

# netcdf.endDef

---

**Purpose** End netCDF file define mode

**Syntax** `netcdf.endDef(ncid)`  
`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)`

**Description** `netcdf.endDef(ncid)` takes a netCDF file out of define mode and into data mode. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.endDef(ncid,h_minfree,v_align,v_minfree,r_align)` takes a netCDF file out of define mode, specifying four additional performance tuning parameters. For example, one reason for using the performance parameters is to reserve extra space in the netCDF file header using the `h_minfree` parameter:

```
ncid = netcdf.endDef(ncid,20000,4,0,4);
```

This reserves 20,000 bytes in the header, which can be used later when adding attributes. This can be extremely efficient when working with very large netCDF 3 files. To understand how to use these performance tuning parameters, see the netCDF library documentation.

This function corresponds to the `nc_enddef` and `nc__enddef` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples **Take File out of Define Mode**

When you create a file using `netcdf.create`, the functions opens the file in define mode. This example uses `netcdf.endDef` to take the file out of define mode.

Create a netCDF file.

```
ncid = netcdf.create('foo.c','NC_NOCLlobber');
```

Define a dimension.

```
dimid = netcdf.defDim(ncid,'lat',50);
```

Leave define mode.

```
netcdf.endDef(ncid)
```

Test if still in define mode.

```
dimid = netcdf.defDim(ncid,'lon',50);
```

Error using netcdflib

```
The NetCDF library encountered an error during execution of 'defDim' t
(NC_ENOTINDEFINE)'.
Error in netcdf.defDim (line 25)
dimid = netcdfdeflib('defDim', ncid,dimname,dimlen);
```

netcdf.defDim errors, as expected.

## See Also

[netcdf.create](#) | [netcdf.reDef](#)

# netcdf.getAtt

---

**Purpose** Return netCDF attribute

**Syntax**  
`attrvalue = netcdf.getAtt(ncid,varid,attname)`  
`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)`

**Description** `attrvalue = netcdf.getAtt(ncid,varid,attname)` returns `attrvalue`, the value of the attribute specified by the text string `attname`. When it chooses the data type of `attrvalue`, MATLAB attempts to match the netCDF class of the attribute. For example, if the attribute has the netCDF data type `NC_INT`, MATLAB uses the `int32` class for the output data. If an attribute has the netCDF data type `NC_BYTE`, the class of the output data is `int8` value.

`attrvalue = netcdf.getAtt(ncid,varid,attname,output_datatype)` returns `attrvalue`, the value of the attribute specified by the text string `attname`, using the output class specified by `output_datatype`. You can specify any of the following strings for the output data type.

'int'	'double'	'int16'
'short'	'single'	'int8'
'float'	'int32'	'uint8'

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and gets the value of the attribute associated with the first variable. The example also gets the value of the global variable in the file.

```
% Open a netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name of first variable.
```

```
[varname vartype vardimIDs varatts] = netcdf.inqVar(ncid,0);

% Get ID of variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get attribute name, given variable id.
attname = netcdf.inqAttName(ncid,varid,0);

% Get value of attribute.
attval = netcdf.getAtt(ncid,varid,attname);

% Get name of global attribute
gattname = netcdf.inqAttName(ncid,netcdf.getConstant('NC_GLOBAL'),0);

% Get value of global attribute.
gattval = netcdf.getAtt(ncid,netcdf.getConstant('NC_GLOBAL'),gattname);

gattval =

09-Jun-2008
```

# netcdf.getChunkCache

---

<b>Purpose</b>	Retrieve chunk cache settings for NetCDF library
<b>Syntax</b>	<code>[csize, nelems, premp] = netcdf.getChunkCache()</code>
<b>Description</b>	<code>[csize, nelems, premp] = netcdf.getChunkCache()</code> returns the default chunk cache settings.
<b>Output Arguments</b>	<p><b>csize</b></p> <p>Scalar double specifying the total size of the raw data chunk cache in bytes.</p> <p><b>nelems</b></p> <p>Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.</p> <p><b>premp</b></p> <p>Double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of zero means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.</p>
<b>Examples</b>	<p>Determine information about the chunk cache size used by the NetCDF library.</p> <pre>[csize, nelems, premp] = netcdf.getChunkCache();</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_get_chunk_cache</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.setChunkCache</code>

**Purpose** Return numeric value of named constant

**Syntax** `val = netcdf.getConstant(param_name)`

**Description** `val = netcdf.getConstant(param_name)` returns the numeric value corresponding to the name of a constant defined by the netCDF library. For example, `netcdf.getConstant('NC_NOCLOBBER')` returns the numeric value corresponding to the netCDF constant `NC_NOCLOBBER`.

The value for `param_name` can be either upper- or lowercase, and does not need to include the leading three characters `'NC_'`. To retrieve a list of all the names defined by the netCDF library, use the `netcdf.getConstantNames` function.

This function has no direct equivalent in the netCDF C interface. To find out more about NetCDF, see `netcdf`.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Determine contents of the file.
[ndims nvars natts dimm] = netcdf.inq(ncid);

% Get name of global attribute.
% Note: You must use netcdf.getConstant to specify NC_GLOBAL.
attname = netcdf.inqattname(ncid,netcdf.getConstant('NC_GLOBAL'),0)

attname =

creation_date
```

**See Also** `netcdf.getConstantNames`

# netcdf.getConstantNames

---

**Purpose** Return list of constants known to netCDF library

**Syntax** `val = netcdf.getConstantNames(param_name)`

**Description** `val = netcdf.getConstantNames(param_name)` returns a list of names of netCDF library constants, definitions, and enumerations. When these strings are supplied as actual parameters to MATLAB netCDF package functions, the functions automatically convert the constant to the appropriate numeric value.

This MATLAB function has no direct equivalent in the netCDF C interface. To find out more about netCDF, see `netcdf`.

**Examples** `nc_constants = netcdf.getConstantNames`

```
nc_constants =

 'NC2_ERR'
 'NC_64BIT_OFFSET'
 'NC_BYTE'
 'NC_CHAR'
 'NC_CLOBBER'
 'NC_DOUBLE'
 'NC_EBADDIM'
 'NC_EBADID'
 'NC_EBADNAME'
 'NC_EBADTYPE'
 ...
```

**See Also** `netCDF.getConstantNames`

**Purpose**

Return data from netCDF variable

**Syntax**

```
data = netcdf.getVar(ncid,varid)
data = netcdf.getVar(ncid,varid,start)
data = netcdf.getVar(ncid,varid,start,count)
data = netcdf.getVar(ncid,varid,start,count,stride)
data = netcdf.getVar(...,output_type)
```

**Description**

`data = netcdf.getVar(ncid,varid)` returns `data`, the value of the variable specified by `varid`. MATLAB attempts to match the class of the output data to netCDF class of the variable.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`data = netcdf.getVar(ncid,varid,start)` returns a single value starting at the specified index, `start`.

`data = netcdf.getVar(ncid,varid,start,count)` returns a contiguous section of a variable. `start` specifies the starting point and `count` specifies the amount of data to return.

`data = netcdf.getVar(ncid,varid,start,count,stride)` returns a subset of a section of a variable. `start` specifies the starting point, `count` specifies the extent of the section, and `stride` specifies which values to return.

`data = netcdf.getVar(...,output_type)` specifies the data type of the return value `data`. You can specify any of the following strings for the output data type.

'int8'
--------

'uint8'
---------

'int16'
---------

'int32'
---------

'single'
----------

'double'
----------

# netcdf.getVar

---

This function corresponds to several functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

Open the example netCDF file and get the value of a variable in the file.

```
% Open example file.
ncid = netcdf.open('example.nc', 'NC_NOWRITE');

% Get the name of the first variable.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name.
varid = netcdf.inqVarID(ncid,varname);

% Get the value of the first variable, given its ID.
data = netcdf.getVar(ncid,varid)

data =

 6.0221e+023

% Determine the data type of the output value
whos data
 Name Size Bytes Class Attributes
 data 1x1 8 double

% Get the value again, this time specifying the output data type
data = netcdf.getVar(ncid,varid,'single');

% Determine the data type of the output value
whos data
 Name Size Bytes Class Attributes
 data 1x1 4 single
```

**See Also**

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

# netcdf.inq

---

**Purpose** Return information about netCDF file

**Syntax** `[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)`

**Description** `[ndims,nvars,ngatts,unlimdimid] = netcdf.inq(ncid)` returns the number of dimensions, variables, and global attributes in a netCDF file. The function also returns the ID of the dimension defined with unlimited length, if one exists.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`. You can call `netcdf.inq` in either define mode or data mode.

This function corresponds to the `nc_inq` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and uses the `netcdf.inq` function to get information about the contents of the file.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE')

% Get information about the contents of the file.
[numdims, numvars, numglobalatts, unlimdimID] = netcdf.inq(ncid)

numdims =

 4

numvars =

 4

numglobalatts =
```

1

unlimdimID =

3

**See Also**

`netcdf.create` | `netcdf.open`

# netcdf.inqDimIDs

---

**Purpose** Retrieve list of dimension identifiers in group

**Syntax**  
`dimIDs = netcdf.inqDimIDs(ncid)`  
`dimIDs = netcdf.inqDimIDs(ncid,includeParents)`

**Description**  
`dimIDs = netcdf.inqDimIDs(ncid)` returns a list of dimension identifiers in the group specified by `ncid`.  
`dimIDs = netcdf.inqDimIDs(ncid,includeParents)` includes all dimensions in all parent groups if `includeParents` is true.

**Input Arguments**  
**ncid**  
Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**includeParents**  
Boolean value. If set to true, `netcdf.inqDimIDs` includes the dimensions of all parent groups.

**Default:** false

**Output Arguments**  
**dimIDs**  
Array of dimension IDs

**Examples**  
This example opens the NetCDF sample file and gets the IDs of all the dimensions.

```
ncid = netcdf.open('example.nc','NOWRITE');
gid = netcdf.inqNcid(ncid,'grid1');
dimids = netcdf.inqDimIDs(gid);
dimids_all = netcdf.inqDimIDS(gid, true);
netcdf.close(ncid);
```

**References**  
This function corresponds to the `nc_inq_dimids` function in the NetCDF library C API.

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

`netcdf` | `netcdf.inqVarIDs`

# netcdf.inqFormat

---

**Purpose** Determine format of NetCDF file

**Syntax** `format = netcdf.inqFormat(ncid)`

**Description** `format = netcdf.inqFormat(ncid)` returns the format for the file specified by NetCDF file identifier, `ncid`.

**Input Arguments** **ncid**  
Identifier of a NetCDF file, returned by `netcdf.create` or `netcdf.open`, or of a NetCDF group, returned by `netcdf.defGrp`.

**Output Arguments** **format**  
Text string that specifies the format of the NetCDF file. Values include:

Format String	Description
FORMAT_CLASSIC	Classic format — Original NetCDF format, used by all NetCDF files created between 1989 and 2004
FORMAT_64BIT	Classic format, 64-bit — Original format with 64-bit addressing capability to allow creation and access of much larger files.
FORMAT_NETCDF4	Enhanced model, HDF5-based — Introduced in 2008, NetCDF, version 4, extends the classic model and is based on HDF5.
FORMAT_NETCDF4_CLASSIC	Classic model, HDF5-based — Introduced in 2008, NetCDF, version 4, implements classic model but is based on HDF5.

**Examples** This example opens the sample NetCDF file and determines the format.

```
ncid = netcdf.open('example.nc', 'NOWRITE');
fmt = netcdf.inqFormat(ncid)
```

```
format =
FORMAT_NETCDF4
netcdf.close(ncid);
```

# netcdf.inqGrpName

---

<b>Purpose</b>	Retrieve name of group
<b>Syntax</b>	<code>groupName = netcdf.inqGrpName(ncid)</code>
<b>Description</b>	<code>groupName = netcdf.inqGrpName(ncid)</code> returns the name of a group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>groupName</b> Text string specifying name of a group. The root group has the name <code>'/'</code> .
<b>Examples</b>	This example opens the NetCDF sample file and gets the names of groups in the dataset. <pre>ncid = netcdf.open('example.nc','nowrite'); name = netcdf.inqGrpName(ncid); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_inq_grpname</code> function in the NetCDF library C API. For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqGrpNameFull</code>

<b>Purpose</b>	Complete pathname of group
<b>Syntax</b>	<code>groupName = netcdf.inqGrpNameFull(ncid)</code>
<b>Description</b>	<code>groupName = netcdf.inqGrpNameFull(ncid)</code> returns the complete pathname of the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>groupName</b> Text string specifying complete path of group.  The root group has the name <code>'/'</code> . The names of parent groups and child groups use the forward slash <code>'/'</code> separator, as in UNIX folder names, for example, <code>/group1/subgrp2/subsubgrp3</code> .
<b>Examples</b>	Open the NetCDF sample dataset and retrieve the names of all groups.  <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid2'); fullName = netcdf.inqGrpNameFull(gid); netcdf.close(ncid);</pre>

# netcdf.inqGrpParent

---

<b>Purpose</b>	Retrieve ID of parent group.
<b>Syntax</b>	<code>parentGroupID = netcdf.inqGrpParent(ncid)</code>
<b>Description</b>	<code>parentGroupID = netcdf.inqGrpParent(ncid)</code> returns the ID of the parent group given the location of the child group, specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of a NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>parentGroupID</b> Identifier of the NetCDF group or file that is the parent of the specified file or group.
<b>Examples</b>	<p>This example opens the NetCDF sample file and gets the full path of the parent of the specified group.</p> <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid2'); parentId = netcdf.inqGrpParent(gid); fullName = netcdf.inqGrpNameFull(parentId); netcdf.close(ncid);</pre>
<b>References</b>	<p>This function corresponds to the <code>nc_inq_grp_parent</code> function in the NetCDF library C API.</p> <p>For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.</p>
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqGrps</code>

<b>Purpose</b>	Retrieve array of child group IDs
<b>Syntax</b>	<code>childGrps = netcdf.inqGrps(ncid)</code>
<b>Description</b>	<code>childGrps = netcdf.inqGrps(ncid)</code> returns all the child group IDs in the parent group, specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>childGrps</b> Array containing identifiers of child groups in the specified NetCDF file or group.
<b>Examples</b>	This example opens the sample NetCDF file and then gets information about the groups it contains. <pre>ncid = netcdf.open('example.nc', 'nowrite'); childGroups = netcdf.inqGrps(ncid); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_inq_grps</code> function in the netCDF library C API. For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.

# netcdf.inqVarIDs

---

<b>Purpose</b>	IDs of all variables in group
<b>Syntax</b>	<code>varids = netcdf.inqVarIDs(ncid)</code>
<b>Description</b>	<code>varids = netcdf.inqVarIDs(ncid)</code> returns IDs of the all the variables in the group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .
<b>Output Arguments</b>	<b>varids</b> Array containing identifiers of variables in a NetCDF file or group.
<b>Examples</b>	This example opens the NetCDF sample file and gets the IDs of all the variables in a group. <pre>ncid = netcdf.open('example.nc', 'NOWRITE'); gid = netcdf.inqNcid(ncid, 'grid1'); varids = netcdf.inqVarIDs(gid); netcdf.close(ncid);</pre>
<b>References</b>	This function corresponds to the <code>nc_inq_varids</code> function in the NetCDF library C API. For copyright information, read the <code>netcdfcopyright.txt</code> and <code>mexnccopyright.txt</code> files.
<b>See Also</b>	<code>netcdf</code>   <code>netcdf.inqDimIDs</code>   <code>netcdf.inqVarID</code>

<b>Purpose</b>	Determine chunking settings for NetCDF variable
<b>Syntax</b>	<code>[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)</code>
<b>Description</b>	<code>[storage,chunkSizes] = netcdf.inqVarChunking(ncid,varid)</code> returns the type of chunking and the dimensions of a chunk for the NetCDF variable specified by <code>varid</code> , in the file or group specified by <code>ncid</code> .
<b>Input Arguments</b>	<b>ncid</b> Identifier of NetCDF file, returned by <code>netcdf.create</code> or <code>netcdf.open</code> , or of a NetCDF group, returned by <code>netcdf.defGrp</code> .  <b>varid</b> Identifier of NetCDF variable, returned by <code>netcdf.defVar</code> .
<b>Output Arguments</b>	<b>storage</b> Text string specifying if NetCDF breaks the data into chunks when writing to a file. <code>CHUNKED</code> indicates the data is chunked; <code>CONTIGUOUS</code> indicates that the data is not chunked.  <b>chunkSizes</b> Array specifying the dimensions of the chunk.  Because MATLAB uses FORTRAN-style ordering, the order of dimensions in <code>chunkdims</code> is reversed relative to what would be in the NetCDF C API.  If the storage type specified is <code>CONTIGUOUS</code> , <code>netcdf.inqVarChunking</code> returns an empty array, <code>[]</code> .
<b>Examples</b>	This example opens the NetCDF sample dataset and gets the values of chunking parameters associated with a variable.  <pre>ncid = netcdf.open('example.nc','NOWRITE');</pre>

# netcdf.inqVarChunking

---

```
groupid = netcdf.inqNcid(ncid,'grid1');
varid = netcdf.inqVarID(groupid,'temp');
[storage,chunkSize] = netcdf.inqVarChunking(groupid,varid);
netcdf.close(ncid);
```

## Purpose

Return ID of netCDF attribute

## Syntax

```
attnum = netcdf.inqAttID(ncid,varid,attname)
```

## Description

`attnum = netcdf.inqAttID(ncid,varid,attname)` retrieves `attnum`, the identifier of the attribute specified by the text string `attname`.

`varid` specifies the variable the attribute is associated with.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_attid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example opens the netCDF example file included with MATLAB, `example.nc`.

```
% Open the netCDF example file.
```

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get the identifier of a variable in the file.
```

```
varid = netcdf.inqVarID(ncid,'avagadros_number');
```

```
% Retrieve the identifier of the attribute associated with the variable.
```

```
attid = netcdf.inqAttID(ncid,varid,'description');
```

# netcdf.inqDim

---

**Purpose** Return netCDF dimension name and length

**Syntax** [dimname, dimlen] = netcdf.inqDim(ncid,dimid)

**Description** [dimname, dimlen] = netcdf.inqDim(ncid,dimid) returns the name, dimname, and length, dimlen, of the dimension specified by dimid. If ndims is the number of dimensions defined for a netCDF file, each dimension has an ID between 0 and ndims-1. For example, the dimension identifier of the first dimension is 0, the second dimension is 1, and so on.

ncid is a netCDF file identifier returned by netcdf.create or netcdf.open.

This function corresponds to the nc\_inq\_dim function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See netcdf for more information.

**Examples** The example opens the example netCDF file include with MATLAB, example.nc.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');
```

```
% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0)
```

```
dimname =
```

```
x
```

```
dimlen =
```

```
50
```

**See Also** netcdf.inqDimID

**Purpose** Return dimension ID

**Syntax** `dimid = netcdf.inqDimID(ncid,dimname)`

**Description** `dimid = netcdf.inqDimID(ncid,dimname)` returns `dimid`, the identifier of the dimension specified by the character string `dimname`. You can use the `netcdf.inqDim` function to retrieve the dimension name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_dimid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF example file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get name and length of first dimension
[dimname, dimlen] = netcdf.inqDim(ncid,0);

% Retrieve identifier of dimension.
dimid = netcdf.inqDimID(ncid,dimname)

dimid =

 0
```

**See Also** `netcdf.inqDim`

# netcdf.inqLibVers

---

**Purpose** Return NetCDF library version information

**Syntax** `libvers = netcdf.inqLibVers`

**Description** `libvers = netcdf.inqLibVers` returns a string identifying the version of the NetCDF library.

This function corresponds to the `nc_inq_libvers` function in the NetCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** `libvers = netcdf.inqLibVers`

```
libvers =
```

```
4.1.3
```

<b>Purpose</b>	Information about variable
<b>Syntax</b>	<code>[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)</code>
<b>Description</b>	<p><code>[varname,xtype,dimids,natts] = netcdf.inqVar(ncid,varid)</code> returns information about the variable identified by <code>varid</code>. The argument, <code>ncid</code>, is a netCDF file identifier returned by <code>netcdf.create</code> or <code>netcdf.open</code>.</p> <p>The output argument, <code>varname</code>, is the name of the variable. <code>xtype</code> is the data type, <code>dimids</code> is the dimension IDs, and <code>natts</code> is the number of attributes associated with the variable. Dimension IDs are zero-based.</p> <p>This function corresponds to the <code>nc_inq_var</code> function in the netCDF library C API. Because MATLAB uses FORTRAN-style ordering, however, the order of the dimension IDs is reversed relative to what would be obtained from the C API. To use this function, you should be familiar with the netCDF programming paradigm. See <code>netcdf</code> for more information.</p>

**Examples** Open the example netCDF file included with MATLAB, `example.nc`, and get information about a variable in the file.

```
% Open the example netCDF file.
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about third variable in the file.
[varname, xtype, dimids, numatts] = netcdf.inqVar(ncid,2)

## See Also

[netcdf.create](#) | [netcdf.inqVarID](#) | [netcdf.open](#)

**Purpose** Return ID associated with variable name

**Syntax** `varid = netcdf.inqVarID(ncid,varname)`

**Description** `varid = netcdf.inqVarID(ncid,varname)` returns `varid`, the ID of a netCDF variable specified by the text string, `varname`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

This function corresponds to the `nc_inq_varid` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example netCDF file included with MATLAB, `example.nc`, and uses several inquiry functions to get the ID of the first variable.

```
ncid = netcdf.open('example.nc','NC_NOWRITE');

% Get information about first variable in the file.
[varname, xtype, dimids, atts] = netcdf.inqVar(ncid,0);

% Get variable ID of the first variable, given its name
varid = netcdf.inqVarID(ncid,varname)

varid =

 0
```

**See Also** `netcdf.create` | `netcdf.inqVar` | `netcdf.open`

# netcdf.open

---

**Purpose** Open NetCDF data source

**Syntax**

```
ncid = netcdf.open(source)
ncid = netcdf.open(source,mode)
[chosen_chunksize, ncid] = netcdf.open(source,mode,chunksize)
```

**Description** `ncid = netcdf.open(source)` opens `source`, which can be the name of a NetCDF file or the URL of an OPeNDAP NetCDF data source, for read-only access. Returns a NetCDF ID in `ncid`.

`ncid = netcdf.open(source,mode)` opens `source` with the type of access specified by `mode`, which can have any of the following values.

Value	Description
'WRITE'	Read-write access
'SHARE'	Synchronous file updates
'NOWRITE'	Read-only access (Default)

You can also specify `mode` as a numeric value that can be retrieved using `netcdf.getConstant`. Use these numeric values when you want to specify a bitwise-OR of several modes.

```
[chosen_chunksize, ncid] =
netcdf.open(source,mode,chunksize)
```

opens `source`, an existing netCDF data source, specifying the additional I/O performance tuning parameter, `chunksize`. The actual value used by the NetCDF library might not correspond to the input value you specify.

This function corresponds to the `nc_open` and `nc__open` functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example opens the example NetCDF file included with MATLAB, `example.nc`.

```
ncid = netcdf.open('example.nc','NOWRITE');
netcdf.close(ncid);
```

# netcdf.putAtt

---

**Purpose** Write netCDF attribute

**Syntax** `netcdf.putAtt(ncid,varid,attrname,attrvalue)`

**Description** `netcdf.putAtt(ncid,varid,attrname,attrvalue)` writes the attribute named `attrname` with value `attrvalue` to the netCDF variable specified by `varid`. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

`ncid` is a netCDF file identifier returned by `netCDF.create` or `netCDF.open`.

---

**Note** You cannot use `netcdf.putAtt` to set the `'_FillValue'` attribute of NetCDF4 files. Use the `netcdf.defVarFill` function to set the fill value for a variable.

---

This function corresponds to several attribute I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## Examples

This example creates a new netCDF file, defines a dimension and a variable, adds data to the variable, and then creates an attribute associated with the variable. To run this example, you must have writer permission in your current directory.

```
% Create a variable in the workspace.
my_vardata = linspace(0,50,50);

% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Define a dimension in the file.
dimid = netcdf.defDim(ncid,'my_dim',50);

% Define a new variable in the file.
```

```
varid = netcdf.defVar(ncid,'my_var','double',dimid);

% Leave define mode and enter data mode to write data.
netcdf.endDef(ncid);

% Write data to variable.
netcdf.putVar(ncid,varid,my_vardata);

% Re-enter define mode.
netcdf.reDef(ncid);

% Create an attribute associated with the variable.
netcdf.putAtt(ncid,0,'my_att',10);

% Verify that the attribute was created.
[xtype xlen] = netcdf.inqAtt(ncid,0,'my_att')

xtype =

 6

xlen =

 1
```

---

This example creates a new netCDF file, specifies a global attribute, and assigns a value to the attribute.

```
ncid = netcdf.create('myfile.nc','CLOBBER');
varid = netcdf.getConstant('GLOBAL');
netcdf.putAtt(ncid,varid,'creation_date',datestr(now));
netcdf.close(ncid);
```

## See Also

[netcdf.getAtt](#) | [netcdf.defVarFill](#) | [netcdf.getConstant](#)

# netcdf.putVar

---

**Purpose** Write data to netCDF variable

**Syntax**

```
netcdf.putVar(ncid,varid,data)
netcdf.putVar(ncid,varid,start,data)
netcdf.putVar(ncid,varid,start,count,data)
netcdf.putVar(ncid,varid,start,count,stride,data)
```

**Description** `netcdf.putVar(ncid,varid,data)` writes data to a netCDF variable identified by `varid`.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`netcdf.putVar(ncid,varid,start,data)` writes a single data value into the variable at the index specified by `start`.

`netcdf.putVar(ncid,varid,start,count,data)` writes a section of values into the netCDF variable at the index specified by the vector `start` to the extent specified by the vector `count`, along each dimension of the specified variable.

`netcdf.putVar(ncid,varid,start,count,stride,data)` writes the subsection specified by sampling interval, `stride`, of the values in the section of the variable beginning at the index `start` and to the extent specified by `count`.

This function corresponds to several variable I/O functions in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

## **Examples**      **Write Variable to New netCDF File**

Create a new netCDF file and write a variable to the file.

Create a 50 element vector for a variable.

```
my_vardata = linspace(0,50,50);
```

Open the netCDF file.

```
ncid = netcdf.create('foo.nc', 'NOCLOBBER');
```

Define the dimensions of the variable.

```
dimid = netcdf.defDim(ncid, 'my_dim', 50);
```

Define a new variable in the file.

```
my_varID = netcdf.defVar(ncid, 'my_var', 'double', dimid);
```

Leave define mode and enter data mode to write data.

```
netcdf.endDef(ncid);
```

Write data to variable.

```
netcdf.putVar(ncid, my_varID, my_vardata);
```

Verify that the variable was created.

```
[varname xtype dimid natts] = netcdf.inqVar(ncid, 0)
```

```
varname =
```

```
my_var
```

```
xtype =
```

```
6
```

```
dimid =
```

```
0
```

```
natts =
```

# netcdf.putVar

---

0

Close the file.

```
netcdf.close(ncid)
```

## Write Elements of Variable

Write to the first ten elements of the example temperature variable.

```
srcFile = fullfile(matlabroot,'toolbox','matlab','demos','example.nc');
copyfile(srcFile,'myfile.nc');
fileattrib('myfile.nc','+w');
ncid = netcdf.open('myfile.nc','WRITE');
varid = netcdf.inqVarID(ncid,'temperature');
data = [100:109];
netcdf.putVar(ncid,varid,0,10,data);
netcdf.close(ncid);
```

## See Also

# netcdf.renameAtt

---

**Purpose** Change name of attribute

**Syntax** `netcdf.renameAtt(ncid,varid,oldName,newName)`

**Description** `netcdf.renameAtt(ncid,varid,oldName,newName)` changes the name of the attribute specified by the character string `oldName`.

`newName` is a character string that specifies the new name.

`ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`.

`varid` identifies the variable to which the attribute is associated. To specify a global attribute, use `netcdf.getConstant('NC_GLOBAL')` for `varid`.

This function corresponds to the `nc_rename_att` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Get the ID of a variable the attribute is associated with.
varID = netcdf.inqVarID(ncid,'avagadros_number')

% Rename the attribute.
netcdf.renameAtt(ncid,varID,'description','Description');

% Verify that the name changed.
attname = netcdf.inqAttName(ncid,varID,0)

attname =

Description
```

**See Also**      `netcdf.inqAttName`

# netcdf.renameDim

---

**Purpose** Change name of netCDF dimension

**Syntax** `netcdf.renameDim(ncid,dimid,newName)`

**Description** `netcdf.renameDim(ncid,dimid,newName)` renames the dimension identified by the dimension identifier, `dimid`.

`newName` is a character string specifying the new name. `ncid` is a netCDF file identifier returned by `netcdf.create` or `netcdf.open`

This function corresponds to the `nc_rename_dim` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This examples modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file is define mode.
netcdf.reDef(ncid)

% Get the identifier of a dimension to rename.
dimid = netcdf.inqDimID(ncid,'x');

% Rename the dimension.
netcdf.renameDim(ncid,dimid,'Xdim')

% Verify that the name changed.
data = netcdf.inqDim(ncid,dimid)

data =

Xdim
```

**See Also** `netcdf.defDim`

**Purpose** Change name of netCDF variable

**Syntax** `netcdf.renameVar(ncid,varid,newName)`

**Description** `netcdf.renameVar(ncid,varid,newName)` renames the variable identified by `varid` in the netCDF file identified by `ncid`. `newName` is a character string specifying the new name.

This function corresponds to the `nc_rename_var` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example modifies a local copy of the example netCDF file included with MATLAB, `example.nc`.

```
% Open netCDF file.
ncid = netcdf.open('my_example.nc','NC_WRITE')

% Put file in define mode.
netcdf.redef(ncid)

% Get name of first variable
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname

varname =

avagadros_number

% Rename the variable, using a capital letter to start the name.
netcdf.renameVar(ncid,0,'Avagadros_number')

% Verify that the name of the variable changed.
[varname, xtype, varDimIDs, varAtts] = netcdf.inqVar(ncid,0);

varname
```

# netcdf.renameVar

---

varname =

Avagadros\_number

<b>Purpose</b>	Set default chunk cache settings for NetCDF library
<b>Syntax</b>	<code>netcdf.setChunkCache(csize, nelems, premp)</code>
<b>Description</b>	<p><code>netcdf.setChunkCache(csize, nelems, premp)</code> sets the default chunk cache settings used by the NetCDF library.</p> <p>Settings apply for subsequent file open or create operations, for the remainder of the MATLAB session or until you issue a <code>clear mex</code> call. This function does not change the chunk cache settings of files already open.</p>
<b>Input Arguments</b>	<p><b>csize</b></p> <p>Scalar double specifying the total size of the raw data chunk cache in bytes.</p> <p><b>nelems</b></p> <p>Scalar double specifying the number of chunk slots in the raw data chunk cache hash table.</p> <p><b>premp</b></p> <p>Scalar double, between 0 and 1, inclusive, that specifies how the library handles preempting fully read chunks in the chunk cache. A value of 0 means fully read chunks are treated no differently than other chunks, that is, preemption occurs solely based on the Least Recently Used (LRU) algorithm. A value of 1 means fully read chunks are always preempted before other chunks.</p>
<b>Examples</b>	<p>This example sets the cache chunk size used by the NetCDF library.</p> <pre>netcdf.setChunkCache(32000000, 2003, .75)</pre>
<b>References</b>	This function corresponds to the <code>nc_set_chunk_cache</code> function in the NetCDF library C API.

# netcdf.setChunkCache

---

For copyright information, read the `netcdfcopyright.txt` and `mexnccopyright.txt` files.

## **See Also**

`netcdf` | `netcdf.getChunkCache`

**Purpose** Change default netCDF file format

**Syntax** `oldFormat = netcdf.setDefaultFormat(newFormat)`

**Description** `oldFormat = netcdf.setDefaultFormat(newFormat)` changes the default format used by `netCDF.create` when creating new netCDF files, and returns the value of the old format. You can use this function to change the format used by a netCDF file without having to change the creation mode flag used in each call to `netCDF.create`.

`newFormat` can be either of the following values.

Value	Description
'NC_FORMAT_CLASSIC'	Original netCDF file format
'NC_FORMAT_64BIT'	64-bit offset format; relaxes limitations on creating very large files

You can also specify the numeric equivalent of these values, as retrieved by `netcdf.getConstant`.

This function corresponds to the `nc_set_default_format` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** `oldFormat = netcdf.setDefaultFormat('NC_FORMAT_64BIT');`

**See Also** `netcdf.create`

# netcdf.setFill

---

**Purpose** Set netCDF fill mode

**Syntax** `old_mode = netcdf.setFill(ncid,new_mode)`

**Description** `old_mode = netcdf.setFill(ncid,new_mode)` sets the fill mode for a netCDF file identified by `ncid`.

`new_mode` can be either 'FILL' or 'NOFILL' or their numeric equivalents, as retrieved by `netcdf.getConstant`. The default mode is 'FILL'. netCDF pre-fills data with fill values. Specifying 'NOFILL' can be used to enhance performance, because it avoids the duplicate writes that occur when the netCDF writes fill values that are later overwritten with data.

This function corresponds to the `nc_set_fill` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new file and specifies the fill mode used by netCDF with the file.

```
ncid = netcdf.open('foo.nc','NC_WRITE');

% Set filling behavior
old_mode = netcdf.setFill(ncid,'NC_NOFILL');
```

**See Also** `netcdf.getConstant`

**Purpose** Synchronize netCDF file to disk

**Syntax** `netcdf.sync(ncid)`

**Description** `netcdf.sync(ncid)` synchronizes the state of a netCDF file to disk. The netCDF library normally buffers accesses to the underlying netCDF file, unless you specify the `NC_SHARE` mode when you opened the file with `netcdf.open` or `netcdf.create`. To call `netcdf.sync`, the netCDF file must be in data mode.

This function corresponds to the `nc_sync` function in the netCDF library C API. To use this function, you should be familiar with the netCDF programming paradigm. See `netcdf` for more information.

**Examples** This example creates a new netCDF file for write access, performs an operation on the file, takes the file out of define mode, and then synchronizes the file to disk.

```
% Create a netCDF file.
ncid = netcdf.create('foo.nc','NC_WRITE');

% Perform an operation.
dimid = netcdf.defDim(ncid,'Xdim',50);

% Take file out of define mode.
netcdf.endDef(ncid);

% Synchronize the file to disk.
netcdf.sync(ncid)
```

**See Also** `netcdf.close` | `netcdf.create` | `netcdf.open` | `netcdf.endDef`

# newplot

---

**Purpose** Determine where to draw graphics objects

**Syntax**

```
newplot
h = newplot
h = newplot(hsave)
```

**Description** `newplot` prepares a figure and axes for subsequent graphics commands.

`h = newplot` prepares a figure and axes for subsequent graphics commands and returns a handle to the current axes.

`h = newplot(hsave)` prepares and returns an axes, but does not delete any objects whose handles you have assigned to the `hsave` argument, which can be a vector of handles. If `hsave` is not empty, the figure and axes containing `hsave` are prepared for plotting instead of the current axes of the current figure. If `hsave` is empty, `newplot` behaves as if it were called without any inputs.

**Tips** To create a simple 2-D plot, use the `plot` function instead.

Use `newplot` at the beginning of high-level graphics code to determine which figure and axes to target for graphics output. Calling `newplot` can change the current figure and current axes. Basically, there are three options when you are drawing graphics in existing figures and axes:

- Add the new graphics without changing any properties or deleting any objects.
- Delete all existing objects whose handles are not hidden before drawing the new objects.
- Delete all existing objects regardless of whether or not their handles are hidden, and reset most properties to their defaults before drawing the new objects (refer to the following table for specific information).

The figure and axes `NextPlot` properties determine how `newplot` behaves. The following two tables describe this behavior with various property values.

First, `newplot` reads the current figure's `NextPlot` property and acts accordingly.

NextPlot	What Happens
new	Create a new figure and use it as the current figure.
add	Draw to the current figure without clearing any graphics objects already present.
replacechildren	<p>Remove all child objects whose HandleVisibility property is set to on and reset figure NextPlot property to add.</p> <p>This clears the current figure and is equivalent to issuing the clf command.</p>
replace	<p>Remove all child objects (regardless of the setting of the HandleVisibility property) and reset figure properties to their defaults, except NextPlot is reset to add regardless of user-defined defaults.</p> <ul style="list-style-type: none"> <li>• Position, Units, PaperPosition, and PaperUnits are not reset.</li> </ul> <p>This clears and resets the current figure and is equivalent to issuing the clf reset command.</p>

After newplot establishes which figure to draw in, it reads the current axes' NextPlot property and acts accordingly.

NextPlot	Description
add	Draw into the current axes, retaining all graphics objects already present.
replacechildren	Remove all child objects whose HandleVisibility property is set to on, but do not reset axes properties. This clears the current axes like the cla command.
replace	Remove all child objects (regardless of the setting of the HandleVisibility property) and reset axes properties to their defaults, except Position and Units.  This clears and resets the current axes like the cla reset command.

## How To

- Controlling Graphics Output

**Purpose** Make next IFD current IFD

**Syntax** `tiffobj.nextDirectory()`

**Description** `tiffobj.nextDirectory()` makes the next image file directory (IFD) in the file the current IFD. `Tiff` object methods operate on the current IFD. Use this method to navigate among IFDs in a TIFF file containing multiple images.

**Examples**      **Make Next Directory the Current Directory**

Open a `Tiff` object and change the current IFD to the next IFD in the file.

```
t = Tiff('example.tif', 'r');
t.nextDirectory();
t.close();
```

**References** This method corresponds to the `TIFFReadDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.setDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

# nextpow2

---

**Purpose** Exponent of next higher power of 2

**Syntax** `P = nextpow2(A)`

**Description** `P = nextpow2(A)` returns the exponents for the smallest powers of two that satisfy

$$2^p \geq |A|$$

for each element in A.

You can use `nextpow2` to pad the signal you pass to `fft`. Doing so can speed up the computation of the FFT when the signal length is not an exact power of 2.

## Input Arguments

### A - Input values

scalar, vector, or array of real numbers

Input values, specified as a scalar, vector, or array of real numbers of any numeric type.

**Example:** 15

**Example:** `[-15.123 32.456 63.111]`

**Example:** `int16([-15 32 63])`

### Data Types

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64`

## Examples

### Next Power of 2 of Double Integer Values

Define a vector of double integer values and calculate the exponents for the next power of 2 higher than those values.

```
a = [1 -2 3 -4 5 9 519];
p = nextpow2(a)
```

```
p =
```

```

0 1 2 2 3 4 10

```

Calculate the positive next powers of 2.

```
np2 = 2.^p
```

```
np2 =
```

```

1 2 4 4 8 16 1024

```

Preserve the sign of the original input values.

```
np2.*sign(a)
```

```
ans =
```

```

1 -2 4 -4 8 16 1024

```

### Next Power of 2 of Unsigned Integer Values

Define a vector of unsigned integers and calculate the exponents for the next power of 2 higher than those values.

```
a = uint32([1020 4000 32700]);
p = nextpow2(a)
```

```
p =
```

```

10 12 15

```

Calculate the next powers of 2 higher than the values in a.

```
2.^p
```

```
ans =
```

```

1024 4096 32768

```

## Optimize FFT with Padding

Use `nextpow2` to increase the performance of `fft` when the length of your signal is not a power of 2.

Create a 1-D vector containing 8191 sample values.

```
x = gallery('uniformdata',[1,8191],0);
```

Calculate the next power of 2 higher than 8191.

```
p = nextpow2(8191);
```

```
n = 2^p
```

```
n =
```

```
8192
```

Pass the signal and the next power of 2 to the `fft` function.

```
y = fft(x,n);
```

---

<b>Purpose</b>	Number of nonzero matrix elements
<b>Syntax</b>	<code>n = nnz(X)</code>
<b>Description</b>	<code>n = nnz(X)</code> returns the number of nonzero elements in matrix <code>X</code> . The density of a sparse matrix is <code>nnz(X)/prod(size(X))</code> .
<b>Examples</b>	The matrix  <code>w = sparse(wilkinson(21));</code>  is a tridiagonal matrix with 20 nonzeros on each of three diagonals, so <code>nnz(w) = 60</code> .
<b>See Also</b>	<code>find</code>   <code>isa</code>   <code>nonzeros</code>   <code>nzmax</code>   <code>size</code>   <code>whos</code>

# noanimate

---

**Purpose** Change EraseMode of all objects to normal

---

**Note** noanimate will be removed in a future release.

---

**Syntax** noanimate(state, fig\_handle)  
noanimate(state)

**Description** noanimate(state, fig\_handle) sets the EraseMode of all image, line, patch, surface, and text graphics objects in the specified figure to normal. state can be the following strings:

- 'save' — Set the values of the EraseMode properties to normal for all the appropriate objects in the designated figure.
- 'restore' — Restore the EraseMode properties to the previous values (i.e., the values before calling noanimate with the 'save' argument).

noanimate(state) operates on the current figure.

noanimate is useful if you want to print the figure to a TIFF or JPEG format.

**See Also** print

**Purpose** Nonzero matrix elements

**Syntax** `s = nonzeros(A)`

**Description** `s = nonzeros(A)` returns a full column vector of the nonzero elements in A, ordered by columns.

This gives the s, but not the i and j, from `[i,j,s] = find(A)`.  
Generally,

`length(s) = nnz(A) <= nzmax(A) <= prod(size(A))`

**See Also** `find` | `isa` | `nnz` | `nzmax` | `size` | `whos`

# norm

---

**Purpose** Vector and matrix norms

**Syntax**  
`n = norm(X)`  
`n = norm(X,p)`

**Description** `n = norm(X)` returns the 2-norm of input  $X$  and is equivalent to `norm(X,2)`. If  $X$  is a vector, this is equal to the Euclidean distance. If  $X$  is a matrix, this is equal to the largest singular value of  $X$ .

`n = norm(X,p)` returns the  $p$ -norm of input  $X$ .

**Input Arguments**  
**X - Numeric array**  
scalar | vector | matrix

Numeric array, specified as a scalar, vector, or matrix. If  $X$  is sparse, then `norm(X)` returns an error.

**Data Types**

single | double

**Complex Number Support:** Yes

**p - Norm type**

2 (default) | positive integer scalar | Inf | -Inf | 'fro'

Norm type, specified as 2 (default), a positive integer scalar, Inf, -Inf, or 'fro'. Whether  $X$  is a matrix or vector determines the allowed values of  $p$  (and what they return). The following table lists the calculated values for each allowed value of  $p$ .

---

**Note** The table does not reflect the actual algorithms used in calculations.

---

<b>p</b>	<b>Matrix</b>	<b>Vector</b>
1	$\max(\text{sum}(\text{abs}(X)))$	$\text{sum}(\text{abs}(X))$
2	$\max(\text{svd}(X))$	$\text{sum}(\text{abs}(X).^2)^{(1/2)}$
positive, real-valued numeric p	–	$\text{sum}(\text{abs}(X).^p)^{(1/p)}$
Inf	$\max(\text{sum}(\text{abs}(X')))$	$\max(\text{abs}(X))$
-Inf	–	$\min(\text{abs}(X))$
'fro'	$\text{sqrt}(\text{sum}(\text{diag}(X'*X)))$	$\text{norm}(X)$

## Output Arguments

### **n** - Matrix or vector norm

scalar

Matrix or vector norm, returned as a scalar. The norm gives a measure of the magnitude of the elements. By convention, norm returns NaN if the input contains NaN values.

## Examples

### **1- and 2- Norm of Vector**

Create a vector corresponding to the point (-2,3,-1) in 3-D space.

```
X = [-2 3 -1];
```

Calculate the 2-norm of the vector.

```
n = norm(X)
```

```
n =
```

```
3.7417
```

The 2-norm is equal to the Euclidean length of the vector.

Calculate the 1-norm of the vector.

```
n = norm(X,1)
```

```
n =
```

```
6
```

The 1-norm is equal to the sum of the element magnitudes.

## **2-Norm of Matrix**

Create a matrix.

```
X = [2 0 1; -1 1 0; -3 3 0];
```

The matrix has  $\text{rank}(X) = 2$ , so it has two nonzero singular values.

Calculate the 2-norm of the matrix.

```
n = norm(X)
```

```
n =
```

```
4.7234
```

The 2-norm is equal to the largest singular value of X.

## **Frobenius Norm of Sparse Matrix**

Create a sparse identity matrix, S.

```
S = sparse(1:25,1:25,1);
```

Attempt to use `norm(S)` to calculate the 2-norm of S.

```
n = norm(S)
```

```
Error using norm
```

```
Sparse norm(S,2) is not available.
```

When the input matrix is sparse, `norm(S)` returns an error.

Now use 'fro' to calculate the Frobenius norm of the sparse matrix.

```
n = norm(S, 'fro')
```

```
n =
```

```
5
```

This calculates the 2-norm of the column vector,  $S(:)$ .

**See Also**

[cond](#) | [rcond](#) | [condest](#) | [normest](#) | [hypot](#)

# normest

---

**Purpose** 2-norm estimate

**Syntax**  
`nrm = normest(S)`  
`nrm = normest(S,tol)`  
`[nrm,count] = normest(...)`

**Description** This function is intended primarily for sparse matrices, although it works correctly and may be useful for large, full matrices as well.

`nrm = normest(S)` returns an estimate of the 2-norm of the matrix  $S$ .

`nrm = normest(S,tol)` uses relative error `tol` instead of the default tolerance  $1.e-6$ . The value of `tol` determines when the estimate is considered acceptable.

`[nrm,count] = normest(...)` returns an estimate of the 2-norm and also gives the number of power iterations used.

**Algorithms** The power iteration involves repeated multiplication by the matrix  $S$  and its transpose,  $S'$ . The iteration is carried out until two successive estimates agree to within the specified relative tolerance.

**See Also** `cond` | `condest` | `norm` | `rcond` | `svd`

**Purpose** Find logical NOT

**Syntax** ~A  
not(A)

**Description** ~A performs a logical NOT of input array A, and returns an array containing elements set to either logical 1 (true) or logical 0 (false). An element of the output array is set to 1 if the input array contains a zero value element at that same array location. Otherwise, that element is set to 0.

The input of the expression can be an array or can be a scalar value. If the input is an array, then the output is an array of the same dimensions. If the input is scalar, then the output is scalar.

not(A) is called for the syntax ~A when A is an object.

**Examples** If matrix A is

0	29	0	36	0
23	34	35	0	39
0	24	31	27	0
0	29	0	0	34

then

```
~A
ans =
 1 0 1 0 1
 0 0 0 1 0
 1 0 0 0 1
 1 0 1 1 0
```

# notebook

---

**Purpose** Open MATLAB Notebook in Microsoft Word software (on Microsoft Windows platforms)

**Syntax** `notebook`  
`notebook('filename')`  
`notebook('-setup')`

**Description** `notebook` starts Microsoft Word software and creates a new MATLAB Notebook titled Document 1.

`notebook('filename')` starts Microsoft Word and opens the notebook `filename`, where `filename` is either in the MATLAB current folder or is a full path. If `filename` does not exist, MATLAB creates a new notebook titled `filename`. If the file name extension is not specified, MATLAB assumes `.doc`.

`notebook('-setup')` runs an interactive setup function for MATLAB Notebook. It copies the notebook template, `m-book.dot`, to the Microsoft Word template folder, whose location MATLAB automatically determines from the Windows system registry. Upon completion, MATLAB displays a message indicating whether or not the setup was successful.

**How To**

- “Create a MATLAB Notebook with Microsoft Word”
- “Publishing MATLAB Code”

**Purpose** Notify listeners that event is occurring

**Syntax** `notify(Hobj, 'EventName')`  
`notify(Hobj, 'EventName', data)`

**Description** `notify(Hobj, 'EventName')` notifies listeners that the specified event is taking place on the specified handle objects.

`notify(Hobj, 'EventName', data)` includes user-defined event data.

### **Input Arguments**

**Hobj**

Array of handle objects triggering the specified event.

**EventName**

Name of the event.

**data**

An `event.EventData` object encapsulating information about the event. You can define custom event data by subclassing `event.EventData` and passing an instance of your subclass as the data argument. See “Defining Event-Specific Data” for information on defining event data.

### **See Also**

See “Events and Listeners — Syntax and Techniques”

`handle`, `addlistener`

# now

---

**Purpose** Current date and time as serial date number

**Syntax** `t = now`

**Description** `t = now` returns the current date and time as a serial date number. A serial date number represents the whole and fractional number of days from a fixed, preset date (January 0, 0000).

`floor(now)` returns the current date as a serial date number, and `rem(now,1)` returns the current time as a serial date number. `datestr(now)` returns the current date and time as a string.

**Examples** `t1 = now, t2 = rem(now,1)`

```
t1 =

 7.2908e+05
```

```
t2 =

 0.4013
```

**See Also** `clock` | `date` | `datenum` | `datestr`

---

<b>Purpose</b>	Real nth root of real numbers
<b>Syntax</b>	$y = \text{nthroot}(X, n)$
<b>Description</b>	$y = \text{nthroot}(X, n)$ returns the real nth root of the elements of $X$ . Both $X$ and $n$ must be real and $n$ must be a scalar. If $X$ has negative entries, $n$ must be an odd integer.
<b>Examples</b>	$\text{nthroot}(-2, 3)$  returns the real cube root of -2.  $\text{ans} =$  -1.2599  By comparison,  $(-2)^{(1/3)}$  returns a complex cube root of -2.  $\text{ans} =$  $0.6300 + 1.0911i$
<b>See Also</b>	<a href="#">sqrt</a>   <a href="#">power</a>

# null

---

**Purpose** Null space

**Syntax** `Z = null(A)`  
`Z = null(A, 'r')`

**Description** `Z = null(A)` is an orthonormal basis for the null space of  $A$  obtained from the singular value decomposition. That is,  $A*Z$  has negligible elements, `size(Z,2)` is the nullity of  $A$ , and  $Z'*Z = I$ .

`Z = null(A, 'r')` is a “rational” basis for the null space obtained from the reduced row echelon form.  $A*Z$  is zero, `size(Z,2)` is an estimate for the nullity of  $A$ , and, if  $A$  is a small matrix with integer elements, the elements of the reduced row echelon form (as computed using `rref`) are ratios of small integers.

The orthonormal basis is preferable numerically, while the rational basis may be preferable pedagogically.

## Examples **Example 1**

Compute the orthonormal basis for the null space of a matrix  $A$ .

```
A = [1 2 3
 1 2 3
 1 2 3];
```

```
Z = null(A);
A*Z
```

```
ans =
 1.0e-015 *
 0.2220 0.2220
 0.2220 0.2220
 0.2220 0.2220
```

```
Z'*Z
```

```
ans =
```

```
1.0000 -0.0000
-0.0000 1.0000
```

### Example 2

Compute the 1-norm of the matrix  $A*Z$  and determine that it is within a small tolerance.

```
norm(A*Z,1) < 1e-12
ans =
1
```

### Example 3

Compute the rational basis for the null space of the same matrix A.

```
ZR = null(A, 'r')
```

```
ZR =
-2 -3
1 0
0 1
```

```
A*ZR
```

```
ans =
0 0
0 0
0 0
```

# num2cell

---

**Purpose** Convert array to cell array with consistently sized cells

**Syntax**  
`C = num2cell(A)`  
`C = num2cell(A,dim)`

**Description** `C = num2cell(A)` converts array `A` into cell array `C` by placing each element of `A` into a separate cell in `C`. Array `A` need not be numeric.

`C = num2cell(A,dim)` splits the contents of `A` into separate cells of `C`, where `dim` specifies which dimensions of `A` to include in each cell. `dim` can be a scalar or a vector of dimensions. For example, if `A` has 2 rows and 3 columns, then:

- `num2cell(A,1)` creates a 1-by-3 cell array `C`, where each cell contains a 2-by-1 column of `A`.
- `num2cell(A,2)` creates a 2-by-1 cell array `C`, where each cell contains a 1-by-3 row of `A`.
- `num2cell(A,[1 2])` creates a 1-by-1 cell array `C`, where the cell contains the entire array `A`.

## Input Arguments

**A - Input**  
any type of multidimensional array

Input, specified as any type of multidimensional array.

**Data Types**  
`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `struct` | `cell` | `function_handle`

**dim - Dimension of A**  
positive integer | positive vector of integers

Dimension of `A`, specified as a positive integer or a vector of positive integers. `dim` must be between 1 and `ndims(A)`.

Elements need not be in numeric order. However, num2cell permutes the dimensions of the arrays in each cell of C to match the order of the specified dimensions.

**Data Types**

double

**Output Arguments**

**C - Resulting array**

cell array

Resulting array, returned as a cell array. The size of C depends on the size of A and the values of dim.

- If dim is not specified, then C is the same size as A.
- If dim is a scalar, then C contains numel(A)/size(A,dim) cells. If dim is 1 or 2, then each cell contains a column or row vector, respectively. If dim > 2, then each cell contains an array whose dimth dimensional length is size(A,dim), and whose other dimensions are all singletons.

For example, given a 4-by-7-by-3 array, A, this figure shows how num2cell creates cells corresponding to dim values of 1, 2, and 3.

- If dim is a vector containing N values, then C has numel(A)/prod([size(A,dim(1)), ..., size(A,vdim(N))]) cells. Each cell contains an array whose dim(i)th dimension has a length of size(A,dim(i)) and whose other dimensions are singletons.

For example, given a 4-by-7-by-3 array, you can specify dim as an positive integer vector to create cell arrays of different dimensions.

# num2cell

## Examples

### Convert Arrays to Cell Array

Place all elements of a numeric array into separate cells.

```
a = magic(3)
c = num2cell(a)
```

a =

```
8 1 6
3 5 7
4 9 2
```

c =

```
[8] [1] [6]
[3] [5] [7]
[4] [9] [2]
```

Place individual letters of a word into separate cells of an array.

```
a = ['four'; 'five'; 'nine']
c = num2cell(a)
```

a =

```
four
five
nine
```

```
c =
```

```
 'f' 'o' 'u' 'r'
 'f' 'i' 'v' 'e'
 'n' 'i' 'n' 'e'
```

### Create Cell Array of Numeric Arrays

Generate a 4-by-3-by-2 numeric array, and then create a 1-by-3-by-2 cell array of 4-by-1 column vectors.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
C = num2cell(A,1)
```

```
A(:,:,1) =
```

```
 1 5 9
 2 6 10
 3 7 11
 4 8 12
```

```
A(:,:,2) =
```

```
 10 50 90
 20 60 100
 30 70 110
 40 80 120
```

# num2cell

---

```
C(:,:,1) =
 [4x1 double] [4x1 double] [4x1 double]
```

```
C(:,:,2) =
 [4x1 double] [4x1 double] [4x1 double]
```

Each 4-by-1 vector contains elements from along the *first* dimension of A:

```
C{1}
```

```
ans =
```

```
 1
 2
 3
 4
```

Create a 4-by-1-by-2 cell array of 1-by-3 numeric arrays.

```
C = num2cell(A,2)
```

```
C(:,:,1) =
 [1x3 double]
 [1x3 double]
 [1x3 double]
 [1x3 double]
```

```
C(:, :, 2) =
```

```

 [1x3 double]
 [1x3 double]
 [1x3 double]
 [1x3 double]

```

Each 1-by-3 row vector contains elements from along the *second* dimension of A:

```
C{1}
```

```
ans =
```

```

 1 5 9

```

Finally, create a 4-by-3 cell array of 1-by-1-by-2 numeric arrays.

```
C = num2cell(A,3)
```

```
C =
```

```

 [1x1x2 double] [1x1x2 double] [1x1x2 double]
 [1x1x2 double] [1x1x2 double] [1x1x2 double]
 [1x1x2 double] [1x1x2 double] [1x1x2 double]
 [1x1x2 double] [1x1x2 double] [1x1x2 double]

```

Each 1-by-1-by-2 vector contains elements from along the *third* dimension of A:

```
C{1}
```

# num2cell

---

```
ans(:,:,1) =
```

```
1
```

```
ans(:,:,2) =
```

```
10
```

## Combine Across Multiple Dimensions

Create a cell array by combining elements into numeric arrays along several dimensions.

```
A = reshape(1:12,4,3);
A(:,:,2) = A*10
c = num2cell(A,[1 3])
```

```
A(:,:,1) =
```

```
1 5 9
2 6 10
3 7 11
4 8 12
```

```
A(:,:,2) =
```

```
10 50 90
20 60 100
30 70 110
40 80 120
```

```
c =

 [4x1x2 double] [4x1x2 double] [4x1x2 double]
```

Each 4-by-1-by-2 array contains elements from along the first and third dimension of A:

```
c{1}
```

```
ans(:,:,1) =

 1
 2
 3
 4
```

```
ans(:,:,2) =

 10
 20
 30
 40
```

```
c = num2cell(A,[2 3])
```

```
c =

 [1x3x2 double]
 [1x3x2 double]
 [1x3x2 double]
 [1x3x2 double]
```

# num2cell

---

## See Also

[cat](#) | [mat2cell](#) | [cell2mat](#)

<b>Purpose</b>	Convert singles and doubles to IEEE hexadecimal strings
<b>Syntax</b>	<code>num2hex(X)</code>
<b>Description</b>	If <code>X</code> is a single or double precision array with <code>n</code> elements, <code>num2hex(X)</code> is an <code>n-by-8</code> or <code>n-by-16</code> char array of the hexadecimal floating-point representation. The same representation is printed with format <code>hex</code> .
<b>Examples</b>	<pre>num2hex([1 0 0.1 -pi Inf NaN])  returns  ans =  3ff0000000000000 0000000000000000 3fb9999999999999a c00921fb54442d18 7ff0000000000000 fff8000000000000 num2hex(single([1 0 0.1 -pi Inf NaN]))  returns  ans =  3f800000 00000000 3dcccccd c0490fdb 7f800000 ffc00000</pre>
<b>See Also</b>	<code>hex2num</code>   <code>dec2hex</code>   <code>format</code>

# num2str

---

**Purpose** Convert number to string

**Syntax**

```
str = num2str(A)
str = num2str(A,precision)
str = num2str(A,formatSpec)
```

**Description** `str = num2str(A)` converts array `A` into a string representation `str`. The output format depends upon the magnitude of the original values and sometimes includes exponents. `num2str` is useful for labeling and titling plots with numeric values.

`str = num2str(A,precision)` returns a string representation with the maximum number of digits specified by `precision`.

`str = num2str(A,formatSpec)` applies a format specified by `formatSpec` to all elements of `A`.

## Input Arguments

### **A - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array of real or complex numbers.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **precision - Numeric precision**

positive integer

Numeric precision of the output string, specified as a positive integer. This is the maximum number of digits in the output string.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**formatSpec - Format of the output fields**

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18

Value Type	Conversion	Details
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Identifier

Order for processing inputs. Use the syntax `n$`, where `n` represents the position of the value in the input list.

For example, `'%3$s %2$s %1$s %2$s'` prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

- ' ' Left-justify. Example: `%-5.2f`
- '+' Print sign character (+) for positive values. Example:  `%+5.2f`
- ' ' Pad to field width with spaces before the value. Example:  `% 5.2f`

'0' Pad to field width with zeros. Example: %05.2f

'#' Modify selected numeric conversions:

- For %o, %x, or %X, print 0, 0x, or 0X prefix.
- For %f, %e, or %E, print decimal point even when precision is 0.
- For %g or %G, do not remove trailing zeros or decimal point.

Example: %#5.0f

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

- Precision

For %f, %e, or %E: Number of digits to the right of the decimal point.

Example: '%6.4f' prints pi as '3.1416'

For %g or %G: Number of significant digits.

Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include '' in formatSpec.
- Control characters, including:

<code>%%</code>	Percent character
<code>\\</code>	Backslash
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\xN</code>	Character whose ASCII code is the hexadecimal number, <i>N</i>
<code>\w</code>	Character whose ASCII code is the octal number, <i>N</i>

The following limitations apply to conversions:

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses `%e`.
- If you apply a string conversion (`%s`) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, `'%s'` converts `[65 66 67]` to `ABC`.

## Output Arguments

### **str** - String representation of input array

character array

String representation of the input array, *A*, returned as a character array.

## Algorithms

num2str trims any leading spaces from a string, even when formatSpec includes a space character flag. For example, num2str(42.67, '%10.2f') returns a 1-by-5 character array '42.67'.

## Examples

### Default Conversions of Floating-Point Values

Convert pi and eps to text strings.

```
str = num2str(pi)
```

```
str =
```

```
3.1416
```

```
str = num2str(eps)
```

```
str =
```

```
2.2204e-16
```

### Specifying Precision

Specify the number of significant digits for floating-point values.

```
A = gallery('normaldata',[2,2],0);
precision = 3;
str = num2str(A,precision)
```

```
str =
```

```
-0.433 0.125
-1.67 0.288
```

## Specifying Formatting

Specify the width, precision, and other formatting for an array of floating-point values.

```
A = gallery('uniformdata',[2,3],0) * 9999;
formatSpec = '%10.5e\n';
str = num2str(A,formatSpec)
```

```
str =

9.50034e+03
6.06782e+03
8.91210e+03
2.31115e+03
4.85934e+03
7.62021e+03
```

The format `'%10.5e'` prints each value in exponential format with five decimal places, and `'\n'` prints a new line character.

**Purpose** Total number of strips in image

**Syntax** `numStrips = tiffobj.numberOfStrips()`

**Description** `numStrips = tiffobj.numberOfStrips()` returns the total number of strips in the image.

## **Examples Determine Number of Strips in Image**

Determine the number of strips in the second image of a file.

Create a Tiff object associated with the example file, `example.tif`.

```
t = Tiff('example.tif', 'r');
```

When the Tiff object is created, the first image in the file is the current image file directory.

Make the second image the current directory.

```
t.nextDirectory();
```

Get the number of strips in the image if the image has a stripped organization.

```
if ~t.isTiled()
 numStrips = t.numberOfStrips()
end
```

```
numStrips =
```

```
 7
```

The image has 7 strips.

Close the Tiff object.

```
t.close();
```

# Tiff.numberOfStrips

---

## References

This method corresponds to the `TIFFNumberOfStrips` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**Purpose** Total number of tiles in image

**Syntax** numTiles = tiffobj.numberOfTiles()

**Description** numTiles = tiffobj.numberOfTiles() returns the total number of tiles in the image.

## **Examples** Determine Number of Tiles in Image

Create a Tiff object associated with the example file, `example.tif`. Get the number of tiles in the image if the image has a tiled organization.

```
t = Tiff('example.tif', 'r');
if t.isTiled()
 nTiles = t.numberOfTiles()
end
```

```
nTiles =

 110
```

The image has 110 tiles.

Close the Tiff object.

```
t.close();
```

# numel

---

**Purpose** Number of array elements

**Syntax** `n = numel(A)`

**Description** `n = numel(A)` returns the number of elements, `n`, in array `A`, equivalent to `prod(size(A))`.

**Input Arguments** **A - Input array**  
scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array. This includes numeric arrays, logical arrays, character arrays, categorical arrays, tables, structure arrays, cell arrays, and object arrays.

## Examples **Number of Elements in 3-D Matrix**

Create a 4-by-4-by-2 matrix.

```
A = magic(4);
A(:,:,2) = A'
```

```
A(:,:,1) =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
A(:,:,2) =
 16 5 9 4
 2 11 7 14
 3 10 6 15
 13 8 12 1
```

`numel` counts 32 elements in the matrix.

```
n = numel(A)
```

```
n =
```

```
 32
```

### Number of Elements in Cell Array of Strings

Create a cell array of strings.

```
A = {'dog','cat','fish','horse'};
```

numel counts 4 string elements in the array.

```
n = numel(A)
```

```
n =
```

```
 4
```

### Number of Elements in Table

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
```

```
Age = [38;43;38;40;49];
```

```
Height = [71;69;64;67;64];
```

```
Weight = [176;163;131;133;119];
```

```
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
A = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
A =
```

```

 Age Height Weight BloodPressure
 --- -

```

# numel

---

Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the number of elements in the table.

```
n = numel(A)
```

```
n =
```

```
20
```

`numel` returns a value equivalent to `prod(size(A))` corresponding to the 5 rows and 4 variables.

## Limitations

- If `A` is a table, `numel` returns the number of elements in the table, `A`, equivalent to `prod(size(A))`. Variables in a table can have multiple columns, but `numel(A)` only accounts for the number of rows and number of variables.

## Concepts

- “Caution When Customizing Classes”

**Purpose**

Amount of storage allocated for nonzero matrix elements

**Syntax**

`n = nzmax(S)`

**Description**

`n = nzmax(S)` returns the amount of storage allocated for nonzero elements.

If `S` is a sparse matrix...      `nzmax(S)` is the number of storage locations allocated for the nonzero elements in `S`.

If `S` is a full matrix...      `nzmax(S) = prod(size(S))`.

Often, `nnz(S)` and `nzmax(S)` are the same. But if `S` is created by an operation which produces fill-in matrix elements, such as sparse matrix multiplication or sparse LU factorization, more storage may be allocated than is actually required, and `nzmax(S)` reflects this. Alternatively, `sparse(i, j, s, m, n, nzmax)` or its simpler form, `spalloc(m, n, nzmax)`, can set `nzmax` in anticipation of later fill-in.

# ode15i

---

**Purpose** Solve fully implicit differential equations, variable order method

**Syntax**

```
[T,Y] = ode15i(odefun,tspan,y0,yp0)
[T,Y] = ode15i(odefun,tspan,y0,yp0,options)
[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)
sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)
```

**Arguments** The following table lists the input arguments for `ode15i`.

<code>odefun</code>	A function handle that evaluates the left side of the differential equations, which are of the form $f(t,y,y') = 0$ .
<code>tspan</code>	A vector specifying the interval of integration, $[t_0, t_f]$ . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .
<code>y0, yp0</code>	Vectors of initial conditions for $y$ and $y'$ respectively.
<code>options</code>	Optional integration argument created using the <code>odeset</code> function. See <code>odeset</code> for details.

The following table lists the output arguments for `ode15i`.

<code>T</code>	Column vector of time points
<code>Y</code>	Solution array. Each row in $y$ corresponds to the solution at a time returned in the corresponding row of $t$ .

**Description** `[T,Y] = ode15i(odefun,tspan,y0,yp0)` with `tspan = [t0 tf]` integrates the system of differential equations  $f(t,y,y') = 0$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$  and  $yp_0$ . `odefun` is a function handle. Function `ode15i` solves ODEs and DAEs of index 1. The initial conditions must be consistent, meaning that  $f(t_0,y_0,yp_0) = 0$ . You can use the function `decic` to compute consistent initial conditions close to guessed values. Function `odefun(t,y,yp)`, for a scalar  $t$  and column vectors  $y$  and  $yp$ , must return a column vector corresponding to  $f(t,y,y')$ . Each row in the solution array  $Y$  corresponds to a time returned in the

column vector  $T$ . To obtain solutions at specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $tspan = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`[T,Y] = ode15i(odefun,tspan,y0,yp0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used options include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components  $1e-6$  by default). See `odeset` for details.

`[T,Y,TE,YE,IE] = ode15i(odefun,tspan,y0,yp0,options...)` with the 'Events' property in `options` set to a function `events`, solves as above while also finding where functions of  $(t,y,y')$ , called event functions, are zero. The function `events` is of the form `[value,isterminal,direction] = events(t,y,yp)` and includes the necessary event functions. Code the function `events` so that the  $i$ th element of each output vector corresponds to the  $i$ th event. For the  $i$ th event function in `events`:

- `value(i)` is the value of the function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise.
- `direction(i) = 0` if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Output `TE` is a column vector of times at which events occur. Rows of `YE` are the corresponding solutions, and indices in vector `IE` specify which event occurred. See “Integrator Options” in the MATLAB Mathematics documentation for more information.

`sol = ode15i(odefun,[t0 tfinal],y0,yp0,...)` returns a structure that can be used with `deval` to evaluate the solution at any point between `t0` and `tfinal`. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver. If you specify the <code>Events</code> option and a terminal event is detected, <code>sol.x(end)</code> contains the end of the step at which the event occurred.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

## Options

`ode15i` accepts the following parameters in `options`. For more information, see `odeset` and [Changing ODE Integration Properties](#) in the MATLAB Mathematics documentation.

Error control	<code>RelTol</code> , <code>AbsTol</code> , <code>NormControl</code>
Solver output	<code>OutputFcn</code> , <code>OutputSel</code> , <code>Refine</code> , <code>Stats</code>
Event location	<code>Events</code>
Step size	<code>MaxStep</code> , <code>InitialStep</code>
Jacobian matrix	<code>Jacobian</code> , <code>JPattern</code> , <code>Vectorized</code>

## Solver Output

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, and `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen. By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

## Jacobian Matrices

The Jacobian matrices  $\partial f/\partial y$  and  $\partial f/\partial y'$  are critical to reliability and efficiency. You can provide these matrices as one of the following:

- Function of the form `[dfdy,dfdyp] = FJAC(t,y,yp)` that computes the Jacobian matrices. If `FJAC` returns an empty matrix `[]` for either `dfdy` or `dfdyp`, then `ode15i` approximates that matrix by finite differences.
- Cell array of two constant matrices `{dfdy,dfdyp}`, either of which could be empty.

Use `odeset` to set the `Jacobian` option to the function or cell array. If you do not set the `Jacobian` option, `ode15i` approximates both Jacobian matrices by finite differences.

For `ode15i`, `Vectorized` is a two-element cell array. Set the first element to `'on'` if `odefun(t,[y1,y2,...],yp)` returns `[odefun(t,y1,yp),odefun(t,y2,yp),...]`. Set the second element to `'on'` if `odefun(t,y,[yp1,yp2,...])` returns `[odefun(t,y,yp1),odefun(t,y,yp2),...]`. The default value of `Vectorized` is `{'off','off'}`.

For `ode15i`, `JPattern` is also a two-element sparse matrix cell array. If  $\partial f/\partial y$  or  $\partial f/\partial y'$  is a sparse matrix, set `JPattern` to the sparsity patterns, `{SPDY, SPDYP}`. A sparsity pattern of  $\partial f/\partial y$  is a sparse matrix `SPDY` with `SPDY(i,j) = 1` if component `i` of  $f(t,y,yp)$  depends on component `j` of  $y$ , and 0 otherwise. Use `SPDY = []` to indicate that  $\partial f/\partial y$  is a full matrix. Similarly for  $\partial f/\partial y'$  and `SPDYP`. The default value of `JPattern` is `{[], []}`.

## Examples

### Solve Weissinger Implicit ODE

This example uses a helper function, `decic`, to hold fixed the initial value for  $y(t_0)$  and compute a consistent initial value for  $y'(t_0)$  for the Weissinger implicit ODE. The Weissinger function evaluates the residual of the implicit ODE.

```
t0 = 1;
y0 = sqrt(3/2);
yp0 = 0;
[y0,yp0] = decic(@weissinger,t0,y0,1,yp0,0);
```

Use `ode15i` to solve the ODE, and then plot the numerical solution, `y`, against the analytical solution, `ytrue`.

```
[t,y] = ode15i(@weissinger,[1 10],y0,yp0);
ytrue = sqrt(t.^2 + 0.5);
plot(t,y,t,ytrue,'o');
```

### Other Examples

The files, `ihb1dae.m` and `iburgersode.m`, are examples of implicit ODEs.

### See Also

`decic` | `deval` | `odeget` | `odeset` | `function_handle` | `ode45` | `ode23` | `ode113` | `ode15s` | `ode23s` | `ode23t` | `ode23tb`

**Purpose** Solve stiff differential equations and DAEs; variable order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
sol           Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t,y)$ , for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0, t1, ..., tf` (all increasing or all decreasing), use `tspan = [t0,t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the *i*th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the JPattern property or a sparse  $\partial f/\partial y$  using the Jacobian property.
- For strongly state-dependent  $M(t,y)$ , set MvPattern to a sparse matrix S with  $S(i, j) = 1$  if for any k, the (i, k) component of  $M(t,y)$  depends on component j of y, and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The ode15s and ode23t solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use odeset to set the MassSingular property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide  $yp_0$  as the value of the InitialSlope property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4696 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

## ode15s

---

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode15s

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose**

Solve nonstiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
 sol          Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4711 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode23

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve stiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
sol           Structure to evaluate the solution.

## Description

`[T,Y] = solver(odefun,tspan,y0)` with `tspan = [t0 tf]` integrates the system of differential equations  $y' = f(t,y)$  from time `t0` to `tf` with initial conditions `y0`. The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t,y)$ , for a scalar `t` and a column vector `y`, must return a column vector `f` corresponding to  $f(t,y)$ . Each row in the solution array `Y` corresponds to a time returned in column vector `T`. To obtain solutions at the specific times `t0, t1, ..., tf` (all increasing or all decreasing), use `tspan = [t0,t1, ..., tf]`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[T,Y] = solver(odefun,tspan,y0,options)` solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

`[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)` solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function `[value,isterminal,direction] = events(t,y)`. For the *i*th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4726 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode23s

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE	The index <i>i</i> of the event function that vanishes.
sol	Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4741 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned}y_1' &= y_2 & y_1(0) &= 2 \\y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0\end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

**Purpose** Solve stiff differential equations; low order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE	The index <i>i</i> of the event function that vanishes.
sol	Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4756 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode23tb

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

### Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

## See Also

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose**

Solve nonstiff differential equations; medium order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments**

The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

T	Column vector of time points.
Y	Solution array. Each row in Y corresponds to the solution at a time returned in the corresponding row of T.
TE	The time at which an event occurs.
YE	The solution at the time of the event.

IE            The index  $i$  of the event function that vanishes.  
 sol          Structure to evaluate the solution.

## Description

$[T,Y] = \text{solver}(\text{odefun},\text{tspan},\text{y0})$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t,y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t,y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t,y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T,Y] = \text{solver}(\text{odefun},\text{tspan},\text{y0},\text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T,Y,TE,YE,IE] = \text{solver}(\text{odefun},\text{tspan},\text{y0},\text{options})$  solves as above while also finding where functions of  $(t,y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value},\text{isterminal},\text{direction}] = \text{events}(t,y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i)` = 0 if all zeros are to be computed (the default), +1 if only the zeros where the event function increases, and -1 if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MVPattern` to a sparse matrix `S` with `S(i,j) = 1` if for any `k`, the `(i,k)` component of  $M(t,y)$  depends on component `j` of `y`, and `0` otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

Solver	Problem Type	Order of Accuracy	When to Use
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4771 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

# ode45

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

## Example 3

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

ode45 is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, ode45 is the best function to apply as a *first try* for most problems. [3]

ode23 is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than ode45 at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear's method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

deval | ode15i | odeget | odeset | function\_handle

**Purpose** Solve nonstiff differential equations; variable order method

**Syntax**

```
[T,Y] = solver(odefun,tspan,y0)
[T,Y] = solver(odefun,tspan,y0,options)
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
sol = solver(odefun,[t0 tf],y0...)
```

This page contains an overview of the solver functions: `ode23`, `ode45`, `ode113`, `ode15s`, `ode23s`, `ode23t`, and `ode23tb`. You can call any of these solvers by substituting the placeholder, `solver`, with any of the function names.

**Arguments** The following table describes the input arguments to the solvers.

<code>odefun</code>	A function handle that evaluates the right side of the differential equations. All solvers solve systems of equations in the form $y' = f(t,y)$ or problems that involve a mass matrix, $M(t,y)y' = f(t,y)$ . The <code>ode23s</code> solver can solve only equations with constant mass matrices. <code>ode15s</code> and <code>ode23t</code> can solve problems with a mass matrix that is singular, i.e., differential-algebraic equations (DAEs).
<code>tspan</code>	A vector specifying the interval of integration, <code>[t0,tf]</code> . The solver imposes the initial conditions at <code>tspan(1)</code> , and integrates from <code>tspan(1)</code> to <code>tspan(end)</code> . To obtain solutions at specific times (all increasing or all decreasing), use <code>tspan = [t0,t1,...,tf]</code> .  For <code>tspan</code> vectors with two elements <code>[t0 tf]</code> , the solver returns the solution evaluated at every integration step. For <code>tspan</code> vectors with more than two elements, the solver returns solutions evaluated at the given time points. The time values must be in order, either increasing or decreasing.

Specifying `tspan` with more than two elements does not affect the internal time steps that the solver uses to traverse the interval from `tspan(1)` to `tspan(end)`. All solvers in the ODE suite obtain output values by means of continuous extensions of the basic formulas. Although a solver does not necessarily step precisely to a time point specified in `tspan`, the solutions produced at the specified time points are of the same order of accuracy as the solutions computed at the internal time points.

Specifying `tspan` with more than two elements has little effect on the efficiency of computation, but for large systems, affects memory management.

`y0`

A vector of initial conditions.

`options`

Structure of optional parameters that change the default integration properties. This is the fourth input argument.

```
[t,y] = solver(odefun,tspan,y0,options)
```

You can create options using the `odeset` function. See `odeset` for details.

The following table lists the output arguments for the solvers.

<code>T</code>	Column vector of time points.
<code>Y</code>	Solution array. Each row in <code>Y</code> corresponds to the solution at a time returned in the corresponding row of <code>T</code> .
<code>TE</code>	The time at which an event occurs.
<code>YE</code>	The solution at the time of the event.

IE            The index *i* of the event function that vanishes.  
sol           Structure to evaluate the solution.

## Description

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0)$  with  $\text{tspan} = [t_0 \text{ } t_f]$  integrates the system of differential equations  $y' = f(t, y)$  from time  $t_0$  to  $t_f$  with initial conditions  $y_0$ . The first input argument, `odefun`, is a function handle. The function,  $f = \text{odefun}(t, y)$ , for a scalar  $t$  and a column vector  $y$ , must return a column vector  $f$  corresponding to  $f(t, y)$ . Each row in the solution array  $Y$  corresponds to a time returned in column vector  $T$ . To obtain solutions at the specific times  $t_0, t_1, \dots, t_f$  (all increasing or all decreasing), use  $\text{tspan} = [t_0, t_1, \dots, t_f]$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

$[T, Y] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above with default integration parameters replaced by property values specified in `options`, an argument created with the `odeset` function. Commonly used properties include a scalar relative error tolerance `RelTol` ( $1e-3$  by default) and a vector of absolute error tolerances `AbsTol` (all components are  $1e-6$  by default). If certain components of the solution must be nonnegative, use the `odeset` function to set the `NonNegative` property to the indices of these components. See `odeset` for details.

$[T, Y, TE, YE, IE] = \text{solver}(\text{odefun}, \text{tspan}, y_0, \text{options})$  solves as above while also finding where functions of  $(t, y)$ , called event functions, are zero. For each event function, you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Do this by setting the 'Events' property to a function, e.g., `events` or `@events`, and creating a function  $[\text{value}, \text{isterminal}, \text{direction}] = \text{events}(t, y)$ . For the  $i$ th event function in `events`,

- `value(i)` is the value of the function.
- `isterminal(i) = 1`, if the integration is to terminate at a zero of this event function and 0 otherwise.

- `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only the zeros where the event function increases, and `-1` if only the zeros where the event function decreases.

Corresponding entries in `TE`, `YE`, and `IE` return, respectively, the time at which an event occurs, the solution at the time of the event, and the index `i` of the event function that vanishes.

`sol = solver(odefun,[t0 tf],y0...)` returns a structure that you can use with `deval` to evaluate the solution at any point on the interval `[t0,tf]`. You must pass `odefun` as a function handle. The structure `sol` always includes these fields:

<code>sol.x</code>	Steps chosen by the solver.
<code>sol.y</code>	Each column <code>sol.y(:,i)</code> contains the solution at <code>sol.x(i)</code> .
<code>sol.solver</code>	Solver name.

If you specify the `Events` option and events are detected, `sol` also includes these fields:

<code>sol.xe</code>	Points at which events, if any, occurred. <code>sol.xe(end)</code> contains the exact point of a terminal event, if any.
<code>sol.ye</code>	Solutions that correspond to events in <code>sol.xe</code> .
<code>sol.ie</code>	Indices into the vector returned by the function specified in the <code>Events</code> option. The values indicate which event the solver detected.

If you specify an output function as the value of the `OutputFcn` property, the solver calls it with the computed solution after each time step. Four output functions are provided: `odeplot`, `odephas2`, `odephas3`, `odeprint`. When you call the solver with no output arguments, it calls the default `odeplot` to plot the solution as it is computed. `odephas2` and `odephas3` produce two- and three-dimensional phase plane plots, respectively. `odeprint` displays the solution components on the screen.

By default, the ODE solver passes all components of the solution to the output function. You can pass only specific components by providing a vector of indices as the value of the `OutputSel` property. For example, if you call the solver with no output arguments and set the value of `OutputSel` to `[1,3]`, the solver plots solution components 1 and 3 as they are computed.

For the stiff solvers `ode15s`, `ode23s`, `ode23t`, and `ode23tb`, the Jacobian matrix  $\partial f/\partial y$  is critical to reliability and efficiency. Use `odeset` to set `Jacobian` to `@FJAC` if `FJAC(T,Y)` returns the Jacobian  $\partial f/\partial y$  or to the matrix  $\partial f/\partial y$  if the Jacobian is constant. If the `Jacobian` property is not set (the default),  $\partial f/\partial y$  is approximated by finite differences. Set the `Vectorized` property 'on' if the ODE function is coded so that `odefun(T,[Y1,Y2 ...])` returns `[odefun(T,Y1),odefun(T,Y2) ...]`. If  $\partial f/\partial y$  is a sparse matrix, set the `JPattern` property to the sparsity pattern of  $\partial f/\partial y$ , i.e., a sparse matrix `S` with `S(i,j) = 1` if the *i*th component of  $f(t,y)$  depends on the *j*th component of  $y$ , and 0 otherwise.

The solvers of the ODE suite can solve problems of the form  $M(t,y)y' = f(t,y)$ , with time- and state-dependent mass matrix  $M$ . (The `ode23s` solver can solve only equations with constant mass matrices.) If a problem has a mass matrix, create a function `M = MASS(t,y)` that returns the value of the mass matrix, and use `odeset` to set the `Mass` property to `@MASS`. If the mass matrix is constant, the matrix should be used as the value of the `Mass` property. Problems with state-dependent mass matrices are more difficult:

- If the mass matrix does not depend on the state variable  $y$  and the function `MASS` is to be called with one input argument, `t`, set the `MStateDependence` property to 'none'.
- If the mass matrix depends weakly on  $y$ , set `MStateDependence` to 'weak' (the default); otherwise, set it to 'strong'. In either case, the function `MASS` is called with the two arguments `(t,y)`.

If there are many differential equations, it is important to exploit sparsity:

- Return a sparse  $M(t,y)$ .

- Supply the sparsity pattern of  $\partial f/\partial y$  using the `JPattern` property or a sparse  $\partial f/\partial y$  using the `Jacobian` property.
- For strongly state-dependent  $M(t,y)$ , set `MvPattern` to a sparse matrix `S` with  $S(i, j) = 1$  if for any  $k$ , the  $(i, k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise.

If the mass matrix  $M$  is singular, then  $M(t,y)y' = f(t,y)$  is a system of differential algebraic equations. DAEs have solutions only when  $y_0$  is consistent, that is, if there is a vector  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . The `ode15s` and `ode23t` solvers can solve DAEs of index 1 provided that  $y_0$  is sufficiently close to being consistent. If there is a mass matrix, you can use `odeset` to set the `MassSingular` property to 'yes', 'no', or 'maybe'. The default value of 'maybe' causes the solver to test whether the problem is a DAE. You can provide `yp0` as the value of the `InitialSlope` property. The default is the zero vector. If a problem is a DAE, and  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve the problem. When solving DAEs, it is very advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semi-explicit DAE).

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode45	Nonstiff	Medium	Most of the time. This should be the first solver you try.
ode23	Nonstiff	Low	For problems with crude error tolerances or for solving moderately stiff problems.

<b>Solver</b>	<b>Problem Type</b>	<b>Order of Accuracy</b>	<b>When to Use</b>
ode113	Nonstiff	Low to high	For problems with stringent error tolerances or for solving computationally intensive problems.
ode15s	Stiff	Low to medium	If ode45 is slow because the problem is stiff.
ode23s	Stiff	Low	If using crude error tolerances to solve stiff systems and the mass matrix is constant.
ode23t	Moderately Stiff	Low	For moderately stiff problems if you need a solution without numerical damping.
ode23tb	Stiff	Low	If using crude error tolerances to solve stiff systems.

The algorithms used in the ODE solvers vary according to order of accuracy [6] and the type of systems (stiff or nonstiff) they are designed to solve. See “Algorithms” on page 1-4786 for more details.

## Options

Different solvers accept different parameters in the options list. For more information, see `odeset` and “Integrator Options” in the MATLAB Mathematics documentation.

Parameters	ode45	ode23	ode113	ode15s	ode23s	ode23t	ode23tb
RelTol, AbsTol, NormControl	√	√	√	√	√	√	√
OutputFcn, OutputSel, Refine, Stats	√	√	√	√	√	√	√
NonNegative	√	√	√	√ *	—	√ *	√ *
Events	√	√	√	√	√	√	√
MaxStep, InitialStep	√	√	√	√	√	√	√
Jacobian, JPattern, Vectorized	—	—	—	√	√	√	√
Mass	√	√	√	√	√	√	√
MStateDependence	√	√	√	√	—	√	√
MvPattern	—	—	—	√	—	√	√
MassSingular	—	—	—	√	—	√	—
InitialSlope	—	—	—	√	—	√	—
MaxOrder, BDF	—	—	—	√	—	—	—

---

**Note** You can use the NonNegative parameter with ode15s, ode23t, and ode23tb only for those problems for which there is no mass matrix.

---

## Examples

### Example 1

An example of a nonstiff system is the system of equations describing the motion of a rigid body without external forces.

$$\begin{aligned}y_1' &= y_2 y_3 & y_1(0) &= 0 \\y_2' &= -y_1 y_3 & y_2(0) &= 1 \\y_3' &= -0.51 y_1 y_2 & y_3(0) &= 1\end{aligned}$$

To simulate this system, create a function `rigid` containing the equations

```
function dy = rigid(t,y)
dy = zeros(3,1); % a column vector
dy(1) = y(2) * y(3);
dy(2) = -y(1) * y(3);
dy(3) = -0.51 * y(1) * y(2);
```

In this example we change the error tolerances using the `odeset` command and solve on a time interval `[0 12]` with an initial condition vector `[0 1 1]` at time 0.

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-4 1e-4 1e-5]);
[T,Y] = ode45(@rigid,[0 12],[0 1 1],options);
```

Plotting the columns of the returned array `Y` versus `T` shows the solution

```
plot(T,Y(:,1),'-',T,Y(:,2),'-.',T,Y(:,3),'-.')
```

### Example 2

An example of a stiff system is provided by the van der Pol equations in relaxation oscillation. The limit cycle has portions where the solution components change slowly and the problem is quite stiff, alternating with regions of very sharp change where it is not stiff.

$$\begin{aligned} y_1' &= y_2 & y_1(0) &= 2 \\ y_2' &= 1000(1 - y_1^2)y_2 - y_1 & y_2(0) &= 0 \end{aligned}$$

To simulate this system, create a function `vdp1000` containing the equations

```
function dy = vdp1000(t,y)
```

# ode113

```
dy = zeros(2,1); % a column vector
dy(1) = y(2);
dy(2) = 1000*(1 - y(1)^2)*y(2) - y(1);
```

For this problem, we will use the default relative and absolute tolerances ( $1e-3$  and  $1e-6$ , respectively) and solve on a time interval of  $[0 \ 3000]$  with initial condition vector  $[2 \ 0]$  at time 0.

```
[T,Y] = ode15s(@vdp1000,[0 3000],[2 0]);
```

Plotting the first column of the returned matrix Y versus T shows the solution

```
plot(T,Y(:,1),'-o')
```

**Example 3**

This example solves an ordinary differential equation with time-dependent terms.

Consider the following ODE, with time-dependent parameters defined only through the set of data points given in two vectors:

$$y'(t) + f(t)y(t) = g(t)$$

The initial condition is  $y(0) = 0$ , where the function  $f(t)$  is defined through the  $n$ -by-1 vectors  $tf$  and  $f$ , and the function  $g(t)$  is defined through the  $m$ -by-1 vectors  $tg$  and  $g$ .

First, define the time-dependent parameters  $f(t)$  and  $g(t)$  as the following:

```
ft = linspace(0,5,25); % Generate t for f
f = ft.^2 - ft - 3; % Generate f(t)
gt = linspace(1,6,25); % Generate t for g
g = 3*sin(gt-0.25); % Generate g(t)
```

Write a function to interpolate the data sets specified above to obtain the value of the time-dependent terms at the specified time:

```
function dydt = myode(t,y,ft,f,gt,g)
f = interp1(ft,f,t); % Interpolate the data set (ft,f) at time t
g = interp1(gt,g,t); % Interpolate the data set (gt,g) at time t
dydt = -f.*y + g; % Evaluate ODE at time t
```

Call the derivative function `myode.m` within the MATLAB `ode45` function specifying time as the first input argument :

```
Tspan = [1 5]; % Solve from t=1 to t=5
IC = 1; % y(t=0) = 1
[T Y] = ode45(@(t,y) myode(t,y,ft,f,gt,g),Tspan,IC); % Solve ODE
```

Plot the solution  $y(t)$  as a function of time:

```
plot(T, Y);
```

```
title('Plot of y as a function of time');
xlabel('Time'); ylabel('Y(t)');
```

## Algorithms

`ode45` is based on an explicit Runge-Kutta (4,5) formula, the Dormand-Prince pair. It is a *one-step* solver – in computing  $y(t_n)$ , it needs only the solution at the immediately preceding time point,  $y(t_{n-1})$ . In general, `ode45` is the best function to apply as a *first try* for most problems. [3]

`ode23` is an implementation of an explicit Runge-Kutta (2,3) pair of Bogacki and Shampine. It may be more efficient than `ode45` at crude

tolerances and in the presence of moderate stiffness. Like `ode45`, `ode23` is a one-step solver. [2]

`ode113` is a variable order Adams-Bashforth-Moulton PECE solver. It may be more efficient than `ode45` at stringent tolerances and when the ODE file function is particularly expensive to evaluate. `ode113` is a *multistep* solver — it normally needs the solutions at several preceding time points to compute the current solution. [7]

The above algorithms are intended to solve nonstiff systems. If they appear to be unduly slow, try using one of the stiff solvers below.

`ode15s` is a variable order solver based on the numerical differentiation formulas (NDFs). Optionally, it uses the backward differentiation formulas (BDFs, also known as Gear’s method) that are usually less efficient. Like `ode113`, `ode15s` is a multistep solver. Try `ode15s` when `ode45` fails, or is very inefficient, and you suspect that the problem is stiff, or when solving a differential-algebraic problem. [9], [10]

`ode23s` is based on a modified Rosenbrock formula of order 2. Because it is a one-step solver, it may be more efficient than `ode15s` at crude tolerances. It can solve some kinds of stiff problems for which `ode15s` is not effective. [9]

`ode23t` is an implementation of the trapezoidal rule using a “free” interpolant. Use this solver if the problem is only moderately stiff and you need a solution without numerical damping. `ode23t` can solve DAEs. [10]

`ode23tb` is an implementation of TR-BDF2, an implicit Runge-Kutta formula with a first stage that is a trapezoidal rule step and a second stage that is a backward differentiation formula of order two. By construction, the same iteration matrix is used in evaluating both stages. Like `ode23s`, this solver may be more efficient than `ode15s` at crude tolerances. [8], [1]

`deval` | `ode15i` | `odeget` | `odeset` | `function_handle`

**Purpose** Ordinary differential equation options parameters

**Syntax**

```
o = odeget(options,'name')
o = odeget(options,'name',default)
```

**Description** `o = odeget(options,'name')` extracts the value of the property specified by string 'name' from integrator options structure `options`, returning an empty matrix if the property value is not specified in `options`. It is only necessary to type the leading characters that uniquely identify the property name. Case is ignored for property names.

`o = odeget(options,'name',default)` returns `o = default` if the named property is not specified in `options`.

The empty matrix `[]` is a valid `options` argument, and the syntax `odeget([], 'name', default)` always returns `default`.

## Examples

Having constructed an ODE options structure,

```
options = odeset('RelTol',1e-4,'AbsTol',[1e-3 2e-3 3e-3]);
```

you can view these property settings with `odeget`.

```
odeget(options,'RelTol')
ans =
```

```
1.0000e-04
```

```
odeget(options,'AbsTol')
ans =
```

```
0.0010 0.0020 0.0030
```

```
odeget([], 'RelTol',1e-3)
ans =
```

```
1.0000e-03
```

# odeget

---

## See Also

[odeset](#)

**Purpose**

Create or alter options structure for ordinary differential equation solvers

**Syntax**

```
options = odeset('name1',value1,'name2',value2,...)
options = odeset(olddopts,'name1',value1,...)
options = odeset(olddopts,newopts)
odeset
```

**Description**

The `odeset` function lets you adjust the integration parameters of the following ODE solvers.

For solving fully implicit differential equations:

```
ode15i
```

For solving initial value problems:

```
ode23, ode45, ode113, ode15s, ode23s, ode23t, ode23tb
```

See below for information about the integration parameters.

`options = odeset('name1',value1,'name2',value2,...)` creates an options structure that you can pass as an argument to any of the ODE solvers. In the resulting structure, `options`, the named properties have the specified values. For example, `'name1'` has the value `value1`. Any unspecified properties have default values. It is sufficient to type only the leading characters that uniquely identify a property name. Case is ignored for property names.

`options = odeset(olddopts,'name1',value1,...)` alters an existing options structure `olddopts`. This sets `options` equal to the existing structure `olddopts`, overwrites any values in `olddopts` that are respecified using name/value pairs, and adds any new pairs to the structure. The modified structure is returned as an output argument.

`options = odeset(olddopts,newopts)` alters an existing options structure `olddopts` by combining it with a new options structure `newopts`. Any new options not equal to the empty matrix overwrite corresponding options in `olddopts`.

odeset with no input arguments displays all property names as well as their possible and default values.

## ODE Properties

The following sections describe the properties that you can set using odeset. The available properties depend on the ODE solver you are using. There are several categories of properties:

- “Error Control Properties” on page 1-4792
- “Solver Output Properties” on page 1-4794
- “Step-Size Properties” on page 1-4797
- “Event Location Property” on page 1-4799
- “Jacobian Matrix Properties” on page 1-4800
- “Mass Matrix and DAE Properties” on page 1-4804
- “ode15s and ode15i-Specific Properties” on page 1-4806

---

**Note** This reference page describes the ODE properties for MATLAB, Version 7. The Version 5 properties are supported only for backward compatibility. For information on the Version 5 properties, type at the MATLAB command line: `more on`, type `odeset`, `more off`.

---

## Error Control Properties

At each step, the solver estimates the local error  $e$  in the  $i$ th component of the solution. This error must be less than or equal to the acceptable error, which is a function of the specified relative tolerance, `RelTol`, and the specified absolute tolerance, `AbsTol`.

$$|e(i)| \leq \max(\text{RelTol} * \text{abs}(y(i)), \text{AbsTol}(i))$$

For routine problems, the ODE solvers deliver accuracy roughly equivalent to the accuracy you request. They deliver less accuracy for problems integrated over "long" intervals and problems that are moderately unstable. Difficult problems may require tighter tolerances than the default values. For relative accuracy, adjust `RelTol`. For

the absolute error tolerance, the scaling of the solution components is important: if  $|y|$  is somewhat smaller than `AbsTol`, the solver is not constrained to obtain any correct digits in  $y$ . You might have to solve a problem more than once to discover the scale of solution components.

Roughly speaking, this means that you want `RelTol` correct digits in all solution components except those smaller than thresholds `AbsTol(i)`. Even if you are not interested in a component  $y(i)$  when it is small, you may have to specify `AbsTol(i)` small enough to get some correct digits in  $y(i)$  so that you can accurately compute more interesting components.

The following table describes the error control properties. Further information on each property is given following the table.

Property	Value	Description
<code>RelTol</code>	Positive scalar {1e-3}	Relative error tolerance that applies to all components of the solution vector $y$ .
<code>AbsTol</code>	Positive scalar or vector {1e-6}	Absolute error tolerances that apply to the individual components of the solution vector.
<code>NormControl</code>	on   {off}	Control error relative to norm of solution.

### Description of Error Control Properties

**RelTol** — This tolerance is a measure of the error relative to the size of each solution component. Roughly, it controls the number of correct digits in all solution components, except those smaller than thresholds `AbsTol(i)`.

The default, `1e-3`, corresponds to 0.1% accuracy.

**AbsTol** — `AbsTol(i)` is a threshold below which the value of the  $i$ th solution component is unimportant. The absolute error tolerances determine the accuracy when the solution approaches zero.

If `AbsTol` is a vector, the length of `AbsTol` must be the same as the length of the solution vector `y`. If `AbsTol` is a scalar, the value applies to all components of `y`.

**NormControl** — Set this property on to request that the solvers control the error in each integration step with  $\text{norm}(e) \leq \max(\text{RelTol} \cdot \text{norm}(y), \text{AbsTol})$ . By default the solvers use a more stringent componentwise error control.

## Solver Output Properties

The following table lists the solver output properties that control the output that the solvers generate. Further information on each property is given following the table.

Property	Value	Description
NonNegative	Vector of integers	Specifies which components of the solution vector must be nonnegative. The default value is <code>[]</code> .
OutputFcn	Function handle	A function for the solver to call after every successful integration step.
OutputSel	Vector of indices	Specifies which components of the solution vector are to be passed to the output function.
Refine	Positive integer	Increases the number of output points by a factor of <code>Refine</code> .
Stats	on   {off}	Determines whether the solver should display statistics about its computations. By default, <code>Stats</code> is off.

### Description of Solver Output Properties

**NonNegative** — The `NonNegative` property is not available in `ode23s`, `ode15i`. In `ode15s`, `ode23t`, and `ode23tb`, `NonNegative` is not available for problems where there is a mass matrix.

**OutputFcn** — To specify an output function, set 'OutputFcn' to a function handle. For example,

```
options = odeset('OutputFcn',@myfun)
```

sets 'OutputFcn' to @myfun, a handle to the function myfun. See the `function_handle` reference page for more information.

The output function must be of the form

```
status = myfun(t,y,flag)
```

“Parameterizing Functions” explains how to provide additional parameters to myfun, if necessary.

The solver calls the specified output function with the following flags. Note that the syntax of the call differs with the flag. The function must respond appropriately:

Flag	Description
init	The solver calls <code>myfun(tspan,y0,'init')</code> before beginning the integration to allow the output function to initialize. <code>tspan</code> and <code>y0</code> are the input arguments to the ODE solver.
{[]}	The solver calls <code>status = myfun(t,y,[])</code> after each integration step on which output is requested. <code>t</code> contains points where output was generated during the step, and <code>y</code> is the numerical solution at the points in <code>t</code> . If <code>t</code> is a vector, the <i>i</i> th column of <code>y</code> corresponds to the <i>i</i> th element of <code>t</code> .  When <code>length(tspan) &gt; 2</code> the output is produced at every point in <code>tspan</code> . When <code>length(tspan) = 2</code> the output is produced according to the <code>Refine</code> option.

Flag	Description
	myfun must return a status output value of 0 or 1. If status = 1, the solver halts integration. You can use this mechanism, for instance, to implement a <b>Stop</b> button.
done	The solver calls myfun([],[], 'done') when integration is complete to allow the output function to perform any cleanup chores.

You can use these general purpose output functions or you can edit them to create your own. Type `help function` at the command line for more information.

- `odeplot` — Time series plotting (default when you call the solver with no output arguments and you have not specified an output function)
- `odephas2` — Two-dimensional phase plane plotting
- `odephas3` — Three-dimensional phase plane plotting
- `odeprint` — Print solution as it is computed

---

**Note** If you call the solver with no output arguments, the solver does not allocate storage to hold the entire solution history.

---

**OutputSel** — Use `OutputSel` to specify which components of the solution vector you want passed to the output function. For example, if you want to use the `odeplot` output function, but you want to plot only the first and third components of the solution, you can do this using

```
options = ...
odeset('OutputFcn',@odeplot,'OutputSel',[1 3]);
```

By default, the solver passes all components of the solution to the output function.

**Refine** — If `Refine` is 1, the solver returns solutions only at the end of each time step. If `Refine` is  $n > 1$ , the solver subdivides each time step into  $n$  smaller intervals and returns solutions at each time point. `Refine` does not apply when `length(tspan) > 2` or the ODE solver returns the solution as a structure.

---

**Note** In all the solvers, the default value of `Refine` is 1. Within `ode45`, however, the default is 4 to compensate for the solver's large step sizes. To override this and see only the time steps chosen by `ode45`, set `Refine` to 1.

---

The extra values produced for `Refine` are computed by means of continuous extension formulas. These are specialized formulas used by the ODE solvers to obtain accurate solutions between computed time steps without significant increase in computation time.

**Stats** — By default, `Stats` is off. If it is on, after solving the problem the solver displays

- Number of successful steps
- Number of failed attempts
- Number of times the ODE function was called to evaluate  $f(t,y)$

Solvers based on implicit methods, including `ode23s`, `ode23t`, `ode15s`, and `ode15i`, also display

- Number of times that the partial derivatives matrix  $\partial f/\partial x$  was formed
- Number of LU decompositions
- Number of solutions of linear systems

## Step-Size Properties

The step-size properties specify the size of the first step the solver tries, potentially helping it to better recognize the scale of the problem. In addition, you can specify bounds on the sizes of subsequent time steps.

The following table describes the step-size properties. Further information on each property is given following the table.

Property	Value	Description
InitialStep	Positive scalar	Suggested initial step size.
MaxStep	Positive scalar {0.1*abs(t0-tf)}	Upper bound on solver step size.

### Description of Step-Size Properties

**InitialStep** — InitialStep sets an upper bound on the magnitude of the first step size the solver tries. If you do not set InitialStep, the initial step size is based on the slope of the solution at the initial time `tspan(1)`, and if the slope of all solution components is zero, the procedure might try a step size that is much too large. If you know this is happening or you want to be sure that the solver resolves important behavior at the start of the integration, help the code start by providing a suitable InitialStep.

**MaxStep** — If the differential equation has periodic coefficients or solutions, it might be a good idea to set MaxStep to some fraction (such as 1/4) of the period. This guarantees that the solver does not enlarge the time step too much and step over a period of interest. Do *not* reduce MaxStep for any of the following purposes:

- To produce more output points. This can significantly slow down solution time. Instead, use `Refine` to compute additional outputs by continuous extension at very low cost.
- When the solution does not appear to be accurate enough. Instead, reduce the relative error tolerance `RelTol`, and use the solution you just computed to determine appropriate values for the absolute error tolerance vector `AbsTol`. See “Error Control Properties” on page 1-4792 for a description of the error tolerance properties.
- To make sure that the solver doesn’t step over some behavior that occurs only once during the simulation interval. If you know the time at which the change occurs, break the simulation interval into

two pieces and call the solver twice. If you do not know the time at which the change occurs, try reducing the error tolerances `RelTol` and `AbsTol`. Use `MaxStep` as a last resort.

## Event Location Property

In some ODE problems the times of specific events are important, such as the time at which a ball hits the ground, or the time at which a spaceship returns to the earth. While solving a problem, the ODE solvers can detect such events by locating transitions to, from, or through zeros of user-defined functions.

The following table describes the `Events` property. Further information on each property is given following the table.

### ODE Events Property

String	Value	Description
Events	Function handle	Handle to a function that includes one or more event functions.

### Description of Event Location Properties

**Events** — The function is of the form

```
[value, isterminal, direction] = events(t,y)
```

`value`, `isterminal`, and `direction` are vectors for which the `i`th element corresponds to the `i`th event function:

- `value(i)` is the value of the `i`th event function.
- `isterminal(i) = 1` if the integration is to terminate at a zero of this event function, otherwise, 0.
- `direction(i) = 0` if all zeros are to be located (the default), +1 if only zeros where the event function is increasing, and -1 if only zeros where the event function is decreasing.

If you specify an events function and events are detected, the solver returns three additional outputs:

- A column vector of times at which events occur
- Solution values corresponding to these times
- Indices into the vector returned by the events function. The values indicate which event the solver detected.

If you call the solver as

```
[T,Y,TE,YE,IE] = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as TE, YE, and IE respectively. If you call the solver as

```
sol = solver(odefun,tspan,y0,options)
```

the solver returns these outputs as sol.xe, sol.ye, and sol.ie, respectively.

For examples that use an event function, see “Event Location” and “Advanced Event Location” in the MATLAB Mathematics documentation.

## Jacobian Matrix Properties

The stiff ODE solvers often execute faster if you provide additional information about the Jacobian matrix  $\partial f/\partial y$ , a matrix of partial derivatives of the function that defines the differential equations.

$$\frac{\partial f}{\partial y} = \begin{bmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} & \dots \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} & \dots \\ \vdots & \vdots & \ddots \end{bmatrix}$$

The Jacobian matrix properties pertain only to those solvers for stiff problems (`ode15s`, `ode23s`, `ode23t`, `ode23tb`, and `ode15i`) for which the Jacobian matrix  $\partial f/\partial y$  can be critical to reliability and efficiency. If you do not provide a function to calculate the Jacobian, these solvers

approximate the Jacobian numerically using finite differences. In this case, you might want to use the `Vectorized` or `JPattern` properties.

The following table describes the Jacobian matrix properties for all implicit solvers except `ode15i`. Further information on each property is given following the table. See [Jacobian Properties for `ode15i`](#) on page 1-4803 for `ode15i`-specific information.

### Jacobian Properties for All Implicit Solvers Except `ode15i`

Property	Value	Description
Jacobian	Function handle   constant matrix	Matrix or function that evaluates the Jacobian.
JPattern	Sparse matrix of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Allows the solver to reduce the number of function evaluations required.

### Description of Jacobian Properties

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function `FJac`, where `FJac(t,y)` computes  $\partial f/\partial y$ , or to the constant value of  $\partial f/\partial y$ .

The Jacobian for the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, can be coded as

```
function J = vdp1000jac(t,y)
J = [0 1
 (-2000*y(1)*y(2)-1) (1000*(1-y(1)^2))];
```

**JPattern** — `JPattern` is a sparsity pattern with 1s where there might be nonzero entries in the Jacobian.

---

**Note** If you specify **Jacobian**, the solver ignores any setting for **JPattern**.

---

Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if component  $i$  of  $f(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. The solver uses this sparsity pattern to generate a sparse Jacobian matrix numerically. If the Jacobian matrix is large and sparse, this can greatly accelerate execution. For an example using the **JPattern** property, see [Example: Large, Stiff, Sparse Problem](#) in the MATLAB Mathematics documentation.

**Vectorized** — The **Vectorized** property allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

Set on to inform the solver that you have coded the ODE function  $F$  so that  $F(t, [y1\ y2\ \dots])$  returns  $[F(t,y1)\ F(t,y2)\ \dots]$ . This allows the solver to reduce the number of function evaluations required to compute all the columns of the Jacobian matrix, and might significantly reduce solution time.

---

**Note** If you specify **Jacobian**, the solver ignores a setting of 'on' for 'Vectorized'.

---

With the MATLAB array notation, it is typically an easy matter to vectorize an ODE function. For example, you can vectorize the “van der Pol Equation (Stiff)”, described in the MATLAB Mathematics documentation, by introducing colon notation into the subscripts and by using the array power ( $\wedge$ ) and array multiplication ( $\cdot$ ) operators.

```
function dydt = vdp1000(t,y)
dydt = [y(2,:); 1000*(1-y(1,:)).^2).*y(2,:)-y(1,:)];
```

---

**Note** Vectorization of the ODE function used by the ODE solvers differs from the vectorization used by the boundary value problem (BVP) solver, `bvp4c`. For the ODE solvers, the ODE function is vectorized only with respect to the second argument, while `bvp4c` requires vectorization with respect to the first and second arguments.

---

The following table describes the Jacobian matrix properties for `ode15i`.

### Jacobian Properties for `ode15i`

Property	Value	Description
Jacobian	Function handle   Cell array of constant values	Function that evaluates the Jacobian or a cell array of constant values.
JPattern	Sparse matrices of {0,1}	Generates a sparse Jacobian matrix numerically.
Vectorized	on   {off}	Vectorized ODE function

### Description of Jacobian Properties for `ode15i`

**Jacobian** — Supplying an analytical Jacobian often increases the speed and reliability of the solution for stiff problems. Set this property to a function

$$[dFd_y, dFd_p] = Fjac(t, y, y_p)$$

or to a cell array of constant values  $[\partial F/\partial y, (\partial F/\partial y)']$ .

**JPattern** — `JPattern` is a sparsity pattern with 1's where there might be nonzero entries in the Jacobian.

Set this property to  $\{dFd_yPattern, dFd_y_pPattern\}$ , the sparsity patterns of  $\partial F/\partial y$  and  $\partial F/\partial y'$ , respectively.

**Vectorized** —

Set this property to {yVect, ypVect}. Setting yVect to 'on' indicates that

```
F(t, [y1 y2 ...], yp)
```

returns

```
[F(t,y1,yp), F(t,y2,yp) ...]
```

Setting ypVect to 'on' indicates that

```
F(t,y,[yp1 yp2 ...])
```

returns

```
[F(t,y,yp1) F(t,y,yp2) ...]
```

## Mass Matrix and DAE Properties

This section describes mass matrix and differential-algebraic equation (DAE) properties, which apply to all the solvers except `ode15i`. These properties are not applicable to `ode15i` and their settings do not affect its behavior.

The solvers of the ODE suite can solve ODEs of the form

$$M(t,y)y' = f(t,y) \tag{1-3}$$

with a mass matrix  $M(t,y)$  that can be sparse.

When  $M(t,y)$  is nonsingular, the equation above is equivalent to  $y' = M^{-1}f(t,y)$  and the ODE has a solution for any initial values  $y_0$  at  $t_0$ . The more general form (Equation 1-3) is convenient when you express a model naturally in terms of a mass matrix. For large, sparse  $M(t,y)$ , solving Equation 1-3 directly reduces the storage and run-time needed to solve the problem.

When  $M(t,y)$  is singular, then  $M(t,y)$  times  $M(t,y)y' = f(t,y)$  is a DAE. A DAE has a solution only when  $y_0$  is consistent; that is, there exists an initial slope  $yp_0$  such that  $M(t_0,y_0)yp_0 = f(t_0,y_0)$ . If  $y_0$  and  $yp_0$  are not consistent, the solver treats them as guesses, attempts to compute consistent values that are close to the guesses, and continues to solve

the problem. For DAEs of index 1, solving an initial value problem with consistent initial conditions is much like solving an ODE.

The `ode15s` and `ode23t` solvers can solve DAEs of index 1. For examples of DAE problems, see Example: Differential-Algebraic Problem, in the MATLAB Mathematics documentation, and the examples `amp1dae` and `hb1dae`.

The following table describes the mass matrix and DAE properties. Further information on each property is given following the table.

### Mass Matrix and DAE Properties (Solvers Other Than `ode15i`)

Property	Value	Description
Mass	Matrix   function handle	Mass matrix or a function that evaluates the mass matrix $M(t,y)$ .
MStateDependence	none   {weak}   strong	Dependence of the mass matrix on $y$ .
MvPattern	Sparse matrix	$\partial(M(t,y)v)/\partial y$ sparsity pattern.
MassSingular	yes   no   {maybe}	Indicates whether the mass matrix is singular.
InitialSlope	Vector {zero vector}	Vector representing the consistent initial slope $yp_0$ .

### Description of Mass Matrix and DAE Properties

**Mass** — For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a mass matrix  $M$ . For problems of the form  $M(t)y' = f(t,y)$ , set 'Mass' to a function handle `@Mfun`, where `Mfun(t,y)` evaluates the mass matrix  $M(t,y)$ . The `ode23s` solver can only solve problems with a constant mass matrix  $M$ . When solving DAEs, using `ode15s` or `ode23t`, it is advantageous to formulate the problem so that  $M$  is a diagonal matrix (a semiexplicit DAE).

For example problems, see “Finite Element Discretization” in the MATLAB Mathematics documentation, or the examples `fem2ode` or `batonode`.

**MStateDependence** — Set this property to `none` for problems

$M(t)y' = f(t,y)$ . Both `weak` and `strong` indicate  $M(t,y)$ , but `weak` results in implicit solvers using approximations when solving algebraic equations.

**MvPattern** — Set this property to a sparse matrix  $S$  with  $S(i,j) = 1$  if, for any  $k$ , the  $(i,k)$  component of  $M(t,y)$  depends on component  $j$  of  $y$ , and 0 otherwise. For use with the `ode15s`, `ode23t`, and `ode23tb` solvers when `MStateDependence` is `strong`. See `burgersode` as an example.

**MassSingular** — Set this property to `no` if the mass matrix is not singular and you are using either the `ode15s` or `ode23t` solver. The default value of `maybe` causes the solver to test whether the problem is a DAE, by testing whether  $M(t_0,y_0)$  is singular.

**InitialSlope** — Vector representing the consistent initial slope  $yp_0$ , where  $yp_0$  satisfies  $M(t_0,y_0) \cdot yp_0 = f(t_0,y_0)$ . The default is the zero vector.

This property is for use with the `ode15s` and `ode23t` solvers when solving DAEs.

## ode15s and ode15i-Specific Properties

`ode15s` is a variable-order solver for stiff problems. It is based on the numerical differentiation formulas (NDFs). The NDFs are generally more efficient than the closely related family of backward differentiation formulas (BDFs), also known as Gear’s methods. The `ode15s` properties let you choose among these formulas, as well as specifying the maximum order for the formula used.

`ode15i` solves fully implicit differential equations of the form

$$f(t,y,y') = 0$$

using the variable order BDF method.

The following table describes the `ode15s` and `ode15i`-specific properties. Further information on each property is given following the table. Use `odeset` to set these properties.

### ode15s and ode15i-Specific Properties

Property	Value	Description
MaxOrder	1   2   3   4   {5}	Maximum order formula used to compute the solution.
BDF (ode15s only)	on   {off}	Specifies whether you want to use the BDFs instead of the default NDFs.

### Description of ode15s and ode15i-Specific Properties

**MaxOrder** — Maximum order formula used to compute the solution.

**BDF** (ode15s only) — Set BDF on to have `ode15s` use the BDFs.

For both the NDFs and BDFs, the formulas of orders 1 and 2 are A-stable (the stability region includes the entire left half complex plane). The higher order formulas are not as stable, and the higher the order the worse the stability. There is a class of stiff problems (stiff oscillatory) that is solved more efficiently if `MaxOrder` is reduced (for example to 2) so that only the most stable formulas are used.

# odextend

---

## Purpose

Extend solution of initial value problem for ordinary differential equation

## Syntax

```
solext = odextend(sol, odefun, tfinal)
solext = odextend(sol,[],tfinal)
solext = odextend(sol, odefun, tfinal, yinit)
solext = odextend(sol, odefun, tfinal, [yinit, ypinit])
solext = odextend(sol, odefun, tfinal, yinit, options)
```

## Description

`solext = odextend(sol, odefun, tfinal)` extends the solution stored in `sol` to an interval with upper bound `tfinal` for the independent variable. Specify `odefun` as a function handle. Specify `sol` as an ODE solution structure created using an ODE solver. The lower bound for the independent variable in `solext` is the same as in `sol`. If you created `sol` with an ODE solver other than `ode15i`, the function `odefun` computes the right-hand side of the ODE equation, which is of the form  $y' = f(t,y)$ . If you created `sol` using `ode15i`, the function `odefun` computes the left-hand side of the ODE equation, which is of the form  $f(t,y,y') = 0$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `odefun`, if necessary.

`odextend` extends the solution by integrating `odefun` from the upper bound for the independent variable in `sol` to `tfinal`, using the same ODE solver that created `sol`. By default, `odextend` uses

- The initial conditions `y = sol.y(:,end)` for the subsequent integration
- The same integration properties and additional input arguments the ODE solver originally used to compute `sol`. This information is stored as part of the solution structure `sol` and is subsequently passed to `solext`. Unless you want to change these values, you do not need to pass them to `odextend`.

`solext = odextend(sol,[],tfinal)` uses the same ODE function that the ODE solver uses to compute `sol` to extend the solution. It is

not necessary to pass in `odefun` explicitly unless it differs from the original ODE function.

`solx = odextend(sol, odefun, tfinal, yinit)` uses the column vector `yinit` as new initial conditions for the subsequent integration, instead of the vector `sol.y(end)`.

---

**Note** To extend solutions obtained with `ode15i`, use the following syntax, in which the column vector `ypinit` is the initial derivative of the solution:

---

```
solx = odextend(sol, odefun, tfinal, [yinit, ypinit])
```

---

`solx = odextend(sol, odefun, tfinal, yinit, options)` uses the integration properties specified in `options` instead of the options the ODE solver originally used to compute `sol`. The new options are then stored within the structure `solx`. See `odeset` for details on setting options properties. Set `yinit = []` as a placeholder to specify the default initial conditions.

## Examples

The following command

```
sol=ode45(@vdp1,[0 10],[2 0]);
```

uses `ode45` to solve the system  $y' = \text{vdp1}(t, y)$ , where `vdp1` is an example of an ODE function provided with MATLAB software, on the interval `[0 10]`. Then, the commands

```
sol=odextend(sol,@vdp1,20);
plot(sol.x,sol.y(1,:));
```

extend the solution to the interval `[0 20]` and plot the first component of the solution on `[0 20]`.

# onCleanup

---

**Purpose** Cleanup tasks upon function completion

**Syntax** `cleanupObj = onCleanup(cleanupFun)`

**Description** `cleanupObj = onCleanup(cleanupFun)` creates an object that, when destroyed, executes the function `cleanupFun`. MATLAB implicitly clears all local variables at the termination of a function, whether by normal completion, or a forced exit, such as an error, or **Ctrl+C**.

If you reference or pass `cleanupObj` outside your function, then `cleanupFun` does not run when that function terminates. Instead, it runs whenever the MATLAB destroys the object.

## Input Arguments

### **cleanupFun - Clean-up task**

function handle

Clean-up task, specified as a handle to a function.

You can declare any number of `onCleanup` objects in a program file. However, if the clean-up tasks depend on the order of execution, then you should define only one object that calls a script or function, containing the relevant clean-up commands.

You should use an anonymous function handle to call your clean-up task. This allows you to pass arguments to your clean-up function.

**Example:** `@() fclose('file.m')`

**Example:** `@() user_script`

**Example:** `@() function(input)`

### **Data Types**

function\_handle

## Examples

### **Close a Figure After Executing Function**

Save the following code in `action.m` and type `action` in the Command Window.

```
function [] = action()
```

```
f = figure;
finishup = onCleanup(@() myCleanupFun(f));
disp('Display Figure');
end
```

```
function myCleanupFun(f)
close(f);
disp('Close Figure')
end
```

```
Display Figure
Close Figure
```

### Switch Directories After Executing Function

Pass your own script to the `onCleanup` object so that it executes when MATLAB destroys the cleanup object.

Save the following code in `cleanup.m`.

```
cd(tempdir);
disp('You are now in the temporary folder')
```

Save the following code in `youraction.m` and type `youraction` in the Command Window.

```
function [] = youraction
changeup = onCleanup(@cleanup);
disp('Execute Code');
end
```

```
Execute Code
You are now in the temporary folder
```

## Tips

- Avoid using nested functions during cleanup. MATLAB can clear variables used in nested functions before the clean-up function tries to read from them.
- If your program contains multiple cleanup objects, MATLAB does not guarantee the order that it destroys these objects.

# onCleanup

---

- If the order of your cleanup functions matters, define one `onCleanup` object for all the tasks.

## Concepts

- “Clean Up When Functions Complete”
- “Object Lifecycle”
- “Function Handles”
- “What Are Anonymous Functions?”

**Purpose**

Create array of all ones

**Syntax**

```
X = ones
X = ones(n)
X = ones(sz1, ..., szN)
X = ones(sz)

X = ones(classname)
X = ones(n, classname)
X = ones(sz1, ..., szN, classname)
X = ones(sz, classname)

X = ones('like', p)
X = ones(n, 'like', p)
X = ones(sz1, ..., szN, 'like', p)
X = ones(sz, 'like', p)
```

**Description**

`X = ones` returns the scalar 1.

`X = ones(n)` returns an n-by-n matrix of ones.

`X = ones(sz1, ..., szN)` returns an sz1-by-...-by-szN array of ones where sz1, ..., szN indicates the size of each dimension. For example, `ones(2,3)` returns a 2-by-3 array of ones.

`X = ones(sz)` returns an array of ones where the size vector, `sz`, defines `size(X)`. For example, `ones([2,3])` returns a 2-by-3 array of ones.

`X = ones(classname)` returns a scalar 1 where the string, `classname`, specifies the data type. For example, `ones('int8')` returns a scalar, 8-bit integer 1.

`X = ones(n, classname)` returns an n-by-n array of ones of data type `classname`.

`X = ones(sz1, ..., szN, classname)` returns an `sz1`-by-...-by-`szN` array of ones of data type `classname`.

`X = ones(sz, classname)` returns an array of ones where the size vector, `sz`, defines `size(X)` and `classname` defines `class(X)`.

`X = ones('like', p)` returns a scalar 1 with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = ones(n, 'like', p)` returns an `n`-by-`n` array of ones like `p`.

`X = ones(sz1, ..., szN, 'like', p)` returns an `sz1`-by-...-by-`szN` array of ones like `p`.

`X = ones(sz, 'like', p)` returns an array of ones like `p` where the size vector, `sz`, defines `size(X)`.

## Input Arguments

### **n - Size of square matrix**

integer value

Size of square matrix, specified as an integer value, defines the output as a square, `n`-by-`n` matrix of ones.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### **sz1,...,szN - Size of each dimension**

two or more integer values

Size of each dimension, specified as two or more integer values, defines `X` as a `sz1`-by-...-by-`szN` array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**sz - Output size**

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

**Example:** `sz = [2,3,4]` defines X as a 2-by-3-by-4 array.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**classname - Output class**

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

**Data Types**

char

**p - Prototype**

numeric variable

Prototype, specified as a numeric variable.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**Complex Number Support:** Yes

## Examples

### Square Array of Ones

Create a 4-by-4 array of ones.

```
X = ones(4)
```

```
X =
```

```
 1 1 1 1
 1 1 1 1
 1 1 1 1
 1 1 1 1
```

### 3-D Array of Ones

Create a 2-by-3-by-4 array of ones.

```
X = ones(2,3,4);
```

```
size(X)
```

```
ans =
```

```
 2 3 4
```

### Size Defined by Existing Array

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =

 3 2
```

Create an array of ones that is the same size as A

```
X = ones(sz)
```

```
X =

 1 1
 1 1
 1 1
```

### Nondefault Numeric Data Type

Create a 1-by-3 vector of ones whose elements are 16-bit unsigned integers.

```
X = ones(1,3,'uint16'),
class(X)
```

```
X =

 1 1 1
```

```
ans =
```

```
uint16
```

### Complex One

Create a scalar 1 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 1 that is complex like p.

```
X = ones('like',p)
```

```
X =
```

```
1.0000 + 0.0000i
```

## Size and Numeric Data Type of Defined by Existing Array

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of ones that is the same size and data type as p.

```
X = ones(size(p),'like',p),
class(X)
```

```
X =
```

```
1 1 1
1 1 1
```

```
ans =
```

```
uint8
```

## Concepts

- “Class Support for Array-Creation Functions”
- “Preallocating Arrays”

---

<b>Purpose</b>	Open file in appropriate application
<b>Syntax</b>	<code>open(name)</code> <code>output = open(name)</code>
<b>Description</b>	<p><code>open(name)</code> opens the specified file or variable in the appropriate application.</p> <p><code>output = open(name)</code> returns an empty <code>output</code> (<code>[]</code>) for most cases. If opening a MAT-file, <code>output</code> is a structure that contains the variables in the file. If opening a figure, <code>output</code> is a handle to that figure.</p>
<b>Tips</b>	<p>The <code>open</code> function opens files based on their extension. You can extend the functionality of <code>open</code> by defining your own file handling function of the form <code>openxxx</code>, where <code>xxx</code> is a file extension. For example, if you create a function <code>openlog</code>, the <code>open</code> function calls <code>openlog</code> to process any files with the <code>.log</code> extension. The <code>open</code> function returns any single <code>output</code> defined by your function.</p>
<b>Input Arguments</b>	<p><b>name</b></p> <p>Name of file or variable to open. If <code>name</code> does not include an extension, the <code>open</code> function:</p> <ol style="list-style-type: none"><li>1 Searches for a variable named <code>name</code>. If the variable exists, <code>open</code> opens it in the Variables editor.</li><li>2 Searches the MATLAB path for <code>name.mdl</code>, <code>name.slx</code>, or <code>name.m</code>. If <code>name.mdl</code> or <code>name.slx</code> exists, then <code>open</code> opens the model in Simulink. If only <code>name.m</code> exists, <code>open</code> opens the file in the MATLAB Editor.</li></ol> <p>If more than one file named <code>name</code> exists on the MATLAB path, the <code>open</code> function opens the file returned by <code>which(name)</code>.</p> <p>The <code>open</code> function performs the following actions based on the file extension:</p>

## (Continued)

.m	Open in MATLAB Editor.
.mat	Return variables in structure <i>st</i> when called with the syntax:  <i>st</i> = open( <i>name</i> )
.fig	Open figure in Handle Graphics.
.mdl or .slx	Open model in Simulink.
.prj	Open project in the MATLAB Compiler Deployment Tool.
.doc*	Open document in Microsoft Word.
.exe	Run executable file (only on Windows systems).
.pdf	Open document in Adobe® Acrobat®.
.ppt*	Open document in Microsoft PowerPoint.
.xls*	Start MATLAB Import Wizard.
.htm or .html	Open document in MATLAB browser.
.url	Open file in your default Web browser.

## Examples

Open Contents.m in the MATLAB Editor by typing:

```
open Contents.m
```

Generally, MATLAB opens `matlabroot\toolbox\matlab\general\Contents.m`. However, if you have a file called `Contents.m` in a directory that is before `toolbox\matlab\general` on the MATLAB path, then `open` opens that file instead.

---

Open a file not on the MATLAB path by including the complete file specification:

```
open('D:\temp\data.mat')
```

If the file does not exist, MATLAB displays an error message.

---

Create a function called `opentxt` to handle files with extension `.txt`:

```
function opentxt(filename)

 fprintf('You have requested file: %s\n', filename);

 wh = which(filename);
 if exist(filename, 'file') == 2
 fprintf('Opening in MATLAB Editor: %s\n', filename);
 edit(filename);
 elseif ~isempty(wh)
 fprintf('Opening in MATLAB Editor: %s\n', wh);
 edit(wh);
 else
 warning('MATLAB:fileNotFound', ...
 'File was not found: %s', filename);
 end

end
```

Open the file `ngc6543a.txt` (a description of `ngc6543a.jpg`, located in `matlabroot\toolbox\matlab\demos`):

```
photo_text = 'ngc6543a.txt';
open(photo_text)
```

`open` calls your function with the following syntax:

```
opentxt(photo_text)
```

## See Also

`edit` | `load` | `openfig` | `openvar` | `path` | `uiopen` | `which` | `winopen`

# VideoWriter.open

---

<b>Purpose</b>	Open file for writing video data
<b>Syntax</b>	<code>open(writerObj)</code>
<b>Description</b>	<code>open(writerObj)</code> opens the file associated with <code>writerObj</code> for writing. When you open the file, all properties of the object become read only. <code>open</code> discards any existing contents of the file.
<b>Input Arguments</b>	<b>writerObj</b> VideoWriter object created by the <code>VideoWriter</code> function.
<b>Examples</b>	Open a new AVI file: <pre>myObj = VideoWriter('newfile.avi'); open(myObj);</pre>
<b>See Also</b>	<code>writeVideo</code>   <code>VideoWriter</code>   <code>close</code>

**Purpose** Open new copy or raise existing copy of saved figure

**Syntax**

```
openfig('filename.fig')
openfig('filename.fig','new')
openfig('filename.fig','reuse')
openfig('filename.fig','new','invisible')
openfig('filename.fig','reuse','invisible')
openfig('filename.fig','new','visible')
openfig('filename.fig','reuse','visible')
figure_handle = openfig(...)
```

**Description** `openfig('filename.fig')` and `openfig('filename.fig','new')` opens the figure contained in the FIG-file, `filename.fig`, and ensures it is visible and positioned completely on screen. You do not have to specify the full path to the FIG-file as long as it is on your MATLAB path. The `.fig` extension is optional.

`openfig('filename.fig','reuse')` opens the figure contained in the FIG-file only if a copy of the figure is not currently open. Otherwise, `openfig` brings the existing copy forward, making sure it is still visible and completely on screen.

`openfig('filename.fig','new','invisible')` or `openfig('filename.fig','reuse','invisible')` opens the figure as in the preceding example, while forcing the figure to be invisible.

`openfig('filename.fig','new','visible')` or `openfig('filename.fig','reuse','visible')` opens the figure, while forcing the figure to be visible.

`figure_handle = openfig(...)` returns the handle to the figure.

**Tips** `openfig` is designed for use with GUI figures. Use this function to:

- Open the FIG-file creating the GUI and ensure it is displayed on screen. This provides compatibility with different screen sizes and resolutions.

# openfig

---

- Control whether the MATLAB software displays one or multiple instances of the GUI at any given time.
- Return the handle of the figure created, which is typically hidden for GUI figures.

If the FIG-file contains an invisible figure, `openfig` returns its handle and leaves it invisible. The caller should make the figure visible when appropriate.

Do not use `openfig` or double-click a FIG-file to open a GUI created with GUIDE. Instead open the GUI code file by typing its name in the command window or by right-clicking its name in the Current Folder Browser and selecting **Run File**. To open a GUIDE GUI, for example one called `guifile.m`, in an invisible state, specify the `Visible` property in your command:

```
guifile('Visible','off')
```

Your code should then make the figure visible at an appropriate time.

## See Also

`guide` | `guihandles` | `movegui` | `open` | `hgload` | `save`

**Purpose** Control OpenGL rendering

**Syntax**

```
opengl selection_mode
opengl info
s = opengl('data')
opengl software
opengl hardware
opengl verbose
opengl quiet
opengl DriverBugWorkaround
opengl('DriverBugWorkaround',WorkaroundState)
```

**Description** `opengl selection_mode` determines how MATLAB selects the OpenGL renderer. Possible values for `selection_mode` are

- `autoselect` – allows OpenGL to be automatically selected if OpenGL is available and if there is graphics hardware on the host machine.
- `neverselect` – disables autoselection of OpenGL.
- `advise` – prints a message to the command window if OpenGL rendering is advised, but `RenderMode` is set to `manual`.

`opengl`, by itself, returns the current autoselection state.

Note that the autoselection state only specifies whether OpenGL should or should not be considered for rendering; it does not explicitly set the rendering to OpenGL. You can do this by setting the `Renderer` property of the figure to `OpenGL`. For example,

```
set(figure_handle, 'Renderer', 'OpenGL')
```

---

**Note** The OpenGL autoselection mode applies when the `RenderMode` of the figure is `auto`

---

`opengl info` prints information with the version and vendor of the OpenGL on your system. Also indicates whether your system is

currently using hardware or software OpenGL and the state of various driver bug workarounds. Note that calling `opengl info` loads the OpenGL Library.

For example, the following output is generated on a Windows computer:

```
>> opengl info
 Version: '3.3.0'
 Vendor: 'NVIDIA Corporation'
 Renderer: 'Quadro 400/PCI/SSE2'
MaxTextureSize: 8192
 Visual: ''
 Software: ''
 Extensions: {235x1 cell}
MaxFrameBufferSize: 8192
```

Note that different computer systems may not list all OpenGL bugs.

`s = opengl('data')` returns a structure containing the same data that is displayed when you call `opengl info`, with the exception of the driver bug workaround state.

`opengl software` forces the MATLAB software to use software OpenGL rendering instead of hardware OpenGL. Note that Macintosh systems do not support software OpenGL.

`opengl hardware` reverses the `opengl software` command and enables MATLAB to use hardware OpenGL rendering if it is available. If your computer does not have OpenGL hardware acceleration, MATLAB automatically switches to software OpenGL rendering (except on Macintosh systems, which do not support software OpenGL).

Note that on UNIX systems, the `software` or `hardware` options with the `opengl` command works only if MATLAB has not yet used the OpenGL renderer or you have not issued the `opengl info` command (which attempts to load the OpenGL Library).

`opengl verbose` displays verbose messages about OpenGL initialization (if OpenGL is not already loaded) and other runtime messages.

`opengl quiet` disables verbose message setting.

`opengl DriverBugWorkaround` queries the state of the specified driver bug workaround. Use the command `opengl info` to see a list of all driver bug workarounds. See “Driver Bug Workarounds” on page 1-4827 for more information.

`opengl('DriverBugWorkaround',WorkaroundState)` sets the state of the specified driver bug workaround. You can set `WorkaroundState` to one of three values:

- 0 – Disable the specified *DriverBugWorkaround* (if enabled) and do not allow MATLAB to autoselect this workaround.
- 1 – Enable the specified *DriverBugWorkaround*.
- -1 – Set the specified *DriverBugWorkaround* to autoselection mode, which allows MATLAB to enable this workaround if the requisite conditions exist.

## Driver Bug Workarounds

---

**Note** Always check with your graphics hardware vendor to ensure you are using the latest driver software. Use the `opengl info` command to see your current version number.

---

The MATLAB software enables various OpenGL driver bug workarounds when it detects certain known problems with installed hardware. However, because there are many versions of graphics drivers, you might encounter situations when MATLAB does not enable a workaround that would solve a problem you are having with OpenGL rendering.

This section describes the symptoms that each workaround is designed to correct so you can decide if you want to try using one to fix an OpenGL rendering problem.

Use the `opengl info` command to see what driver bug workarounds are available on your computer.

---

**Note** These workarounds have not been tested under all driver combinations and therefore might produce undesirable results under certain conditions.

---

## **OpenGLBitmapZbufferBug**

Symptom: text with background color (including data tips) and text displayed on image, patch, or surface objects is not visible when using OpenGL renderer.

Possible side effect: text is always on top of other objects.

Command to enable:

```
opengl('OpenGLBitmapZbufferBug',1)
```

## **OpenGLWobbleTesselatorBug**

Symptom: Rendering complex patch object causes segmentation violation and returns a tessellator error message in the stack trace.

Command to enable:

```
opengl('OpenGLWobbleTesselatorBug',1)
```

## **OpenGLLineSmoothingBug**

Symptom: Lines with a LineWidth greater than 3 look bad.

Command to enable:

```
opengl('OpenGLLineSmoothingBug',1)
```

## **OpenGLDockingBug**

Symptom: MATLAB crashes when you dock a figure that has its Renderer property set to opengl.

Command to enable:

```
opengl('OpenGLDockingBug',1)
```

### **OpenGLClippedImageBug**

Symptom: Images (as well as colorbar displays) do not display when the `Renderer` property set to `opengl`.

Command to enable:

```
opengl('OpenGLClippedImageBug',1)
```

### **OpenGLERaseModeBug**

Symptom: Graphics objects with `EraseMode` property set to non-normal erase modes (`xor`, `none`, or `background`) do not draw when the figure `Renderer` property is set to `opengl`.

Command to enable:

```
opengl('OpenGLERaseModeBug',1)
```

## **See Also**

`Renderer`

# openvar

---

**Purpose** Open workspace variable in Variables editor or other graphical editing tool

**Syntax** `openvar(varname)`

**Description** `openvar(varname)` opens the workspace variable named by the string, `varname`, in the Variables editor for graphical editing. Changes that you make to variables in the Variables editor occur in the workspace as soon as you enter them.

In some toolboxes, `openvar` opens a tool appropriate for viewing or editing objects indicated by `varname` instead of opening the Variables editor.

MATLAB does not impose any limitation on the size of a variable that you can open in the Variables editor. However, your operating system or the amount of physical memory installed on your computer can impose such limits.

## Input Arguments

### **varname - Variable name**

string

Variable name, specified as a string. The named variable can be an array, character string, cell array, structure, or an object and its properties. If the named variable is a multidimensional array, then you can only view the array in the Variables editor, and not edit it.

**Example:** `'myVariable'`

**Example:** `'A'`

## Examples

### **Identify Outliers in a Linked Graph**

Use data brushing to identify observations in a vector or matrix that might warrant further analysis.

Make a scatter plot of data in the sample MAT-file `count.dat`, and open the variable `count` in the Variables editor.

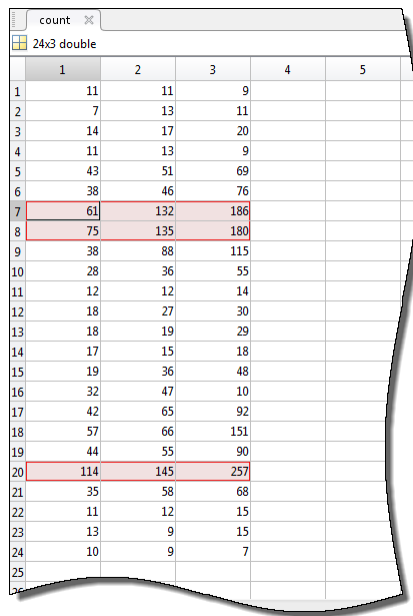

```
load count.dat
```

```
scatter(count(:,1),count(:,2))
openvar('count')
```

Right-click a cell in the Variables editor and select **Brushing > Brushing On**. This turns on data brushing in the Variables editor.

Select the rows 7, 8, and 20. (Select noncontiguous rows by holding down the **Ctrl** key and clicking in each row.)

	1	2	3	4	5
1	11	11	9		
2	7	13	11		
3	14	17	20		
4	11	13	9		
5	43	51	69		
6	38	46	76		
7	61	132	186		
8	75	135	180		
9	38	88	115		
10	28	36	55		
11	12	12	14		
12	18	27	30		
13	18	19	29		
14	17	15	18		
15	19	36	48		
16	32	47	10		
17	42	65	92		
18	57	66	151		
19	44	55	90		
20	114	145	257		
21	35	58	68		
22	11	12	15		
23	13	9	15		
24	10	9	7		
25					

In the Figure window with the scatter plot, click **Brush/Select Data**  to enable data brushing, and **Link Plot**  to enable data linking.

The data observations you brushed in the Variables editor appear highlighted in the scatter plot.

As long as data linking is enabled in the figure, observations that you brush in the scatter plot are highlighted in the Variables editor. When a figure is not linked to its data sources, you can still brush its graphs and you can brush the same data in the Variables editor, but only the display that you brush responds by highlighting.

## Tips

- As an alternative to the `openvar` function, double-click a variable in the Workspace browser.

<b>Purpose</b>	Optimization options values
<b>Syntax</b>	<pre>val = optimget(options,'param') val = optimget(options,'param',default)</pre>
<b>Description</b>	<p><code>val = optimget(options,'param')</code> returns the value of the specified parameter in the optimization options structure <code>options</code>. You need to type only enough leading characters to define the parameter name uniquely. Case is ignored for parameter names.</p> <p><code>val = optimget(options,'param',default)</code> returns <code>default</code> if the specified parameter is not defined in the optimization options structure <code>options</code>. Note that this form of the function is used primarily by other optimization functions.</p>
<b>Examples</b>	<p>This statement returns the value of the <code>Display</code> optimization options parameter in the structure called <code>my_options</code>.</p> <pre>val = optimget(my_options,'Display')</pre> <p>This statement returns the value of the <code>Display</code> optimization options parameter in the structure called <code>my_options</code> (as in the previous example) except that if the <code>Display</code> parameter is not defined, it returns the value <code>'final'</code>.</p> <pre>optnew = optimget(my_options,'Display','final');</pre>
<b>See Also</b>	<code>optimset</code>   <code>fminbnd</code>   <code>fminsearch</code>   <code>fzero</code>   <code>lsqnonneg</code>

# optimset

---

**Purpose** Create or edit optimization options structure

**Syntax**

```
options = optimset('param1',value1,'param2',value2,...)
optimset
options = optimset
options = optimset(optimfun)
options = optimset(olddopts,'param1',value1,...)
options = optimset(olddopts,newopts)
```

**Description** The function `optimset` creates an options structure that you can pass as an input argument to the following four MATLAB optimization functions:

- `fminbnd`
- `fminsearch`
- `fzero`
- `lsqnonneg`

You can use the `options` structure to change the default parameters for these functions.

---

**Note** If you have an Optimization Toolbox™ license, you can also use `optimset` to create an expanded options structure containing additional options specifically designed for the functions provided in that toolbox. For more information about these additional options, see the reference page for the enhanced Optimization Toolbox `optimset` function.

---

`options = optimset('param1',value1,'param2',value2,...)` creates an optimization options structure called `options`, in which the specified parameters (`param`) have specified values. Any unspecified parameters are set to `[]` (parameters with value `[]` indicate to use the default value for that parameter when `options` is passed to the optimization function). It is sufficient to type only enough leading

characters to define the parameter name uniquely. Case is ignored for parameter names.

`optimset` with no input or output arguments displays a complete list of parameters with their valid values.

`options = optimset` (with no input arguments) creates an options structure `options` where all fields are set to `[]`.

`options = optimset(optimfun)` creates an options structure `options` with all parameter names and default values relevant to the optimization function `optimfun`.

`options = optimset(olddopts,'param1',value1,...)` creates a copy of `olddopts`, modifying the specified parameters with the specified values.

`options = optimset(olddopts,newopts)` combines an existing options structure `olddopts` with a new options structure `newopts`. Any parameters in `newopts` with nonempty values overwrite the corresponding old parameters in `olddopts`.

## Options

The following table lists the available options for the MATLAB optimization functions.

Option	Value	Description	Solvers
Display	'off'   'iter'   {'final'}   'notify'	Level of display. 'off' displays no output; 'iter' displays output at each iteration (not available for <code>lsqnonneg</code> ); 'final' displays just the final output; 'notify' displays output only if	fminbnd, fminsearch,fzero, lsqnonneg

# optimset

Option	Value	Description	Solvers
		the function does not converge.	
FunValCheck	'off'   'on'	Check whether objective function values are valid. 'on' displays an error when the objective function returns a value that is complex or NaN. 'off' displays no error.	fminbnd, fminsearch, fzero
MaxFunEvals	positive integer	Maximum number of function evaluations allowed.	fminbnd, fminsearch
MaxIter	positive integer	Maximum number of iterations allowed.	fminbnd, fminsearch
OutputFcn	function   {}	User-defined function that an optimization function calls at each iteration. See “Output Functions”.	fminbnd, fminsearch, fzero
PlotFcns	function   {}	User-defined or built-in plot function that an optimization function calls at each iteration. Built-in functions: <ul style="list-style-type: none"> <li>• @optimplotx plots the current point</li> <li>• @optimplotfval plots the function value</li> </ul>	fminbnd, fminsearch, fzero

Option	Value	Description	Solvers
		<ul style="list-style-type: none"> <li>@optimplotfunccount plots the function count (not available for fzero)</li> </ul> See “Plot Functions”.	
TolFun	positive scalar	Termination tolerance on the function value. See “Tolerances and Stopping Criteria”.	fminsearch
TolX	positive scalar	Termination tolerance on $x$ , the current point. See “Tolerances and Stopping Criteria”.	fminbnd, fminsearch, fzero, lsqnonneg

## Examples

This statement creates an optimization options structure called `options` in which the `Display` parameter is set to `'iter'` and the `TolFun` parameter is set to `1e-8`.

```
options = optimset('Display','iter','TolFun',1e-8)
```

This statement makes a copy of the options structure called `options`, changing the value of the `TolX` parameter and storing new values in `optnew`.

```
optnew = optimset(options,'TolX',1e-4);
```

This statement returns an optimization options structure that contains all the parameter names and default values relevant to the function `fminbnd`.

```
optimset('fminbnd')
```

**Purpose** Find logical OR

**Syntax** A | B | ...  
or(A, B)

**Description** A | B | ... performs a logical OR of all input arrays A, B, etc., and returns an array containing elements set to either logical 1 (true) or logical 0 (false). An element of the output array is set to 1 if any input arrays contain a nonzero element at that same array location. Otherwise, that element is set to 0.

Each input of the expression can be an array or can be a scalar value. All nonscalar input arrays must have equal dimensions. If one or more inputs are an array, then the output is an array of the same dimensions. If all inputs are scalar, then the output is scalar.

If the expression contains both scalar and nonscalar inputs, then each scalar input is treated as if it were an array having the same dimensions as the other input arrays. In other words, if input A is a 3-by-5 matrix and input B is the number 1, then B is treated as if it were a 3-by-5 matrix of ones.

or(A, B) is called for the syntax A | B when either A or B is an object.

---

**Note** The symbols | and || perform different operations in a MATLAB application. The element-wise OR operator described here is |. The short-circuit OR operator is ||.

---

## Examples

If matrix A is

0.4235	0.5798	0	0.7942	0
0.5155	0	0	0	0.8744
0	0	0	0.4451	0.0150
0.4329	0.6405	0.6808	0	0

and matrix B is

0	1	0	1	0
1	1	0	0	1
0	0	0	1	0
0	1	0	0	1

then

A		B			
ans	=				
1		1	0	1	0
1		1	0	0	1
0		0	0	1	1
1		1	1	0	1

# ordeig

---

**Purpose** Eigenvalues of quasitriangular matrices

**Syntax** `E = ordeig(T)`  
`E = ordeig(AA,BB)`

**Description** `E = ordeig(T)` takes a quasitriangular Schur matrix `T`, typically produced by `schur`, and returns the vector `E` of eigenvalues in their order of appearance down the diagonal of `T`.

`E = ordeig(AA,BB)` takes a quasitriangular matrix pair `AA` and `BB`, typically produced by `qz`, and returns the generalized eigenvalues in their order of appearance down the diagonal of `AA -  $\lambda$ *BB`.

`ordeig` is an order-preserving version of `eig` for use with `ordschur` and `ordqz`. It is also faster than `eig` for quasitriangular matrices.

## Examples **Example 1**

```
T=diag([1 -1 3 -5 2]);
```

`ordeig(T)` returns the eigenvalues of `T` in the same order they appear on the diagonal.

```
ordeig(T)
```

```
ans =
```

```
 1
 -1
 3
 -5
 2
```

`eig(T)`, on the other hand, returns the eigenvalues in order of increasing magnitude.

```
eig(T)
```

```
ans =
```

```
-5
-1
 1
 2
 3
```

### Example 2

```
A = rand(10);
[U, T] = schur(A);
abs(ordeig(T))
```

```
ans =
```

```

schur | qz | ordschur | ordqz | eig

**Purpose** Order fields of structure array

**Syntax**

```
s = orderfields(s1)
s = orderfields(s1, s2)
s = orderfields(s1, c)
s = orderfields(s1, perm)
[s, perm] = orderfields(...)
```

**Description**

`s = orderfields(s1)` orders the fields in `s1` so that the new structure array `s` has field names in ASCII dictionary order.

`s = orderfields(s1, s2)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in `s2`. Structures `s1` and `s2` must have the same fields.

`s = orderfields(s1, c)` orders the fields in `s1` so that the new structure array `s` has field names in the same order as those in the cell array of field name strings `c`. Structure `s1` and cell array `c` must contain the same field names.

`s = orderfields(s1, perm)` orders the fields in `s1` so that the new structure array `s` has fieldnames in the order specified by the indices in permutation vector `perm`.

If `s1` has `N` fieldnames, the elements of `perm` must be an arrangement of the numbers from 1 to `N`. This is particularly useful if you have more than one structure array that you would like to reorder in the same way.

`[s, perm] = orderfields(...)` returns a permutation vector representing the change in order performed on the fields of the structure array that results in `s`.

**Tips** `orderfields` only orders top-level fields. It is not recursive.

**Examples** Create a structure `s`. Then create a new structure from `s`, but with the fields ordered alphabetically:

```
s = struct('b', 2, 'c', 3, 'a', 1)
s =
```

# orderfields

---

```
b: 2
c: 3
a: 1
```

```
snew = orderfields(s)
snew =
 a: 1
 b: 2
 c: 3
```

Arrange the fields of `s` in the order specified by the second (cell array) argument of `orderfields`. Return the new structure in `snew` and the permutation vector used to create it in `perm`:

```
[snew, perm] = orderfields(s, {'b', 'a', 'c'})
snew =
 b: 2
 a: 1
 c: 3
perm =
 1
 3
 2
```

Now create a new structure, `s2`, having the same fieldnames as `s`. Reorder the fields using the permutation vector returned in the previous operation:

```
s2 = struct('b', 3, 'c', 7, 'a', 4)
s2 =
 b: 3
 c: 7
 a: 4

snew = orderfields(s2, perm)
snew =
 b: 3
 a: 4
```

c: 7

# ordqz

**Purpose** Reorder eigenvalues in QZ factorization

**Syntax**  
[AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select)  
[...] = ordqz(AA,BB,Q,Z,keyword)  
[...] = ordqz(AA,BB,Q,Z,clusters)

**Description** [AAS,BBS,QS,ZS] = ordqz(AA,BB,Q,Z,select) reorders the QZ factorizations  $Q^*A^*Z = AA$  and  $Q^*B^*Z = BB$  produced by the qz function for a matrix pair (A,B). It returns the reordered pair (AAS,BBS) and the cumulative orthogonal transformations QS and ZS such that  $QS^*A^*ZS = AAS$  and  $QS^*B^*ZS = BBS$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular pair (AAS,BBS), and the corresponding invariant subspace is spanned by the leading columns of ZS. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where E is the vector of eigenvalues as they appear along the diagonal of  $AA^{-1}BB$ .

---

**Note** To extract E from AA and BB, use `ordeig(BB)`, instead of `eig`. This ensures that the eigenvalues in E occur in the same order as they appear on the diagonal of  $AA^{-1}BB$ .

---

[...] = ordqz(AA,BB,Q,Z,keyword) sets the selected cluster to include all eigenvalues in the region specified by keyword:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

[...] = ordqz(AA,BB,Q,Z,clusters) reorders multiple clusters at once. Given a vector `clusters` of cluster indices commensurate with  $E = \text{ordeig}(AA,BB)$ , such that all eigenvalues with the same `clusters`

value from one cluster, `ordqz` sorts the specified clusters in descending order along the diagonal of  $(AAS, BBS)$ . The cluster with highest index appears in the upper left corner.

**See Also**

`ordeig` | `ordschur` | `qz`

# ordschur

---

**Purpose** Reorder eigenvalues in Schur factorization

**Syntax**  
[US,TS] = ordschur(U,T,select)  
[US,TS] = ordschur(U,T,keyword)  
[US,TS] = ordschur(U,T,clusters)

**Description** [US,TS] = ordschur(U,T,select) reorders the Schur factorization  $X = U^*T^*U'$  produced by the schur function and returns the reordered Schur matrix TS and the cumulative orthogonal transformation US such that  $X = US^*TS^*US'$ . In this reordering, the selected cluster of eigenvalues appears in the leading (upper left) diagonal blocks of the quasitriangular Schur matrix TS, and the corresponding invariant subspace is spanned by the leading columns of US. The logical vector `select` specifies the selected cluster as  $E(\text{select})$  where  $E$  is the vector of eigenvalues as they appear along  $T$ 's diagonal.

---

**Note** To extract  $E$  from  $T$ , use  $E = \text{ordeig}(T)$ , instead of `eig`. This ensures that the eigenvalues in  $E$  occur in the same order as they appear on the diagonal of  $TS$ .

---

[US,TS] = ordschur(U,T,keyword) sets the selected cluster to include all eigenvalues in one of the following regions:

keyword	Selected Region
'lhp'	Left-half plane ( $\text{real}(E) < 0$ )
'rhp'	Right-half plane ( $\text{real}(E) > 0$ )
'udi'	Interior of unit disk ( $\text{abs}(E) < 1$ )
'udo'	Exterior of unit disk ( $\text{abs}(E) > 1$ )

[US,TS] = ordschur(U,T,clusters) reorders multiple clusters at once. Given a vector `clusters` of cluster indices, commensurate with  $E = \text{ordeig}(T)$ , and such that all eigenvalues with the same `clusters` value form one cluster, `ordschur` sorts the specified clusters

in descending order along the diagonal of  $TS$ , the cluster with highest index appearing in the upper left corner.

ordeig | ordqz | schur

# orient

---

**Purpose** Hardcopy paper orientation

**Alternatives** Use **File** → **Print Preview** on the figure window menu to directly manipulate print layout, paper size, headers, fonts and other properties when printing figures. For details, see Using Print Preview in the MATLAB Graphics documentation.

**Syntax**

```
orient
orient landscape
orient portrait
orient tall
orient(fig_handle)
orient(simulink_model)
orient(fig_handle,orientation)
orient(simulink_model,orientation)
```

**Description** `orient` returns a string with the current paper orientation: `portrait`, `landscape`, or `tall`.

`orient landscape` sets the paper orientation of the current figure to full-page landscape, orienting the longest page dimension horizontally. The figure is centered on the page and scaled to fit the page with a 0.25 inch border.

`orient portrait` sets the paper orientation of the current figure to `portrait`, orienting the longest page dimension vertically. The `portrait` option returns the page orientation to the MATLAB default. (Note that the result of using the `portrait` option is affected by changes you make to figure properties. See the "Algorithm" section for more specific information.)

`orient tall` maps the current figure to the entire page in `portrait` orientation, leaving a 0.25 inch border.

`orient(fig_handle)` returns the current orientation of the specified figure.

`orient(simulink_model)` returns the current orientation of the Simulink model.

`orient(fig_handle,orientation)` sets the orientation for the specified figure to the specified orientation (landscape, portrait, or tall).

`orient(simulink_model,orientation)` sets the orientation for the Simulink model.

## Algorithms

`orient` sets the `PaperOrientation`, `PaperPosition`, and `PaperUnits` properties of the current figure. Subsequent print operations use these properties. The result of using the `portrait` option can be affected by default property values as follows:

- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the current values of `PaperOrientation` and `PaperPosition` to place the figure on the page.
- If the current figure `PaperType` is the same as the default figure `PaperType` and the default figure `PaperOrientation` has been set to `landscape`, then the `orient portrait` command uses the default figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.
- If the current figure `PaperType` is different from the default figure `PaperType`, then the `orient portrait` command uses the current figure `PaperPosition` with the `x`, `y` and `width`, `height` values reversed (i.e., `[y,x,height,width]`) to position the figure on the page.

# orth

---

**Purpose** Orthonormal basis for range of matrix

**Syntax** `Q = orth(A)`

**Description** `Q = orth(A)` returns an orthonormal basis for the range of A. The columns of Q are vectors, which span the range of A. The number of columns in Q is equal to the rank of A.

**Input Arguments**

**A - Input matrix**  
scalar | vector | matrix

Input matrix, specified as a scalar, vector, or matrix.

**Data Types**  
single | double

**Complex Number Support:** Yes

**Examples**

**Basis for Full Rank Matrix**

Calculate and verify the orthonormal basis vectors for the range of a full rank matrix.

Define a matrix and find the rank.

```
A = [1 0 1; -1 -2 0; 0 1 -1];
r = rank(A)
```

```
r =
```

```
3
```

Since A is a square matrix of full rank, the orthonormal basis calculated by `orth(A)` matches the matrix U calculated in the singular value decomposition, `[U,S] = svd(A, 'econ')`. This is because the singular values of A are all nonzero.

Calculate the orthonormal basis for the range of A using `orth`.

```
Q = orth(A)
```

```
Q =
```

```
-0.1200 -0.8097 0.5744
 0.9018 0.1531 0.4042
-0.4153 0.5665 0.7118
```

The number of columns in  $Q$  is equal to  $\text{rank}(A)$ . Since  $A$  is of full rank,  $Q$  and  $A$  are the same size.

Verify that the basis,  $Q$ , is orthogonal and normalized within a reasonable error range.

```
E = norm(eye(r) - Q' * Q, 'fro')
```

```
E =
```

```
9.6228e-16
```

The error is on the order of  $\text{eps}$ .

### **Basis for Rank Deficient Matrix**

Calculate and verify the orthonormal basis vectors for the range of a rank deficient matrix.

Define a singular matrix and find the rank.

```
A = [1 0 1; 0 1 0; 1 0 1];
```

```
r = rank(A)
```

```
r =
```

```
2
```

Since  $A$  is rank deficient, the orthonormal basis calculated by  $\text{orth}(A)$  matches only the first  $r = 2$  columns of matrix  $U$  calculated in the

# orth

---

singular value decomposition,  $[U,S] = \text{svd}(A, 'econ')$ . This is because the singular values of  $A$  are *not* all nonzero.

Calculate the orthonormal basis for the range of  $A$  using `orth`.

$Q = \text{orth}(A)$

$Q =$

```
-0.7071 0
 0 1.0000
-0.7071 0
```

Since  $A$  is rank deficient,  $Q$  contains one fewer column than  $A$ .

## Definitions

### Range

The column space, or *range*, of a matrix  $A$  is the collection of all linear combinations of the columns of  $A$ . Any vector,  $\mathbf{b}$ , that is a solution to the linear equation,  $A\mathbf{x} = \mathbf{b}$ , is included in the range of  $A$  since you can also write it as a linear combination of the columns of  $A$ .

### Rank

The rank of a matrix is equal to the dimension of the range.

## Algorithms

`orth` is obtained from  $U$  in the singular value decomposition,  $[U,S] = \text{svd}(A, 'econ')$ . If  $r = \text{rank}(A)$ , the first  $r$  columns of  $U$  form an orthonormal basis for the range of  $A$ .

## See Also

`null` | `svd` | `rank`

**Purpose** Outer join between two tables

**Syntax**

```
C = outerjoin(A,B)
C = outerjoin(A,B,Name,Value)
[C,ia,ib] = outerjoin(___)
```

**Description** `C = outerjoin(A,B)` creates the table, `C`, as the outer join between the tables `A` and `B` by matching up rows using all the variables with the same name as key variables.

The outer join includes the rows that match between `A` and `B`, and also unmatched rows from either `A` or `B`, all with respect to the key variables. `C` contains all variables from both `A` and `B`, including the key variables.

`C = outerjoin(A,B,Name,Value)` performs the outer-join operation with additional options specified by one or more `Name,Value` pair arguments.

`[C,ia,ib] = outerjoin( ___ )` also returns index vectors, `ia` and `ib`, indicating the correspondence between rows in `C` and those in `A` and `B` respectively. You can use this syntax with any of the input arguments in the previous syntaxes.

## Input Arguments

### **A,B - Input tables**

tables

Input tables, specified as tables.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' ' ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Keys',2` uses the second variable in `A` and the second variable in `B` as key variables.

## **'Keys' - Variables to use as keys**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys, specified as the comma-separated pair consisting of 'Keys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You cannot use the 'Keys' name-value pair argument with the 'LeftKeys' and 'RightKeys' name-value pair arguments.

**Example:** 'Keys', [1 3] uses the first and third variables in A and B as a key variables.

## **'LeftKeys' - Variables to use as keys in A**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in A, specified as the comma-separated pair consisting of 'LeftKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'LeftKeys' name-value pair argument in conjunction with the 'RightKeys' name-value pair argument. 'LeftKeys' and 'RightKeys' both must specify the same number of key variables. outerjoin pairs key values based on their order.

**Example:** 'LeftKeys', 1 uses only the first variable in A as a key variable.

## **'RightKeys' - Variables to use as keys in B**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables to use as keys in B, specified as the comma-separated pair consisting of 'RightKeys' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You must use the 'RightKeys' name-value pair argument in conjunction with the 'LeftKeys' name-value pair argument.

'LeftKeys' and 'RightKeys' both must specify the same number of key variables. `outerjoin` pairs key values based on their order.

**Example:** 'RightKeys',3 uses only the third variable in B as a key variable.

### 'MergeKeys' - Merge keys flag

false (default) | true | 0 | 1

Merge keys flag, specified as the comma-separated pair consisting of 'MergeKeys' and either false, true, 0 or 1.

**false**                    `outerjoin` includes two separate variables in the output table, C, for each key variable pair from tables A and B.

This is the default behavior.

**true**                    `outerjoin` includes a single variable in the output table, C, for each key variable pair from tables A and B.

`outerjoin` creates the single variable by merging the key values from A and B, taking values from A where a corresponding row exists in A, and taking values from B otherwise.

If you specify, 'MergeKeys',true, then `outerjoin` includes all key variables in the output table, C, and overrides the inclusion or exclusion of key variables specified via the 'LeftVariables' and 'RightVariables' name-value pair arguments.

### 'LeftVariables' - Variables from A to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from A to include in C, specified as the comma-separated pair consisting of 'LeftVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

# outerjoin

---

You can use 'LeftVariables' to include or exclude key variables as well as nonkey variables from the output, C.

By default, outerjoin includes all variables from A.

## 'RightVariables' - Variables from B to include in C

positive integer | vector of positive integers | variable name | cell array containing one or more variable names | logical vector

Variables from B to include in C, specified as the comma-separated pair consisting of 'RightVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

You can use 'RightVariables' to include or exclude key variables as well as nonkey variables from the output, C.

By default, outerjoin includes all the variables from B.

## 'Type' - Type of outer join operation

'full' (default) | 'left' | 'right'

Type of outer-join operation, specified as the comma-separated pair consisting of 'Type' and either 'full', 'left', or 'right'.

- For a left outer join, C contains rows corresponding to key values in A that do not match any values in B, but not vice-versa.
- For a right outer join, C contains rows corresponding to key values in B that do not match any values in A, but not vice-versa.

By default, outerjoin does a full outer join and includes unmatched rows from both A and B.

## Output Arguments

### C - Outer join from A and B

table

Outer join from A and B, returned as a table. The output table, C, contains one row for each pair of rows in tables A and B that share the same combination of key values. If A and B contain variables with the same name, outerjoin adds a unique suffix to the corresponding variable names in C. Variables in C that came from A contain null values

in those rows that had no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

In general, if there are  $m$  rows in table A and  $n$  rows in table B that all contain the same combination of values in the key variables, table C contains  $m*n$  rows for that combination. C also contains rows corresponding to key value combinations in one input table that do not match any row the other input table.

C contains the horizontal concatenation of  $A(ia, LeftVars)$  and  $B(ib, RightVars)$  sorted by the values in the key variables. By default, `LeftVars` consists of all the variables of A, and `RightVars` consists of all the from B. Otherwise, `LeftVars` consists of the variables specified by the 'LeftVariables' name-value pair argument, and `RightVars` consists of the variables specified by the 'RightVariables' name-value pair argument.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

### **ia - Index to A**

column vector

Index to A, returned as a column vector. Each element of `ia` identifies the row in table A that corresponds to that row in the output table, C. The vector `ia` contains zeros to indicate the rows in C that do not correspond to rows in A.

### **ib - Index to B**

column vector

Index to B, returned as a column vector. Each element of `ib` identifies the row in table B that corresponds to that row in the output table, C. The vector `ib` contains zeros to indicate the rows in C that do not correspond to rows in B.

## Definitions

### Key Variable

Variable used to match and combine data between the input tables, A and B.

## Examples

### Outer-Join Operation of Tables with One Variable in Common

Create a table, A.

```
A = table([5;12;23;2;15;6],...
 {'cheerios';'pizza';'salmon';'oreos';'lobster';'pizza'},...
 'VariableNames',{'Age','FavoriteFood'},...
 'RowNames',{'Amy','Bobby','Holly','Harry','Marty','Sally'})
```

A =

	Age	FavoriteFood
Amy	5	'cheerios'
Bobby	12	'pizza'
Holly	23	'salmon'
Harry	2	'oreos'
Marty	15	'lobster'
Sally	6	'pizza'

Create a table, B, with one variable in common with A, called FavoriteFood.

```
B = table({'cheerios';'oreos';'pizza';'salmon';'cake'},...
 [110;160;140;367;243],...
 {'A-';'D';'B';'B';'C-'},...
 'VariableNames',{'FavoriteFood','Calories','NutritionGrade'})
```

B =

FavoriteFood	Calories	NutritionGrade
--------------	----------	----------------

'cheerios'	110	'A-'
'oreos'	160	'D'
'pizza'	140	'B'
'salmon'	367	'B'
'cake'	243	'C-'

Use the `outerjoin` function to create a new table, C, with data from tables A and B.

```
C = outerjoin(A,B)
```

```
C =
```

Age	FavoriteFood_A	FavoriteFood_B	Calories	NutritionG
NaN	''	'cake'	243	'C-'
5	'cheerios'	'cheerios'	110	'A-'
15	'lobster'	''	NaN	''
2	'oreos'	'oreos'	160	'D'
12	'pizza'	'pizza'	140	'B'
6	'pizza'	'pizza'	140	'B'
23	'salmon'	'salmon'	367	'B'

Table C contains a separate variable for the key variable from A, called `FavoriteFood_A`, and the key variable from B, called `FavoriteFood_B`.

### Merge Key Variable Pair to Single Variable

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{'Key1' 'Var1'})
```

```
A =
```

# outerjoin

---

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a','b','d','e'},[4;5;6;7],...
 'VariableNames',{'Key1' 'Var2'})
```

B =

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, C, with data from tables A and B. Merge the key values into a single variable in the output table, C.

```
C = outerjoin(A,B,'MergeKeys',true)
```

C =

Key1	Var1	Var2
'a'	1	4

'b'	2	5
'c'	3	NaN
'd'	NaN	6
'e'	11	7
'h'	17	NaN

Variables in table C that came from A contain null values in the rows that have no match from B. Similarly, variables in C that came from B contain null values in those rows that had no match from A.

### Outer-Join Operation of Tables and Indices to Values

Create a table, A.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
 'VariableNames',{'Key1' 'Var1'})
```

A =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, B, with common values in the variable Key1 between tables A and B, but also containing rows with values of Key1 not present in A.

```
B = table({'a','b','d','e'},[4;5;6;7],...
 'VariableNames',{'Key1' 'Var2'})
```

B =

Key1	Var2
------	------

# outerjoin

---

```
'a' 4
'b' 5
'd' 6
'e' 7
```

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Match up rows with common values in the key variable, `Key1`, but also retain rows whose key values don't have a match.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B)
```

```
C =
```

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	' '	NaN
' '	NaN	'd'	6
'e'	11	'e'	7
'h'	17	' '	NaN

```
ia =
```

```
1
2
3
0
4
5
```

```
ib =
```

```

1
2
0
3
4
0
```

The index vectors `ia` and `ib` contain zeros to indicate the rows in table `C` that do not correspond to rows in tables `A` or `B`, respectively.

### Left Outer-Join Operation of Tables and Indices to Values

Create a table, `A`.

```
A = table({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17],...
 'VariableNames',{'Key1' 'Var1'})
```

```
A =
```

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

Create a table, `B`, with common values in the variable `Key1` between tables `A` and `B`, but also containing rows with values of `Key1` not present in `A`.

```
B = table({'a','b','d','e'},[4;5;6;7],...
 'VariableNames',{'Key1' 'Var2'})
```

```
B =
```

# outerjoin

---

Key1	Var2
'a'	4
'b'	5
'd'	6
'e'	7

Use the `outerjoin` function to create a new table, `C`, with data from tables `A` and `B`. Ignore rows in `B` whose key values do not match any rows in `A`.

Also, return index vectors, `ia` and `ib` indicating the correspondence between rows in `C` and rows in `A` and `B` respectively.

```
[C,ia,ib] = outerjoin(A,B,'Type','left')
```

`C =`

Key1_A	Var1	Key1_B	Var2
'a'	1	'a'	4
'b'	2	'b'	5
'c'	3	' '	NaN
'e'	11	'e'	7
'h'	17	' '	NaN

`ia =`

```
1
2
3
4
5
```

ib =

1  
2  
0  
4  
0

All values of ia are nonzero indicating that all rows in C have corresponding rows in A.

# pack

---

**Purpose** Consolidate workspace memory

**Syntax**  
`pack`  
`pack filename`  
`pack('filename')`

**Description** `pack` frees up needed space by reorganizing information so that it only uses the minimum memory required. All variables from your base and global workspaces are preserved. Any persistent variables that are defined at the time are set to their default value (the empty matrix, []).

The MATLAB software temporarily stores your workspace data in a file called `tp#####.mat` (where ##### is a numeric value) that is located in your temporary folder. (You can use the command `dir(tempdir)` to see the files in this folder).

`pack filename` frees space in memory, temporarily storing workspace data in a file specified by `filename`. This file resides in your current working folder and, unless specified otherwise, has a `.mat` file extension.

`pack('filename')` is the function form of `pack`.

**Tips** You can only run `pack` from the MATLAB command line.

If you specify a `filename` argument, that file must reside in a folder for which you have write permission.

The `pack` function does not affect the amount of memory allocated to the MATLAB process. You must quit MATLAB to free up this memory.

Since MATLAB uses a heap method of memory management, extended MATLAB sessions may cause memory to become fragmented. When memory is fragmented, there may be plenty of free space, but not enough contiguous memory to store a new large variable.

If you get the `Out of memory` message from MATLAB, the `pack` function may find you some free memory without forcing you to delete variables.

The `pack` function frees space by

- Saving all variables in the base and global workspaces to a temporary file.
- Clearing all variables and functions from memory.
- Reloading the base and global workspace variables back from the temporary file and then deleting the file.

If you use `pack` and there is still not enough free memory to proceed, you must clear some variables. If you run out of memory often, you can allocate larger matrices earlier in the MATLAB session and use these system-specific tips:

- When running MATLAB on The Open Group UNIX platforms, ask your system manager to increase your swap space.
- On Microsoft Windowsplatforms, increase virtual memory using the Windows Control Panel.

To maintain persistent variables when you run `pack`, use `mlock` in the function.

## Examples

Change the current folder to one that is writable, run `pack`, and return to the previous folder.

```
cwd = pwd;
cd(tempdir);
pack
cd(cwd)
```

# padecoeff

---

<b>Purpose</b>	Padé approximation of time delays
<b>Syntax</b>	<code>[num,den] = padecoeff(T,N)</code>
<b>Description</b>	<code>[num,den] = padecoeff(T,N)</code> returns the $N$ th-order Padé approximation of the continuous-time delay $T$ in transfer function form. The row vectors <code>num</code> and <code>den</code> contain the numerator and denominator coefficients in descending powers of $s$ . Both are $N$ th-order polynomials. Class support for input $T$ :  float: double, single
<b>Class Support</b>	Input $T$ support floating-point values of type <code>single</code> or <code>double</code> .

**Purpose** Page setup dialog box

**Syntax** `dlg = pagesetupdlg(fig)`

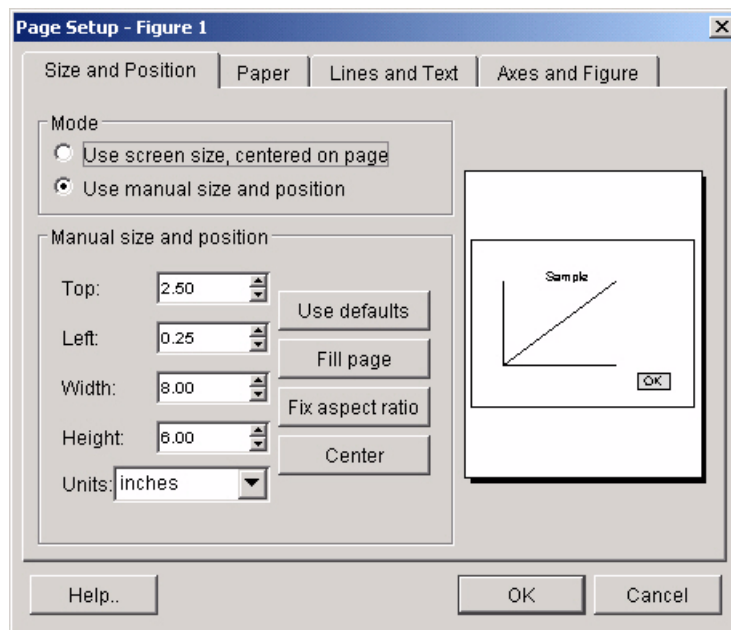

---

**Note** `pagesetupdlg` is not recommended. Use `printpreview` instead.

---

**Description** `dlg = pagesetupdlg(fig)` creates a dialog box from which a set of page layout properties for the figure window, `fig`, can be set. `pagesetupdlg` implements the "Page Setup..." option in the **Figure File Menu**.

`pagesetupdlg` supports setting the layout for a single figure. `fig` must be a single figure handle, not a vector of figures or a Simulink diagram.

# pagesetupdlg

---

## **See Also**

`printdlg` | `printpreview` | `printopt`

**Purpose** Pan view of graph interactively

**Syntax**

```
pan on
pan xon
pan yon
pan off
pan
pan(figure_handle,...)
h = pan(figure_handle)
```

**Description**

`pan on` turns on mouse-based panning in the current figure.

`pan xon` turns on panning only in the *x* direction in the current figure.

`pan yon` turns on panning only in the *y* direction in the current figure.

`pan off` turns panning off in the current figure.

`pan` toggles the pan state in the current figure on or off.

`pan(figure_handle,...)` sets the pan state in the specified figure.

`h = pan(figure_handle)` returns the figure's pan *mode object* for the figure *figure\_handle* for you to customize the mode's behavior.

### Using Pan Mode Objects

Access the following properties of pan mode objects via `get` and modify some of them using `set`:

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of panning enabled for the figure
- `FigureHandle` <handle> — The associated figure handle, a read-only property that cannot be set

### Pan Mode Callbacks

You can program the following callbacks for pan mode operations.

- `ButtonDownFilter` <function\_handle> — Function to intercept `ButtonDown` events

The application can inhibit the panning operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object clicked on
% event_obj event data (empty in this release)
% res [output] a logical flag to determine whether the pan
% operation should take place(for 'res' set to 'false')
% or the 'ButtonDownFcn' property of the object should
% take precedence (when 'res' is 'true')
```

- `ActionPreCallback` <function\_handle> — Function to execute before panning

Set this callback to if you need to execute code when a pan operation begins. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
```

The event data struct has the following field:

Axes	The handle of the axes that is being panned
------	---------------------------------------------

- `ActionPostCallback` <function\_handle> — Function to execute after panning

Set this callback if you need to execute code when a pan operation ends. The function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
% (same as the event data of the
% 'ActionPreCallback' callback)
```

## Pan Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesPan(h,axes)` — Function querying permission to pan axes

Calling the function `isAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a pan operation is permitted on the axes objects.

- `setAllowAxesPan(h,axes,flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesPan` on the pan object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a pan operation on the axes objects.

- `info = getAxesPanMotion(h,axes)` — Function to get style of pan operations

Calling the function `getAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, as input will return a character cell array of the same dimension as the axes handle vector, which indicates the type of pan operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical' or 'both'.

- `setAxesPanMotion(h,axes,style)` — Function to set style of pan operations

Calling the function `setAxesPanMotion` on the pan object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of panning on each axes.

## Examples

### Example 1 – Entering Pan Mode

Plot a graph and turn on Pan mode:

```
plot(magic(10));
pan on
% pan on the plot
```

### Example 2 – Constrained Pan

Constrain pan to  $x$ -axis using set:

```
plot(magic(10));
h = pan;
set(h,'Motion','horizontal','Enable','on');
% pan on the plot in the horizontal direction.
```

### Example 3 – Constrained Pan in Subplots

Create four axes as subplots and give each one a different panning behavior:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = pan;
ax2 = subplot(2,2,2);
plot(rand(3));
setAllowAxesPan(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesPanMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesPanMotion(h,ax4,'vertical');
% pan on the plots.
```

### Example 4 – Coding a ButtonDown Callback

Create a `buttonDown` callback for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = pan;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then
% return true.

% Indicate what the target is.
disp(['Clicked ' get(obj,'Type') ' object'])
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end
end
```

### Example 5 – Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-`ButtonDown` events for pan mode objects to trigger. Copy the following code to a new file, execute it, and observe panning behavior:

```
function demo
% Listen to pan events
plot(1:10);
h = pan;
set(h,'ActionPreCallback',@myprecallback);
```

```
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj, evd)
disp('A pan is about to occur. ');
%
function mypostcallback(obj, evd)
newLim = get(evd.Axes, 'XLim');
msgbox(sprintf('The new X-Limits are [%f,%f].', newLim));
```

## Example 6 – Creating a Context Menu for Pan Mode

Coding a context menu that lets the user to switch to Zoom mode by right-clicking:

```
figure; plot(magic(10));
hCM = uicontextmenu;
hMenu = uimenu('Parent',hCM,'Label','Switch to zoom',...
 'Callback','zoom(gcf,'on')');
hPan = pan(gcf);
set(hPan,'UIContextMenu',hCM);
pan('on')
```

You cannot add items to the built-in pan context menu, but you can replace it with your own.

## Tips

You can create a pan mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure’s callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure’s callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different pan behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the **Pan** tool  on the figure toolbar to enable and disable pan mode on a plot, or select **Pan** from the figure’s **Tools** menu. For details, see “Panning — Shifting Your View of the Graph”.

<b>Concepts</b>	

**Purpose**

Pareto chart

**Syntax**

```
pareto(Y)
pareto(Y, names)
pareto(Y, X)
H = pareto(...)
```

**Description**

Pareto charts display the values in the vector  $Y$  as bars drawn in descending order. Values in  $Y$  must be nonnegative and not include NaNs. Only the first 95% of the cumulative distribution is displayed.

`pareto(Y)` labels each bar with its element index in  $Y$  and also plots a line displaying the cumulative sum of  $Y$ .

`pareto(Y, names)` labels each bar with the associated name in the string matrix or cell array `names`.

`pareto(Y, X)` labels each bar with the associated value from  $X$ .

`pareto(ax, ...)` plots a Pareto chart in existing axes `ax` rather than GCA.

`H = pareto(...)` returns a combination of patch and line object handles.

**Examples****Create Pareto Chart**

Create a Pareto chart of vector `y`.

```
y = [90,75,30,60,5,40,40,5];
figure
pareto(y)
```

## pareto

---

`pareto` displays the elements in `y` as bars in descending order and labels each bar with its index in `y`. Since `pareto` displays only the first 95% of the cumulative distribution, some elements in `y` are not displayed.

### Label Bars in Pareto Chart

Examine the cumulative productivity of a group of programmers to see how normal its distribution is. Label each bar with the name of the programmer.

```
codelines = [200 120 555 608 1024 101 57 687];
coders = {'Fred', 'Ginger', 'Norman', 'Max', 'Julia', 'Wally', 'Heidi', 'Pat'}

figure
pareto(codelines, coders)
title('Lines of Code by Programmer')
```

**Tips**

You can use `pareto` to display the output of `hist`, even for vectors that include negative numbers. Because only the first 95 percent of values

## pareto

---

are displayed, one or more of the smallest bars may not appear. If you extend the `Xlim` of your chart, you can display all the values, but the new bars will not be labeled.

You cannot place datatips (use the Datacursor tool) on graphs created with `pareto`.

`hist` | `bar`

---

<b>Purpose</b>	Parallel for loop
<b>Syntax</b>	<pre>parfor loopvar = initval:endval; <i>statements</i>; end parfor (loopvar = initval:endval, M); <i>statements</i>; end</pre>
<b>Description</b>	<p>parfor loopvar = initval:endval; <i>statements</i>; end executes a series of MATLAB statements for values of loopvar between initval and endval, inclusive, which specify a vector of increasing integer values. The loop runs in parallel when you have the Parallel Computing Toolbox™ or when you create a MEX function with MATLAB Coder™. Unlike a traditional for-loop, iterations are not executed in a guaranteed order.</p> <p>parfor (loopvar = initval:endval, M); <i>statements</i>; end executes statements in a loop using a maximum of M workers or threads, where M is a nonnegative integer.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• If you have Parallel Computing Toolbox software, see the function reference pages for parfor and parpool for additional information.</li><li>• If you have MATLAB Coder software, see the parfor function reference page for additional information.</li></ul>
<b>Examples</b>	<p>Perform three large eigenvalue computations using three workers or cores with Parallel Computing Toolbox software:</p> <pre>parpool(3) parfor i=1:3, c(:,i) = eig(rand(1000)); end</pre>

# inputParser.parse

---

<b>Purpose</b>	Parse function inputs
<b>Syntax</b>	parse(p, argList)
<b>Description</b>	parse(p, argList) parses and validates the inputs in arglist.
<b>Input Arguments</b>	<b>p</b> Object of class inputParser. <b>argList</b> Comma separated list of inputs to parse and validate for your custom function. The class of each input depends upon your function definition.

## Examples **Input Parsing**

Parse and validate required and optional function inputs.

Create a custom function with required and optional inputs in the file findArea.m.

```
function a = findArea(width,varargin)
 p = inputParser;
 defaultHeight = 1;
 defaultUnits = 'inches';
 defaultShape = 'rectangle';
 expectedShapes = {'square','rectangle','parallelogram'};

 addRequired(p,'width',@isnumeric);
 addOptional(p,'height',defaultHeight,@isnumeric);
 addParameter(p,'units',defaultUnits);
 addParameter(p,'shape',defaultShape,...
 @(x) any(validatestring(x,expectedShapes)));

 parse(p,width,varargin{:});
 a = p.Results.width .* p.Results.height;
```

The input parser checks whether `width` and `height` are numeric, and whether the `shape` matches a string in cell array `expectedShapes`. `@` indicates a function handle, and the syntax `@(x)` creates an anonymous function with input `x`.

Call the function with inputs that do not match the scheme. For example, specify a nonnumeric value for the `width` input:

```
findArea('text')
```

```
Error using findArea (line 14)
The value of 'width' is invalid. It must satisfy the function: isnumeric.
```

Specify an unsupported value for `shape`:

```
findArea(4, 'shape', 'circle')
```

```
Error using findArea (line 14)
The value of 'shape' is invalid. Expected input to match one of these strings:

square, rectangle, parallelogram

The input, 'circle', did not match any of the valid strings.
```

# parseSoapResponse

---

**Purpose** Convert response string from SOAP server into MATLAB types

**Syntax** parseSoapResponse(response)

**Description** parseSoapResponse(response) extracts data from response a string returned by a SOAP server from the callSoapService function, and converts it to appropriate MATLAB classes (types).

**Examples** This example uses parseSoapResponse in conjunction with other SOAP functions to retrieve information about books from a library database, specifically, the author's name for a given book title.

---

**Note** The example does not use an actual endpoint; therefore, you cannot run it. The example only illustrates how to use the SOAP functions.

---

```
% Create the message:
message = createSoapMessage(...
'urn:LibraryCatalog',...
'getAuthor',...
{'In the Fall'},...
{'nameToLookUp'},...
{'{http://www.w3.org/2001/XMLSchema}string'},...
'rpc');
%
% Send the message to the service and get the response:
response = callSoapService(...
'http://test/soap/services/LibraryCatalog',...
'urn:LibraryCatalog#getAuthor',...
message)
%
% Extract MATLAB data from the response
author = parseSoapResponse(response)
```

MATLAB returns:

```
author = Kate Alvin
```

where author is a char class (type).

# pascal

---

**Purpose** Pascal matrix

**Syntax**  
A = pascal(n)  
A = pascal(n,1)  
A = pascal(n,2)

**Description** A = pascal(n) returns the Pascal matrix of order n: a symmetric positive definite matrix with integer entries taken from Pascal's triangle. The inverse of A has integer entries.

A = pascal(n,1) returns the lower triangular Cholesky factor (up to the signs of the columns) of the Pascal matrix. It is *involutary*, that is, it is its own inverse.

A = pascal(n,2) returns a transposed and permuted version of pascal(n,1). A is a cube root of the identity matrix.

**Examples** pascal(4) returns

```
1 1 1 1
1 2 3 4
1 3 6 10
1 4 10 20
```

A = pascal(3,2) produces

```
A =
 1 1 1
 -2 -1 0
 1 0 0
```

**See Also** chol

**Purpose**

Create one or more filled polygons

**Syntax**

```
patch(X,Y,C)
patch(X,Y,Z,C)
patch(FV)
patch(X,Y,C, 'PropertyName',propertyvalue...)
patch('PropertyName',propertyvalue,...)
handle = patch(...)
```

**Properties**

For a list of properties, see [Patch Properties](#).

**Description**

`patch(X,Y,C)` adds a filled 2-D patch object to the current axes. A patch object is one or more polygons defined by the coordinates of its vertices. The elements of `X` and `Y` specify the vertices of a polygon. If `X` and `Y` are `m`-by-`n` matrices, MATLAB draws `n` polygons with `m` vertices. `C` determines the color of the patch. For more information on color input requirements, see “Coloring Patches” on page 1-4899.

MATLAB does not require each face to have the same number of vertices. In cases where they do not, pad the end of the `Faces` matrix with NaNs. To define a patch with faces that do not close, add one or more NaNs to the row in the `Vertices` matrix that defines the vertex you do not want connected.

See “Introduction to Patch Objects” for more information on using patch objects.

`patch(X,Y,Z,C)` creates a patch in 3-D coordinates. If the coordinate data does not define closed polygons, `patch` closes the polygons. The data can define concave or intersecting polygons. However, if the edges of an individual patch face intersect themselves, the resulting face might be only partly filled. In that case, it is better to divide the face into smaller polygons.

`patch(FV)` creates a patch using structure `FV`, which contains the fields `vertices`, `faces`, and optionally `facevertexcdata`. These fields correspond to the `Vertices`, `Faces`, and `FaceVertexCData` patch properties. Specifying only unique vertices and their connection matrix

can reduce the size of the data for patches having many faces. For an example of how to specify patches with this method, see “Specifying Patch Object Shapes” on page 1-4896.

`patch(X,Y,C,'PropertyName',propertyvalue...)` follows the `X`, `Y`, (`Z`), and `C` arguments with property name/property value pairs to specify additional patch properties. For a description of the properties, see [Patch Properties](#). You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the [set](#) and [get](#) reference pages for examples of how to specify these data types).

`patch('PropertyName',propertyvalue,...)` specifies all properties using property name/property value pairs. This form lets you omit the color specification because MATLAB uses the default face color and edge color unless you explicitly assign a value to the `FaceColor` and `EdgeColor` properties. This form also lets you specify the patch using the `Faces` and `Vertices` properties instead of `x`-, `y`-, and `z`-coordinates. See “Specifying Patch Object Shapes” on page 1-4896 for more information.

`handle = patch(...)` returns the handle of the patch object it creates.

Unlike high-level area creation functions, such as `fill` or `area`, `patch` does not check the settings of the figure and axes `NextPlot` properties. It simply adds the patch object to the current axes.

## Examples

### Specifying Patch Object Shapes

The next two examples create a patch object using two methods:

- Specifying `x`-, `y`-, and `z`-coordinates and color data (`XData`, `YData`, `ZData`, and `CData` properties)
- Specifying vertices, the connection matrix, and color data (`Vertices`, `Faces`, and `FaceVertexCData` properties)

Create five triangular faces, each having three vertices, by specifying the `x`-, `y`-, and `z`-coordinates of each vertex:

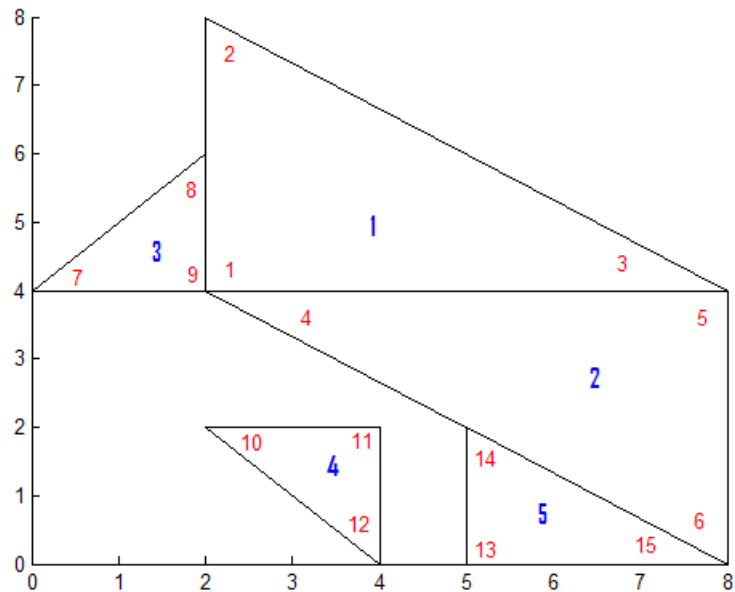

```
xdata = [2 2 0 2 5;
 2 8 2 4 5;
```

```

 8 8 2 4 8];
ydata = [4 4 4 2 0;
 8 4 6 2 2;
 4 0 4 0 0];
zdata = ones(3,5);

% Red numbers denote the vertex indices.
% For this example:
% xindices = [1 4 7 10 13;
% 2 5 8 11 14;
% 3 6 9 12 15];
% Blue numbers denote the face numbers.
patch(xdata,ydata,zdata,'w')

```

Create the five triangular faces, specifying faces and vertices:

% The Vertices property contains the coordinates of each

# patch

---

```
% unique vertex defining the patch. The Faces property
% specifies how to connect these vertices to form each
% face of the patch. More than one face may
% use a given vertex.
% For this example, five triangles have 11 total vertices,
% instead of 15. Each row contains
% the x- and y-coordinates
% of each vertex.
verts = [2 4; ...
 2 8; ...
 8 4; ...
 8 0; ...
 0 4; ...
 2 6; ...
 2 2; ...
 4 2; ...
 4 0; ...
 5 2; ...
 5 0];

% There are five faces, defined by connecting the
% vertices in the order indicated.
faces = [...
 1 2 3; ...
 1 3 4; ...
 5 6 1; ...
 7 8 9; ...
 11 10 4];

% Create the patch by specifying the Faces, Vertices,
% and FaceVertexCData properties as well as the
% FaceColor property. Red numbers denote the vertex
% numbers, as defined in faces. Blue indicate face numbers.
p = patch('Faces',faces,'Vertices',verts,'FaceColor','w');
```

```
% Using the previous values for verts and faces, you can
% create the same patch object using a structure:
patchinfo.Vertices = verts;
patchinfo.Faces = faces;
patchinfo.FaceColor = 'w';
```

```
patch(patchinfo);
```

### Coloring Patches

There are many ways to customize your patch objects using colors. The appropriate input depends on:

- Whether you want to change the edge colors
- How you specified the patch faces:
  - Using face/vertex values
  - Using  $x$ -,  $y$ -, and  $z$ -coordinates

The following sections present the various options available.

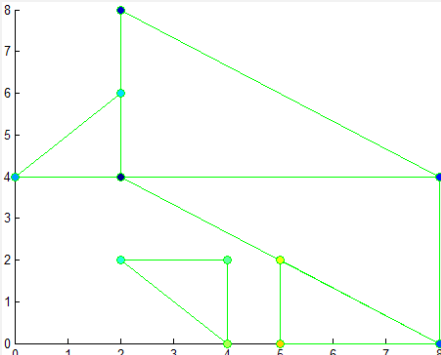

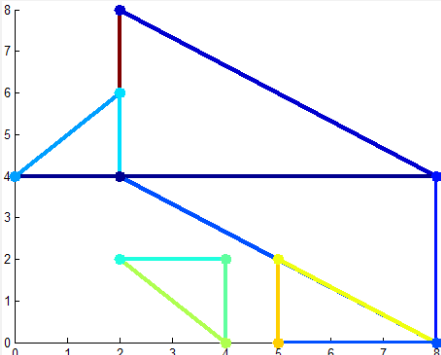

## Specifying Edge Colors

The following options apply to the edge colors of your patch object. The settings are independent of the face colors, but the colors themselves depend on the colors specified at each vertex. Markers show the color at each vertex. Specify the colors using the `EdgeColor` property. To explore the options using the Sample Input Code, create a base patch object:

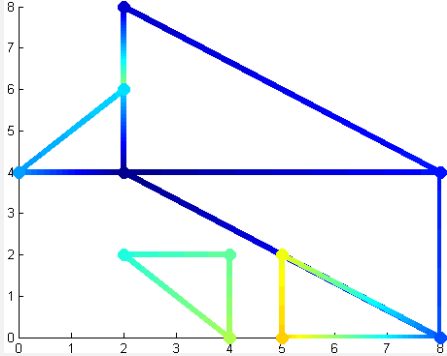

```
xdata = [2 2 0 2 5;
 2 8 2 4 5;
 8 8 2 4 8];
ydata = [4 4 4 2 0;
 8 4 6 2 2;
 4 0 4 0 0];
cdata = [15 0 4 6 10;
 1 2 5 7 9;
 2 3 0 8 3];
p = patch(xdata,ydata,cdata,'Marker','o',...
 'MarkerFaceColor','flat',...
 'FaceColor','none')
```

For more detailed information on how the `EdgeColor` property works, see the [Patch Properties](#) page.

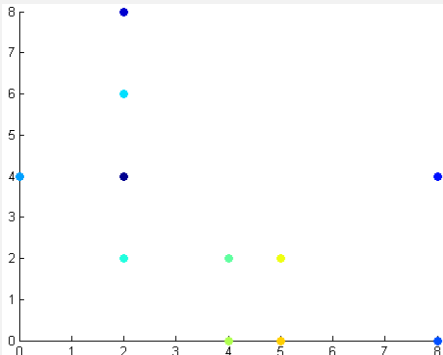

Desired Look	EdgeColor Value	Sample Code
All edges have the same color, around all faces. This option does not rely on the <code>FaceColor</code> value.	<code>ColorSpec</code>	<code>set(p, 'EdgeColor', 'g')</code>

Desired Look	EdgeColor Value	Sample Code
		
<p>Each edge corresponds to the color of the vertex that precedes the edge, with one color per edge. This option requires that the FaceColor property be flat or interp. By default, if you specify CData when creating the patch object, its FaceColor property is interp.</p> 	<p>'flat'</p>	<pre>set(p, 'EdgeColor', 'flat', ...     'LineWidth', 3)</pre>

# patch

Desired Look	EdgeColor Value	Sample Code
<p>Each edge corresponds to the vertex colors, interpolated between vertices. This option requires that the FaceColor property be flat or interp. By default, if you specify CData when creating the patch object, its FaceColor property is interp.</p> 	'interp'	<pre>set(gcf, 'Renderer', 'zbuffer') set(p, 'EdgeColor', 'interp', ... 'LineWidth', 5)</pre>
<p>Edges have no color. This option does not rely on the FaceColor value. If set, markers retain vertex colors.</p>	'none'	<pre>set(p, 'EdgeColor', 'none')</pre>

Desired Look	EdgeColor Value	Sample Code
		

### Specifying Face Colors Using Face/Vertex Input Matrices

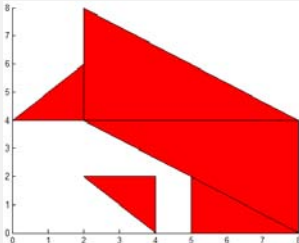

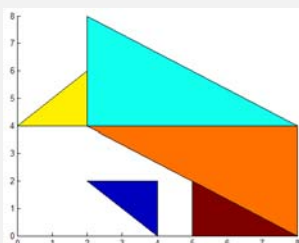

The following options apply to the face colors of your patch object when you specify the faces using face/vertex input matrices. To explore the options, start with a base patch object:

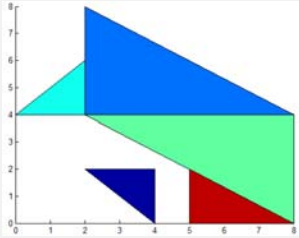

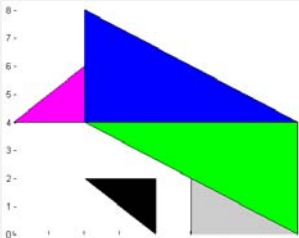

```
% For this example, there are five triangles (m = 5)
% sharing eleven unique vertices (k = 11).
verts = [2 4; ...
 2 8; ...
 8 4; ...
 8 0; ...
 0 4; ...
 2 6; ...
 2 2; ...
 4 2; ...
 4 0; ...
 5 2; ...
 5 0];
faces = [1 2 3; ...
 1 3 4; ...
 5 6 1; ...
 7 8 9; ...
 11 10 4];
```

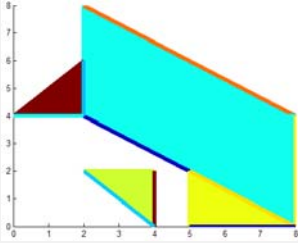

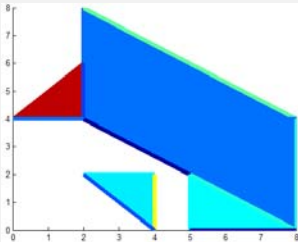

# patch

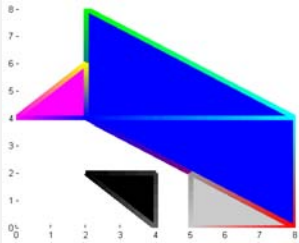

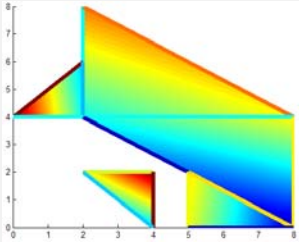

```
p = patch('Faces',faces,'Vertices',verts,'FaceColor','b');
```

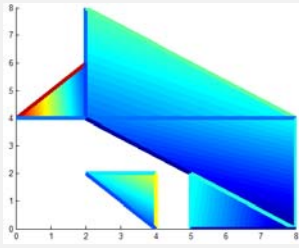

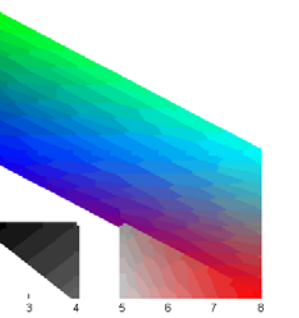

For more information on the relevant properties, see [FaceColor](#), [FaceVertexCData](#), and [CDataMapping](#).

Desired Look	Parameter Values	Sample Code
<p>All faces have the same color.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> ColorSpec</li> <li>• <b>FaceVertexCData:</b> [] (no input) An empty array is the default value, and patch ignores any input until you set FaceColor to 'flat' or 'interp'.</li> <li>• <b>Color source:</b> truecolor</li> <li>• <b>CDataMapping:</b> 'direct' or 'scaled'. 'scaled' is the default value, but neither affects the outcome.</li> </ul>	<pre>set(p,'FaceColor','r')  or  set(p,'FaceColor',[1 0 0])</pre>
<p>Each face has a single, unique color, indexed from a selected section of the colormap.</p> 	<ul style="list-style-type: none"> <li>• <b>FaceColor:</b> 'flat'</li> <li>• <b>FaceVertexCData:</b> m-by-1 matrix of index values</li> <li>• <b>Color source:</b> A selected portion of the colormap</li> <li>• <b>CDataMapping:</b> 'scaled'</li> </ul>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60]'; set(p,'FaceColor','flat',...     'FaceVertexCData',cdata,...     'CDataMapping','scaled')</pre>

Desired Look	Parameter Values	Sample Code
<p>Each unique vertex has a single, unique color, indexed from the whole colormap. Edges may have 'flat' or 'interp' color.</p> 	<ul style="list-style-type: none"> <li>• FaceColor: 'interp'</li> <li>• FaceVertexCData: k-by-1 matrix of index values</li> <li>• Color source: colormap</li> <li>• CDataMapping: 'direct'</li> </ul> <p>'scaled' is the default value when you input CData values. If you want to change the axes CLim property, but want your patch object to index the entire colormap, use 'CDataMapping', 'direct'.</p>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 ...         60 12 23 40 13 26 24]; set(p,'FaceColor','interp',...     'FaceVertexCData',cdata,...     'CDataMapping','direct',...     'EdgeColor','flat',...     'LineWidth',5)</pre>
<p>Each unique vertex has a single, unique color, determined by truecolor value input. Edges may have 'flat' or 'interp' color.</p> 	<ul style="list-style-type: none"> <li>• FaceColor: 'interp'</li> <li>• FaceVertexCData: k-by-3 matrix of truecolor values, from 0 to 1</li> <li>• Color source: truecolor</li> <li>• CDataMapping: 'direct' or 'scaled'.</li> </ul> <p>'scaled' is the default value, but neither affects the outcome.</p>	<pre>clear cdata cdata = [0 0 1;         0 1 0;         0 1 1;         1 0 0;         1 0 1;         1 1 0;         0 0 0;         0.2 0.2 0.2;         0.4 0.4 0.4;         0.6 0.6 0.6;         0.8 0.8 0.8]; set(p,'FaceColor','interp',...     'FaceVertexCData',cdata,...     'EdgeColor','interp',...     'LineWidth',5)</pre>

### Specifying Face Colors Using x-, y-, and z-Coordinate Input

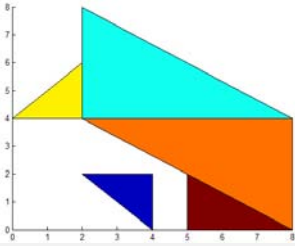

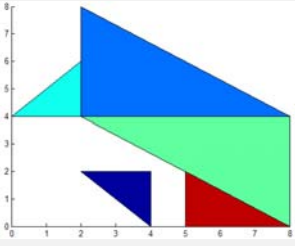

The following options apply to the face colors of your patch object when you specify the faces using x-, y-, and z-coordinates. To explore the options, start with a base patch object:

```
% For this example, there are five (m=5) triangles (n=3).
% The total number of vertices is mxn, or k = 15.
xdata = [2 2 0 2 5;
 2 8 2 4 5;
 8 8 2 4 8];
ydata = [4 4 4 2 0;
 8 4 6 2 2;
 4 0 4 0 0];
zdata = ones(3,5);
p = patch(xdata,ydata,zdata,'b')
```

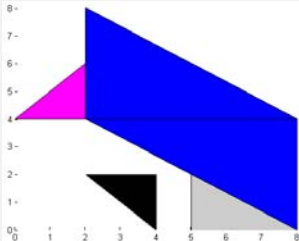

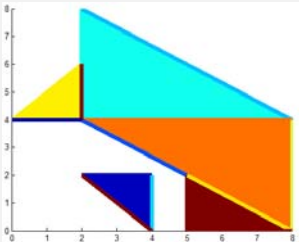

For more information on the relevant properties, see [FaceColor](#), [CData](#), and [CDataMapping](#).

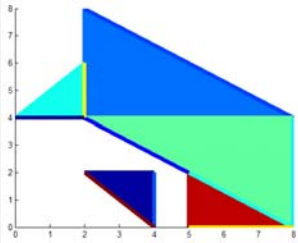

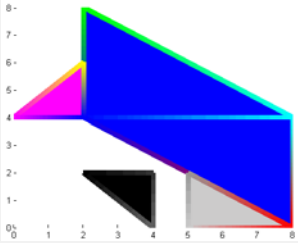

Desired Look	Parameter Values	Sample Code
<p>All faces have the same color.</p> 	<ul style="list-style-type: none"> <li>• FaceColor: ColorSpec</li> <li>• CData: [] (no input)</li> <li>• Color source: truecolor</li> <li>• CDataMapping: 'direct' or 'scaled'.  'scaled' is the default value, but neither affects the outcome.</li> </ul>	<pre>set(p,'FaceColor','r')  or  set(p,'FaceColor',[1 0 0])</pre>
<p>Each face has a single, unique color, indexed from a selected section of the colormap.</p>	<ul style="list-style-type: none"> <li>• FaceColor: 'flat'</li> <li>• CData: m-by-1 matrix of index values</li> </ul>	<pre>clear cdata set(gca,'CLim',[0 40]) cdata = [15 30 25 2 60];</pre>

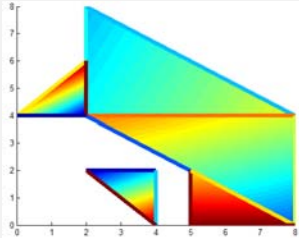

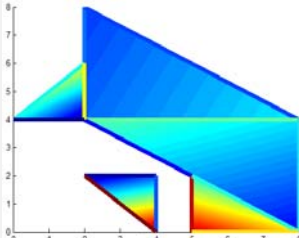

# patch

Desired Look	Parameter Values	Sample Code
	<ul style="list-style-type: none"> <li>• Color source: A selected portion of the colormap</li> <li>• CDataMapping: 'scaled'</li> </ul>	<pre>set(p, 'FaceColor', 'flat', ...       'CData', cdata, ...       'CDataMapping', 'scaled')</pre>
<p>Each face has a single, unique color, indexed from the whole colormap.</p> 	<ul style="list-style-type: none"> <li>• FaceColor: 'flat'</li> <li>• CData: m-by-1 matrix of index values</li> <li>• Color source: colormap</li> <li>• CDataMapping: 'direct'</li> </ul> <p>'scaled' is the default value when you input CData values. If you want to change the axes CLim property, but want your patch object to index the entire colormap, use 'CDataMapping', 'direct'.</p>	<pre>clear cdata set(gca, 'CLim', [0 40]) cdata = [15 30 25 2 60]; set(p, 'FaceColor', 'flat', ...       'CData', cdata, ...       'CDataMapping', 'direct')</pre>

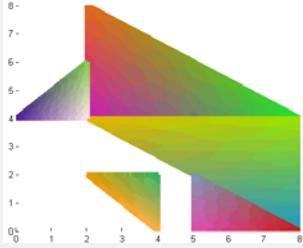

Desired Look	Parameter Values	Sample Code
<p>Each face has a single, unique color, determined by truecolor value input.</p> 	<ul style="list-style-type: none"> <li>• FaceColor: 'flat'</li> <li>• CData: m-by-1-by-3 matrix of truecolor values, from 0 to 1</li> <li>• Color source: truecolor</li> <li>• CDataMapping: 'direct' or 'scaled'. ## Tutorials

- “Introduction to Patch Objects”

## Purpose

Patch properties

## Creating Patch Objects

Use patch to create patch objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “Customize Objects in Graph” is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Patch Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

AlphaDataMapping  
none | {scaled} | direct

*Transparency mapping method.* Determines how the MATLAB software interprets indexed alpha data.

- none — The transparency values of FaceVertexAlphaData are between 0 and 1 or are clamped to this range.
- scaled — Transform the FaceVertexAlphaData to span the portion of the alphamap indicated by the axes ALim property, linearly mapping data values to alpha values.
- direct — Use the FaceVertexAlphaData as indices directly into the alphamap. When not scaled, the data are usually integer values ranging from 1 to length(alphamap). MATLAB maps values less than 1 to the first alpha value in the

# Patch Properties

---

alphamap, and values greater than `length(alphamap)` to the last alpha value in the alphamap. Values with a decimal portion are fixed to the nearest lower integer. If `FaceVertexAlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the alphamap).

## AmbientStrength

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the patch `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

hg.Annotation object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this patch object is represented in a figure legend.

Querying the Annotation property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the patch object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
on	Represent this patch object in a legend (default)
off	Do not include this patch object in a legend
children	Same as on because patch objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Control Legend Content” for more information and examples.

## Selecting which objects to display in legend

Some graphics functions create multiple objects. For example, `contour3` uses patch objects to create a 3D contour graph. You can use the Annotation property set select a subset of the objects for display in the legend.

```
[X,Y] = meshgrid(-2:.1:2);
[Cm hC] = contour3(X.*exp(-X.^2-Y.^2));
hA = get(hC, 'Annotation');
hLL = get([hA{:}], 'LegendInformation');
% Set the IconDisplayStyle property to display
% the first, fifth, and ninth patch in the legend

set([hLL{:}], {'IconDisplayStyle'}, ...
```

# Patch Properties

---

```
 {'on','off','off','off','on','off','off','off','on'})
% Assign DisplayNames for the three patch
% that are displayed in the legend

set(hC([1,5,9]),{'DisplayName'},...
 {'bottom','middle','top'})
legend show
```

**BackFaceLighting**  
unlit | lit | {reverselit}

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- **unlit** — Face not lit.
- **lit** — Face lit in normal way.
- **reverselit** — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

**BeingDeleted**  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to on when the object’s delete function callback is called (see the **DeleteFcn** property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s **BeingDeleted** property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**ButtonDownFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the patch object.

See the figure's **SelectionType** property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. You can also use a string that is a valid MATLAB expression or the name of a MATLAB file. The expressions execute in the MATLAB workspace.

# Patch Properties

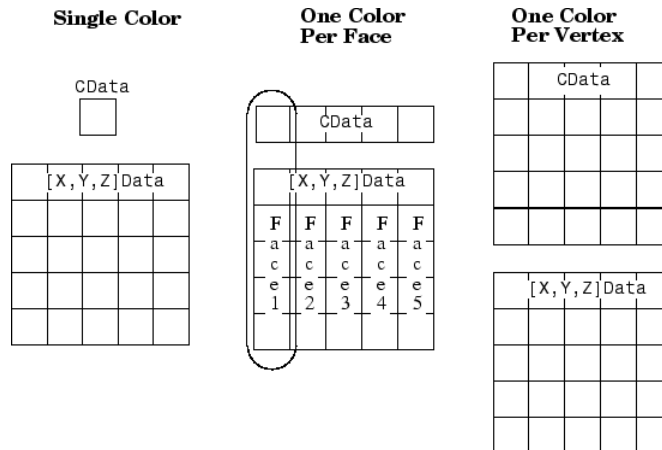

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## CData

scalar | vector | matrix

*Patch colors.* Specifies the color of the patch. You can specify color for each vertex, each face, or a single color for the entire patch. The way MATLAB interprets CData depends on the type of data supplied. The data can be numeric values that are scaled to map linearly into the current colormap, integer values that are used directly as indices into the current colormap, or arrays of RGB values. RGB values are not mapped into the current colormap, but interpreted as the colors defined. On true color systems, MATLAB uses the actual colors defined by the RGB triples.

The following diagrams illustrate the dimensions of CData with respect to the coordinate data arrays, XData, YData, and ZData. The first diagram illustrates the use of indexed color.

The following diagram illustrates the use of true color. True color requires m-by-n-by-3 arrays to define red, green, and blue components for each color.

Note that if CData contains NaNs, MATLAB does not color the faces.

See the Faces, Vertices, and FaceVertexCData properties for an alternative method of patch definition.

CDataMapping  
 {scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the patch. If you use true color specification for CData or FaceVertexCData, this property has no effect.

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly

# Patch Properties

---

mapping data values to colors. See the `caxis` command for more information on this mapping.

- `direct` — Use the color data as indices directly into the colormap. When not scaled, the data are usually integer values ranging from 1 to `length(colormap)`. MATLAB maps values less than 1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

## Children

matrix of handles

Always the empty matrix; patch objects have no children.

## Clipping

`{on}` | `off`

*Clipping to axes rectangle.* When `Clipping` is on, MATLAB does not display any portion of the patch outside the axes rectangle.

## CreateFcn

string | function handle

*Callback routine executed during object creation.* Executes when MATLAB creates a patch object. You must define this property as a default value for patches or in a call to the `patch` function that creates a new object.

For example, the following statement creates a patch (assuming `x`, `y`, `z`, and `c` are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
patch(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes the create function after setting all properties for the patch created. Setting this property on an existing patch object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DeleteFcn

string | function handle

*Delete patch callback routine.* Executes when you delete the patch object (for example, when you issue a `delete` command or clear the axes (`cla`) or figure (`clf`) containing the patch). MATLAB executes the routine before deleting the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DiffuseStrength

scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the patch. Diffuse light comes from light objects in the axes.

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

## DisplayName

string

# Patch Properties

---

*String used by legend.* The `legend` function uses the `DisplayName` property to label the patch object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where  $n$  is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

## EdgeAlpha

{scalar = 1} | flat | interp

*Transparency of the edges of patch faces.*

- `scalar` — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.
- `flat` — The alpha data (`FaceVertexAlphaData`) of each vertex controls the transparency of the edge that follows it.
- `interp` — Linear interpolation of the alpha data (`FaceVertexAlphaData`) at each vertex determines the transparency of the edge.

Note that you cannot specify `flat` or `interp` `EdgeAlpha` without first setting `FaceVertexAlphaData` to a matrix containing one alpha value per face (`flat`) or one alpha value per vertex (`interp`).

## EdgeColor

`{ColorSpec} | none | flat | interp`

*Color of the patch edge.* Determines how MATLAB colors the edges of the individual faces that make up the patch.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (black). See the `ColorSpec` reference page for more information on specifying color.
- `none` — Edges not drawn.
- `flat` — The color of each vertex controls the color of the edge that follows it. This means `flat` edge coloring is dependent on the order in which you specify the vertices:

- `interp` — Linear interpolation of the `CData` or `FaceVertexCData` values at the vertices determines the edge color.

## EdgeLighting

`{none} | flat | gouraud | phong`

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on patch edges.

- `none` — Lights do not affect the edges of this object.

# Patch Properties

---

- `flat` — The effect of light objects is uniform across each edge of the patch.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase patch objects. Alternative erase modes are useful in creating animated sequences, where control of the way individual objects redraw is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the patch when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the patch by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the patch does not damage the color of the objects behind it. However, patch color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.

- **background** — Erase the patch by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is none. This damages objects that are behind the erased patch, but the patch is always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

### FaceAlpha

{scalar = 1} | flat | interp

*Transparency of the patch face.*

- **scalar** — A single non-`NaN` value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).
- **flat** — The values of the alpha data (`FaceVertexAlphaData`) determine the transparency for each face. The alpha data at the first vertex determines the transparency of the entire face.
- **interp** — Bilinear interpolation of the alpha data (`FaceVertexAlphaData`) at each vertex determines the transparency of each face.

# Patch Properties

---

Note that you cannot specify `flat` or `interp` `FaceAlpha` without first setting `FaceVertexAlphaData` to a matrix containing one alpha value per face (`flat`) or one alpha value per vertex (`interp`).

## FaceColor

`{ColorSpec} | none | flat | interp`

*Color of the patch face.*

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the `ColorSpec` reference page for more information on specifying color.
- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The `CData` or `FaceVertexCData` property must contain one value per face and determines the color for each face in the patch. The color data at the first vertex determines the color of the entire face.
- `interp` — Bilinear interpolation of the color at each vertex determines the coloring of each face. The `CData` or `FaceVertexCData` property must contain one value per vertex.

## FaceLighting

`{none} | flat | gouraud | phong`

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of `light` objects on patch faces.

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the patch. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.

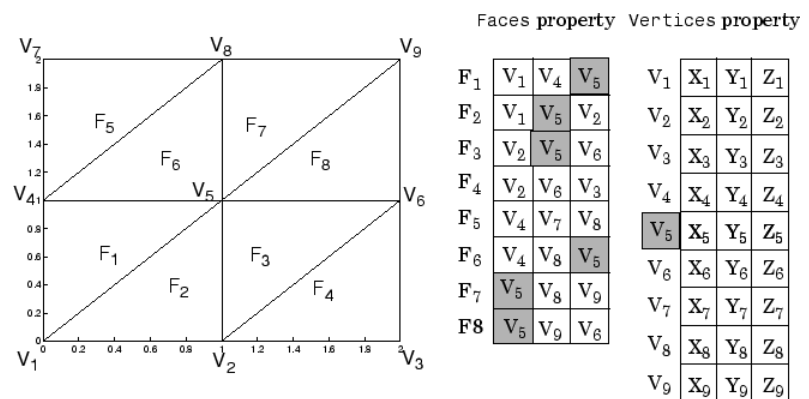

- phong — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## Faces

m-by-n matrix

*Vertex connection defining each face.* Specifies which vertices in the Vertices property are connected. The Faces matrix defines  $m$  faces with up to  $n$  vertices each. Each row designates the connections for a single face, and the number of elements in that row that are not NaN defines the number of vertices for that face.

The Faces and Vertices properties provide an alternative way to specify a patch that can be more efficient than using  $x$ ,  $y$ , and  $z$  coordinates in most cases. For example, consider the following patch. It is composed of eight triangular faces defined by nine vertices.

The corresponding Faces and Vertices properties are shown to the right of the patch. Note how some faces share vertices with other faces. For example, the fifth vertex (V5) is used six times,

# Patch Properties

---

once each by faces one, two, and three and six, seven, and eight. Without sharing vertices, this same patch requires 24 vertex definitions.

**FaceVertexAlphaData**  
m-by-1 matrix

*Face and vertex transparency data.* Specifies the transparency of patches that have been defined by the **Faces** and **Vertices** properties. The interpretation of the values specified for **FaceVertexAlphaData** depends on the dimensions of the data.

**FaceVertexAlphaData** can be one of the following:

- A single value, which applies the same transparency to the entire patch. The **FaceAlpha** property must be set to **flat**.
- An m-by-1 matrix (where m is the number of rows in the **Faces** property), which specifies one transparency value per face. The **FaceAlpha** property must be set to **flat**.
- An m-by-1 matrix (where m is the number of rows in the **Vertices** property), which specifies one transparency value per vertex. The **FaceAlpha** property must be set to **interp**.

The **AlphaDataMapping** property determines how MATLAB interprets the **FaceVertexAlphaData** property values.

**FaceVertexCData**  
matrix

*Face and vertex colors.* Specifies the color of patches defined by the **Faces** and **Vertices** properties. You must also set the values of the **FaceColor**, **EdgeColor**, **MarkerFaceColor**, or **MarkerEdgeColor** appropriately. The interpretation of the values specified for **FaceVertexCData** depends on the dimensions of the data.

For indexed colors, **FaceVertexCData** can be:

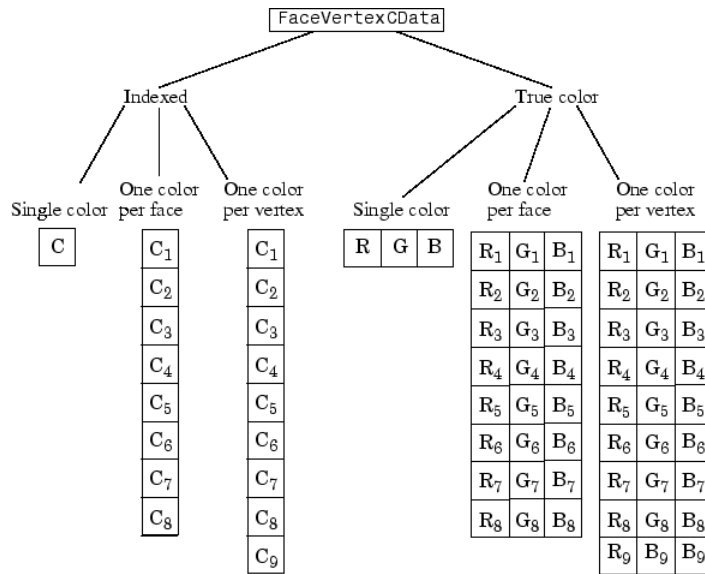

- A single value, which applies a single color to the entire patch.
- An  $n$ -by-1 matrix, where  $n$  is the number of rows in the `Faces` property, which specifies one color per face.
- An  $n$ -by-1 matrix, where  $n$  is the number of rows in the `Vertices` property, which specifies one color per vertex.

For true colors, `FaceVertexCData` can be:

- A 1-by-3 matrix, which applies a single color to the entire patch.
- An  $n$ -by-3 matrix, where  $n$  is the number of rows in the `Faces` property, which specifies one color per face.
- An  $n$ -by-3 matrix, where  $n$  is the number of rows in the `Vertices` property, which specifies one color per vertex.

The following diagram illustrates the various forms of the `FaceVertexCData` property for a patch having eight faces and nine vertices. The `CDataMapping` property determines how MATLAB interprets the `FaceVertexCData` property when you specify indexed colors.

# Patch Properties

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such

as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the patch can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the patch. If `HitTest` is `off`, clicking the patch selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

# Patch Properties

---

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

**LineStyle**

{-} | -- | : | -. | none

*Line style of the patch edges.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use **LineStyle** `none` when you want to place a marker at each point but do not want the points connected with a line (see the **Marker** property).

**LineWidth**

width in points

*Edge line width.* The width, in points, of the patch edges 1 point =  $\frac{1}{72}$  inch. The default value is 0.5 points.

# Patch Properties

---

## Marker

character (see table)

*Marker symbol.* Specifies marks that locate vertices. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto} | flat

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — Defines the color to use.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Sets `MarkerEdgeColor` to the same color as the `EdgeColor` property.
- `flat` — The color of each vertex controls the color of the marker that denotes it.

`MarkerFaceColor`

`ColorSpec` | `{none}` | `auto` | `flat`

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — Defines the color to use.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes color, or the figure color, if the axes `Color` property is `none`.
- `flat` — The color of each vertex controls the color of the marker that denotes it.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

# Patch Properties

---

## NormalMode

{auto} | manual

*MATLAB generated or user-specified normal vectors.*

- **auto** — MATLAB calculates vertex normals based on the coordinate data
- **manual** — If you specify your own vertex normals, MATLAB sets this property to **manual** and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of axes, hggroup, or hgtransform

*Parent of patch object.* Contains the handle of the patch object's parent. The parent of a patch object is the axes, hggroup, or hgtransform object that contains it.

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays selection handles or a dashed box (depending on the number of faces) if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by:

- Drawing handles at each vertex for a single-faced patch
- Drawing a dashed bounding box for a multifaced patch

When `SelectionHighlight` is off, MATLAB does not draw the indicators.

## `SpecularColorReflectance`

scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

## `SpecularExponent`

scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

## `SpecularStrength`

scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the patch. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the patch object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

## `Tag`

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

# Patch Properties

---

For example, suppose you use `patch` objects to create borders for a group of `uicontrol` objects and want to change the color of the borders in a `uicontrol`'s callback routine. Specify a `Tag` with the patch definition:

```
patch(X,Y,'k','Tag','PatchBorder')
```

Then use `findobj` in the `uicontrol`'s callback routine to obtain the handle of the patch and set its `FaceColor` property.

```
set(findobj('Tag','PatchBorder'),'FaceColor','w')
```

## Type

string (read-only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For patch objects, `Type` is always `'patch'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate a context menu with the patch.* Assign this property the handle of a `uicontextmenu` object created in the same figure as the patch. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the patch.

## UserData

matrix

*User-specified data.* Data you want to associate with the patch object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VertexNormals

matrix

*Surface normal vectors.* Contains the vertex normals for the patch. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. Use this property to produce interesting lighting effects.

## Vertices

matrix

*Vertex coordinates.* A matrix containing the  $x$ -,  $y$ -,  $z$ -coordinates for each vertex. See the Faces property for more information.

## Visible

{on} | off

*Patch object visibility.*

- on — All patches are visible.
- off — The patch is not visible, but still exists, and you can query and set its properties.

## XData

vector | matrix

*X-coordinates.* The  $x$ -coordinates of the patch vertices. If XData is a matrix, each column represents the  $x$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

## YData

vector | matrix

*Y-coordinates.* The  $y$ -coordinates of the patch vertices. If YData is a matrix, each column represents the  $y$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

## ZData

vector | matrix

# Patch Properties

---

*Z-coordinates.* The  $z$ -coordinates of the patch vertices. If ZData is a matrix, each column represents the  $z$ -coordinates of a single face of the patch. In this case, XData, YData, and ZData must have the same dimensions.

**See Also** `patch`

<b>Purpose</b>	View or change search path
<b>Alternatives</b>	As an alternative to the path function, use the Set Path dialog box.
<b>Syntax</b>	<pre>path path('newpath') path(path,'newpath') path('newpath',path) p = path</pre>
<b>Description</b>	<p>path displays the MATLAB search path, which is stored in pathdef.m.</p> <p>path('newpath') changes the search path to newpath, where newpath is a string array of folders.</p> <p>path(path,'newpath') adds the newpath folder to the end of the search path. If newpath is already on the search path, then path(path,'newpath') moves newpath to the end of the search path.</p> <p>path('newpath',path) adds the newpath folder to the top of the search path. If newpath is already on the search path, then path('newpath',path) moves newpath to the top of the search path. To add multiple folders in one statement, instead use addpath.</p> <p>p = path returns the search path to string variable p.</p>
<b>Examples</b>	<p>Display the search path:</p> <pre>path</pre> <p>MATLAB returns, for example</p> <pre>MATLABPATH  H:\My Documents\MATLAB C:\Program Files\MATLAB\R200nn\toolbox\matlab\general C:\Program Files\MATLAB\R200nn\toolbox\matlab\ops C:\Program Files\MATLAB\R200nn\toolbox\matlab\lang C:\Program Files\MATLAB\R200nn\toolbox\matlab\elmat</pre>

```
C:\Program Files\MATLAB\R200nn\toolbox\matlab\elfun
...
```

R200nn represents the folder for the MATLAB release, for example, R2009b.

Add a new folder to the search path on Microsoft Windows platforms:

```
path(path, 'c:/tools/goodstuff')
```

Add a new folder to the search path on UNIX<sup>5</sup> platforms:

```
path(path, '/home/tools/goodstuff')
```

Temporarily add the folder `my_files` to the search path, run `my_function` in `my_files`, then restore the previous search path:

```
p = path
path(p, 'my_files')
my_function
path(p)
```

## How To

- “What Is the MATLAB Search Path?”
- “Files and Folders that MATLAB Accesses”

5. UNIX is a registered trademark of The Open Group in the United States and other countries.

**Purpose** Save current search path to pathdef.m file

**Syntax** path2rc

**Description** path2rc runs savepath. The savepath function is replacing path2rc. Use savepath instead of path2rc and replace instances of path2rc with savepath.

# pathsep

---

**Purpose** Search path separator for current platform

**Syntax** `c = pathsep`

**Description** `c = pathsep` returns the search path separator character for this platform. The search path separator is the character that separates path names in the `pathdef.m` file, as returned by the `path` function. The character is a semicolon (;). For versions of MATLAB software earlier than version 7.7 (R2008b), the character on UNIX<sup>6</sup> platforms was a colon (:). Use `pathsep` to work programmatically with the content of the search path file.

**See Also** `fileparts` | `filesep` | `fullfile` | `path`

**How To**

- “What Is the MATLAB Search Path?”

6. UNIX is a registered trademark of The Open Group in the United States and other countries.

<b>Purpose</b>	Open Set Path dialog box to view and change search path
<b>Syntax</b>	<code>pathtool</code>
<b>Description</b>	<code>pathtool</code> opens the Set Path dialog box, a graphical user interface you use to view and modify the MATLAB search path.

# pathtool

## See Also

`addpath` | `cd` | `dir` | `genpath` | `matlabroot` | `path` | `pathsep` | `rehash`  
| `restoredefaultpath` | `rmpath` | `savepath` | `startup` | `what`

## How To

- “What Is the MATLAB Search Path?”

**Purpose** Halt execution temporarily

**Syntax**

```

pause
pause(n)
pause on
pause off
pause query
state = pause('query')
oldstate = pause(newstate)

```

**Description** `pause`, by itself, causes the currently executing function to stop and wait for you to press any key before continuing. Pausing must be enabled for this to take effect. (See `pause on`, below). `pause` without arguments also blocks execution of Simulink models, but not repainting of them.

`pause(n)` pauses execution for `n` seconds before continuing, where `n` is any nonnegative real number. Pausing must be enabled for this to take effect.

Typing `pause(inf)` puts you into an infinite loop. To return to the MATLAB prompt, type **Ctrl+C**.

`pause on` enables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. Pausing remains enabled until you enter `pause off` in your function or at the command line.

`pause off` disables the pausing of MATLAB execution via the `pause` and `pause(n)` commands. This allows normally interactive scripts to run unattended. Pausing remains disabled until you enter `pause on` in your function or at the command line, or start a new MATLAB session.

`pause query` displays 'on' if pausing is currently enabled. Otherwise, it displays 'off'.

`state = pause('query')` returns 'on' in character array `state` if pausing is currently enabled. Otherwise, the value of `state` is 'off'.

`oldstate = pause(newstate)`, enables or disables pausing, depending on the 'on' or 'off' value in `newstate`, and returns the former setting (also either 'on' or 'off') in character array `oldstate`.

# pause

---

## Tips

The accuracy of `pause` is subject to the scheduling resolution of the operating system you are using, and also to other system activity. It cannot be guaranteed with 100% confidence. Asking for finer resolutions shows higher relative error.

While MATLAB is paused, the following continue to execute:

- Repainting of figure windows, Simulink block diagrams, and Java windows
- HG callbacks from figure windows
- Event handling from Java windows

`keyboard` | `input` | `drawnow`

**Purpose** Set or query plot box aspect ratio

**Syntax**

```
pbaspect
pbaspect([aspect_ratio])
pbaspect('mode')
pbaspect('auto')
pbaspect('manual')
pbaspect(axes_handle,...)
```

**Description** The plot box aspect ratio determines the relative size of the  $x$ -,  $y$ -, and  $z$ -axes.

`pbaspect` with no arguments returns the plot box aspect ratio of the current axes.

`pbaspect([aspect_ratio])` sets the plot box aspect ratio in the current axes to the specified value. Specify the aspect ratio as three relative values representing the ratio of the  $x$ -,  $y$ -, and  $z$ -axes size. For example, a value of `[1 1 1]` (the default) means the plot box is a cube (although with stretch-to-fill enabled, it may not appear as a cube). See [Tips](#).

`pbaspect('mode')` returns the current value of the plot box aspect ratio mode, which can be either `auto` (the default) or `manual`. See [Remarks](#).

`pbaspect('auto')` sets the plot box aspect ratio mode to `auto`.

`pbaspect('manual')` sets the plot box aspect ratio mode to `manual`.

`pbaspect(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. If you do not specify an axes handle, `pbaspect` operates on the current axes.

**Tips** `pbaspect` sets or queries values of the axes object `PlotBoxAspectRatio` and `PlotBoxAspectRatioMode` properties.

When the plot box aspect ratio mode is `auto`, the MATLAB software sets the ratio to `[1 1 1]`, but may change it to accommodate manual settings of the data aspect ratio, camera view angle, or axis limits. See the axes `DataAspectRatio` property for a table listing the interactions between various properties.

Setting a value for the plot box aspect ratio or setting the plot box aspect ratio mode to `manual` disables the MATLAB stretch-to-fill feature (stretching of the axes to fit the window). This means setting the plot box aspect ratio to its current value,

```
pbaspect(pbaspect)
```

can cause a change in the way the graphs look. See the Remarks section of the `axes` reference description, “Axes Aspect Ratio Properties” in the 3-D Visualization manual, and “Setting Aspect Ratio” in the MATLAB Graphics manual for a discussion of stretch-to-fill.

## Examples

### Query Plot Box Aspect Ratio

Plot the function  $z = xe^{-x^2-y^2}$  over the range  $-2 \leq x \leq 2$  and  $-2 \leq y \leq 2$ .

```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2 - y.^2);
surf(x,y,z)
```

Query the plot box aspect ratio to show that the plot box is square.

```
plotboxaspect = pbaspect
```

```
plotboxaspect =
```

```
 1 1 1
```

# pbaspect

---

Change the data aspect ratio.

```
daspect([1,1,1])
```

Query the plot box aspect ratio to show how it changes to accommodate the specified data aspect ratio.

```
plotboxaspect = pbaspect
```

```
plotboxaspect =
 4 4 1
```

Make the plot box square again by changing the plot box aspect ratio to [1,1,1].

```
pbaspect([1,1,1])
```

# pbaspect

---

## How To

- [Setting Aspect Ratio](#)
- [Axes Aspect Ratio Properties](#)

**Purpose** Preconditioned conjugate gradients method

**Syntax**

```
x = pcg(A,b)
pcg(A,b,tol)
pcg(A,b,tol,maxit)
pcg(A,b,tol,maxit,M)
pcg(A,b,tol,maxit,M1,M2)
pcg(A,b,tol,maxit,M1,M2,x0)
[x,flag] = pcg(A,b,...)
[x,flag,relres] = pcg(A,b,...)
[x,flag,relres,iter] = pcg(A,b,...)
[x,flag,relres,iter,resvec] = pcg(A,b,...)
```

**Description** `x = pcg(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric and positive definite, and should also be large and sparse. The column vector  $b$  must have length  $n$ . You also can specify  $A$  to be a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `pcg` converges, a message to that effect is displayed. If `pcg` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`pcg(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `pcg` uses the default,  $1e-6$ .

`pcg(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `pcg` uses the default,  $\min(n,20)$ .

`pcg(A,b,tol,maxit,M)` and `pcg(A,b,tol,maxit,M1,M2)` use symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]`

then `pcg` applies no preconditioner. `M` can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`pcg(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If `x0` is `[]`, then `pcg` uses the default, an all-zero vector.

`[x,flag] = pcg(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>pcg</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>pcg</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner <code>M</code> was ill-conditioned.
3	<code>pcg</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>pcg</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution `x` returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = pcg(A,b,...)` also returns the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = pcg(A,b,...)` also returns the iteration number at which `x` was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = pcg(A,b,...)` also returns a vector of the residual norms at each iteration including  $\text{norm}(b-A*x0)$ .

## Examples

### Using `pcg` with Large Matrices

This example shows how to use `pcg` with a matrix input and with a function handle.

```
n1 = 21;
A = gallery('moler',n1);
b1 = sum(A,2);
```

```

tol = 1e-6;
maxit = 15;
M1 = spdiags((1:n1)',0,n1,n1);
[x1,flag1,rr1,iter1,rv1] = pcg(A,b1,tol,maxit,M1);

```

Alternatively, you can use the following function in place of the matrix A:

```

function y = applyMoler(x)
y = x;
y(end-1:-1:1) = y(end-1:-1:1) - cumsum(y(end:-1:2));
y(2:end) = y(2:end) - cumsum(y(1:end-1));

```

By using this function, you can solve larger systems more efficiently as there is no need to store the entire matrix A:

```

n2 = 21;
b2 = applyMoler(ones(n2,1));
tol = 1e-6;
maxit = 15;
M2 = spdiags((1:n2)',0,n2,n2);
[x2,flag2,rr2,iter2,rv2] = pcg(@applyMoler,b2,tol,maxit,M2);

```

### Using pcg with a Preconditioner

This example demonstrates how to use a preconditioner matrix with `pcg`.

Create an input matrix and try to solve the system with `pcg`.

```

A = delsq(numgrid('S',100));
b = ones(size(A,1),1);
[x0,f10,rr0,it0,rv0] = pcg(A,b,1e-8,100);

```

`f10` is 1 because `pcg` does not converge to the requested tolerance of  $1e-8$  within the requested maximum 100 iterations. A preconditioner can make the system converge more quickly.

Use `ichol` with only one input argument to construct an incomplete Cholesky factorization with zero fill.

```
L = ichol(A);
[x1,f11,rr1,it1,rv1] = pcg(A,b,1e-8,100,L,L');
```

f11 is 0 because pcg drives the relative residual to  $9.8e-09$  (the value of rr1) which is less than the requested tolerance of  $1e-8$  at the seventy-seventh iteration (the value of it1) when preconditioned by the zero-fill incomplete Cholesky factorization.  $rv1(1) = \text{norm}(b)$  and  $rv1(78) = \text{norm}(b-A*x1)$ .

The previous matrix represents the discretization of the Laplacian on a 100x100 grid with Dirichlet boundary conditions. This means that a modified incomplete Cholesky preconditioner might perform even better.

Use the michol option to create a modified incomplete Cholesky preconditioner.

```
L = ichol(A,struct('michol','on'));
[x2,f12,rr2,it2,rv2] = pcg(A,b,1e-8,100,L,L');
```

In this case you attain convergence in only forty-seven iterations.

You can see how the preconditioners affect the rate of convergence of pcg by plotting each of the residual histories starting from the initial estimate (iterate number 0).

```
figure;
semilogy(0:it0,rv0/norm(b),'b.');
```

```
hold on;
semilogy(0:it1,rv1/norm(b),'r.');
```

```
semilogy(0:it2,rv2/norm(b),'k.');
```

```
legend('No Preconditioner','IC(0)','MIC(0)');
```

```
xlabel('iteration number');
```

```
ylabel('relative residual');
```

```
hold off;
```

# pchip

---

**Purpose** Piecewise Cubic Hermite Interpolating Polynomial (PCHIP)

**Syntax**  
`yi = pchip(x,y,xi)`  
`pp = pchip(x,y)`

**Description** `yi = pchip(x,y,xi)` returns vector `yi` containing elements corresponding to the elements of `xi` and determined by piecewise cubic interpolation within vectors `x` and `y`. The vector `x` specifies the points at which the data `y` is given. If `y` is a matrix, then the interpolation is performed for each column of `y` and `yi` is `length(xi)-by-size(y,2)`.

`pp = pchip(x,y)` returns a piecewise polynomial structure for use by `ppval`. `x` can be a row or column vector. `y` is a row or column vector of the same length as `x`, or a matrix with `length(x)` columns.

`pchip` finds values of an underlying interpolating function  $P(x)$  at intermediate points, such that:

- On each subinterval  $x_k \leq x \leq x_{k+1}$ ,  $P(x)$  is the cubic Hermite interpolant to the given values and certain slopes at the two endpoints.
- $P(x)$  interpolates  $y$ , i.e.,  $P(x_j) = y_j$ , and the first derivative  $P'(x)$  is continuous.  $P''(x)$  is probably not continuous; there may be jumps at the  $x_j$ .
- The slopes at the  $x_j$  are chosen in such a way that  $P(x)$  preserves the shape of the data and respects monotonicity. This means that, on intervals where the data are monotonic, so is  $P(x)$ ; at points where the data has a local extremum, so does  $P(x)$ .

---

**Note** If  $y$  is a matrix,  $P(x)$  satisfies the above for each column of  $y$ .

---

**Tips**

`spline` constructs  $S(x)$  in almost the same way `pchip` constructs  $P(x)$ . However, `spline` chooses the slopes at the  $x_j$  differently, namely to make even  $S''(x)$  continuous. This has the following effects:

- `spline` produces a smoother result, i.e.  $S''(x)$  is continuous.
- `spline` produces a more accurate result if the data consists of values of a smooth function.
- `pchip` has no overshoots and less oscillation if the data are not smooth.
- `pchip` is less expensive to set up.
- The two are equally expensive to evaluate.

**Examples****Data Interpolation Using `spline` and `pchip`**

```
x = -3:3;
y = [-1 -1 -1 0 1 1 1];
t = -3:.01:3;
p = pchip(x,y,t);
s = spline(x,y,t);
plot(x,y,'o',t,p,'-',t,s,'-.')
legend('data','pchip','spline',4)
```

**Purpose** Create protected function file

**Syntax**

```
pcode(fun)
pcode(fun1,...,funN)
pcode(fun, '-inplace')
```

**Description** `pcode(fun)` obfuscates the code in `fun.m` and produces a file called `fun.p`, known as a P-file. If `fun` is a folder, then all the script or function files in that folder are obfuscated in P-files. MATLAB creates the P-files in the current folder. The original `.m` file or folder can be anywhere on the search path.

`pcode(fun1,...,funN)` creates N P-files from the listed files. If any inputs are folders, then MATLAB creates a P-file for every `.m` file the folders contain.

`pcode(fun, '-inplace')` creates P-files in the same folder as the script or function files.

---

**Note** The `pcode` function *obfuscates* your `.m` files, it does not *encrypt* them. While the content in a `.p` file is difficult to understand, it should not be considered secure. It is not recommended that you P-code files to protect your intellectual property.

---

## Tips

- The `pcode` algorithm was redesigned in MATLAB 7.5 (Release R2007b). You can run older P-files in any current version of MATLAB; however, upcoming releases will not run P-files created before version 7.5. Files generated in 7.5, or later versions, cannot run in MATLAB 7.4 or earlier.
- When obfuscating all files in a folder, `pcode` does not obfuscate any files within subfolders.
- A P-file takes precedence over the corresponding `.m` file for execution, even after modifications to the `.m` file.

- MATLAB does not display any of the help comments that might be in the original `.m` file.

## Input Arguments

### **fun**

MATLAB file or directory containing MATLAB files. If `fun` resides within a package and/or class folder, then `pcode` creates the same package and/or class structure to house the resulting P-files.

An input argument with no file extension and that is not a folder must be a function in the MATLAB path or in the current folder.

When using wild cards `*`, `pcode` ignores all files with extensions other than `.m`.

## Examples

### **P-Coding Multiple Files**

Convert selected files from the `sparfun` folder into P-files.

Create a temporary folder and define an existing path to `.m` files.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
```

Create the P-files.

```
pcode(fun)
dir(tmp)

.
.. sprand.p sprandn.p sprandsym.p sprank.p
```

The temporary folder now contains encoded P-files.

### **P-Coding Files That Belong to a Package and/or Class**

Generate P-files from input files that are part of a package and/or class. This example uses an existing MATLAB example class.

Define `funclass` as an existing a class folder that contains `.m` files.

```
funclass = fullfile(docroot, 'techdoc', 'matlab_oop', ...
 'examples', '@BankAccount')
dir(funclass)
```

```
funclass =
C:\Program Files\MATLAB\R2013a\help\techdoc\matlab_oop\examples\@BankAccount

. .. BankAccount.m
```

Create a temporary folder. This folder has no package or class structure at this time.

```
tmp = tempname;
mkdir(tmp);
cd(tmp);
dir(tmp)
```

```
. ..
```

Create a P-file for every .m file in the path funclass. Because the input files are part of a package and/or class, MATLAB creates a folder structure so that the output file belongs to the same package and/or class.

```
pcode(funclass)
dir(tmp)
```

```
. .. @BankAccount
```

You see that the P-file resides in the same folder structure.

```
dir('@BankAccount')

. .. BankAccount.p
```

## P-Coding In Place

Generate P-files in the same folder as the input files using the option `inplace`

Copy several MATLAB files to a temporary folder.

```
fun = fullfile(matlabroot, 'toolbox', 'matlab', 'sparfun', 'spr*.m');
tmp = tempname;
mkdir(tmp);
copyfile(fun, tmp)
dir(tmp)
```

```
. .. sprand.m sprandn.m sprandsym.m sprank.m
```

Create P-files in the same folder as the original `.m` files.

```
pcode(tmp, '-inplace')
dir(tmp)
```

```
. sprand.m sprandn.m sprandsym.m sprank.m
.. sprand.p sprandn.p sprandsym.p sprank.p
```

## Concepts

- “Protect Your Source Code”

**Purpose** Pseudocolor (checkerboard) plot

**Syntax**

```
pcolor(C)
pcolor(X,Y,C)
pcolor(axes_handles,...)
h = pcolor(...)
```

**Description** A pseudocolor plot is a rectangular array of cells with colors determined by **C**. MATLAB creates a pseudocolor plot using each set of four adjacent points in **C** to define a surface rectangle (i.e., cell).

The default shading is `faceted`, which colors each cell with a single color. The last row and column of **C** are not used in this case. With shading `interp`, each cell is colored by bilinear interpolation of the colors at its four vertices, using all elements of **C**.

The minimum and maximum elements of **C** are assigned the first and last colors in the colormap. Colors for the remaining elements in **C** are determined by a linear mapping from value to colormap element.

`pcolor(C)` draws a pseudocolor plot. The elements of **C** are linearly mapped to an index into the current colormap. The mapping from **C** to the current colormap is defined by `colormap` and `caxis`.

`pcolor(X,Y,C)` draws a pseudocolor plot of the elements of **C** at the locations specified by **X** and **Y**. The plot is a logically rectangular, two-dimensional grid with vertices at the points  $[X(i,j), Y(i,j)]$ . **X** and **Y** are vectors or matrices that specify the spacing of the grid lines. If **X** and **Y** are vectors, **X** corresponds to the columns of **C** and **Y** corresponds to the rows. If **X** and **Y** are matrices, they must be the same size as **C**.

`pcolor(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = pcolor(...)` returns a handle to a surface graphics object.

## Tips

A pseudocolor plot is a flat surface plot viewed from above. `pcolor(X,Y,C)` is the same as viewing `surf(X,Y,zeros(size(X)),C)` using `view([0 90])`.

When you use `shading faceted` or `shading flat`, the constant color of each cell is the color associated with the corner having the smallest  $x$ - $y$  coordinates. Therefore, `C(i,j)` determines the color of the cell in the  $i$ th row and  $j$ th column. The last row and column of `C` are not used.

When you use `shading interp`, each cell's color results from a bilinear interpolation of the colors at its four vertices, and all elements of `C` are used.

## Examples

A Hadamard matrix has elements that are +1 and -1. A colormap with only two entries is appropriate when displaying a pseudocolor plot of this matrix.

```
pcolor(hadamard(20))
colormap(gray(2))
axis ij
axis square
```

A simple color wheel illustrates a polar coordinate system.

```
n = 6;
r = (0:n)'/n;
theta = pi*(-n:n)/n;
X = r*cos(theta);
Y = r*sin(theta);
C = r*cos(2*theta);
pcolor(X,Y,C)
```

axis equal tight

## Algorithms

The number of vertex colors for `pcolor(C)` is the same as the number of cells for `image(C)`. `pcolor` differs from `image` in that `pcolor(C)` specifies the colors of vertices, which are scaled to fit the colormap; changing the axes `clim` property changes this color mapping. `image(C)` specifies the colors of cells and directly indexes into the colormap without scaling. Additionally, `pcolor(X,Y,C)` can produce parametric grids, which is not possible with `image`.

# pdepe

---

## Purpose

Solve initial-boundary value problems for parabolic-elliptic PDEs in 1-D

## Syntax

```
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)
sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,options)
[sol,tsol,sole,te,ie] = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan,
 options)
```

## Arguments

m	A parameter corresponding to the symmetry of the problem. m can be slab = 0, cylindrical = 1, or spherical = 2.
pdefun	A handle to a function that defines the components of the PDE.
icfun	A handle to a function that defines the initial conditions.
bcfun	A handle to a function that defines the boundary conditions.
xmesh	A vector [x0, x1, ..., xn] specifying the points at which a numerical solution is requested for every value in tspan. The elements of xmesh must satisfy $x_0 < x_1 < \dots < x_n$ . The length of xmesh must be $\geq 3$ .
tspan	A vector [t0, t1, ..., tf] specifying the points at which a solution is requested for every value in xmesh. The elements of tspan must satisfy $t_0 < t_1 < \dots < t_f$ . The length of tspan must be $\geq 3$ .
options	Some options of the underlying ODE solver are available in pdepe: RelTol, AbsTol, NormControl, InitialStep, MaxStep, and Events. In most cases, default values for these options provide satisfactory solutions. See odeset for details.

**Description**

`sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)` solves initial-boundary value problems for systems of parabolic and elliptic PDEs in the one space variable  $x$  and time  $t$ . `pdefun`, `icfun`, and `bcfun` are function handles. See the `function_handle` reference page for more information. The ordinary differential equations (ODEs) resulting from discretization in space are integrated to obtain approximate solutions at times specified in `tspan`. The `pdepe` function returns values of the solution on a mesh provided in `xmesh`.

“Parameterizing Functions” explains how to provide additional parameters to the functions `pdefun`, `icfun`, or `bcfun`, if necessary.

`pdepe` solves PDEs of the form:

$$c\left(x,t,u,\frac{\partial u}{\partial x}\right)\frac{\partial u}{\partial t} = x^{-m}\frac{\partial}{\partial x}\left(x^m f\left(x,t,u,\frac{\partial u}{\partial x}\right)\right) + s\left(x,t,u,\frac{\partial u}{\partial x}\right) \quad (1-4)$$

The PDEs hold for  $t_0 \leq t \leq t_f$  and  $a \leq x \leq b$ . The interval  $[a,b]$  must be finite.  $m$  can be 0, 1, or 2, corresponding to slab, cylindrical, or spherical symmetry, respectively. If  $m > 0$ , then  $a$  must be  $\geq 0$ .

In Equation 1-4,  $f(x,t,u,\partial u/\partial x)$  is a flux term and  $s(x,t,u,\partial u/\partial x)$  is a source term. The coupling of the partial derivatives with respect to time is restricted to multiplication by a diagonal matrix  $c(x,t,u,\partial u/\partial x)$ . The diagonal elements of this matrix are either identically zero or positive. An element that is identically zero corresponds to an elliptic equation and otherwise to a parabolic equation. There must be at least one parabolic equation. An element of  $c$  that corresponds to a parabolic equation can vanish at isolated values of  $x$  if those values of  $x$  are mesh points. Discontinuities in  $c$  and/or  $s$  due to material interfaces are permitted provided that a mesh point is placed at each interface.

For  $t = t_0$  and all  $x$ , the solution components satisfy initial conditions of the form

$$u(x,t_0) = u_0(x) \quad (1-5)$$

For all  $t$  and either  $x = a$  or  $x = b$ , the solution components satisfy a boundary condition of the form

$$p(x,t,u) + q(x,t)f\left(x,t,u,\frac{\partial u}{\partial x}\right) = 0 \quad (1-6)$$

Elements of  $q$  are either identically zero or never zero. Note that the boundary conditions are expressed in terms of the flux  $f$  rather than  $\partial u/\partial x$ . Also, of the two coefficients, only  $p$  can depend on  $u$ .

In the call `sol = pdepe(m,pdefun,icfun,bcfun,xmesh,tspan)`:

- $m$  corresponds to  $m$ .
- `xmesh(1)` and `xmesh(end)` correspond to  $a$  and  $b$ .
- `tspan(1)` and `tspan(end)` correspond to  $t_0$  and  $t_f$ .
- `pdefun` computes the terms  $c$ ,  $f$ , and  $s$  (Equation 1-4). It has the form

$$[c,f,s] = \text{pdefun}(x,t,u,\text{dudx})$$

The input arguments are scalars  $x$  and  $t$  and vectors  $u$  and  $\text{dudx}$  that approximate the solution  $u$  and its partial derivative with respect to  $x$ , respectively.  $c$ ,  $f$ , and  $s$  are column vectors.  $c$  stores the diagonal elements of the matrix  $c$  (Equation 1-4).

- `icfun` evaluates the initial conditions. It has the form

$$u = \text{icfun}(x)$$

When called with an argument  $x$ , `icfun` evaluates and returns the initial values of the solution components at  $x$  in the column vector  $u$ .

- `bcfun` evaluates the terms  $p$  and  $q$  of the boundary conditions (Equation 1-6). It has the form

$$[p1,q1,pr,qr] = \text{bcfun}(x1,u1,xr,ur,t)$$

$u1$  is the approximate solution at the left boundary  $x1 = a$  and  $ur$  is the approximate solution at the right boundary  $xr = b$ .  $p1$  and  $q1$  are column vectors corresponding to  $p$  and  $q$  evaluated at  $x1$ , similarly  $pr$  and  $qr$  correspond to  $xr$ . When  $m > 0$  and  $a = 0$ , boundedness of the solution near  $x = 0$  requires that the flux  $f$  vanish at  $a = 0$ . `pdepe`

imposes this boundary condition automatically and it ignores values returned in `pl` and `ql`.

`pdepe` returns the solution as a multidimensional array `sol`.

$u_i = \text{ui} = \text{sol}(:, :, i)$  is an approximation to the  $i$ th component of the solution vector  $u$ . The element  $\text{ui}(j, k) = \text{sol}(j, k, i)$  approximates  $u_i$  at  $(t, x) = (\text{tspan}(j), \text{xmesh}(k))$ .

$\text{ui} = \text{sol}(j, :, i)$  approximates component  $i$  of the solution at time  $\text{tspan}(j)$  and mesh points  $\text{xmesh}(:)$ . Use `pdeval` to compute the approximation and its partial derivative  $\partial u_i / \partial x$  at points not included in `xmesh`. See `pdeval` for details.

`sol = pdepe(m, pdefun, icfun, bcfun, xmesh, tspan, options)` solves as above with default integration parameters replaced by values in `options`, an argument created with the `odeset` function. Only some of the options of the underlying ODE solver are available in `pdepe`: `RelTol`, `AbsTol`, `NormControl`, `InitialStep`, and `MaxStep`. The defaults obtained by leaving off the input argument `options` will generally be satisfactory. See `odeset` for details.

`[sol, tsol, sole, te, ie] = pdepe(m, pdefun, icfun, bcfun, xmesh, tspan, options)` with the 'Events' property in `options` set to a function handle `Events`, solves as above while also finding where event functions  $g(t, u(x, t))$  are zero. For each function you specify whether the integration is to terminate at a zero and whether the direction of the zero crossing matters. Three column vectors are returned by `events`: `[value, isterminal, direction] = events(m, t, xmesh, umesh)`. `xmesh` contains the spatial mesh and `umesh` is the solution at the mesh points. Use `pdeval` to evaluate the solution between mesh points. For the  $I$ -th event function, `value(i)` is the value of the function, `ISTERMINAL(I) = 1` if the integration is to terminate at a zero of this event function and 0 otherwise. `direction(i) = 0` if all zeros are to be computed (the default), `+1` if only zeros where the event function is increasing, and `-1` if only zeros where the event function is decreasing. Output `tsol` is a column vector of times specified in `tspan`, prior to first terminal event. `SOL(j, :, :)` is the solution at  $T(j)$ . `TE` is a vector of

times at which events occur. `SOLE(j, :, :)` is the solution at `TE(j)` and indices in vector `IE` specify which event occurred.

If `UI = SOL(j, :, i)` approximates component `i` of the solution at time `TSPAN(j)` and mesh points `XMESH`, `pdeval` evaluates the approximation and its partial derivative  $\partial u_i / \partial x$  at the array of points `XOUT` and returns them in `UOUT` and `DUOUTDX`: `[UOUT, DUOUTDX] = PDEVAL(M, XMESH, UI, XOUT)`

---

**Note** The partial derivative  $\partial u_i / \partial x$  is evaluated here rather than the flux. The flux is continuous, but at a material interface the partial derivative may have a jump.

---

## Tips

- The arrays `xmesh` and `tspan` play different roles in `pdepe`.  
**tspan** – The `pdepe` function performs the time integration with an ODE solver that selects both the time step and formula dynamically. The elements of `tspan` merely specify where you want answers and the cost depends weakly on the length of `tspan`.  
**xmesh** – Second order approximations to the solution are made on the mesh specified in `xmesh`. Generally, it is best to use closely spaced mesh points where the solution changes rapidly. `pdepe` does *not* select the mesh in  $x$  automatically. You must provide an appropriate fixed mesh in `xmesh`. The cost depends strongly on the length of `xmesh`. When  $m > 0$ , it is not necessary to use a fine mesh near  $x = 0$  to account for the coordinate singularity.
- The time integration is done with `ode15s`. `pdepe` exploits the capabilities of `ode15s` for solving the differential-algebraic equations that arise when Equation 1-4 contains elliptic equations, and for handling Jacobians with a specified sparsity pattern.
- After discretization, elliptic equations give rise to algebraic equations. If the elements of the initial conditions vector that correspond to elliptic equations are not "consistent" with the discretization, `pdepe` tries to adjust them before beginning the time integration. For

this reason, the solution returned for the initial time may have a discretization error comparable to that at any other time. If the mesh is sufficiently fine, pdepe can find consistent initial conditions close to the given ones. If pdepe displays a message that it has difficulty finding consistent initial conditions, try refining the mesh.

No adjustment is necessary for elements of the initial conditions vector that correspond to parabolic equations.

## Examples

**Example 1.** This example illustrates the straightforward formulation, computation, and plotting of the solution of a single PDE.

$$\pi^2 \frac{\partial u}{\partial t} = \frac{\partial}{\partial x} \left( \frac{\partial u}{\partial x} \right)$$

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial condition

$$u(x, 0) = \sin \pi x$$

and boundary conditions

$$u(0, t) \equiv 0$$

$$\pi e^{-t} + \frac{\partial u}{\partial x}(1, t) = 0$$

It is convenient to use local functions to place all the functions required by pdepe in a single function.

```
function pdex1

m = 0;
x = linspace(0,1,20);
t = linspace(0,2,5);

sol = pdepe(m,@pdex1pde,@pdex1ic,@pdex1bc,x,t);
% Extract the first solution component as u.
```

```
u = sol(:,:,1);

% A surface plot is often a good way to study a solution.
surf(x,t,u)
title('Numerical solution computed with 20 mesh points.')
xlabel('Distance x')
ylabel('Time t')

% A solution profile can also be illuminating.
figure
plot(x,u(end,:))
title('Solution at t = 2')
xlabel('Distance x')
ylabel('u(x,2)')
% -----
function [c,f,s] = pdex1pde(x,t,u,DuDx)
c = pi^2;
f = DuDx;
s = 0;
% -----
function u0 = pdex1ic(x)
u0 = sin(pi*x);
% -----
function [pl,ql,pr,qr] = pdex1bc(xl,ul,xr,ur,t)
pl = ul;
ql = 0;
pr = pi * exp(-t);
qr = 1;
```

In this example, the PDE, initial condition, and boundary conditions are coded in local functions `pdex1pde`, `pdex1ic`, and `pdex1bc`.

The surface plot shows the behavior of the solution.

The following plot shows the solution profile at the final value of  $t$  (i.e.,  $t = 2$ ).

**Example 2.** This example illustrates the solution of a system of PDEs. The problem has boundary layers at both ends of the interval. The solution changes rapidly for small  $t$ .

The PDEs are

$$\frac{\partial u_1}{\partial t} = 0.024 \frac{\partial^2 u_1}{\partial x^2} - F(u_1 - u_2)$$

$$\frac{\partial u_2}{\partial t} = 0.170 \frac{\partial^2 u_2}{\partial x^2} + F(u_1 - u_2)$$

where  $F(y) = \exp(5.73y) - \exp(-11.46y)$ .

This equation holds on an interval  $0 \leq x \leq 1$  for times  $t \geq 0$ .

The PDE satisfies the initial conditions

$$u_1(x, 0) \equiv 1$$

$$u_2(x, 0) \equiv 0$$

and boundary conditions

$$\frac{\partial u_1}{\partial x}(0, t) \equiv 0$$

$$u_2(0, t) \equiv 0$$

$$u_1(1, t) \equiv 1$$

$$\frac{\partial u_2}{\partial x}(1, t) \equiv 0$$

In the form expected by pdepe, the equations are

$$\begin{bmatrix} 1 \\ 1 \end{bmatrix} \cdot * \frac{\partial}{\partial t} \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \frac{\partial}{\partial x} \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} + \begin{bmatrix} -F(u_1 - u_2) \\ F(u_1 - u_2) \end{bmatrix}$$

The boundary conditions on the partial derivatives of  $u$  have to be written in terms of the flux. In the form expected by pdepe, the left boundary condition is

$$\begin{bmatrix} 0 \\ u_2 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

and the right boundary condition is

$$\begin{bmatrix} u_1 - 1 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix} \cdot * \begin{bmatrix} 0.024(\partial u_1 / \partial x) \\ 0.170(\partial u_2 / \partial x) \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The solution changes rapidly for small  $t$ . The program selects the step size in time to resolve this sharp change, but to see this behavior in the plots, the example must select the output times accordingly. There are boundary layers in the solution at both ends of  $[0, 1]$ , so the example places mesh points near 0 and 1 to resolve these sharp changes. Often

some experimentation is needed to select a mesh that reveals the behavior of the solution.

```
function pdex4
m = 0;
x = [0 0.005 0.01 0.05 0.1 0.2 0.5 0.7 0.9 0.95 0.99 0.995 1];
t = [0 0.005 0.01 0.05 0.1 0.5 1 1.5 2];

sol = pdepe(m,@pdex4pde,@pdex4ic,@pdex4bc,x,t);
u1 = sol(:,:,1);
u2 = sol(:,:,2);

figure
surf(x,t,u1)
title('u1(x,t)')
xlabel('Distance x')
ylabel('Time t')

figure
surf(x,t,u2)
title('u2(x,t)')
xlabel('Distance x')
ylabel('Time t')
% -----
function [c,f,s] = pdex4pde(x,t,u,DuDx)
c = [1; 1];
f = [0.024; 0.17] .* DuDx;
y = u(1) - u(2);
F = exp(5.73*y) - exp(-11.47*y);
s = [-F; F];
% -----
function u0 = pdex4ic(x);
u0 = [1; 0];
% -----
function [pl,ql,pr,qr] = pdex4bc(xl,ul,xr,ur,t)
pl = [0; ul(2)];
ql = [1; 0];
```

```
pr = [ur(1)-1; 0];
qr = [0; 1];
```

In this example, the PDEs, initial conditions, and boundary conditions are coded in local functions `pdex4pde`, `pdex4ic`, and `pdex4bc`.

The surface plots show the behavior of the solution components.

**Purpose** Evaluate numerical solution of PDE using output of pdepe

**Syntax** `[uout,duoutdx] = pdeval(m,x,ui,xout)`

### Arguments

m	Symmetry of the problem: slab = 0, cylindrical = 1, spherical = 2. This is the first input argument used in the call to pdepe.
xmesh	A vector <code>[x0, x1, ..., xn]</code> specifying the points at which the elements of <code>ui</code> were computed. This is the same vector with which pdepe was called.
ui	A vector <code>sol(j,:,i)</code> that approximates component <code>i</code> of the solution at time $t_j$ and mesh points <code>xmesh</code> , where <code>sol</code> is the solution returned by pdepe.
xout	A vector of points from the interval <code>[x0,xn]</code> at which the interpolated solution is requested.

### Description

`[uout,duoutdx] = pdeval(m,x,ui,xout)` approximates the solution  $u_i$  and its partial derivative  $\partial u_i / \partial x$  at points from the interval `[x0,xn]`. The pdeval function returns the computed values in `uout` and `duoutdx`, respectively.

---

**Note** pdeval evaluates the partial derivative  $\partial u_i / \partial x$  rather than the flux  $f$ . Although the flux is continuous, the partial derivative may have a jump at a material interface.

---

# peaks

---

## Purpose

Example function of two variables

## Syntax

```
Z = peaks;
Z = peaks(n);
Z = peaks(V);
Z = peaks(X,Y);
peaks(...)
[X,Y,Z] = peaks(...);
```

## Description

`peaks` is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating `mesh`, `surf`, `pcolor`, `contour`, and so on.

`Z = peaks`; returns a 49-by-49 matrix.

`Z = peaks(n)`; returns an n-by-n matrix.

`Z = peaks(V)`; returns an n-by-n matrix, where `n = length(V)`.

`Z = peaks(X,Y)`; evaluates `peaks` at the given `X` and `Y` (which must be the same size) and returns a matrix the same size.

`peaks(...)` (with no output argument) plots the `peaks` function with `surf`. Use any of the input argument combinations in the previous syntaxes.

`[X,Y,Z] = peaks(...)`; returns two additional matrices, `X` and `Y`, for parametric plots, for example, `surf(X,Y,Z,de12(Z))`. If not given as input, the underlying matrices `X` and `Y` are

```
[X,Y] = meshgrid(V,V)
```

where  $V$  is a given vector, or  $V$  is a vector of length  $n$  with elements equally spaced from  $-3$  to  $3$ . If no input argument is given, the default  $n$  is 49.

## Examples

This example creates a 5-by-5 matrix of peaks and displays the image:

```
peaks(5);
```

See Examples section from `surf` for a more elaborate use case.

# peaks

---

**Purpose**

Call Perl script using appropriate operating system executable

**Syntax**

```
perl('perlfile')
perl('perlfile',arg1,arg2,...)
result = perl(...)
[result, status] = perl(...)
```

**Description**

`perl('perlfile')` calls the Perl script `perlfile`, using the appropriate operating system Perl executable. Perl is included with the MATLAB software on Microsoft Windows systems, and thus MATLAB users can run user-created MATLAB functions containing the `perl` function. On Linux and Macintosh systems, MATLAB calls the Perl interpreter available with the operating system.

`perl('perlfile',arg1,arg2,...)` calls the Perl script `perlfile`, using the appropriate operating system Perl executable, and passes the arguments `arg1`, `arg2`, and so on, to `perlfile`.

`result = perl(...)` returns the results of attempted Perl call to `result`.

`[result, status] = perl(...)` returns the results of attempted Perl call to `result` and its exit status to `status`.

It is sometimes beneficial to use Perl scripts instead of MATLAB code. The `perl` function allows you to run those scripts from MATLAB. Specific examples where you might choose to use a Perl script include:

- Perl script already exists
- Perl script preprocesses data quickly, formatting it in a way more easily read by MATLAB
- Perl has features not supported by MATLAB

**Examples**

Given the Perl script, `hello.pl`:

```
$input = $ARGV[0];
print "Hello $input.";
```

# perl

---

At the MATLAB command line, type:

```
perl('hello.pl','World')
```

```
ans =
Hello World.
```

`dos` | `regexp` | `system` | `unix` | `!` (exclamation point)

<b>Purpose</b>	All possible permutations
<b>Syntax</b>	<code>P = perms(v)</code>
<b>Description</b>	<code>P = perms(v)</code> returns a matrix containing all permutations of the elements of vector <code>v</code> in reverse lexicographic order. Each row of <code>P</code> contains a different permutation of the $n$ elements in <code>v</code> . Matrix <code>P</code> has the same data type as <code>v</code> , and it has $n!$ rows and $n$ columns.
<b>Input Arguments</b>	<p><b>v - Set of items</b> vector of numeric, logical, or char values</p> <p>Set of items, specified as a vector of numeric, logical, or char values.</p> <p><b>Example:</b> <code>[1 2 3 4]</code></p> <p><b>Example:</b> <code>[1+1i 2+1i 3+1i 4+1i]</code></p> <p><b>Example:</b> <code>int16([1 2 3 4])</code></p> <p><b>Example:</b> <code>['abcd']</code></p> <p><b>Example:</b> <code>[true false true false]</code></p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char</p> <p><b>Complex Number Support:</b> Yes</p>
<b>Limitations</b>	<code>perms(v)</code> is practical when <code>length(v)</code> is less than about 10.
<b>Examples</b>	<p><b>All Permutations of Double Integers</b></p> <pre>v = [2 4 6]; P = perms(v)  P =       6     4     2      6     2     4</pre>

```
4 6 2
4 2 6
2 4 6
2 6 4
```

## All Permutations of Unsigned Integers

```
v = uint16([1023 4095 65535]);
P = perms(v)
```

P =

```
65535 4095 1023
65535 1023 4095
 4095 65535 1023
 4095 1023 65535
1023 4095 65535
1023 65535 4095
```

## All Permutations of Complex Numbers

```
v = [1+1i 2+1i 3+1i];
P = perms(v)
```

P =

```
3.0000 + 1.0000i 2.0000 + 1.0000i 1.0000 + 1.0000i
3.0000 + 1.0000i 1.0000 + 1.0000i 2.0000 + 1.0000i
2.0000 + 1.0000i 3.0000 + 1.0000i 1.0000 + 1.0000i
2.0000 + 1.0000i 1.0000 + 1.0000i 3.0000 + 1.0000i
1.0000 + 1.0000i 2.0000 + 1.0000i 3.0000 + 1.0000i
1.0000 + 1.0000i 3.0000 + 1.0000i 2.0000 + 1.0000i
```

## See Also

[nchoosek](#) | [permute](#) | [randperm](#)

**Purpose** Rearrange dimensions of N-D array

**Syntax** `B = permute(A,order)`

**Description** `B = permute(A,order)` rearranges the dimensions of `A` so that they are in the order specified by the vector `order`. `B` has the same values of `A` but the order of the subscripts needed to access any particular element is rearranged as specified by `order`. All the elements of `order` must be unique, real, positive, integer values.

**Tips** `permute` and `ipermute` are a generalization of transpose (`.'`) for multidimensional arrays.

**Examples** Given any matrix `A`, the statement

```
permute(A,[2 1])
```

is the same as `A.'`

For example:

```
A = [1 2; 3 4]; permute(A,[2 1])
ans =
 1 3
 2 4
```

The following code permutes a three-dimensional array:

```
X = rand(12,13,14);
Y = permute(X,[2 3 1]);
size(Y)
ans =
 13 14 12
```

**See Also** `ipermute` | `circshift` | `flip1r` | `flipud` | `reshape` | `shiftdim`

# persistent

---

**Purpose** Define persistent variable

**Syntax** `persistent X Y Z`

**Description** `persistent X Y Z` defines X, Y, and Z as variables that are local to the function in which they are declared; yet their values are retained in memory between calls to the function. Persistent variables are similar to global variables because the MATLAB software creates permanent storage for both. They differ from global variables in that persistent variables are known only to the function in which they are declared. This prevents persistent variables from being changed by other functions or from the MATLAB command line.

Whenever you clear or modify a function that is in memory, MATLAB also clears all persistent variables declared by that function. To keep a function in memory until MATLAB quits, use `mlock`.

If the persistent variable does not exist the first time you issue the `persistent` statement, it is initialized to the empty matrix.

It is an error to declare a variable persistent if a variable with the same name exists in the current workspace. MATLAB also errors if you declare any of a function's input or output arguments as persistent within that same function. For example, the following persistent declaration is invalid:

```
function myfun(argA, argB, argC)
persistent argB
```

**Tips** There is no function form of the `persistent` command (i.e., you cannot use parentheses and quote the variable names).

**Examples** This function writes a large array to a spreadsheet file and then reads several rows from the same file. Because you only need to write the array to the spreadsheet one time, the program tests whether an array can be read from the file and, if so, does not waste time in repeating that task. By defining the `dblArray` variable as persistent, you can easily check whether the array has been read from the spreadsheet file.

Here is the arrayToXLS function:

```
function arrayToXLS(A, xlsfile, x1, x2)
persistent dblArray;

if isempty(dblArray)
 disp 'Writing spreadsheet file ...'
 xlswrite(xlsfile, A);
end

disp 'Reading array from spreadsheet ...'
dblArray = xlsread(xlsfile, 'Sheet1', [x1 ':' x2])
fprintf('\n');
```

Run the function three times and observe the time elapsed for each run. The second and third run take approximately one tenth the time of the first run in which the function must create the spreadsheet:

```
largeArray = rand(4000, 200);

tic, arrayToXLS(largeArray, 'myTest.xls','E254', 'J256'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
 0.0982 0.3783 0.1264 0.7880 0.1902 0.5811
 0.2251 0.2704 0.5682 0.7271 0.8028 0.2834
 0.6453 0.5568 0.8254 0.4961 0.9096 0.5402
```

Elapsed time is 8.990525 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls','E257', 'J258'), toc
Reading array from spreadsheet ...
dblArray =
 0.4620 0.3781 0.6386 0.5930 0.0946 0.4865
 0.1605 0.1251 0.8709 0.5188 0.6702 0.2138
```

Elapsed time is 0.912534 seconds.

```
tic, arrayToXLS(largeArray, 'myTest.xls','E259', 'J262'), toc
Reading array from spreadsheet ...
dblArray =
 0.7015 0.6588 0.4023 0.0359 0.4512 0.6097
 0.1308 0.6441 0.0431 0.6396 0.7481 0.8688
 0.8278 0.2686 0.5475 0.8550 0.5896 0.1080
 0.9437 0.1671 0.0505 0.1203 0.2461 0.7306
```

Elapsed time is 0.928843 seconds.

Now clear the arrayToXLS function from memory and observe that running it takes much longer again:

```
clear functions
```

```
tic, arrayToXLS(largeArray, 'myTest.xls','E263', 'J264'), toc
Writing spreadsheet file ...
Reading array from spreadsheet ...
dblArray =
 0.6292 0.7788 0.0732 0.6481 0.9299 0.8631
 0.7700 0.5181 0.9805 0.5092 0.8658 0.4070
```

Elapsed time is 7.603461 seconds.

## See Also

**Purpose** Ratio of circle's circumference to its diameter

**Syntax** pi

**Description** pi returns the floating-point number nearest the value of  $\pi$ . The expressions `4*atan(1)` and `imag(log(-1))` provide the same value.

**Examples** Find the sine of  $\pi$ :

```
sin(pi)
```

```
returns
```

```
ans =
```

```
1.2246e-16
```

The expression `sin(pi)` is not exactly zero because `pi` is not exactly  $\pi$ .

# pie

---

## Purpose

Pie chart

## Syntax

```
pie(X)
pie(X,explode)
pie(...,labels)
pie(axes_handle,...)
h = pie(...)
```

## Description

`pie(X)` draws a pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If  $\text{sum}(X) = 1$ , then the values in `X` directly specify the area of the pie slices. `pie` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If the sum of the elements in `X` is greater than one, then `pie` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.

`pie(X,explode)` offsets a slice from the pie. `explode` is a vector or matrix of zeros and nonzeros that correspond to `X`. A nonzero value offsets the corresponding slice from the center of the pie chart, so that `X(i,j)` is offset from the center if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie(...)` returns a vector of handles to patch and text graphics objects.

## Examples

### Create Pie Chart

Create a pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];
figure
pie(x)
```

To offset the second and fourth pie slices, set the corresponding explode elements to 1.

```
explode = [0,1,0,1,0];
figure
pie(x,explode)
```

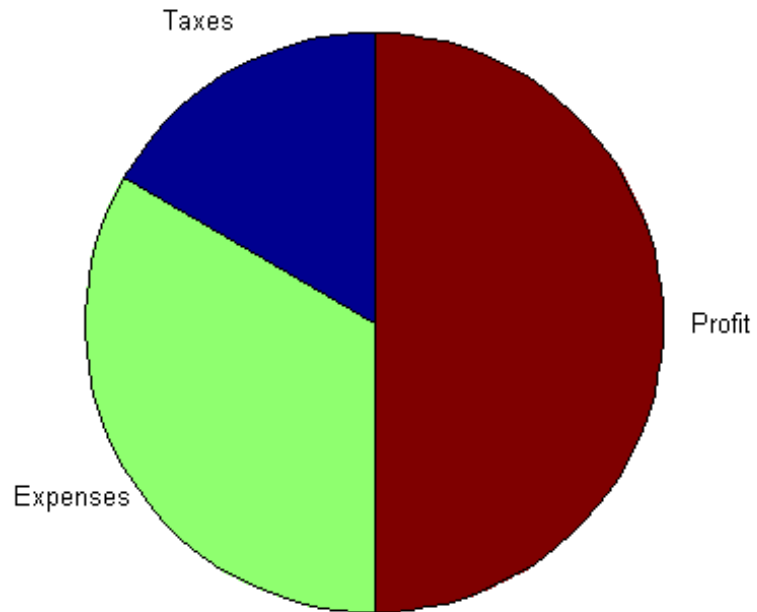

### Specify Text Labels for Pie Chart

Specify the text labels for a pie chart.

```
x = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
```

```
figure
pie(x, labels)
```

### Remove Piece From Pie Chart

Create a pie chart of `x`.

```
x = [0.19,0.22,0.41];
figure
pie(x)
```

Since the sum of the elements in `x` is less than 1, `pie` draws a partial pie.

## See Also

`pie3`

## How To

- “Offset Pie Slice with Greatest Contribution”
- “Label Pie Chart With Text and Percent Values”

**Purpose**

3-D pie chart

**Syntax**

```
pie3(X)
pie3(X,explode)
pie3(...,labels)
pie3(axes_handle,...)
h = pie3(...)
```

**Description**

`pie3(X)` draws a three-dimensional pie chart using the data in `X`. Each element in `X` is represented as a slice in the pie chart.

- If  $\text{sum}(X) = 1$ , then the values in `X` directly specify the area of the pie slices. `pie3` draws only a partial pie if  $\text{sum}(X) < 1$ .
- If the sum of the elements in `X` is greater than one, then `pie3` normalizes the values by  $X/\text{sum}(X)$  to determine the area of each slice of the pie.

`pie3(X,explode)` specifies whether to offset a slice from the center of the pie chart. `X(i,j)` is offset from the center of the pie chart if `explode(i,j)` is nonzero. `explode` must be the same size as `X`.

`pie3(...,labels)` specifies text labels for the slices. The number of labels must equal the number of elements in `X`.

`pie3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = pie3(...)` returns a vector of handles to patch, surface, and text graphics objects.

**Examples****Create 3-D Pie Chart**

Create a 3-D pie chart of vector `x`.

```
x = [1,3,0.5,2.5,2];
```

# pie3

---

```
figure
pie3(x);
```

To offset the second pie slice, set the corresponding `explode` element to 1.

```
explode = [0,1,0,0,0];
figure
pie3(x,explode)
```

### Specify Text Labels for 3-D Pie Chart

Create a 3-D pie chart and specify the text labels.

```
x = 1:3;
labels = {'Taxes', 'Expenses', 'Profit'};
```

```
figure
pie3(x, labels)
```

**See Also** [pie](#)

<b>Purpose</b>	Moore-Penrose pseudoinverse of matrix
<b>Syntax</b>	$B = \text{pinv}(A)$ $B = \text{pinv}(A, \text{tol})$
<b>Definitions</b>	<p>The Moore-Penrose pseudoinverse is a matrix <math>B</math> of the same dimensions as <math>A'</math> satisfying four conditions:</p> $A*B*A = A$ $B*A*B = B$ $A*B \text{ is Hermitian}$ $B*A \text{ is Hermitian}$ <p>The computation is based on <math>\text{svd}(A)</math> and any singular values less than <math>\text{tol}</math> are treated as zero.</p>
<b>Description</b>	<p><math>B = \text{pinv}(A)</math> returns the Moore-Penrose pseudoinverse of <math>A</math>.</p> <p><math>B = \text{pinv}(A, \text{tol})</math> returns the Moore-Penrose pseudoinverse and overrides the default tolerance, <math>\max(\text{size}(A)) * \text{norm}(A) * \text{eps}</math>.</p>
<b>Examples</b>	<p>If <math>A</math> is square and not singular, then <math>\text{pinv}(A)</math> is an expensive way to compute <math>\text{inv}(A)</math>. If <math>A</math> is not square, or is square and singular, then <math>\text{inv}(A)</math> does not exist. In these cases, <math>\text{pinv}(A)</math> has some of, but not all, the properties of <math>\text{inv}(A)</math>.</p> <p>If <math>A</math> has more rows than columns and is not of full rank, then the overdetermined least squares problem</p> $\text{minimize } \text{norm}(A*x-b)$ <p>does not have a unique solution. Two of the infinitely many solutions are</p> $x = \text{pinv}(A)*b$ <p>and</p> $y = A \setminus b$

These two are distinguished by the facts that  $\text{norm}(x)$  is smaller than the norm of any other solution and that  $y$  has the fewest possible nonzero components.

For example, the matrix generated by

```
A = magic(8); A = A(:,1:6)
```

is an 8-by-6 matrix that happens to have  $\text{rank}(A) = 3$ .

```
A =
 64 2 3 61 60 6
 9 55 54 12 13 51
 17 47 46 20 21 43
 40 26 27 37 36 30
 32 34 35 29 28 38
 41 23 22 44 45 19
 49 15 14 52 53 11
 8 58 59 5 4 62
```

The right-hand side is  $b = 260 \cdot \text{ones}(8, 1)$ ,

```
b =
 260
 260
 260
 260
 260
 260
 260
 260
 260
```

The scale factor 260 is the 8-by-8 magic sum. With all eight columns, one solution to  $A \cdot x = b$  would be a vector of all 1's. With only six columns, the equations are still consistent, so a solution exists, but it is not all 1's. Since the matrix is rank deficient, there are infinitely many solutions. Two of them are

```
x = pinv(A)*b
```

which is

```
x =
 1.1538
 1.4615
 1.3846
 1.3846
 1.4615
 1.1538
```

and

```
y = A\b
```

which produces this result.

```
Warning: Rank deficient, rank = 3 tol = 1.8829e-013.
```

```
y =
 4.0000
 5.0000
 0
 0
 0
 -1.0000
```

Both of these are exact solutions in the sense that  $\text{norm}(A*x-b)$  and  $\text{norm}(A*y-b)$  are on the order of roundoff error. The solution  $x$  is special because

```
norm(x) = 3.2817
```

is smaller than the norm of any other solution, including

```
norm(y) = 6.4807
```

On the other hand, the solution  $y$  is special because it has only three nonzero components.

# planerot

---

**Purpose** Givens plane rotation

**Syntax** `[G,y] = planerot(x)`

**Description** `[G,y] = planerot(x)` where  $x$  is a 2-component column vector, returns a 2-by-2 orthogonal matrix  $G$  so that  $y = G*x$  has  $y(2) = 0$ .

**Examples**

```
x = [3 4];
[G,y] = planerot(x')
```

```
G =
 0.6000 0.8000
 -0.8000 0.6000
```

```
y =
 5
 0
```

**See Also** `qrdelete` | `qrinsert`

**Purpose**

Play audio from audioplayer object

**Syntax**

```
play(playerObj)
play(playerObj, start)
play(playerObj, [start, stop])
```

**Description**

`play(playerObj)` plays the audio associated with audioplayer object `playerObj` from beginning to end.

`play(playerObj, start)` plays audio from the sample indicated by `start` to the end.

`play(playerObj, [start, stop])` plays audio from the sample indicated by `start` to the sample indicated by `stop`.

**Examples****Play with and without Blocking**

Play two audio samples with and without blocking using the `play` and `playblocking` methods.

Load data from example files `chirp.mat` and `gong.mat`.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y, chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y, gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

# audioplayer.play

---

## Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

play(playerObj,start);
```

## Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

play(playerObj,[start,stop]);
```

## See Also

## How To

- “Play Audio”

**Purpose** Play audio from audiorecorder object

**Syntax**

```
player = play(recObj)
player = play(recObj, start)
player = play(recObj, [start stop])
```

**Description**

*player* = play(*recObj*) plays the audio associated with audiorecorder object *recObj* from beginning to end, and returns an audioplayer object.

*player* = play(*recObj*, *start*) plays audio from the sample indicated by *start* to the end.

*player* = play(*recObj*, [*start stop*]) plays audio from the sample indicated by *start* to the sample indicated by *stop*.

**Examples** Record 5 seconds of your speech with a microphone, and play it back. Display the properties of the audioplayer object.

```
myVoice = audiorecorder;

disp('Start speaking. ');
recordblocking(myVoice, 5);
disp('End of recording. Playing back ...');

playerObj = play(myVoice);

disp('Properties of playerObj:');
get(playerObj)
```

---

Play back only the first 3 seconds of the speech recorded in the previous example:

```
play(myVoice, [1 myVoice.SampleRate*3]);
```

**See Also** audioplayer | audiorecorder

# audioplayer.playblocking

---

**Purpose** Play audio from audioplayer object, holding control until playback completes

**Syntax**

```
playblocking(playerObj)
playblocking(playerObj,start)
playblocking(playerObj,[start,stop])
```

**Description**

playblocking(playerObj) plays the audio associated with audioplayer object playerObj from beginning to end. playblocking does not return control until playback completes.

playblocking(playerObj,start) plays audio from the sample indicated by start to the end.

playblocking(playerObj,[start,stop]) plays audio from the sample indicated by start to the sample indicated by stop.

## **Examples**      **Play with and without Blocking**

Play two audio samples with and without blocking using the play and playblocking methods.

Load data from example files chirp.mat and gong.mat.

```
chirpData = load('chirp.mat');
chirpObj = audioplayer(chirpData.y,chirpData.Fs);
```

```
gongData = load('gong.mat');
gongObj = audioplayer(gongData.y,gongData.Fs);
```

Play the samples with blocking, one after the other.

```
playblocking(chirpObj);
playblocking(gongObj);
```

Play without blocking. The audio can overlap.

```
play(chirpObj);
play(gongObj);
```

## Starting Sample

Play audio from the example file `handel.mat` starting 4 seconds from the beginning.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = playerObj.SampleRate * 4;

playblocking(playerObj,start);
beep;
```

## Sample Range

Play the first 3 seconds of audio from the example file `handel.mat`.

```
load handel.mat;
playerObj = audioplayer(y,Fs);
start = 1;
stop = playerObj.SampleRate * 3;

playblocking(playerObj,[start,stop]);
beep;
```

## How To

- “Play Audio”

# plot

---

**Purpose** 2-D line plot

**Syntax**

```
plot(X,Y)
plot(X,Y,LineStyle)
plot(X1,Y1,...,Xn,Yn)
plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)

plot(Y)
plot(Y,LineStyle)

plot(__,Name,Value)
plot(axes_handle, __)

h = plot(__)
```

**Description** `plot(X,Y)` creates a 2-D line plot of the data in `Y` versus the corresponding values in `X`.

- If `X` and `Y` are both vectors, then they must have equal length and MATLAB plots `Y` versus `X`.
- If `X` and `Y` are both matrices, then they must have equal size and MATLAB plots columns of `Y` versus columns of `X`.
- If one of `X` or `Y` is a vector and the other is a matrix, then the matrix must have dimensions such that one of its dimensions equals the vector length. If the number of matrix rows equals the vector length, then MATLAB plots each matrix column versus the vector. If the number of matrix columns equals the vector length, then MATLAB plots each matrix row versus the vector. If the matrix is square, then MATLAB plots each column versus the vector.
- If one of `X` or `Y` is a scalar and the other is a vector, then MATLAB plots the vector as discrete points at the scalar value.

`plot(X,Y,LineStyle)` sets the line style, marker symbol, and color.

`plot(X1,Y1,...,Xn,Yn)` plots multiple X, Y pairs using the same axes for all lines.

`plot(X1,Y1,LineStyle1,...,Xn,Yn,LineStylen)` sets the line style, marker type, and color for each line. You can mix X, Y, LineSpec triplets with X, Y pairs. For example, `plot(X1,Y1,X2,Y2,LineStyle2,X3,Y3)`.

`plot(Y)` creates a 2-D line plot of the data in Y versus the index of each value.

- If Y is a vector, then the x-axis scale ranges from 1 to `length(Y)`.
- If Y is a matrix, then MATLAB plots the columns of Y versus their row number. The x-axis scale ranges from 1 to the number of rows in Y.
- If Y is complex, then MATLAB plots the imaginary part of Y versus the real part of Y, such that `plot(Y)` is equivalent to `plot(real(Y),imag(Y))`.

`plot(Y,LineStyle)` sets the line style, marker symbol, and color.

`plot(___,Name,Value)` specifies lineseries properties using one or more Name, Value pair arguments. Use this option with any of the input argument combinations in the previous syntaxes. Name, Value pair settings apply to all the lines plotted. You cannot specify different Name, Value pairs for each line using this syntax.

`plot(axes_handle, ___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle` can precede any of the input combinations in the previous syntaxes.

`h = plot(___)` returns a column vector of lineseries handles, where h contains one handle per line plotted. When multiple lines are present, you can make changes to properties of a specific line by specifying its handle.

# plot

---

## Input Arguments

### Y - Data values to plot

scalar | vector | matrix

Data values to plot, specified as a scalar, a vector, or a matrix. To plot against specific  $x$ -values you must also specify X.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

### X - Locations along the x-axis to plot data values in Y

scalar | vector | matrix

Locations along the  $x$ -axis to plot data values in Y, specified as a scalar, a vector, or a matrix. If you specify both X and Y input arguments, and if either X or Y is complex, then plot ignores the imaginary components.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### LineStyle - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. The elements of the string can appear in any order, and you can omit one or more options from the string specifier. If you omit the line style and specify the marker character, then the plot shows only the marker and no line.

If Y is a matrix and you specify a color with LineSpec, then all lines are plotted using the specified color. If you specify a marker type or line style and do not specify a color, then MATLAB cycles through the predefined color order.

**Example:** '- -or' is a red dashed line with circle markers

Specifier	Line Style
-	Solid line (default)
--	Dashed line
:	Dotted line
-.	Dash-dot line

Specifier	Marker
o	Circle
+	Plus sign
*	Asterisk
.	Point
x	Cross
s	Square
d	Diamond
^	Upward-pointing triangle
v	Downward-pointing triangle
>	Right-pointing triangle
<	Left-pointing triangle
p	Pentagram
h	Hexagram

Specifier	Color
y	yellow
m	magenta
c	cyan

Specifier	Color
r	red
g	green
b	blue
w	white
k	black

## **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

For a complete list of lineseries properties, see `lineseries` properties.

**Example:** `'Marker','o','MarkerFaceColor','red'`

## **'Color' - Color**

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'Color',[0 1 0]

Example: 'Color','green'

Example: 'Color','g'

### 'LineStyle' - Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as the comma-separated pair consisting of 'LineStyle' and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

**Example:** 'LineStyle','-.'

## 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. Specify the value in points, where one point equals 1/72 inches. If any markers are displayed, then LineWidth also sets the width of the marker edges.

**Example:** 'LineWidth',0.75

## 'Marker' - Marker symbol

'none' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. By default, a plot line does not have markers. You can add markers at each data point along the line by specifying a marker symbol.

This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

Specifier	Marker Symbol
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

'auto' (default) | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'

RGB Vector	Short Name	Long Name
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** `'MarkerEdgeColor',[1 .8 .1]`

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. `MarkerFaceColor` sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses the value of the axes <code>Color</code> property to fill the markers. If the axes <code>Color</code> property is 'none', then <code>plot</code> uses the figure <code>Color</code> value instead.
'none'	Makes the interior of the marker transparent, allowing the background to show through (default).

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

### 'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'MarkerSize',3.75

## Output Arguments

### h - One or more lineseries handles

scalar | vector

One or more lineseries handles, returned as a scalar or a vector. These are unique identifiers, which you can use to query and modify properties of a specific line.

## Examples

### Create Line Plot

Define  $x$  as a vector of linearly spaced values between 0 and  $2\pi$ . Use an increment of  $\pi/100$  between the values. Define  $y$  as sine values of  $x$ .

```
x = 0:pi/100:2*pi;
y = sin(x);
```

# plot

---

Create a line plot of the data.

```
figure % opens new figure window
plot(x,y)
```

## Plot Multiple Lines

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y_1$  and  $y_2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data.

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);

figure
plot(x,y1,x,y2)
```

# plot

## Create Line Plot From Matrix

Define  $Y$  as the 4-by-4 matrix returned by the `magic` function.

```
Y = magic(4)
```

```
Y =
```

```
 16 2 3 13
```

```
5 11 10 8
9 7 6 12
4 14 15 1
```

Create a 2-D line plot of Y. MATLAB® plots each matrix column as a separate line.

```
figure
plot(Y)
```

# plot

## Specify Line Style

Plot three sine curves with a small phase shift between each line. Use the default line style for the first line. Specify a dashed line style for the second line and a dotted line style for the third line.

```
x = 0:pi/100:2*pi;
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);
```

```
figure
plot(x,y1,x,y2,'--',x,y3,':')
```

MATLAB® cycles the line color through the default color order.

### **Specify Line Style, Color, and Marker**

Plot three sine curves with a small phase shift between each line. Use a green line with no markers for the first sine curve. Use a blue dashed

# plot

---

line with circle markers for the second sine curve. Use only cyan star markers for the third sine curve.

```
x = 0:pi/10:2*pi;
y1 = sin(x);
y2 = sin(x-0.25);
y3 = sin(x-0.5);

figure
plot(x,y1,'g',x,y2,'b-o',x,y3,'c*')
```

### Specify Line Width, Marker Size, and Marker Color

Create a line plot and use the `LineStyle` option to specify a dashed green line with square markers. Use `Name,Value` pairs to specify the line width, marker size, and marker colors. Set the marker edge color to blue and set the marker face color using an RGB color value.

```
x = -pi:pi/10:pi;
y = tan(sin(x)) - sin(tan(x));
```

# plot

```
figure
plot(x,y,'--gs',...
 'LineWidth',2,...
 'MarkerSize',10,...
 'MarkerEdgeColor','b',...
 'MarkerFaceColor',[0.5,0.5,0.5])
```

## Add Title and Axis Labels

Use the `linspace` function to define `x` as a vector of 150 values between 0 and 10. Define `y` as cosine values of `x`.

```
x = linspace(0,10,150);
y = cos(5*x);
```

Create a 2-D line plot of the cosine curve. Change the line color to a shade of blue-green using an RGB color value. Add a title and axis labels to the graph using the `title`, `xlabel`, and `ylabel` functions.

```
figure
plot(x,y,'Color',[0,0.7,0.9])

title('2-D Line Plot')
xlabel('x')
ylabel('cos(5x)')
```

## Specify Axes for Line Plot

Create a figure with two subplots and return the handle to each subplot axes, `s(1)` and `s(2)`.

```
figure; % new figure
s(1) = subplot(2,1,1); % top subplot
s(2) = subplot(2,1,2); % bottom subplot
```

Create a 2-D line plot in each axes by referring to the axes handles. Add a title and  $y$ -axis label to each axes by passing the axes handles to the `title` and `ylabel` functions.

```
x = linspace(0,3);
y1 = sin(5*x);
y2 = sin(15*x);

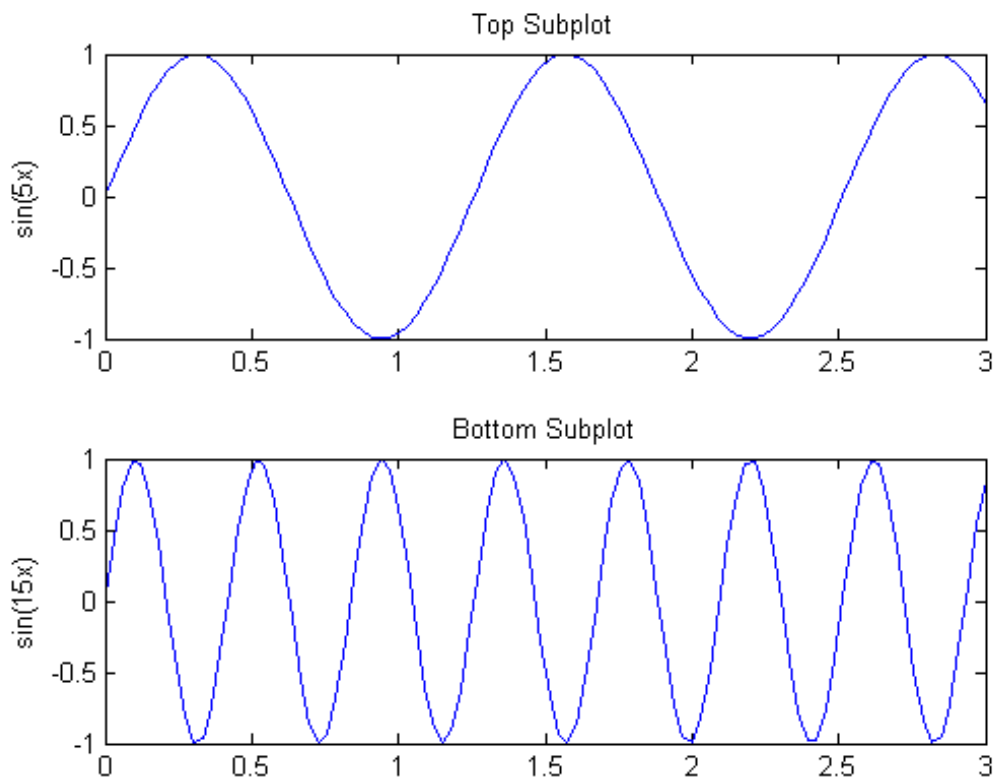

plot(s(1),x,y1)
title(s(1),'Top Subplot')
```

# plot

---

```
ylabel(s(1), 'sin(5x)')

plot(s(2), x, y2)
title(s(2), 'Bottom Subplot')
ylabel(s(2), 'sin(15x)')
```

## Change Line Properties Using Handles

Define  $x$  as 100 linearly spaced values between  $-2\pi$  and  $2\pi$ . Define  $y_1$  and  $y_2$  as sine and cosine values of  $x$ . Create a line plot of both sets of data and return the handles of the two lines in  $h$ .

```
x = linspace(-2*pi,2*pi);
y1 = sin(x);
y2 = cos(x);

figure
h = plot(x,y1,x,y2);
```

# plot

---

Use the handle of the first line, `h(1)`, to change the line width to 2.  
Use the handle of the second line, `h(2)`, to add star markers to the plotted line.

```
set(h(1), 'LineWidth', 2);
set(h(2), 'Marker', '*');
```

**Tips**

- `plot` automatically chooses colors and line styles in the order specified by the `ColorOrder` and `LineStyleOrder` properties of the current axes. `plot` cycles through the color order with the first line style. Then, `plot` cycles through it again with each additional line style.

To change the color and line style orders for the current axes, set the `ColorOrder` and `LineStyleOrder` axes properties. If you do not specify these properties, then `plot` uses the default values. For

# plot

---

example, to set the line style order for the current axes to a solid line with asterisk markers, a dotted line, and circle markers with no line, use this command:

```
set(gca, 'LineStyleOrder', '-*|:|o')
```

- Data can include NaN and inf values, which cause breaks in the lines drawn. For example, this code plots the first two elements, skips the third element, and draws another line using the last two elements:  
`plot([1,2,NaN,4,5]).`

## See Also

`title` | `xlabel` | `ylabel` | `xlim` | `ylim` | `legend` | `hold` | `LineStyleOrder` | `gca`

**Purpose**

3-D line plot

**Syntax**

```
plot3(X1,Y1,Z1,...)
plot3(X1,Y1,Z1,LineStyle,...)
plot3(...,'PropertyName',PropertyValue,...)
plot3(axes_handle,...)
h = plot3(...)
```

**Description**

The `plot3` function displays a three-dimensional plot of a set of data points.

`plot3(X1,Y1,Z1,...)`, where `X1`, `Y1`, `Z1` are vectors or matrices, plots one or more lines in three-dimensional space through the points whose coordinates are the elements of `X1`, `Y1`, and `Z1`.

`plot3(X1,Y1,Z1,LineStyle,...)` creates and displays all lines defined by the `Xn`, `Yn`, `Zn`, `LineStyle` quads, where `LineStyle` is a line specification that determines line style, marker symbol, and color of the plotted lines.

`plot3(...,'PropertyName',PropertyValue,...)` sets line properties to the specified property values for all the lines created by `plot3`. See `lineseries` properties for a description of the properties you can set.

`plot3(axes_handle,...)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle` can precede any of the input combinations in the previous syntaxes.

`h = plot3(...)` returns a column vector of `lineseries` handles, with one handle per object.

**Tips**

If one or more of `X1`, `Y1`, `Z1` is a vector, the vectors are plotted versus the rows or columns of the matrix, depending whether the vectors' lengths equal the number of rows or the number of columns.

# plot3

---

You can mix  $X_n, Y_n, Z_n$  triples with  $X_n, Y_n, Z_n, \text{LineStyle}$  quads, for example,

```
plot3(X1,Y1,Z1,X2,Y2,Z2,LineStyle,X3,Y3,Z3)
```

See `LineStyle` and `plot` for information on line types and markers.

## Examples

### Plot 3-D Helix

Define  $t$  as values between 0 and  $10\pi$ . Define  $st$  and  $ct$  as vectors of sine and cosine values. Plot a 3-D helix.

```
t = 0:pi/50:10*pi;
st = sin(t);
ct = cos(t);
```

```
figure
plot3(st,ct,t)
```

**See Also**

[axis](#) | [bar3](#) | [grid](#) | [line](#) | [LineStyle](#) | [loglog](#) | [plot](#) | [scatter3](#) | [semilogx](#) | [semilogy](#) | [subplot](#)

**Purpose** Show or hide figure **Plot Browser**

**Syntax**

```
plotbrowser('on')
plotbrowser('off')
plotbrowser
plotbrowser(figure_handle,...)
```

**Description**

`plotbrowser('on')` displays the Plot Browser on the current figure.

`plotbrowser('off')` hides the Plot Browser on the current figure.

`plotbrowser` toggles the visibility of the Plot Browser on the current figure. You can use `plotbrowser('toggle')` instead for the same functionality.

`plotbrowser(figure_handle,...)` shows or hides the Plot Browser on the figure specified by *figure\_handle*.

**Tips**

If you call `plotbrowser` in a MATLAB program and subsequent lines depend on the Plot Browser being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives**

To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**, use the smaller icon . Open or close the **Plot Browser** tool from the figure's **View** menu.

**See Also** `plottools` | `figurepalette` | `propertyeditor`

**Purpose** Interactively edit and annotate plots

**Syntax**

```
plottedit on
plottedit off
plottedit
plottedit(h)
plottedit('state')
plottedit(h,'state')
```

**Description** `plottedit on` starts plot edit mode for the current figure, allowing you to use a graphical interface to annotate and edit plots easily. In plot edit mode, you can label axes, change line styles, and add text, line, and arrow annotations.

`plottedit off` ends plot mode for the current figure.

`plottedit` toggles the plot edit mode for the current figure.

`plottedit(h)` toggles the plot edit mode for the figure specified by figure handle `h`.

`plottedit('state')` specifies the `plottedit` state for the current figure. Values for `state` can be as shown.

Value for state	Description
on	Starts plot edit mode
off	Ends plot edit mode
showtoolsmenu	Displays the <b>Tools</b> menu in the menu bar
hidetoolsmenu	Removes the <b>Tools</b> menu from the menu bar

**Note** `hidetoolsmenu` is intended for GUI developers who do not want the **Tools** menu to appear in applications that use the figure window.

`plottedit(h, 'state')` specifies the plottedit state for figure handle `h`.

## Tips

### Plot Editing Mode Graphical Interface Components

To start plot edit mode, click this button.

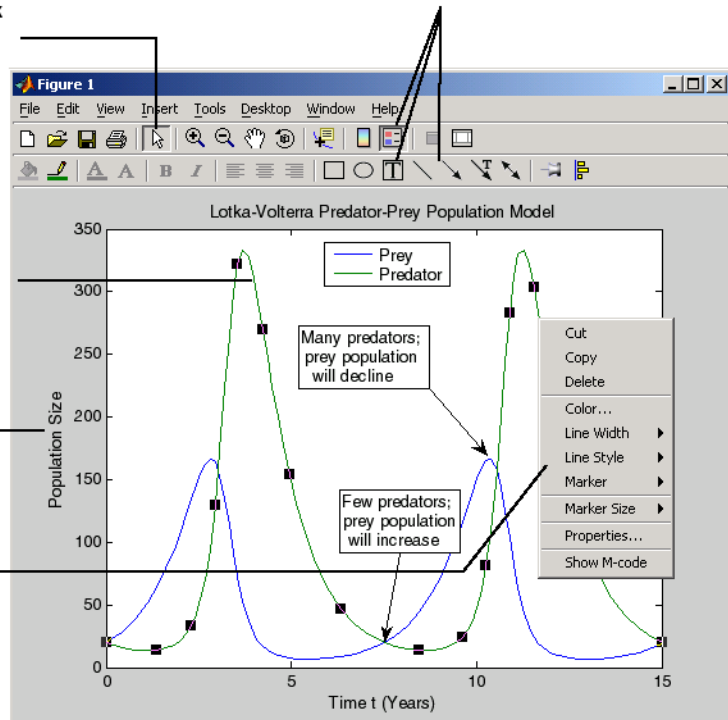

Use these toolbar buttons to add a legend, text, and arrows.

Use the **Edit**, **Insert**, and **Tools** menus to add objects or edit existing objects in a graph.

Double-click on an object to select it.

Position labels, legends, and other objects by clicking and dragging.

Access object-specific plot edit functions through context-sensitive pop-up menus.

## Examples

Start plot edit mode for figure 2.

```
plottedit(2)
```

End plot edit mode for figure 2.

```
plottedit(2, 'off')
```

Hide the **Tools** menu for the current figure:

```
plottedit('hidetoolsmenu')
```

# plotmatrix

---

**Purpose** Scatter plot matrix

**Syntax** `plotmatrix(X,Y)`  
`plotmatrix(X)`  
`plotmatrix( ___,LineStyle)`

`[H,AX,BigAx,P,PAx] = plotmatrix( __ )`

**Description** `plotmatrix(X,Y)` creates a matrix of subaxes containing scatter plots of the columns of  $X$  against the columns of  $Y$ . If  $X$  is  $p$ -by- $n$  and  $Y$  is  $p$ -by- $m$ , then `plotmatrix` produces an  $n$ -by- $m$  matrix of subaxes.

`plotmatrix(X)` is the same as `plotmatrix(X,X)` except that the subaxes along the diagonal are replaced with histogram plots of the data in the corresponding column of  $X$ . For example, the subaxes along the diagonal in the  $i$ th column is replaced by `hist(X(:,i))`.

`plotmatrix( ___,LineStyle)` specifies the line style, marker symbol, and color for the scatter plots. The option `LineStyle` can be preceded by any of the input argument combinations in the previous syntaxes.

`[H,AX,BigAx,P,PAx] = plotmatrix( __ )` returns handles to the graphic objects created as follows:

- `H` – Matrix of handles to the line objects used to create the scatter plots
- `AX` – Matrix of handles to the individual subaxes
- `BigAx` – Handle to the big axes that frames the subaxes
- `P` – Vector of handles for the patch objects that create the histogram plots
- `PAx` – Vector of handles to the invisible histogram axes

`BigAx` is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

## Input Arguments

### X - Data to display

matrix

Data to display, specified as a matrix.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### Y - Data to plot against X

matrix

Data to plot against X, specified as a matrix.

#### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### LineStyle - Line style, marker symbol, and color for scatter plots

string

Line style, marker symbol, and color for the scatter plots, specified as a string. For more information on line style, marker symbol, and color options see LineSpec.

**Example:** `':*r'`

#### Data Types

char

## Output Arguments

### H - Line object handles

matrix

Line object handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific line object. The line objects are used to create the scatter plots.

### AX - Subaxes handles

matrix

Subaxes handles, returned as a matrix. This is a unique identifier, which you can use to query and modify the properties of a specific subaxes.

## **BigAx - Big axes handle**

scalar

Big axes handle, returned as a scalar. This is a unique identifier, which you can use to query and modify properties of the big axes. **BigAx** is left as the current axes (`gca`) so that a subsequent `title`, `xlabel`, or `ylabel` command will center text with respect to the big axes.

## **P - Patch object handles**

vector | []

Patch object handles, returned as a vector or []. If histogram plots are created, then **P** is returned as a vector of patch object handles for the histogram plots. These are unique identifiers, which you can use to query and modify the properties of a specific patch object. If no histogram plots are created, then **P** is returned as empty brackets.

## **PAX - Handle to invisible histogram axes**

vector | []

Handle to invisible histogram axes, returned as a vector or []. If histogram plots are created, then **PAX** is returned as a vector of histogram axes handles. These are unique identifiers, which you can use to query and modify the properties of a specific axes, such as the axes scale. If no histogram plots are created, then **PAX** is returned as empty brackets.

## **Examples**

### **Create Scatter Plot Matrix with Two Matrix Inputs**

Initialize the random-number generator to make the output of `randn` repeatable. Define **X** as a matrix of normally distributed pseudorandom data and **Y** as a matrix of integer values.

```
rng(0,'twister');
X = randn(50,3);
```

```
Y = reshape(1:150,50,3);
```

Create a scatter plot matrix of the columns of X against the columns of Y.

```
figure
plotmatrix(X,Y)
```

The subplot in the  $i$ th row,  $j$ th column of the figure is a scatter plot of the  $i$ th column of Y against the  $j$ th column of X.

## Create Scatter Plot Matrix with One Matrix Input

Initialize the random-number generator to make the output of `randn` repeatable and generate a matrix of normally distributed pseudorandom data

```
rng(0, 'twister');
X = randn(50,3);
```

Create a scatter plot matrix.

```
figure
plotmatrix(X)
```

The subplot in the  $i$ th row,  $j$ th column of the matrix is a scatter plot of the  $i$ th column of  $X$  against the  $j$ th column of  $X$ . Along the diagonal, `plotmatrix` creates a histogram plot of each column of  $X$ .

### **Specify Marker Type and Color**

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

# plotmatrix

---

```
rng(0,'twister');
X = randn(50,3);
```

Create a scatter plot matrix and specify the marker type and the color for the scatter plots.

```
figure
plotmatrix(X, '*r')
```

The `LineStyle` option sets properties for the scatter plots. To set properties for the histogram plots, use the patch object handles.

### **Set Plotmatrix Properties Using Handles**

Initialize the random-number generator to make the output of `randn` repeatable. Generate a matrix of normally distributed pseudorandom data.

```
rng(0, 'twister');
X = randn(50,3);
```

Create a scatter plot matrix and return the object handles and the axes handles.

```
figure
[H,AX,BigAx,P,PAx] = plotmatrix(X);
```

# plotmatrix

---

To set properties for the scatter plots, use the handles in H. To set properties for the histograms, use the patch handles in P. To set axes properties, use the axes handles, AX, BigAX, and PAX.

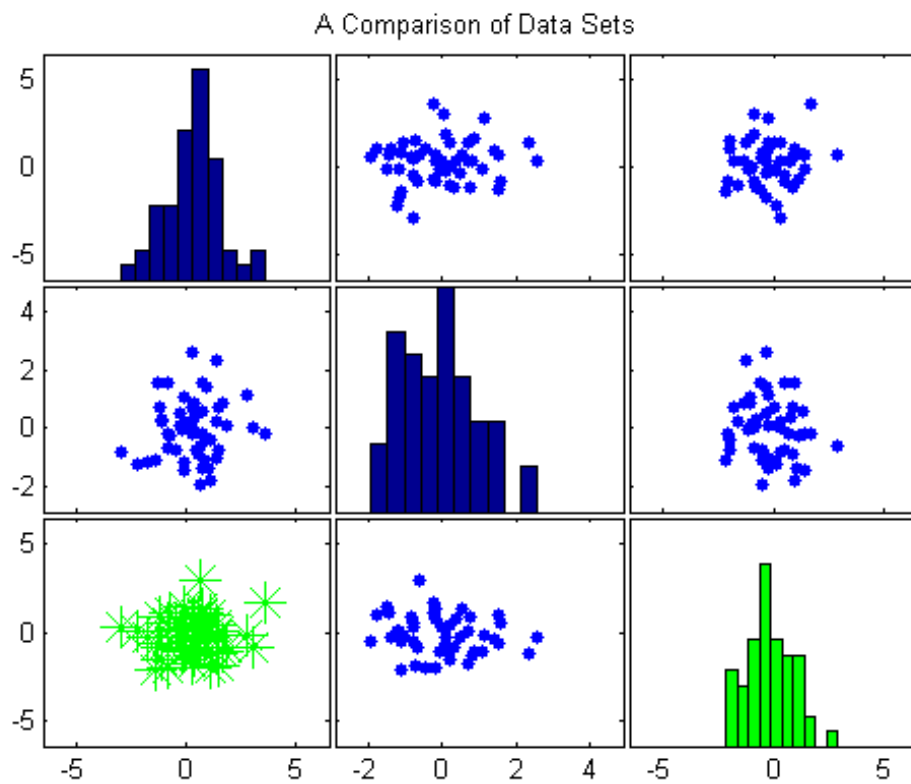

Set the color and marker type for the scatter plot in the lower left corner.

```
set(H(3), 'Color', 'g', 'Marker', '*');
```

Set the color for the histogram plot in the lower right corner. Use the `title` command to title the figure.

```
set(P(3),'EdgeColor','k','FaceColor','g');
title(BigAx,'A Comparison of Data Sets');
```

**See Also** [scatter](#) | [scatter3](#)

**Purpose** Show or hide plot tools

**Syntax**

```

plottools('on')
plottools('off')
plottools
plottools(figure_handle,...)
plottools(..., 'tool')

```

**Description**

`plottools('on')` displays the Figure Palette, Plot Browser, and Property Editor on the current figure, configured as you last used them.

`plottools('off')` hides the Figure Palette, Plot Browser, and Property Editor on the current figure.

`plottools` with no arguments, is the same as `plottools('on')`

# plottools

---

`plottools(figure_handle, ...)` displays or hides the plot tools on the specified figure instead of on the current figure.

`plottools(..., 'tool')` operates on the specified tool only. *tool* can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

---

**Note** The first time you open the plotting tools, all three of them appear, grouped around the current figure as shown above. If you close, move, or undock any of the tools, MATLAB remembers the configuration you left them in and restores it when you invoke the tools for subsequent figures, both within and across MATLAB sessions.

---

## Alternatives

Click the larger **Plotting Tools** icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

## See Also

`figurepalette` | `plotbrowser` | `propertyeditor`

## Purpose

2-D line plots with y-axes on both left and right side

## Syntax

```
plotyy(X1,Y1,X2,Y2)
plotyy(X1,Y1,X2,Y2,function)
plotyy(X1,Y1,X2,Y2,'function1','function2')
[AX,H1,H2] = plotyy(...)
```

## Description

`plotyy(X1,Y1,X2,Y2)` plots  $X1$  versus  $Y1$  with  $y$ -axis labeling on the left and plots  $X2$  versus  $Y2$  with  $y$ -axis labeling on the right.

`plotyy(X1,Y1,X2,Y2,function)` uses the specified plotting function to produce the graph.

`function` can be either a function handle or a string specifying `plot`, `semilogx`, `semilogy`, `loglog`, `stem`, or any MATLAB function that accepts the syntax

```
h = function(x,y)
```

For example,

```
plotyy(x1,y1,x2,y2,@loglog) % function handle
plotyy(x1,y1,x2,y2,'loglog') % string
```

Function handles enable you to access user-defined local functions and can provide other advantages. See `@` for more information on using function handles.

`plotyy(X1,Y1,X2,Y2,'function1','function2')` uses `function1(X1,Y1)` to plot the data for the left axis and `function2(X2,Y2)` to plot the data for the right axis.

`[AX,H1,H2] = plotyy(...)` returns the handles of the two axes created in `AX` and the handles of the graphics objects from each plot in `H1` and `H2`. `AX(1)` is the left axes and `AX(2)` is the right axes.

## Examples

### Plot Two Data Sets with Different y-Axes

Plot two data sets on one graph using two y-axes.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
figure % new figure
plotyy(x,y1,x,y2);
```

## Add Title and Axis Labels

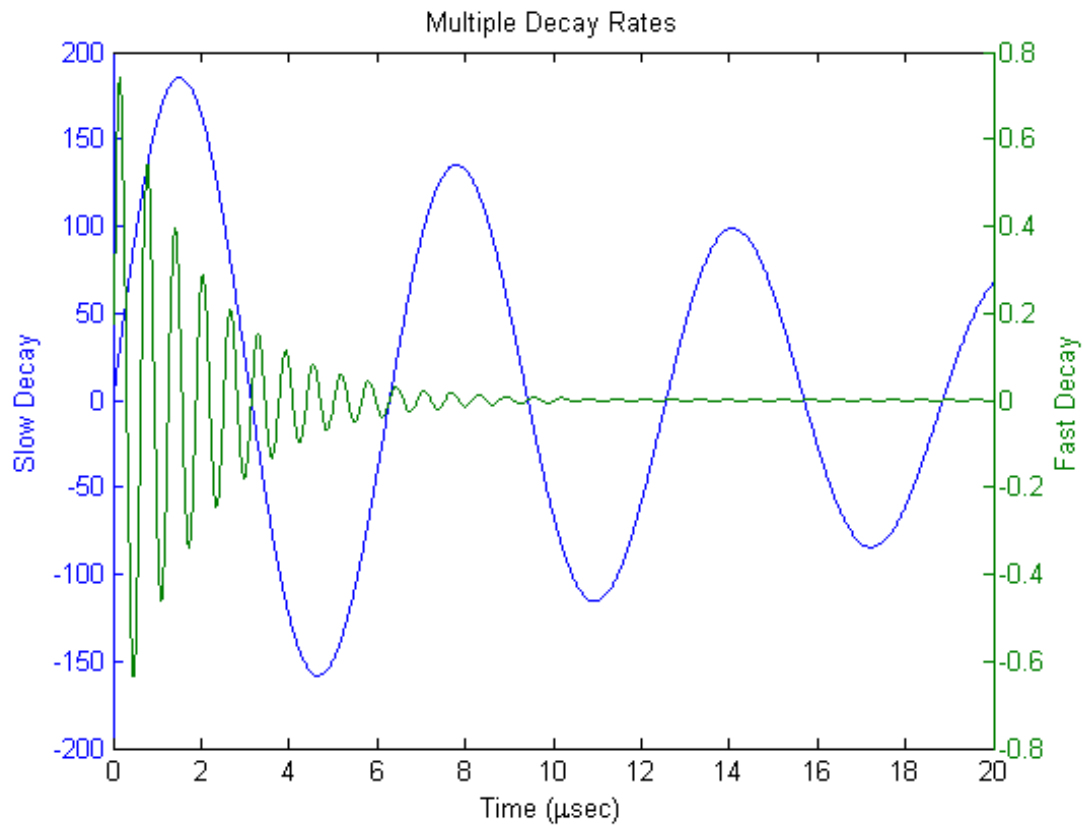

Plot two data sets using a graph with two y-axes. Add a title and axis labels.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure % new figure
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);

title('Multiple Decay Rates')
xlabel('Time (\musec)')

ylabel(hAx(1),'Slow Decay') % left y-axis
ylabel(hAx(2),'Fast Decay') % right y-axis
```

## Change Line Styles

Plot two data sets using a graph with two y-axes. Change the line styles.

```
x = 0:0.01:20;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
```

```
figure % new figure
[hAx,hLine1,hLine2] = plotyy(x,y1,x,y2);
```

```
set(hLine1,'LineStyle','--')
set(hLine2,'LineStyle',':')
```

### Combine Different Types of Plots

Plot two data sets using a graph with two y-axes. Use a line plot for the data associated with the left y-axis. Use a stem plot for the data associated with the right y-axis.

# plotyy

```
x = 0:0.1:10;
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);

figure
plotyy(x,y1,x,y2,'plot','stem');
```

### Use Right y-Axis for Two Data Sets

Plot three data sets using a graph with two y-axes. Plot one set of data associated with the left y-axis. Plot two sets of data associated with the right y-axis by using two-column matrices.

```
x = linspace(0,10);
y1 = 200*exp(-0.05*x).*sin(x);
y2 = 0.8*exp(-0.5*x).*sin(10*x);
y3 = 0.2*exp(-0.5*x).*sin(10*x);

figure
[hAx,hLine1,hLine2] = plotyy(x,y1,[x',x'],[y2',y3']);
```

## How To

- “Create Graph with Two y-Axes”
- “Graph with Multiple x-Axes and y-Axes”

## Purpose

Summary of classes in MATLAB Plugins Interface

## Description

Plugins customize a TestRunner object. The matlab.unittest.plugins package consists of the following customized MATLAB plugins.

matlab.unittest.plugins.DiagnosticsValidationPlugin Validate diagnostic code

matlab.unittest.plugins.FailureDiagnosticsPlugin Show diagnostics on failure

matlab.unittest.plugins.OutputStreamInterface Interface that determines where to send text output

matlab.unittest.plugins.StopOnFailurePlugin Debug test failures

matlab.unittest.plugins.TAPPlugin Plugin that produces Test Anything Protocol stream

matlab.unittest.plugins.TestRunnerPlugin Interface for extending TestRunner

matlab.unittest.plugins.TestSuiteProgressPlugin Outputs progress information as text

matlab.unittest.plugins.ToFile Output stream to write text output to file

matlab.unittest.plugins.ToStandardOutput Output stream to display text information to screen

## Related Examples

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.DiagnosticsValidationPlugin

---

<b>Purpose</b>	Plugin to help validate diagnostic code
<b>Description</b>	<p>The <code>DiagnosticsValidationPlugin</code> creates a plugin to help validate diagnostic code.</p> <p>Add the <code>DiagnosticsValidationPlugin</code> to the <code>TestRunner</code> to confirm that user-supplied diagnostics execute correctly. This plugin is useful because typically tests do not encounter failure conditions. A failure can result in unexercised diagnostic code. If a programming error exists in this diagnostic code, the error is not evident unless the test fails. However, at this point in the testing process, the diagnostics for the failure condition are lost due to the error in the diagnostic code.</p> <p>Use this plugin to unconditionally evaluate the diagnostics supplied by the test writer, regardless of whether the test results in a passing or failing condition. This approach helps you to confirm that all of the diagnostic code is free from programming errors.</p> <p>The diagnostic analysis can reduce the test performance and can result in very verbose text output. Be aware of these impacts before using this plugin for routine testing.</p>
<b>Construction</b>	<p><code>matlab.unittest.plugins.DiagnosticsValidationPlugin</code> creates a plugin to help validate diagnostic code.</p> <p><code>matlab.unittest.plugins.DiagnosticsValidationPlugin(stream)</code> redirects all the text output to the output stream, <code>stream</code>. If you do not specify the output stream, the plugin uses the default <code>ToStandardOutput</code> stream.</p>
<b>Input Arguments</b>	<p><b>stream</b></p> <p>Location where the plugin directs text output, specified as an <code>OutputStream</code>.</p> <p><b>Default:</b> <code>ToStandardOutput</code></p>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects</a> in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

In your working folder, create a file, `ExampleTest.m`, containing the following test class. In this example, the `testThree` method has an intentional error. The method should use a function handle to the `dir` function as a `FunctionHandleDiagnostic`, but `dir` is misspelled.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 function testThree(testCase)
 % The following should use @dir as a function handle,
 % but there is a typo
 testCase.verifyEqual('myfile','myfile', @dri);
 end
 end
end
```

All of the tests in `ExampleTest.m` result in a passing condition, but there is an error in the diagnostic.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.DiagnosticsValidationPlugin;

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withTextOutput;
```

# matlab.unittest.plugins.DiagnosticsValidationPlugin

---

Run the tests.

```
result1 = runner.run(suite);
```

```
Running ExampleTest
```

```
...
```

```
Done ExampleTest
```

---

No diagnostic output is displayed because all the tests passed. The testing framework does not encounter the bug in the `FunctionHandleDiagnostic` of `testThree`.

Add `DiagnosticsValidationPlugin` to the runner and run the tests.

```
runner.addPlugin(DiagnosticsValidationPlugin);
result2 = runner.run(suite);
```

```
Running ExampleTest
```

```
..
```

```

Validation of Test Diagnostic:

```

```
Error occurred while capturing diagnostics:
```

```
Error using evalc
```

```
Undefined function or variable 'dri'.
```

```
Error in ExampleTest/testThree (line 12)
```

```
 testCase.verifyEqual('myfile','myfile', @dri);
```

```
.
```

```
Done ExampleTest
```

---

The framework executes the diagnostic provided by the `FunctionHandleDiagnostic`, even though none of the tests fails. Without this plugin, the test framework only encounters the bug if the test fails.

# matlab.unittest.plugins.DiagnosticsValidationPlugin

---

## Concepts

# matlab.unittest.plugins.FailureDiagnosticsPlugin

---

<b>Purpose</b>	Plugin to show diagnostics on failure
<b>Description</b>	The <code>FailureDiagnosticsPlugin</code> creates a plugin to show diagnostics upon encountering a test failure. Add it to the <code>TestRunner</code> to output test failure diagnostics to the Command Window. This plugin is used by default when you construct a test runner using <code>TestRunner.withTextOutput</code> .
<b>Construction</b>	<code>matlab.unittest.plugins.FailureDiagnosticsPlugin</code> creates a plugin to show diagnostics upon encountering a test failure.  <code>matlab.unittest.plugins.DFailureDiagnosticsPlugin(stream)</code> redirects all the text output to the output stream, <code>stream</code> . If you do not specify the output stream, the plugin uses the <code>ToStandardOutput</code> stream.
<b>Input Arguments</b>	<b>stream</b>  Location where the plugin directs text output, specified as an <code>OutputStream</code> .  <b>Default:</b> <code>ToStandardOutput</code>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects</a> in the MATLAB documentation.
<b>Examples</b>	<b>Add Plugin to TestRunner</b>  In your working folder, create a file, <code>ExampleTest.m</code> , containing the following test class.  <pre>classdef ExampleTest &lt; matlab.unittest.TestCase     methods(Test)         function testPathAdd(testCase)             % test code         end         function testOne(testCase) % Test fails     end end</pre>

# matlab.unittest.plugins.FailureDiagnosticsPlugin

---

```
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
end
end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.FailureDiagnosticsPlugin;

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Run the tests.

```
result1 = runner.run(suite);
```

No output is displayed, but `result1` contains information about the failed test.

Add `FailureDiagnosticsPlugin` to the runner and run the tests.

```
runner.addPlugin(FailureDiagnosticsPlugin);
result2 = runner.run(suite);
```

```
=====
Verification failed in ExampleTest/testOne.
```

# matlab.unittest.plugins.FailureDiagnosticsPlugin

---

```

Test Diagnostic:

Testing 5==4

Framework Diagnostic:

verifyEqual failed.
--> The values are not equal using "isequaln".

Actual Value:
 5
Expected Value:
 4
```

```

Stack Information:

In C:\work\ExampleTest.m (ExampleTest.testOne) at 7
```

=====  
Failure Summary:

Name	Failed	Incomplete	Reason(s)
ExampleTest/testOne	X		Failed by verification.

The framework displays the `DiagnosticResult` of the `StringDiagnostic` for failed tests only. It also displays additional framework diagnostics. The `TestResult` object, `result2`, is the same as `result1`.

## See Also

## Concepts

## Purpose

Interface that determines where to send text output

## Description

The OutputStream interface is an abstract interface class that you can use as a base class to specify where plugins direct their text output. To create a custom output stream, implement a `print` method that correctly handles the formatted text information the testing framework passes to it. Many text-oriented plugins accept an OutputStream to redirect the text they produce in a configurable manner.

## Methods

`print` Print string to output stream

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Create Custom Output Stream

In a file in your working directory, create a new output stream class in the file `ToFigure.m`. This class allows plugin output to be redirected to a figure.

```
classdef ToFigure < matlab.unittest.plugins.OutputStream

 properties(SetAccess=private)
 Figure
 end
 properties(Dependent, Access=private)
 CurrentText
 end
 properties(Access=private)
 ListBox
 end
```

This class uses three properties. `Figure` is the figure that receives and displays the output. `CurrentText` is the current text displayed in the list box and a dependent property that you can use to easily access

# matlab.unittest.plugins.OutputStream

---

and set the current text in the list box. `ListBox` is a handle to the list box that displays the text.

In the same file, add the following methods block.

```
methods
 function print(stream, formatSpec, varargin)
 if isempty(stream.Figure) || ~ishghandle(stream.Figure)
 stream.createFigure;
 end
 newStr = sprintf(formatSpec, varargin{:});
 str = sprintf('%s%s', stream.CurrentText, newStr);
 stream.CurrentText = str;
 end

 function str = get.CurrentText(stream)
 strCell = cellstr(get(stream.ListBox, 'String'));
 str = strjoin(strCell, '\n');
 end

 function set.CurrentText(stream, str)
 strCell = strsplit(str, '\n');
 set(stream.ListBox, 'String', strCell, 'ListBoxTop', numel(str));
 drawnow;
 end
end
```

You must implement the `print` method for any subclass of `OutputStream`. In this example, the method creates a new figure (if necessary), formats the incoming text, and then adds it to the output stream. The `get.CurrentText` function gets the text from the list box on the figure. The `set.CurrentText` function adds the text onto the list box on the figure.

In the same file, add the following methods block containing a helper function to create the figure.

```
methods(Access=private)
```

```
function createFigure(stream)
 stream.Figure = figure;
 stream.ListBox = uicontrol(...
 'Parent', stream.Figure, ...
 'Style', 'listbox', ...
 'Units', 'normalized', ...
 'Position', [.05 .05 .9 .9], ...
 'Max', 2, ...
 'FontSize', 13, ...
 'HorizontalAlignment', 'left');
 end
end
end
```

In a new file in your working folder, create `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestSuite;
```

# matlab.unittest.plugins.OutputStream

---

```
import matlab.unittest.TestRunner;
import matlab.unittest.plugins.DiagnosticsValidationPlugin;
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `DiagnosticsValidationPlugin` that explicitly specifies that its output should go to a figure via the `ToFigure` output stream.

```
plugin = DiagnosticsValidationPlugin(ToFigure);
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin);
result = runner.run(suite);
```

```
Running ExampleTest
```

```

```

...

```
Done ExampleTest
```

---

Failure Summary:

Name	Failed	Incomplete	Reason(s)
ExampleTest/testOne	X		Failed by verification.

Only the test failures produce output to the screen. By default, `TestRunner.withTextOutput` uses a `FailureDiagnosticsPlugin` to display output on the screen.

In addition to the default text output being displayed on the screen, the `DiagnosticsValidationPlugin` output is directed to a figure. The figure shows the following text.

```

Validation of Test Diagnostic:

Testing 5==4

Validation of Test Diagnostic:

Testing 5==5
```

The `DiagnosticsValidationPlugin` displays the diagnostic information regardless of whether the tests encounter failure conditions.

# matlab.unittest.plugins.OutputStream

---

## See Also

[matlab.unittest.plugins](#)

## Concepts

**Purpose**

Print string to output stream

**Syntax**

```
print(stream,formatSpec,A1,...,An)
```

**Description**

`print(stream,formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec`, and sends the result to the output stream, `stream`. Assign `formatSpec` and `A1,...,An` using the same interface that you use for `sprintf` and `fprintf`.

**Input Arguments****stream**

Output stream, specified as an instance of the `OutputStream` class

**formatSpec**

Format of text in output stream, specified as a string. For information on the construction of `formatSpec` string, see the input argument entry on the `fprintf` or `sprint` reference pages.

**A**

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

**See Also**

`fprintf` | `sprintf`

# matlab.unittest.plugins.StopOnFailuresPlugin

---

**Purpose** Plugin to debug test failures

**Description** The `StopOnFailuresPlugin` class provides a plugin to help debug test failures. Adding `StopOnFailuresPlugin` to the test runner pauses execution of a test if it encounters a qualification failure or uncaught error and puts MATLAB into debug mode.

If `StopOnFailuresPlugin` encounters a qualification failure or uncaught error in a test, you can use MATLAB debugging commands, such as `dbup`, `dbstep`, `dbcont`, and `dbquit`, to investigate the cause of the test failure.

If `StopOnFailuresPlugin` encounters an uncaught error in a test, you cannot use `dbup` to shift context to the source of the error because the error disrupts the stack.

**Construction** `matlab.unittest.plugins.StopOnFailuresPlugin` creates a plugin to debug test failures.

`matlab.unittest.plugins.StopOnFailuresPlugin('IncludingAssumptionFailures',tf)` indicates whether to react to assumption failures. By default, `StopOnFailuresPlugin` reacts to only uncaught errors and verification, assertion, and fatal assertion qualification errors. However, when `'IncludingAssumptionFailures'` is set to `true`, the plugin also reacts to assumption failures.

## Input Arguments

### **tf** - Indicator to react to assumption failures

FALSE (default) | TRUE

Indicator to react to assumption failures, specified as logical `false` or `true`. When this value is `true`, the test runner reacts to assumption failures. When the value is `false`, the plugin ignores assumption failures.

## Properties

### IncludeAssumptionFailures

When this property value is `true`, the instance reacts to assumption failures. When the value is `false`, the instance ignores assumption failures. The `IncludeAssumptionFailures` property is `false` by default. To specify the property as `true`, use the `IncludingAssumptionFailures` input when you construct the instance.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Add Plugin to TestRunner

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 act = 3.1416;
 exp = pi;
 testCase.verifyEqual(act, exp);
 end
 function testTwo(testCase) % Test does not complete
 testCase.assumeEqual(5, 4);
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class and a test runner.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.StopOnFailuresPlugin;

suite = TestSuite.fromClass(?ExampleTest);
```

# matlab.unittest.plugins.StopOnFailuresPlugin

---

```
runner = TestRunner.withTextOutput;
```

Run the tests.

```
result = runner.run(suite);
```

```
=====
Verification failed in ExampleTest/testOne.
```

```

Framework Diagnostic:

verifyEqual failed.
--> The values are not equal using "isequaln".
```

```

To enter debug mode for tests that fail by assumption, such as `testTwo` in the `ExampleTest` class, include `'IncludingAssumptionFailures'` option for the plugin.

# matlab.unittest.plugins.StopOnFailuresPlugin

---

```
runner = TestRunner.withTextOutput;
runner.addPlugin(StopOnFailuresPlugin(...
 'IncludingAssumptionFailures', true));
```

If you run the test runner, you enter debug mode for both `testOne` and `testTwo`.

## Concepts

<b>Purpose</b>	Plugin that produces Test Anything Protocol stream
<b>Description</b>	The TAPPlugin creates a plugin that produces a Test Anything Protocol (TAP) stream. Using this plugin, you can integrate MATLAB Unit Test results into third-party systems that recognize the TAP protocol. For example, you can integrate test results with continuous integration systems like Jenkins™ or TeamCity®.
<b>Construction</b>	<p><code>matlab.unittest.plugins.TAPPlugin.producingOriginalFormat</code> creates a plugin that produces output in the form of the original TAP format (version 12). By default, the plugin displays the output to the screen. In this case, other output sent to the screen can invalidate the TAP stream. To avoid this, redirect the output to a different output stream, such as the <code>ToFile</code> stream.</p> <p><code>matlab.unittest.plugins.TAPPlugin.producingOriginalFormat(stream)</code> redirects all the text output to the output stream, <code>stream</code>. If you do not specify the output stream, the plugin uses the <code>ToStandardOutput</code> stream.</p> <p><b>Input Arguments</b></p> <p><b>stream</b></p> <p>Location where the plugin directs text output, specified as an <code>OutputStream</code>.</p> <p><b>Default:</b> <code>ToStandardOutput</code></p>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects</a> in the MATLAB documentation.
<b>Examples</b>	<p><b>Create TAP Plugin</b></p> <p>In a new file in your working folder, create <code>ExampleTest.m</code> containing the following test class.</p> <pre>classdef ExampleTest &lt; matlab.unittest.TestCase</pre>

# matlab.unittest.plugins.TAPPlugin

---

```
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 function testThree(testCase)
 % test code
 end
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.TAPPlugin;
import matlab.unittest.plugins.ToFile;

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window using the default plugin.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file `MyTapOutput.tap`.

```
tapFile = 'MyTAPOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(tapFile));
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin);
result = runner.run(suite);
```

## Concepts

## External Web Sites

- [Jenkins](#)
- [TeamCity](#)
- [testanything.org](#)

**Superclasses**    `OutputStream`

**Purpose**    `Output stream to write text output to file`

**Description**    `The ToFile class creates an output stream that writes text output to a file. Whenever text prints to this stream, the output stream opens the file, appends the text, and closes the file.`

**Construction**    `matlab.unittest.plugins.ToFile(fname)` creates an `OutputStream` that writes text output to the file, `fname`.

### **Input Arguments**

#### **fname**

`Name of file to write the output text, specified as a string. If fname exists, the text from the stream is appended to the file.`

### **Properties**

#### **Filename**

`Name of file to redirect text output from the plugin, specified in the input argument, fname.`

### **Copy Semantics**

`Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.`

### **Examples**

#### **Direct TAPPlugin Output Text to Separate File**

`In your working folder, create the file ExampleTest.m containing the following test class.`

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 end
end
```

## matlab.unittest.plugins.ToFile

---

```
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.TAPPlugin;
import matlab.unittest.plugins.ToFile;
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner that displays output to the command window.

```
runner = TestRunner.withTextOutput;
```

Create a `TAPPlugin` that explicitly specifies that its output should go to the file, `MyTapOutput.tap`.

```
filename = 'MyTapOutput.tap';
plugin = TAPPlugin.producingOriginalFormat(ToFile(filename));
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin);
result = runner.run(suite);
```

```
Running ExampleTest
```

```
=====
Verification failed in ExampleTest/testOne.
```

```

Test Diagnostic:

Testing 5==4

Framework Diagnostic:

verifyEqual failed.
--> The values are not equal using "isequaln".

## Concepts

<b>Superclasses</b>	OutputStream
<b>Purpose</b>	Output stream to display text information to screen
<b>Description</b>	The ToStandardOutput class creates an output stream to display text output to the screen. Many plugins that accept an output stream use ToStandardOutput as their default stream.
<b>Construction</b>	matlab.unittest.plugins.ToStandardOutput creates an OutputStream that prints text output to the screen.
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Direct Plugin Output Text to Standard Output

In your working folder, create the file ExampleTest.m containing the following test class.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testOne(testCase) % Test fails
 testCase.verifyEqual(5, 4, 'Testing 5==4');
 end
 function testTwo(testCase) % Test passes
 testCase.verifyEqual(5, 5, 'Testing 5==5');
 end
 function testThree(testCase)
 % test code
 end
 end
end
```

The `verifyEqual` qualification in `testOne` causes a test failure. The qualifications in `testOne` and `testTwo` include an instance of a `matlab.unittest.diagnostics.StringDiagnostic`.

# matlab.unittest.plugins.ToStandardOutput

---

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.FailureDiagnosticsPlugin;
import matlab.unittest.plugins.ToStandardOutput;
```

```
suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Create a `FailureDiagnosticsPlugin` that explicitly specifies that its output should go to the screen.

```
plugin = FailureDiagnosticsPlugin(ToStandardOutput);
```

Add the plugin to the `TestRunner` and run the suite.

```
runner.addPlugin(plugin);
result = runner.run(suite);
```

```
=====
Verification failed in ExampleTest/testOne.
```

```

Test Diagnostic:
```

```

Testing 5==4
```

```

Framework Diagnostic:
```

```

verifyEqual failed.
--> The values are not equal using "isequaln".
```

```
Actual Value:
```

# matlab.unittest.plugins.ToStandardOutput

---

```
5
Expected Value:
4

Stack Information:

In C:\work\ExampleTest.m (ExampleTest.testOne) at 4
=====
Failure Summary:

Name Failed Incomplete Reason(s)

ExampleTest/testOne X Failed by verification.
```

Only the test failures produce output to the screen.

## Concepts

# matlab.unittest.plugins.TestRunnerPlugin

---

**Purpose** Plugin interface for extending TestRunner

**Description** The TestRunnerPlugin interface enables extension of the matlab.unittest.TestRunner. To customize a test run, create a subclass of TestRunnerPlugin and override select methods. TestRunnerPlugin provides you with a default implementation, so override only methods necessary to achieve your required customization. Every method you implement must invoke its corresponding superclass method, passing along the same instance of pluginData that it receives.

To run tests with this extension, add the custom TestRunnerPlugin to the TestRunner using the addPlugin method of TestRunner.

## Methods

createSharedTestFixture	Extend creation of shared test fixture instances
createTestClassInstance	Extend creation of class-level TestCase instances
createTestMethodInstance	Extend creation of method-level TestCase instances
runTest	Extend running of single TestSuite element
runTestClass	Extend running of TestSuite array from same class or function
runTestMethod	Extend running of single Test method
runTestSuite	Extend running of TestSuite array
setupSharedTestFixture	Extend setting up shared test fixture
setupTestClass	Extend setting up test class
setupTestMethod	Extend setting up of test method

<code>teardownSharedTestFixture</code>	Extend tearing down shared test fixture
<code>teardownTestClass</code>	Extend tearing down of test class
<code>teardownTestMethod</code>	Extend tearing down of test method

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Concepts

# matlab.unittest.plugins.TestRunnerPlugin.runTestSuite

---

**Purpose** Extend running of TestSuite array

**Syntax** runTestSuite(plugin,pluginData)

**Description** runTestSuite(plugin,pluginData) extends the running of the original TestSuite array that the test framework hands to the TestRunner.

## Input Arguments

### plugin

Instance of matlab.unittest.plugins.TestRunnerPlugin.

### pluginData

Test suite information, specified as an instance of matlab.unittest.plugins.pluginData.TestSuiteRunPluginData. The test framework uses this information to introspect into the test content.

## Examples

### Implement runTestSuite Method

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestSuite(plugin, pluginData)

 % Introspect into pluginData to get TestSuite size
 suiteSize = numel(pluginData.TestSuite);
 fprintf('### Running a total of %d tests\n', suiteSize);

 % Invoke the super class method
 runTestSuite@matlab.unittest.plugins.TestRunnerPlugin(plugin,
 end
 end
 end
 end
end
```

## **Related Examples**

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.createSharedTestFixture

**Purpose** Extend creation of shared test fixture instances

**Syntax** `f = createSharedTestFixture(plugin,pluginData)`

**Description** `f = createSharedTestFixture(plugin,pluginData)` extends the creation of shared test fixtures and returns the modified `Fixture` instance, `f`. The testing framework uses the fixture instance to customize running tests that use shared fixtures. The testing framework evaluates this method within the scope of the `runTestSuite` method of the `TestRunnerPlugin` for each shared test fixture it needs to set up. A typical implementation of this method is to add listeners to various events originating from the shared test fixture instance. Since the `Fixture` inherits from the `handle` class, add listeners by calling the `addListener` method from within the `createSharedTestFixture` method.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Shared test fixture creation information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Extend Creation of Shared Test Fixture Instances**

Extend the running of tests to count the number of shared test fixture assertion failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 FixtureAssertionFailureData = {};
 end
```

# matlab.unittest.plugins.TestRunnerPlugin.createSharedTest

```
methods (Access = protected)
 function fixture = createSharedTestFixture(plugin, pluginData)
 % Invoke the super class method
 fixture = createSharedTestFixture@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

 % Get the fixture name
 fixtureName = pluginData.Name;

 % Add a listener to fixture assertion failures
 % and capture the qualification failure information
 fixture.addListener('AssertionFailed', @(~,evd) ...
 plugin.captureFixtureAssertionFailureData(evd, fixtureName));
 end
end

methods (Access = private)
 function captureFixtureAssertionFailureData(plugin, eventData)
 plugin.FixtureAssertionFailureData{end+1} = struct(...
 'FixtureName', fixtureName, ...
 'ActualValue', eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
end
end
```

# matlab.unittest.plugins.TestRunnerPlugin.runTestClass

---

**Purpose** Extend running of TestSuite array from same class or function

**Syntax** runTestClass(plugin,pluginData)

**Description** runTestClass(plugin,pluginData) extends the running of tests that belong to the same test class or the same function-based test. This method applies to a subset of the full TestSuite that the TestRunner. The test framework evaluates this method within the scope of the runTestSuite method of the TestRunnerPlugin. It evaluates this method between setting up and tearing down the shared test fixture (setupSharedTestFixture and teardownSharedTestFixture). Provided the test framework completes shared test fixture setup, it invokes this method one time per test class.

## Input Arguments

### plugin

Instance of matlab.unittest.plugins.TestRunnerPlugin.

### pluginData

Test suite information, specified as an instance of matlab.unittest.plugins.pluginData.TestSuiteRunPluginData. The test framework uses this information to introspect into the test content.

## Examples

### Extend runTestClass method

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestClass(plugin, pluginData)
 fprintf('### Running test class: %s\n', pluginData.Name);

 runTestClass@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);
 end
 end
end
```

# matlab.unittest.plugins.TestRunnerPlugin.runTestClass

## Related Examples

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.createTestClassInstance

**Purpose** Extend creation of class-level `TestCase` instances

**Syntax** `tc = createTestClassInstance(plugin,pluginData)`

**Description** `tc = createTestClassInstance(plugin,pluginData)` extends the creation of class-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework uses the `TestCase` instance to customize running tests that belong to the same test class. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the class level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addListener` method from within the `createTestClassInstance` method. For each class, the test framework passes the instance to any method with the `TestClassSetup` or `TestClassTeardown` attribute.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Class-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Extend Creation of Class-Level `TestCase` Instances**

Extend the running of tests to count the number of class-level assumption failures.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 TestClassAssumptionFailureData = {};
 end
```

# matlab.unittest.plugins.TestRunnerPlugin.createTestClassInstance

```
methods (Access = protected)
 function testCase = createTestClassInstance(plugin, pluginData)
 % Invoke super class method
 testCase = createTestClassInstance@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData);

 % Get the test class name
 instanceName = pluginData.Name;

 % Add a listener to capture assumption failures
 testCase.addListener('AssumptionFailed', @(~,evd) ...
 plugin.captureClassLevelAssumptionFailureData(evd, instanceName));
 end
end

methods (Access = private)
 function captureClassLevelAssumptionFailureData(plugin, eventData)
 plugin.TestClassAssumptionFailureData{end+1} = struct(...
 'InstanceName', instanceName, ...
 'ActualValue' , eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
end
end
```

# matlab.unittest.plugins.TestRunnerPlugin.setupTestClass

<b>Purpose</b>	Extend setting up test class
<b>Syntax</b>	<code>setupTestClass(plugin,pluginData)</code>
<b>Description</b>	<code>setupTestClass(plugin,pluginData)</code> extends the setting up of a test class. This method defines how the <code>TestRunner</code> performs test class setup. The test framework evaluates this method within the scope of the <code>runTestClass</code> method of the <code>TestRunnerPlugin</code> . If the test class contains properties with the <code>ClassSetupParameter</code> attribute, the test framework evaluates the <code>setupTestClass</code> method as many times as the class setup parameterization dictates.

<b>Input Arguments</b>	<b>plugin</b> Instance of <code>matlab.unittest.plugins.TestRunnerPlugin</code> .
	<b>pluginData</b> Test class setup information, specified as an instance of <code>matlab.unittest.plugins.plugindata.PluginData</code> . The test framework uses this information to introspect into the test content.

## Examples **Implement setupTestClass Method**

Display the test class name at setup time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function setupTestClass(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name);
 setupTestClass@matlab.unittest.plugins.TestRunnerPlugin...
 (plugin, pluginData);
 end
 end
end
```

## Related Examples

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.runTest

---

**Purpose** Extend running of single TestSuite element

**Syntax** runTest(plugin,pluginData)

**Description** runTest(plugin,pluginData) extends the running of a single TestSuite element. This method allows the test author to override the method that runs a scalar test element in the TestSuite array, including the creation of the TestCase, and the TestMethodSetup and TestMethodTeardown routines. Provided the test framework completes all fixture setup, it invokes this method one time per test element.

## Input Arguments

### plugin

Instance of matlab.unittest.plugins.TestRunnerPlugin.

### pluginData

Test element information, specified as an instance of matlab.unittest.plugins.pluginData.TestSuiteRunPluginData. The test framework uses this information to introspect into the test content.

## Examples

### Extend runTest method

Print the label of the test content element at run time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTest(plugin, pluginData)
 fprintf('### Running test: %s\n', pluginData.Name);
 runTest@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);
 end
 end
end
```

- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.createTestMethodInst

**Purpose** Extend creation of method-level `TestCase` instances

**Syntax** `tc = createTestMethodInstance(plugin,pluginData)`

**Description** `tc = createTestMethodInstance(plugin,pluginData)` extends the creation of method-level `TestCase` instances, and returns the modified `TestCase` instance, `tc`. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`. A typical implementation of this method is to add listeners to various events originating from the method level instance. Since the `TestCase` inherits from the `handle` class, add listeners by calling the `addlistener` method from within the `createTestMethodInstance` method. The test framework creates instances for every element of the `matlab.unittest.Test` array and passes each instance to its corresponding `Test` methods and to any method with the `TestMethodSetup` or `TestMethodTeardown` attribute.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Method-level `TestCase` creation information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Implement createMethodInstance Method**

Add a listener to listen for assumption failures. Use the helper function, `captureMethodLevelAssumptionFailureData`, to populate the `TestMethodAssumptionFailureData` property.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 properties (SetAccess = private)
 TestMethodAssumptionFailureData = {};
 end
end
```

# matlab.unittest.plugins.TestRunnerPlugin.createTestMethod

```
end

methods (Access = protected)
 function testCase = createTestMethodInstance(plugin, pluginData)
 testCase = createTestMethodInstance@...
 matlab.unittest.plugins.TestRunnerPlugin(plugin, pluginData)

 instanceName = pluginData.Name;
 testCase.addListener('AssumptionFailed', @(~,evd) ...
 plugin.captureMethodLevelAssumptionFailureData(evd, instanceName));
 end
end

methods (Access = private)
 function captureMethodLevelAssumptionFailureData(...
 plugin, eventData, instanceName)
 plugin.TestMethodAssumptionFailureData{end+1} = struct(...
 'InstanceName', instanceName, ...
 'ActualValue' , eventData.ActualValue, ...
 'Constraint' , eventData.Constraint, ...
 'Stack' , eventData.Stack);
 end
end

end
```

Test method information, specified as an instance of `matlab.unittest.plugins.pluginData.TestSuiteRunPluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Extend runTestMethod method**

Print the time taken to evaluate the test method.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function runTestMethod(plugin, pluginData)
 tic;

 runTestMethod@matlab.unittest.plugins.TestRunnerPlugin(...
 plugin, pluginData);

 fprintf('### %s ran in %f seconds excluding fixture time.',...
 pluginData.Name, toc)
 end
 end
end
```

# matlab.unittest.plugins.TestRunnerPlugin.runTestMethod

---

matlab.unittest.plugins.TestRunnerPlugin.runTestClass

## Related Examples

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.tearDownTestMethod

**Purpose** Extend tearing down of test method

**Syntax** `tearDownTestMethod(plugin,pluginData)`

**Description** `tearDownTestMethod(plugin,pluginData)` extends the tearing down of a test method. This method defines how the `TestRunner` performs test method teardown for the single test suite element. The test framework evaluates this method within the scope of the `runTest` method of the `TestRunnerPlugin`.

**Input Arguments**

**plugin**  
Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

**pluginData**  
Test method teardown information, specified as an instance of `matlab.unittest.plugins.plugindata.PluginData`. The test framework uses this information to introspect into the test content.

## Examples **Implement tearDownTestMethod Method**

Display the test method name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin
 methods (Access = protected)
 function tearDownTestMethod(plugin, pluginData)
 fprintf('### Tearing down: %s\n', pluginData.Name);
 tearDownTestMethod@matlab.unittest.plugins.TestRunnerPlugin.
 (plugin, pluginData);
 end
 end
end
```

**See Also** `matlab.unittest.TestRunner` | `matlab.unittest.plugins.plugindata.PluginData` | `matlab.unittest.plugins.TestRunnerPlugin.setupTestMethod`

## **Related Examples**

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.tearDownTestClass

**Purpose** Extend tearing down of test class

**Syntax** `tearDownTestClass(plugin,pluginData)`

**Description** `tearDownTestClass(plugin,pluginData)` extends the tearing down of a test class. This method defines how the `TestRunner` performs test class teardown. The test framework evaluates this method within the scope of the `runTestClass` method of the `TestRunnerPlugin`. If the test class contains properties with the `ClassSetupParameter` attribute, the test framework evaluates the `tearDownTestClass` method as many times as the class setup parameterization dictates.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Test class teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.PluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Implement tearDownTestClass Method**

Display the test class name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function tearDownTestClass(plugin, pluginData)
 fprintf('### Tearing down: %s\n', pluginData.Name);
 steardownTestClass@matlab.unittest.plugins.TestRunnerPlugin.
 (plugin, pluginData);
 end
 end
end
```

# matlab.unittest.plugins.TestRunnerPlugin.teardownTestClass

## Related Examples

- “Write Plugins to Extend TestRunner”
- “Create Custom Plugin”

# matlab.unittest.plugins.TestRunnerPlugin.tearDownSharedTestF

**Purpose** Extend tearing down shared test fixture

**Syntax** `tearDownSharedTestFixture(plugin,pluginData)`

**Description** `tearDownSharedTestFixture(plugin,pluginData)` extends the tearing down of a shared test fixture. This method defines how the TestRunner performs shared fixture teardown. The test framework evaluates this method one time for each shared test fixture, within the scope of the `runTestSuite` method of the TestRunnerPlugin.

## Input Arguments

### **plugin**

Instance of `matlab.unittest.plugins.TestRunnerPlugin`.

### **pluginData**

Shared test fixture teardown information, specified as an instance of `matlab.unittest.plugins.pluginData.SharedTestFixturePluginData`. The test framework uses this information to introspect into the test content.

## Examples

### **Implement tearDownSharedTestFixture Method**

Display the shared test fixture name at teardown time.

```
classdef ExamplePlugin < matlab.unittest.plugins.TestRunnerPlugin

 methods (Access = protected)
 function tearDownSharedTestFixture(plugin, pluginData)
 fprintf('### Setting up: %s\n', pluginData.Name);
 tearDownSharedTestFixturer@matlab.unittest.plugins.TestRunner
 (plugin, pluginData);
 end
 end
end
```

- “Create Custom Plugin”

# matlab.unittest.plugins.TestSuiteProgressPlugin

---

<b>Purpose</b>	Plugin that outputs progress information as text
<b>Description</b>	The <code>TestSuiteProgressPlugin</code> class creates a plugin to output progress information as text. <code>TestSuiteProgressPlugin</code> is added to the <code>TestRunner</code> to show the progress of the testing to the Command Window. This plugin is used by default when you construct a test runner with <code>TestRunner.withTextOutput</code> .
<b>Construction</b>	<code>matlab.unittest.plugins.TestSuiteProgressPlugin</code> creates a plugin to output progress information as text.  <code>matlab.unittest.plugins.TestSuiteProgressPlugin(stream)</code> redirects all the text output to the output stream, <code>stream</code> . If you do not specify the output stream, the plugin uses the <code>ToStandardOutput</code> stream.
<b>Input Arguments</b>	<b>stream</b>  Location where the plugin directs text output, specified as an <code>OutputStream</code> .  <b>Default:</b> <code>ToStandardOutput</code>
<b>Copy Semantics</b>	Handle. To learn how handle classes affect copy operations, see <a href="#">Copying Objects</a> in the MATLAB documentation.
<b>Examples</b>	<b>Add Plugin to TestRunner</b>  In your working folder, create the file <code>ExampleTest.m</code> containing the following test class.  <pre>classdef ExampleTest &lt; matlab.unittest.TestCase     methods(Test)         function testOne(testCase)             % test code         end         function testTwo(testCase) % Test fails     end end</pre>

# matlab.unittest.plugins.TestSuiteProgressPlugin

---

```
 % test code
 end
 function testThree(testCase) % Test passes
 % test code
 end
end
end
end
```

At the command prompt, create a test suite from the `ExampleTest` class.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
import matlab.unittest.plugins.TestSuiteProgressPlugin;

suite = TestSuite.fromClass(?ExampleTest);
```

Create a test runner with no plugins. This code creates a silent runner and provides you with complete control over the installed plugins.

```
runner = TestRunner.withNoPlugins;
```

Run the tests.

```
result1 = runner.run(suite);
```

No output is displayed.

Add `TestSuiteProgressPlugin` to the runner and run the tests.

```
runner.addPlugin(TestSuiteProgressPlugin);
result2 = runner.run(suite);
```

```
Running ExampleTest
...
Done ExampleTest
```

---

## Concepts

## Purpose

Summary of classes in MATLAB Plugin Data Interface

## Description

The `plugindata` classes store information about test content for use by the plugins and plugin methods. The `TestRunner` passes instances of these classes to various plugin methods. The `matlab.unittest.plugins.plugindata` package consists of the following MATLAB plugin data classes.

`matlab.unittest.plugins.plugindata.PluginData` passed to `TestRunnerPlugin` methods

`matlab.unittest.plugins.plugindata.PluginTestFixtureData` test fixture information

`matlab.unittest.plugins.plugindata.PluginSelectedTestInfo` selected test information

## See Also

`TestRunnerPlugin` | `matlab.unittest.plugins`

# matlab.unittest.plugins.plugindata.PluginData

---

**Purpose** Data object passed to TestRunnerPlugin methods

**Description** The PluginData class defines the data the TestRunner passes to various plugin methods. It is created by the TestRunner, so there is no need for test plugin authors to construct this class directly.

**Properties**

Name
Label of test content executed by the test runner within the scope of a plugin method, represented as a string. Use the Name property for informational, labeling, and display purposes. Do not use Nameprogrammatically to introspect into the content.

**See Also** TestRunnerPlugin

**Concepts**

# matlab.unittest.plugins.plugindata.SharedTestFixturePlug

---

**Purpose** Plugin data containing shared test fixture information

**Description** The SharedTestFixturePluginData defines the data the TestRunner passes to plugin methods related to shared test fixtures. The TestRunner creates this, so there is no need for test plugin authors to construct this class directly.

**Properties**

**Name**

Label of shared test fixture, represented as a string. Use the Name property for informational, labeling, and display purposes. Do not use Nameprogrammatically to introspect into the content.

**Description**

Description of action performed during setup and teardown of a shared text fixture, represented as a string

**See Also** TestRunnerPlugin | matlab.unittest.fixtures.Fixture

**Concepts**

# matlab.unittest.plugins.plugindata.TestSuiteRunPluginData

---

**Purpose** Plugin data containing selected test information

**Description** The `TestSuiteRunPluginData` defines the data the `TestRunner` passes to plugin methods related to running tests from the suite. The `TestRunner` creates this, so there is no need for test plugin authors to construct this class directly.

**Properties**

Name
Name corresponding to the portion of the test suite the runner executes within a plugin method, represented as a string. Use the <code>Name</code> property for informational, labeling, and display purposes. Do not use <code>Name</code> programmatically to introspect into the content.

**TestSuite**

Select test methods, represented as a `matlab.unittest.TestSuite` instance

**TestResult**

Results from running select test methods listed in `TestSuite`, represented as a `matlab.unittest.TestResult` array

**See Also** `TestRunnerPlugin` | `matlab.unittest.TestSuite` | `matlab.unittest.TestResult`

**Concepts**

<b>Purpose</b>	Addition
<b>Syntax</b>	$C = A + B$ <code>C = plus(A,B)</code>
<b>Description</b>	<p><math>C = A + B</math> adds arrays A and B and returns the result in C.</p> <p><math>C = \text{plus}(A,B)</math> is an alternate way to execute <math>A + B</math>, but is rarely used. It enables operator overloading for classes.</p>
<b>Input Arguments</b>	<p><b>A - Input array</b> scalar   vector   matrix   multidimensional array</p> <p>Input array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char <b>Complex Number Support:</b> Yes</p> <p><b>B - Input array</b> scalar   vector   matrix   multidimensional array</p> <p>Input array, specified as a scalar, vector, matrix, or multidimensional array. Inputs A and B must be the same size unless one is a scalar. You can add a scalar value to any other value.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char <b>Complex Number Support:</b> Yes</p>
<b>Examples</b>	<p><b>Add Scalar to Array</b></p> <p>Create an array, A, and add a scalar value to it.</p>

```
A = [0 1; 1 0];
C = A + 2
```

```
C =
```

```
 2 3
 3 2
```

The scalar value is added to each entry of A.

## Add Two Arrays

Create two arrays, A and B, and add them together.

```
A = [1 0; 2 4];
B = [5 9; 2 1];
C = A + B
```

```
C =
```

```
 6 9
 4 5
```

The elements of A are added to the corresponding elements of B.

**Purpose** (Will be removed) Simplex containing specified location

---

**Note** `pointLocation(DelaunayTri)` will be removed in a future release. Use `pointLocation(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

**Syntax**

```
SI = pointLocation(DT,QX)
SI = pointLocation(DT,QX,QY)
SI = pointLocation(DT,QX,QY,QZ)
[SI, BC] = pointLocation(DT,...)
```

**Description** `SI = pointLocation(DT,QX)` returns the indices `SI` of the enclosing simplex (triangle/tetrahedron) for each query point location in `QX`. The enclosing simplex for point `QX(k,:)` is `SI(k)`. `pointLocation` returns `NaN` for all points outside the convex hull.

`SI = pointLocation(DT,QX,QY)` and `SI = pointLocation(DT,QX,QY,QZ)` allow the query point locations to be specified in alternative column vector format when working in 2-D and 3-D.

`[SI, BC] = pointLocation(DT,...)` returns the barycentric coordinates `BC`.

**Input Arguments**

<code>DT</code>	Delaunay triangulation.
<code>QX</code>	Matrix of size <code>mpts-by-ndim</code> , <code>mpts</code> being the number of query points.

# DelaunayTri.pointLocation

---

## Output Arguments

SI	Column vector of length <code>mpts</code> containing the indices of the enclosing simplex for each query point. <code>mpts</code> is the number of query points.
BC	BC is a <code>mpts-by-ndim</code> matrix, each row <code>BC(i,:)</code> represents the barycentric coordinates of <code>QX(i,:)</code> with respect to the enclosing simplex <code>SI(i)</code> .

## Examples

### Example 1

Create a 2-D Delaunay triangulation:

```
X = rand(10,2);
dt = DelaunayTri(X);
```

Find the triangles that contain specified query points:

```
qrypts = [0.25 0.25; 0.5 0.5];
triids = pointLocation(dt, qrypts)
```

### Example 2

Create a 3-D Delaunay triangulation:

```
x = rand(10,1);
y = rand(10,1);
z = rand(10,1);
dt = DelaunayTri(x,y,z);
```

Find the triangles that contain specified query points and evaluate the barycentric coordinates:

```
qrypts = [0.25 0.25 0.25; 0.5 0.5 0.5];
[tetids, bcs] = pointLocation(dt, qrypts)
```

**Purpose** Transform polar or cylindrical coordinates to Cartesian

**Syntax**  
 $[X,Y] = \text{pol2cart}(\text{THETA},\text{RHO})$   
 $[X,Y,Z] = \text{pol2cart}(\text{THETA},\text{RHO},Z)$

**Description**  $[X,Y] = \text{pol2cart}(\text{THETA},\text{RHO})$  transforms the polar coordinate data stored in corresponding elements of THETA and RHO to two-dimensional Cartesian, or *xy*, coordinates. The arrays THETA and RHO must be the same size (or either can be scalar). The values in THETA must be in radians.

$[X,Y,Z] = \text{pol2cart}(\text{THETA},\text{RHO},Z)$  transforms the cylindrical coordinate data stored in corresponding elements of THETA, RHO, and Z to three-dimensional Cartesian, or *xyz* coordinates. The arrays THETA, RHO, and Z must be the same size (or any can be scalar). The values in THETA must be in radians.

**Algorithms** The mapping from polar and cylindrical coordinates to Cartesian coordinates is:

**Polar to Cartesian Mapping**  
 $x = \text{rho} * \cos(\text{theta})$   
 $y = \text{rho} * \sin(\text{theta})$

**Polar to Cartesian Mapping**  
 $x = \text{rho} * \cos(\text{theta})$   
 $y = \text{rho} * \sin(\text{theta})$   
 $z = z$

# pol2cart

---

## See Also

[cart2pol](#) | [cart2sph](#) | [sph2cart](#)

**Purpose**

Polar coordinate plot

**Syntax**

```
polar(theta,rho)
polar(theta,rho,LineStyle)
polar(axes_handle,...)
h = polar(...)
```

**Description**

The `polar` function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

`polar(theta,rho)` creates a polar coordinate plot of the angle `theta` versus the radius `rho`. `theta` is the angle from the  $x$ -axis to the radius vector specified in radians; `rho` is the length of the radius vector specified in dataspace units.

`polar(theta,rho,LineStyle)` `LineStyle` specifies the line type, plot symbol, and color for the lines drawn in the polar plot.

`polar(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = polar(...)` returns the handle of a line object in `h`.

**Tips**

Negative  $r$  values reflect through the origin, rotating by  $\pi$  (since  $(\theta,r)$  transforms to  $(r\cos(\theta), r\sin(\theta))$ ). If you want different behavior, you can manipulate  $r$  prior to plotting. For example, you can make  $r$  equal to  $\max(0,r)$  or  $\text{abs}(r)$ .

**Examples****Simple Polar Plot**

Create a simple polar plot using a dashed red line.

```
theta = 0:0.01:2*pi;
rho = sin(2*theta).*cos(2*theta);
```

# polar

---

```
figure
polar(theta,rho,'--r')
```

## See Also

**Purpose**

Polynomial with specified roots

**Syntax**

`p = poly(A)`  
`p = poly(r)`

**Description**

`p = poly(A)` where  $A$  is an  $n$ -by- $n$  matrix returns an  $n+1$  element row vector whose elements are the coefficients of the characteristic polynomial,  $\det(\lambda I - A)$ . The coefficients are ordered in descending powers: if a vector  $c$  has  $n+1$  components, the polynomial it represents is  $c_1\lambda^n + c_2\lambda^{n-1} + \dots + c_n\lambda + c_{n+1}$

`p = poly(r)` where  $r$  is a vector returns a row vector whose elements are the coefficients of the polynomial whose roots are the elements of  $r$ .

**Tips**

Note the relationship of this command to

`r = roots(p)`

which returns a column vector whose elements are the roots of the polynomial specified by the coefficients row vector  $p$ . For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

**Examples**

MATLAB displays polynomials as row vectors containing the coefficients ordered by descending powers. The characteristic equation of the matrix

$A =$

1	2	3
4	5	6
7	8	0

is returned in a row vector by `poly`:

`p = poly(A)`

`p =`  

1	-6	-72	-27
---	----	-----	-----

The roots of this polynomial (eigenvalues of matrix A) are returned in a column vector by `roots`:

```
r = roots(p)
```

```
r =
```

```
 12.1229
 -5.7345
 -0.3884
```

## Algorithms

The algorithms employed for `poly` and `roots` illustrate an interesting aspect of the modern approach to eigenvalue computation. `poly(A)` generates the characteristic polynomial of A, and `roots(poly(A))` finds the roots of that polynomial, which are the eigenvalues of A. But both `poly` and `roots` use `eig`, which is based on similarity transformations. The classical approach, which characterizes eigenvalues as roots of the characteristic polynomial, is actually reversed.

If A is an n-by-n matrix, `poly(A)` produces the coefficients `c(1)` through `c(n+1)`, with `c(1) = 1`, in

$$\det(\lambda I - A) = c_1 \lambda^n + \dots + c_n \lambda + c_{n+1}$$

The algorithm is

```
z = eig(A);
c = zeros(n+1,1); c(1) = 1;
for j = 1:n
 c(2:j+1) = c(2:j+1) - z(j)*c(1:j);
end
```

This recursion is easily derived by expanding the product.

$$(\lambda - \lambda_1)(\lambda - \lambda_2)\dots(\lambda - \lambda_n)$$

It is possible to prove that `poly(A)` produces the coefficients in the characteristic polynomial of a matrix within roundoff error of A. This is

true even if the eigenvalues of  $A$  are badly conditioned. The traditional algorithms for obtaining the characteristic polynomial, which do not use the eigenvalues, do not have such satisfactory numerical properties.

`conv` | `polyval` | `residue` | `roots`

# polyarea

---

**Purpose** Area of polygon

**Syntax**  
`A = polyarea(X,Y)`  
`A = polyarea(X,Y,dim)`

**Description** `A = polyarea(X,Y)` returns the area of the polygon specified by the vertices in the vectors `X` and `Y`.

If `X` and `Y` are matrices of the same size, then `polyarea` returns the area of polygons defined by the columns `X` and `Y`.

If `X` and `Y` are multidimensional arrays, `polyarea` returns the area of the polygons in the first nonsingleton dimension of `X` and `Y`.

`A = polyarea(X,Y,dim)` operates along the dimension specified by scalar `dim`.

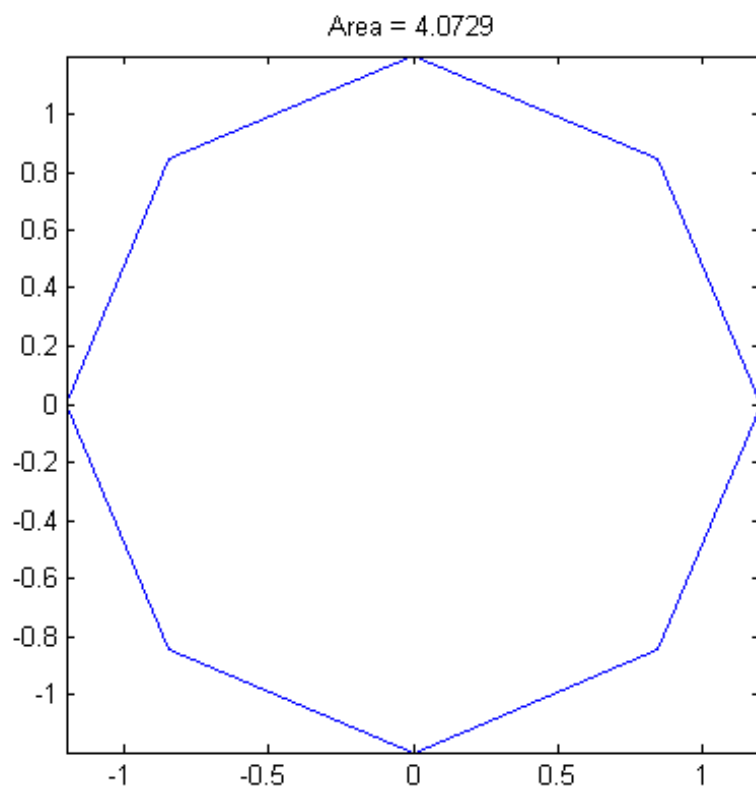

## Examples **Find Area of Polygon**

```
L = linspace(0,2.*pi,9); xv = 1.2*cos(L)';yv = 1.2*sin(L)';
xv = [xv ; xv(1)]; yv = [yv ; yv(1)];
A = polyarea(xv,yv)
```

```
A =
```

```
4.0729
```

```
plot(xv,yv); title(['Area = ' num2str(A)]); axis image
```

# polyder

---

## Purpose

Polynomial derivative

## Syntax

```
k = polyder(p)
k = polyder(a,b)
[q,d] = polyder(b,a)
```

## Description

The `polyder` function calculates the derivative of polynomials, polynomial products, and polynomial quotients. The operands `a`, `b`, and `p` are vectors whose elements are the coefficients of a polynomial in descending powers.

`k = polyder(p)` returns the derivative of the polynomial `p`.

`k = polyder(a,b)` returns the derivative of the product of the polynomials `a` and `b`.

`[q,d] = polyder(b,a)` returns the numerator `q` and denominator `d` of the derivative of the polynomial quotient `b/a`.

## Examples

The derivative of the product

$$(3x^2 + 6x + 9)(x^2 + 2x)$$

is obtained with

```
a = [3 6 9];
b = [1 2 0];
k = polyder(a,b)
k =
 12 36 42 18
```

This result represents the polynomial

$$12x^3 + 36x^2 + 42x + 18$$

## See Also

`conv` | `deconv`

**Purpose**

Polynomial eigenvalue problem

**Syntax**

```
[X,e] = polyeig(A0,A1,...,Ap)
e = polyeig(A0,A1,...,Ap)
[X, e, s] = polyeig(A0,A1,...,AP)
```

**Description**

`[X,e] = polyeig(A0,A1,...,Ap)` solves the polynomial eigenvalue problem of degree  $p$

$$(A_0 + \lambda A_1 + \dots + \lambda^p A_p)x = 0$$

where polynomial degree  $p$  is a non-negative integer, and  $A_0, A_1, \dots, A_p$  are input matrices of order  $n$ . The output consists of a matrix  $X$  of size  $n$ -by- $n \times p$  whose columns are the eigenvectors, and a vector  $e$  of length  $n \times p$  containing the eigenvalues.

If  $\lambda$  is the  $j$ th eigenvalue in  $e$ , and  $x$  is the  $j$ th column of eigenvectors in  $X$ , then  $(A_0 + \lambda A_1 + \dots + \lambda^p A_p)x$  is approximately 0.

`e = polyeig(A0,A1,...,Ap)` is a vector of length  $n \times p$  whose elements are the eigenvalues of the polynomial eigenvalue problem.

`[X, e, s] = polyeig(A0,A1,...,AP)` also returns a vector  $s$  of length  $p \times n$  containing condition numbers for the eigenvalues. At least one of  $A_0$  and  $A_p$  must be nonsingular. Large condition numbers imply that the problem is close to a problem with multiple eigenvalues.

**Tips**

Based on the values of  $p$  and  $n$ , `polyeig` handles several special cases:

- $p = 0$ , or `polyeig(A)` is the standard eigenvalue problem: `eig(A)`.
- $p = 1$ , or `polyeig(A,B)` is the generalized eigenvalue problem: `eig(A,-B)`.
- $n = 1$ , or `polyeig(a0,a1,...,ap)` for scalars  $a_0, a_1, \dots, a_p$  is the standard polynomial problem: `roots([ap ... a1 a0])`.

If both  $A_0$  and  $A_p$  are singular the problem is potentially ill-posed. Theoretically, the solutions might not exist or might not be unique. Computationally, the computed solutions might be inaccurate. If one, but not both, of  $A_0$  and  $A_p$  is singular, the problem is well posed, but some of the eigenvalues might be zero or infinite.

Note that scaling  $A_0, A_1, \dots, A_p$  to have  $\text{norm}(A_i)$  roughly equal 1 may increase the accuracy of `polyeig`. In general, however, this cannot be achieved. (See Tisseur [3] for more detail.)

## Algorithms

The `polyeig` function uses the QZ factorization to find intermediate results in the computation of generalized eigenvalues. It uses these intermediate results to determine if the eigenvalues are well-determined. See the descriptions of `eig` and `qz` for more on this.

`condeig` | `eig` | `qz`

**Purpose** Polynomial curve fitting

**Syntax**

```
p = polyfit(x,y,n)
[p,S] = polyfit(x,y,n)
[p,S,mu] = polyfit(x,y,n)
```

**Description** `p = polyfit(x,y,n)` finds the coefficients of a polynomial  $p(x)$  of degree  $n$  that fits the data,  $p(x(i))$  to  $y(i)$ , in a least squares sense. The result `p` is a row vector of length  $n+1$  containing the polynomial coefficients in descending powers:

$$p(x) = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}.$$

`[p,S] = polyfit(x,y,n)` returns the polynomial coefficients `p` and a structure `S` for use with `polyval` to obtain error estimates or predictions. Structure `S` contains fields `R`, `df`, and `normr`, for the triangular factor from a QR decomposition of the Vandermonde matrix of `x`, the degrees of freedom, and the norm of the residuals, respectively. If the data `y` are random, an estimate of the covariance matrix of `p` is  $(R \backslash y - p) * (R \backslash y - p)' * \text{normr}^2 / \text{df}$ , where `R \backslash y` is the inverse of `R`. If the errors in the data `y` are independent normal with constant variance, `polyval` produces error bounds that contain at least 50% of the predictions.

`[p,S,mu] = polyfit(x,y,n)` finds the coefficients of a polynomial in

$$\hat{x} = \frac{x - \mu_1}{\mu_2}$$

where  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . `mu` is the two-element vector `[mu1,mu2]`. This centering and scaling transformation improves the numerical properties of both the polynomial and the fitting algorithm.

## Examples **Fit Polynomial to Error Function**

This example involves fitting the error function,  $\text{erf}(x)$ , by a polynomial in `x`. This is a risky project because  $\text{erf}(x)$  is a bounded function, while polynomials are unbounded, so the fit might not be very good.

First generate a vector of  $x$  points, equally spaced in the interval  $[0, 2.5]$ , then evaluate  $\text{erf}(x)$  at those points.

```
x = (0: 0.1: 2.5)';
y = erf(x);
```

The coefficients in the approximating polynomial of degree 6 are

```
p = polyfit(x,y,6)
```

```
p =
```

```
 0.0084 -0.0983 0.4217 -0.7435 0.1471 1.1064 0.0004
```

There are seven coefficients, and the polynomial is

$$0.0084x^6 - 0.0983x^5 + 0.4217x^4 - 0.7435x^3 + 0.1471x^2 + 1.1064x + 0.0004$$

To see how good the fit is, evaluate the polynomial at the data points.

```
f = polyval(p,x);
```

A table showing the data, fit, and error is

```
table = [x y f y-f]
```

```
table =
```

```
 0 0 0.0004 -0.0004
 0.1000 0.1125 0.1119 0.0006
 0.2000 0.2227 0.2223 0.0004
 0.3000 0.3286 0.3287 -0.0001
 0.4000 0.4284 0.4288 -0.0004
 0.5000 0.5205 0.5209 -0.0004
 0.6000 0.6039 0.6041 -0.0002
```

0.7000	0.6778	0.6778	0.0000
0.8000	0.7421	0.7418	0.0003
0.9000	0.7969	0.7965	0.0004
1.0000	0.8427	0.8424	0.0003
1.1000	0.8802	0.8800	0.0002
1.2000	0.9103	0.9104	-0.0000
1.3000	0.9340	0.9342	-0.0002
1.4000	0.9523	0.9526	-0.0003
1.5000	0.9661	0.9664	-0.0003
1.6000	0.9763	0.9765	-0.0002
1.7000	0.9838	0.9838	0.0000
1.8000	0.9891	0.9889	0.0002
1.9000	0.9928	0.9925	0.0003
2.0000	0.9953	0.9951	0.0002
2.1000	0.9970	0.9969	0.0001
2.2000	0.9981	0.9982	-0.0001
2.3000	0.9989	0.9991	-0.0003
2.4000	0.9993	0.9995	-0.0002
2.5000	0.9996	0.9994	0.0002

On this interval, the interpolated values and the actual values agree fairly closely. Outside this interval, the extrapolated values quickly diverge from the actual data values, as the following plot demonstrates.

```
x = (0: 0.1: 5)';
y = erf(x);
f = polyval(p,x);
plot(x,y,'o',x,f,'-')
axis([0 5 0 2])
```

## Algorithms

The `polyfit` MATLAB file forms the Vandermonde matrix,  $V$ , whose elements are powers of  $x$ .  $v_{i,j} = x_i^{n-j}$

It then uses the backslash operator, `\`, to solve the least squares problem  $Vp \cong y$ .

See “Programmatic Fitting” for information about fitting different functions of  $x$ .

`poly` | `polyval` | `roots` | `lskov` | `cov`

# polyint

---

**Purpose** Integrate polynomial analytically

**Syntax** `polyint(p,k)`  
`polyint(p)`

**Description** `polyint(p,k)` returns a polynomial representing the integral of polynomial `p`, using a scalar constant of integration `k`. Specify `p` and `k` as type `double` or `single`.

`polyint(p)` assumes a constant of integration `k=0`.

**See Also** `polyder` | `polyval` | `polyvalm` | `polyfit`

**Purpose**

Polynomial evaluation

**Syntax**

```
y = polyval(p,x)
[y,delta] = polyval(p,x,S)
y = polyval(p,x,[],mu)
[y,delta] = polyval(p,x,S,mu)
```

**Description**

`y = polyval(p,x)` returns the value of a polynomial of degree  $n$  evaluated at  $x$ . The input argument  $p$  is a vector of length  $n+1$  whose elements are the coefficients in descending powers of the polynomial to be evaluated.

$$y = p_1x^n + p_2x^{n-1} + \dots + p_nx + p_{n+1}$$

$x$  can be a matrix or a vector. In either case, `polyval` evaluates  $p$  at each element of  $x$ .

`[y,delta] = polyval(p,x,S)` uses the optional output structure  $S$  generated by `polyfit` to generate error estimates `delta`. `delta` is an estimate of the standard deviation of the error in predicting a future observation at  $x$  by  $p(x)$ . If the coefficients in  $p$  are least squares estimates computed by `polyfit`, and the errors in the data input to `polyfit` are independent, normal, and have constant variance, then `y±delta` contains at least 50% of the predictions of future observations at  $x$ .

`y = polyval(p,x,[],mu)` or `[y,delta] = polyval(p,x,S,mu)` use  $\hat{x} = (x - \mu_1) / \mu_2$  in place of  $x$ . In this equation,  $\mu_1 = \text{mean}(x)$  and  $\mu_2 = \text{std}(x)$ . The centering and scaling parameters  $\text{mu} = [\mu_1, \mu_2]$  are optional output computed by `polyfit`.

**Tips**

The `polyvalm(p,x)` function, with  $x$  a matrix, evaluates the polynomial in a matrix sense. See `polyvalm` for more information.

# polyval

---

## Examples

The polynomial  $p(x) = 3x^2 + 2x + 1$  is evaluated at  $x = 5, 7,$  and  $9$  with

```
p = [3 2 1];
polyval(p,[5 7 9])
```

which results in

```
ans =
```

```
86 162 262
```

For another example, see [polyfit](#).

## See Also

[polyfit](#) | [polyvalm](#) | [polyder](#) | [polyint](#)

**Purpose** Matrix polynomial evaluation

**Syntax** `Y = polyvalm(p,X)`

**Description** `Y = polyvalm(p,X)` evaluates a polynomial in a matrix sense. This is the same as substituting matrix `X` in the polynomial `p`.

Polynomial `p` is a vector whose elements are the coefficients of a polynomial in descending powers, and `X` must be a square matrix.

**Examples** The Pascal matrices are formed from Pascal's triangle of binomial coefficients. Here is the Pascal matrix of order 4.

```
X = pascal(4)
X =
 1 1 1 1
 1 2 3 4
 1 3 6 10
 1 4 10 20
```

Its characteristic polynomial can be generated with the `poly` function.

```
p = poly(X)
p =
 1 -29 72 -29 1
```

This represents the polynomial  $x^4 - 29x^3 + 72x^2 - 29x + 1$ .

Pascal matrices have the curious property that the vector of coefficients of the characteristic polynomial is palindromic; it is the same forward and backward.

Evaluating this polynomial at each element is not very interesting.

```
polyval(p,X)
ans =
 16 16 16 16
 16 15 -140 -563
 16 -140 -2549 -12089
```

# polyvalm

---

```
16 -563 -12089 -43779
```

But evaluating it in a matrix sense is interesting.

```
polyvalm(p,X)
ans =
 0 0 0 0
 0 0 0 0
 0 0 0 0
 0 0 0 0
```

The result is the zero matrix. This is an instance of the Cayley-Hamilton theorem: a matrix satisfies its own characteristic equation.

[polyfit](#) | [polyval](#)

**Purpose** Base 2 power and scale floating-point numbers

**Syntax**  
`X = pow2(Y)`  
`X = pow2(F,E)`

**Description** `X = pow2(Y)` returns an array `X` whose elements are 2 raised to the power `Y`.  
`X = pow2(F,E)` computes  $x = f * 2^e$  for corresponding elements of `F` and `E`. The result is computed quickly by simply adding `E` to the floating-point exponent of `F`. Arguments `F` and `E` are real and integer arrays, respectively.

**Tips** This function corresponds to the ANSI C function `ldexp()` and the IEEE floating-point standard function `scalbn()`.

**Examples** For IEEE arithmetic, the statement `X = pow2(F,E)` yields the values:

F	E	X
1/2	1	1
pi/4	2	pi
-3/4	2	-3
1/2	-51	eps
1-eps/2	1024	realmax
1/2	-1021	realmin

**See Also** `log2` | `exp` | `hex2num` | `realmax` | `realmin` | `power` | `mpower`

# power, .^

---

**Purpose** Element-wise power

**Syntax**  
`C = A.^B`  
`C = power(A,B)`

**Description** `C = A.^B` raises each element of `A` to the corresponding power in `B`.

`C = power(A,B)` is an alternate way to execute `A.^B`, but is rarely used. It enables operator overloading for classes.

## Input Arguments

### A - Base

scalar | vector | matrix | multidimensional array

Base, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

### B - Exponent

scalar | vector | matrix | multidimensional array

Exponent, specified as a scalar, vector, matrix, or multidimensional array. Inputs `A` and `B` must be the same size unless one is a scalar. A scalar value expands into an array of the same size as the other input.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

## Examples

### Square Each Element of Vector

Create a vector, `A`, and square each element.

```
A = 1:5;
C = A.^2
```

```
C =
```

```
 1 4 9 16 25
```

### Find Inverse of Each Matrix Element

Create a matrix, A, and take the inverse of each element.

```
A = [1 2 3; 4 5 6; 7 8 9];
C = A.^-1
```

```
C =
```

```
 1.0000 0.5000 0.3333
 0.2500 0.2000 0.1667
 0.1429 0.1250 0.1111
```

An inversion of the elements is not equal to the inverse of the matrix, which is instead written  $A^{-1}$  or `inv(A)`.

### Find Roots of Number

Calculate the roots of -1 to the 1/3 power.

```
A = -1;
B = 1/3;
C = A.^B
```

```
C =
```

```
 0.5000 + 0.8660i
```

For negative base A and noninteger B, if `abs(B)` is less than 1, the power function returns the complex roots of A.

Use the `nthroot` function to obtain the real roots.

## power, .^

---

```
C = nthroot(A,3)
```

```
C =
```

```
-1
```

### See Also

realpow | mpower | nthroot

**Purpose** Evaluate piecewise polynomial

**Syntax** `v = ppval(pp,xx)`

**Description** `v = ppval(pp,xx)` returns the value of the piecewise polynomial  $f$ , contained in `pp`, at the entries of `xx`. You can construct `pp` using the functions `pchip`, `spline`, or the spline utility `mkpp`.

`v` is obtained by replacing each entry of `xx` by the value of  $f$  there. If  $f$  is scalar-valued, `v` is of the same size as `xx`. `xx` may be  $N$ -dimensional.

If `pp` was constructed by `pchip`, `spline`, or `mkpp` using the orientation of non-scalar function values specified for those functions, then:

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` is a vector of length  $N$ , then `V` has size  $[D1, \dots, Dr, N]$ , with `V(:,...,:,J)` the value of  $f$  at `xx(J)`.

If  $f$  is  $[D1, \dots, Dr]$ -valued, and `xx` has size  $[N1, \dots, Ns]$ , then `V` has size  $[D1, \dots, Dr, N1, \dots, Ns]$ , with `V(:,...,:, J1, ..., Js)` the value of  $f$  at `xx(J1, ..., Js)`.

## Examples

Compare the result of integrating  $\cos(x)$  between 0 and 10 to the result of integrating a piece-wise polynomial approximation of the same function.

```
a = 0; b = 10;
int1 = integral(@cos,a,b)
```

```
int1 =
 -0.5440
```

Create a piece-wise polynomial approximation of  $\cos(x)$  and integrate over the same interval.

```
x = a:b;
y = cos(x);
pp = spline(x,y);
int2 = integral(@(x)ppval(pp,x),a,b)
```

```
int2 =
```

# ppval

---

-0.5485

## **See Also**

mkpp | spline | unmkpp

**Purpose**

Folder containing preferences, history, and layout files

**Syntax**

```
prefdir
folder = prefdir
folder = prefdir(1)
```

**Description**

prefdir returns the folder that contains

- Preferences for MATLAB and related products (matlab.prf)
- Command history file (History.xml)
- MATLAB shortcuts (shortcuts\_2.xml)
- MATLAB desktop layout files (MATLABDesktop.xml and Your\_Saved\_LayoutMATLABLayout.xml)
- Other related files

folder = prefdir assigns to folder the name of the folder containing preferences and related files.

folder = prefdir(1) creates a folder for preferences and related files if one does not exist. If the folder does exist, the name is assigned to folder.

**Tips**

- You must have write access to the preferences folder. Otherwise, MATLAB generates an error in the Command Window when you try to change preferences. This can happen if the folder is hidden, for example: myname/.matlab/R2009a.

**Examples**

View the location of the preferences folder:

```
prefdir
```

---

Make the preferences folder become the current folder:

```
cd(prefdir)
```

# prefdir

---

```
% Then, view the files for customizing MathWorks products:
dir
```

On Windows platforms, go directly to the preferences folder in Microsoft Windows Explorer

```
winopen(prefdir)
```

## See Also

preferences | getpref | setpref

## How To

- “Preferences Folder and Files MATLAB Uses When Multiple MATLAB Releases Are Installed”

**Purpose** Open Preferences dialog box

**Syntax** preferences

**Description** preferences displays the Preferences dialog box, from which you can make changes to options for MATLAB and related products.

**See Also** prefdir

**How To** • “Preferences”

# primes

---

**Purpose** Prime numbers less than or equal to input value

**Syntax** `p = primes(n)`

**Description** `p = primes(n)` returns a row vector containing all the prime numbers less than or equal to `n`. The data type of `p` is the same as that of `n`.

**Input Arguments** **n - Input value**  
scalar, real integer value

Input value, specified as a scalar that is a real integer value.

**Example:** 10

**Example:** `int16(32)`

**Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` |  
`uint16` | `uint32` | `uint64`

**Examples** **Primes Less Than or Equal to 25**

```
p = primes(25)
```

```
p =
```

```
 2 3 5 7 11 13 17 19 23
```

**Primes Less Than or Equal to an Unsigned Integer**

```
n = uint16(12);
```

```
p = primes(n)
```

```
p =
```

```
 2 3 5 7 11
```

**See Also** `factor` | `isprime`

**Purpose** Print figure or save to file

“Alternatives” on page 1-5197

### Syntax

```
print
print('argument1', 'argument2', ...)
print(handle, 'filename')
print argument1 argument2 ... argumentn
```

### Description

`print` sends the contents of the current figure, including bitmap representations of any user interface controls, to the printer using the device and system printing command defined by `printopt`.

`print('argument1', 'argument2', ...)` is the function form of `print`. It enables you to pass variables for any input arguments. This form is useful for passing file names and handles (for example, `print(handle, 'filename')`). See “Batch Processing” on page 1-5196 for an example. Also see “Specifying the Figure to Print” on page 1-5195 for further examples.

---

**Note** Print input only takes string variables and handles as inputs. Strings passed in as cell array or struct inputs are not accepted.

---

# print

`print argument1 argument2 ... argumentn` prints the figure using the specified arguments.

The following arguments apply to both the function and the command form:

Argument	Description
<code>handle</code>	Print the specified object.
<code>filename</code>	Direct the output to the PostScript file designated by <code>filename</code> . If <code>filename</code> does not include an extension, <code>print</code> appends an appropriate extension.
<code>-ddriver</code>	Print the figure using the specified printer <code>driver</code> , (such as color PostScript). If you omit <code>-ddriver</code> , <code>print</code> uses the default value stored in <code>printopt.m</code> . The table in “Printer Drivers” on page 1-5179 lists all supported device types.
<code>-dformat</code>	Copy the figure to the system Clipboard (Microsoft Windows platforms only). To be valid, the <code>format</code> for this operation must be either <code>-dmeta</code> (Windows Enhanced Metafile) or <code>-dbitmap</code> (Windows Bitmap).
<code>-dformat filename</code>	Export the figure to the specified file using the specified graphics <code>format</code> (such as TIFF). The table of “Graphics Format Files” on page 1-5183 lists all supported graphics file formats.
<code>-smodelname</code>	Print the current Simulink model <code>modelName</code> .
<code>-options</code>	Specify print options that modify the action of the <code>print</code> command. (For example, the <code>-noui</code> option suppresses printing of user interface controls.) “Printing Options” on page 1-5187 lists available options.

## Printer Drivers

The following table shows the more widely used printer drivers supported by MATLAB software. If you do not specify a driver, the default setting shown in the previous table is used. For a list of all supported printer drivers, type `print -d` at the MATLAB prompt. Some things to remember:

- As indicated in “Description” on page 1-5177 the `-d` switch specifies a printer driver or a graphics file format:
  - Specifying a printer driver without a file name or printer name (the `-P` option) sends the output formatted by the specified driver to your default printer, which may not be what you want to do.

---

**Note** On Windows systems, when you use the `-P` option to identify a printer to use, if you specify any driver other than `-dwin` or `-dwinc`, MATLAB writes the output to a file with an appropriate extension but does not send it to the printer. You can then copy that file to a printer.

---

- Specifying a `-dmeta` or a `-dbitmap` graphics format without a file name places the graphic on the system Clipboard, if possible (Windows platforms only).
- Specifying any other graphics format without a file name creates a file in the current folder with a name such as `figureN.fmt`, where `N` is 1, 2, 3, ... and `fmt` indicates the format type, for example, `eps` or `png`.
- Several drivers come from a product called Ghostscript, which is shipped with MATLAB software. The last column indicates when Ghostscript is used.
- Not all drivers are supported on all platforms. Non support is noted in the first column of the table.
- If you specify a particular printer with the `-P` option and do not specify a driver, a default driver for that printer is selected, either by the operating system or by MATLAB, depending on the platform:

- On Windows, the driver associated with this particular printing device is used.
- On Macintosh and UNIX platforms, the driver specified in `printopt.m` is used

See *Selecting the Printer* in the Graphics documentation for more information.

---

**Note** Support for some print options will be removed in a future release. The affected formats have an asterisk (\*) next to the option string in the following table. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

<b>PostScript Level 2 color</b>	-dpsc2	No
<b>Windows color</b> (Windows only)	-dwinc	No
<b>Windows monochrome</b> (Windows only)	-dwin	No

---

**Tip** Generally, Level 2 PostScript files are smaller and are rendered more quickly when printing than Level 1 PostScript files. However, not all PostScript printers support Level 2, so determine the capabilities of your printer before using those drivers. Level 2 PostScript printing is the default for UNIX platforms. You can change this default by editing the `printopt.m` file. Likewise, if you want color PostScript printing to be the default instead of black-and-white PostScript printing, edit the line in the `printopt.m` file that reads `dev = '-dps2'`; to be `dev = '-dpsc2'`;

---

## Graphics Format Files

To save your figure as a graphics format file, specify a format switch and file name. To set the resolution of the output file for a built-in MATLAB format, use the `-r` switch. (For example, `-r300` sets the output resolution to 300 dots per inch.) The `-r` switch is also supported for Windows Enhanced Metafiles, JPEG, TIFF and PNG files, but is not supported for Ghostscript raster formats. For more information, see “Printing and Exporting without a Display” on page 1-5186 and “Resolution Considerations” on page 1-5189.

---

**Note** When you print to a file, the file name must have fewer than 128 characters, including path name. When you print to a file in your current folder, the filename must have fewer than 126 characters, because MATLAB places `./` or `.\` at the beginning of the filename when referring to it.

---

The following table shows the supported output formats for exporting from figures and the switch settings to use. In some cases, a format is available both as a MATLAB output filter and as a Ghostscript output filter. All formats except for EMF are supported on both Windows and UNIX platforms.

**Note** Support for some print options will be removed in a future release. The affected formats have an asterisk (\*) next to the option string in the following table. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>	<b>MATLAB or Ghostscript</b>

<b>BMP</b> 24-bit	Bitmap	-dbmp	MATLAB
<b>EMF</b>	Vector	-dmeta	MATLAB
<b>EPS</b> black and white	Vector	-deps	MATLAB
<b>EPS</b> color	Vector	-depsc	MATLAB
<b>EPS</b> Level 2 black and white	Vector	-deps2	MATLAB
<b>EPS</b> Level 2 color	Vector	-depsc2	MATLAB
<b>HDF</b> 24-bit	Bitmap	-dhdf	MATLAB
<b>ILL</b> (Adobe Illustrator)	Vector	-dill *	MATLAB
<b>JPEG</b> 24-bit	Bitmap	-djpeg	MATLAB
<b>PBM</b> (plain format) 1-bit	Bitmap	-dpbm	Ghostscript

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>	<b>MATLAB or Ghostscript</b>
<b>PBM</b> (raw format) 1-bit	Bitmap	-dpbmraw	Ghostscript
<b>PCX</b> 1-bit	Bitmap	-dpcxmono	Ghostscript
<b>PCX</b> 24-bit color PCX file format, three 8-bit planes	Bitmap	-dpcx24b	Ghostscript
<b>PCX</b> 8-bit newer color PCX file format (256-color)	Bitmap	-dpcx256	Ghostscript
<b>PCX</b> Older color PCX file format (EGA/VGA, 16-color)	Bitmap	-dpcx16	Ghostscript
<b>PDF</b> Color PDF file format	Vector	-dpdf	Ghostscript
<b>PGM</b> Portable Graymap (plain format)	Bitmap	-dpgm	Ghostscript
<b>PGM</b> Portable Graymap (raw format)	Bitmap	-dpgmraw	Ghostscript
<b>PNG</b> 24-bit	Bitmap	-dpng	MATLAB
<b>PPM</b> Portable Pixmap (plain format)	Bitmap	-dppm	Ghostscript
<b>PPM</b> Portable Pixmap (raw format)	Bitmap	-dppmraw	Ghostscript

<b>Graphics Format</b>	<b>Bitmap or Vector</b>	<b>Print Command Option String</b>	<b>MATLAB or Ghostscript</b>
SVG Scalable Vector Graphics (For Simulink Models Only)	Vector	-dsvg	MATLAB
TIFF 24-bit	Bitmap	-dtiff or -dtiffn	MATLAB
TIFF preview for EPS files	Bitmap	-tiff	

The TIFF image format is supported on all platforms by almost all word processors for importing images. The `-dtiffn` variant writes an uncompressed TIFF. JPEG is a lossy, highly compressed format that is supported on all platforms for image processing and for inclusion into HTML documents on the Web. To create these formats, MATLAB renders the figure using the Z-buffer rendering method and the resulting bitmap is then saved to the specified file.

## Printing and Exporting without a Display

On a UNIX platform (including Macintosh), where you can start in MATLAB `nodisplay` mode (`matlab -nodisplay`), you can print using most of the drivers you can use with a display and export to most of the same file formats. The PostScript and Ghostscript devices all function in `nodisplay` mode on UNIX platforms. The graphic devices `-djpeg`, `-dpng`, `-dtiff` (compressed TIFF bitmaps), and `-tiff` (EPS with TIFF preview) work as well, but under `nodisplay` they use Ghostscript to generate output instead of using the drivers built into MATLAB. However, Ghostscript ignores the `-r` option when generating `-djpeg`, `-dpng`, `-dtiff`, and `-tiff` image files. This means that you cannot vary the resolution of image files when running in `nodisplay` mode.

The same is true for the `-noFigureWindows` startup option which suppresses figures on all platforms. On Windows platforms the `-dwin`, `-dwinc`, and `-dsetup` options operate as usual under `-noFigureWindows`. However, the `printpreview` GUI does not function

in this mode. Naturally, the Windows only `-dwin` and `-dwinc` output formats cannot be used on UNIX or Mac platforms with or without a display.

The formats which you cannot generate in `nodisplay` mode on UNIX and Mac platforms are:

- `bitmap (-dbitmap)` — Windows bitmap file
- `bmp (-dbmp...)` — Monochrome and color bitmaps
- `hdf (-dhdf)` — Hierarchical Data Format
- `svg (-dsvg)` — Scalable Vector Graphics file
- `tifn (-dtifn)` — TIFF image file, no compression

In addition, `uicontrols` do not print or export in `nodisplay` mode.

## Printing Options

This table summarizes options that you can specify for `print`. The second column links to tutorials that provide operational details. Also see “Resolution Considerations” on page 1-5189 for information on controlling output resolution.

---

**Note** Support for some print options will be removed in a future release. The affected formats have an asterisk (\*) next to the option string in the following table. The asterisks provide a link to the Web site which supplies a form for users to give feedback about these changes.

---

Option	Description
<code>-adobecset *</code>	PostScript devices only. Use PostScript default character set encoding. See “Early PostScript 1 Printers”.
<code>-append</code>	PostScript devices only. Append figure to existing PostScript file. See “Settings That Are Driver Specific”.

Option	Description
-cmyk	PostScript devices only. Print with CMYK colors instead of RGB. See “Setting CMYK Color”.
-ddriver	Printing only. Printer driver to use. See “Printer Drivers” on page 1-5179 table.
-dformat	Exporting only. Graphics format to use. See “Graphics Format Files” table.
-dsetup *	Windows printing only. Display the (platform-specific) Print Setup dialog. Settings you make in it are saved, but nothing is printed.
-fhandle	Handle of figure to print. Note that you cannot specify both this option and the <i>-swindowtitle</i> option. See “Which Figure Is Printed”.
-loose	PostScript and Ghostscript printing only. Use loose bounding box for PostScript output. See “Producing Uncropped Figures”.
-noui	Suppress printing of user interface controls. See “Excluding User Interface Controls”.
-opengl	Render using the OpenGL algorithm. Note that you cannot specify this method in conjunction with <i>-zbuffer</i> or <i>-painters</i> . See “Selecting a Renderer”.
-painters	Render using the Painter’s algorithm. Note that you cannot specify this method in conjunction with <i>-zbuffer</i> or <i>-opengl</i> . See “Selecting a Renderer”.
-Pprinter	Specify name of printer to use. See “Selecting the Printer”.

Option	Description
<i>-rnumber</i>	PostScript and built-in raster formats, and Ghostscript vector format only. Specify resolution in dots per inch. Defaults to 90 for Simulink, 150 for figures in image formats and when printing in Z-buffer or OpenGL mode, screen resolution for metafiles, and 864 otherwise. Use <i>-r0</i> to specify screen resolution. For details, see “Resolution Considerations” on page 1-5189 and “Setting the Resolution”.
<i>-swindowtitle</i>	Specify name of Simulink system window to print. Note that you cannot specify both this option and the <i>-fhandle</i> option. See “Which Figure Is Printed”.
<i>-v</i>	Windows printing only. Display the Windows Print dialog box. The <i>v</i> stands for “verbose mode.”
<i>-zbuffer</i>	Render using the Z-buffer algorithm. Note that you cannot specify this method in conjunction with <i>-opengl</i> or <i>-painters</i> . See “Selecting a Renderer”.

### Resolution Considerations

Use *-rnumber* to specify the resolution of the generated output. In general, using a higher value will yield higher quality output but at the cost of larger output files. It affects the resolution and output size of all MATLAB built-in *raster* formats (which are identified in column four of the table in “Graphics Format Files” on page 1-5183).

---

**Note** Built-in graphics formats are generated directly from MATLAB without conversion through the Ghostscript library. Also, in headless (`nodisplay`) mode, writing to certain image formats is not done by built-in drivers, as it is when a display is being used. These formats are `-djpeg`, `-dtiff`, and `-dpng`. Furthermore, the `-dhdf` and `-dbmp` formats cannot be generated in headless mode (but you can substitute `-dbmp16m` for `-dbmp`). See “Printing and Exporting without a Display” on page 1-5186 for details on printing when not using a display.

---

Unlike the built-in MATLAB formats, graphic output generated via Ghostscript does not directly obey `-r` option settings. However, the intermediate PostScript file generated by MATLAB as input for the Ghostscript processor is affected by the `-r` setting and thus can indirectly influence the quality of the final Ghostscript generated output.

The effect of the `-r` option on output quality can be subtle at ordinary magnification when using the OpenGL or ZBuffer renderers and writing to one of the MATLAB built-in raster formats, or when generating vector output that contains an embedded raster image (for example, PostScript or PDF). The effect of specifying higher resolution is more apparent when viewing the output at higher magnification or when printed, since a larger `-r` setting provides more data to use when scaling the image.

When generating fully vectorized output (as when using the Painters renderer to output a vector format such as PostScript or PDF), the resolution setting affects the degree of detail of the output; setting resolution higher generates crisper output (but small changes in the resolution may have no observable effect). For example, the gap widths of lines that do not use a solid (‘-’) linestyle can be affected.

## Paper Sizes

MATLAB printing supports a number of standard paper sizes. You can select from the following list by setting the `PaperType` property of the figure or selecting a supported paper size from the Print dialog box.

<b>Property Value</b>	<b>Size (Width by Height)</b>
usletter	8.5 by 11 inches
uslegal	8.5 by 14 inches
tabloid	11 by 17 inches
A0	841 by 1189 mm
A1	594 by 841 mm
A2	420 by 594 mm
A3	297 by 420 mm
A4	210 by 297 mm
A5	148 by 210 mm
B0	1029 by 1456 mm
B1	728 by 1028 mm
B2	514 by 728 mm
B3	364 by 514 mm
B4	257 by 364 mm
B5	182 by 257 mm
arch-A	9 by 12 inches
arch-B	12 by 18 inches
arch-C	18 by 24 inches
arch-D	24 by 36 inches
arch-E	36 by 48 inches
A	8.5 by 11 inches
B	11 by 17 inches
C	17 by 22 inches

Property Value	Size (Width by Height)
D	22 by 34 inches
E	34 by 43 inches

## Printing Tips

### Setting Default Printer

You can edit the file `printopt.m` to set the default printer type and destination. If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see a printer which is already setup.

### Figures with Resize Functions

The `print` command produces a warning when you print a figure having a callback routine defined for the figure `ResizeFcn`. To avoid the warning, set the figure `PaperPositionMode` property to `auto` or select **Auto (Actual Size, Centered)** in the **File > Print Preview** dialog box.

### Troubleshooting Microsoft Windows Printing

If you encounter problems such as segmentation violations, general protection faults, or application errors, or the output does not appear as you expect when using Microsoft printer drivers, try the following:

- If your printer is PostScript compatible, print with one of the MATLAB built-in PostScript drivers. There are various PostScript device options that you can use with `print`, which all start with `-dps`.
- The behavior you are experiencing might occur only with certain versions of the print driver. Contact the print driver vendor for information on how to obtain and install a different driver.
- Try printing with one of the MATLAB built-in Ghostscript devices. These devices use Ghostscript to convert PostScript files into other formats, such as HP LaserJet, PCX, Canon BubbleJet, and so on.

- Copy the figure as a Windows Enhanced Metafile using the **Edit > Copy Figure** menu item on the figure window menu or the `print -dmeta` option at the command line. You can then import the file into another application for printing.

You can set copy options in the figure's **File > Preferences > Copying Options** dialog box. The Windows Enhanced Metafile Clipboard format produces a better quality image than Windows Bitmap.

### Printing MATLAB GUIs

You can generally obtain better results when printing a figure window that contains MATLAB `uicontrols` by setting these key properties:

- Set the figure `PaperPositionMode` property to `auto`. This ensures that the printed version is the same size as the on-screen version. With `PaperPositionMode` set to `auto` MATLAB does not resize the figure to fit the current value of the `PaperPosition`. This is particularly important if you have specified a figure `ResizeFcn`, because if MATLAB resizes the figure during the print operation, `ResizeFcn` is automatically called.

To set `PaperPositionMode` on the current figure, use the command:

```
set(gcf, 'PaperPositionMode', 'auto')
```

- Set the figure `InvertHardcopy` property to `off`. By default, MATLAB changes the figure background color of printed output to white, but does not change the color of `uicontrols`. If you have set the background color, for example, to match the gray of the GUI devices, you must set `InvertHardcopy` to `off` to preserve the color scheme.

To set `InvertHardcopy` on the current figure, use the command:

```
set(gcf, 'InvertHardcopy', 'off')
```

- Use a color device if you want lines and text that are in color on the screen to be written to the output file as colored objects. Black and

white devices convert colored lines and text to black or white to provide the best contrast with the background and to avoid dithering.

- Use the `print` command's `-loose` option to keep a bounding box from being too tightly wrapped around objects contained in the figure. This is important if you have intentionally used space between `uicontrols` or axes and the edge of the figure and you want to maintain this appearance in the printed output.

If you print or export in `nodisplay` mode, none of the `uicontrols` the figure has will be visible. If you run code that adds `uicontrols` to a figure when the figure is invisible, the controls will not print until the figure is made visible.

## Printing Interpolated Shading with PostScript Drivers

You can print MATLAB surface objects (such as graphs created with `surf` or `mesh`) using interpolated colors. However, only patch objects that are composed of triangular faces can be printed using interpolated shading.

Printed output is always interpolated in RGB space, not in the colormap colors. This means that if you are using indexed color and interpolated face coloring, the printed output can look different from what is displayed on screen.

PostScript files generated for interpolated shading contain the color information of the graphics object's vertices and require the printer to perform the interpolation calculations. This can take an excessive amount of time and in some cases, printers might time out before finishing the print job. One solution to this problem is to interpolate the data and generate a greater number of faces, which can then be flat shaded.

To ensure that the printed output matches what you see on the screen, print using the `-zbuffer` option. To obtain higher resolution (for example, to make text look better), use the `-r` option to increase the resolution. There is, however, a tradeoff between the resolution and the size of the created PostScript file, which can be quite large at higher resolutions. The default resolution of 150 dpi generally produces good

results. You can reduce the size of the output file by making the figure smaller before printing it and setting the figure `PaperPositionMode` to `auto`, or by just setting the `PaperPosition` property to a smaller size.

## Examples

### Specifying the Figure to Print

Pass a figure handle as a variable to the function form of `print`. For example:

```
h = figure;
plot(1:4,5:8)
print(h)
```

Save the figure with the handle `h` to a PostScript file named `Figure2`, which can be printed later:

```
print(h, '-dps', 'Figure2.ps')
```

Pass in a file name as a variable:

```
filename = 'mydata';
print(h, '-dpSC', filename);
```

(Because a file name is specified, the figure will be printed to a file.)

### Specifying the Model to Print

Print a noncurrent Simulink model using the `-s` option with the title of the window (in this case, `f14`):

```
print('-sf14')
```

If the window title includes any spaces, you must call the function form rather than the command form of `print`. For example, this command saves the Simulink window title `Thruster Control`:

```
print('-sThruster Control')
```

To print the current system, use:

```
print('-s')
```

For information about issues specific to printing Simulink windows, see the Simulink documentation.

## Printing Figures at Screen Size

This example prints a surface plot with interpolated shading. Setting the current figure's (`gcf`) `PaperPositionMode` to `auto` enables you to resize the figure window and print it at the size you see on the screen. See “Printing Options” on page 1-5187 and “Printing Interpolated Shading with PostScript Drivers” on page 1-5194 for information on the `-zbuffer` and `-r200` options.

```
surf(peaks)
shading interp
set(gcf, 'PaperPositionMode', 'auto')
print('-dpsc2', '-zbuffer', '-r200')
```

For additional details, see “Printing Images” in the MATLAB Graphics documentation.

## Batch Processing

You can use the function form of `print` to pass variables containing file names. For example, this `for` loop uses file names stored in a cell array to create a series of graphs and prints each one with a different file name:

```
fnames = {'file1', 'file2', 'file3'};
for k=1:length(fnames)
 surf(peaks)
 print('-dtiff', '-r200', fnames{k})
end
```

`fnames` is a cell of string arrays so each element is a string.

## Tiff Preview

The command

```
print('-depsec', '-tiff', '-r300', 'picture1')
```

saves the current figure at 300 dpi, in a color Encapsulated PostScript file named `picture1.eps`. The `-tiff` option creates a 72 dpi TIFF preview, which many word processor applications can display on screen after you import the EPS file. This enables you to view the picture on screen within your word processor and print the document to a PostScript printer using a resolution of 300 dpi.

### Alternatives

Select **File > Print** from the figure window to open the Print dialog box and **File > Print Preview** to open the Print Preview GUI. For details, see “How to Print or Export”.

### See Also

`figure` | `hgsave` | `imwrite` | `orient` | `printdlg` | `printopt` | `saveas`

# printopt

---

**Purpose** Configure printer defaults

**Syntax** [pcmd,dev] = printopt

**Description** [pcmd,dev] = printopt returns strings containing the current system-dependent printing command and output device. printopt is a file used by print to produce the hard-copy output. You can edit the file printopt.m to set your default printer type and destination.

pcmd and dev are platform-dependent strings. pcmd contains the command that print uses to send a file to the printer. dev contains the printer driver or graphics format option for the print command. Their defaults are platform dependent.

Platform	Print Command	Driver or Format
Mac and UNIX	lpr -r	-dps2
Windows	COPY /B %s LPT1:	-dwin

**See Also** printdlg | print

**Purpose** Print dialog box

**Syntax**

```
printdlg
printdlg(fig)
printdlg('-crossplatform',fig)
printdlg('-setup',fig)
```

**Description** `printdlg` prints the current figure.

`printdlg(fig)` creates a modal dialog box from which you can print the figure window identified by the handle `fig`. Note that `uimenu`s do not print.

`printdlg('-crossplatform',fig)` displays the standard cross-platform MATLAB printing dialog rather than the built-in printing dialog box for Microsoft Windows computers. Insert this option before the `fig` argument.

`printdlg('-setup',fig)` forces the printing dialog to appear in a setup mode. This option is obsolete and will be removed in a future release.

---

**Note** If you want to set up a new printer, use the operating system printer management utilities. Restart MATLAB if you do not see the printer which is already setup.

---

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

**See Also** `print` | `printopt` | `printpreview`

# printpreview

---

**Purpose** Preview figure to print

## **Contents**

“Description” on page 1-5200

“Right Pane Controls” on page 1-5201

“The Layout Tab” on page 1-5202

“The Lines/Text Tab” on page 1-5203

“The Color Tab” on page 1-5205

“The Advanced Tab” on page 1-5207

“Alternatives” on page 1-5208

**Syntax** `printpreview`  
`printpreview(f)`

**Description** `printpreview` displays a dialog box showing the figure in the currently active figure window as it will print. A scaled version of the figure displays in the right-hand pane of the GUI.

`printpreview(f)` displays a dialog box showing the figure having the handle `f` as it will print.

Use the Print Preview dialog box, shown below, to control the layout and appearance of figures before sending them to a printer or print file. Controls are grouped into four tabbed panes: **Layout**, **Lines/Text**, **Color**, and **Advanced**.

## Right Pane Controls

You can position and scale plots on the printed page using the rulers in the right-hand pane of the Print Preview dialog. Use the outer ruler handlebars to change margins. Moving them changes plot proportions. Use the center ruler handlebars to change the position of the plot on the page. Plot proportions do not change, but you can move portions of

the plot off the paper. The buttons on that pane let you refresh the plot, close the dialog (preserving all current settings), print the page immediately, or obtain context-sensitive help. Use the **Zoom** box and scroll bars to view and position page elements more precisely.

## The Layout Tab

Use the **Layout** tab, shown above, to control the paper format and placement of the plot on printed pages. The following table summarizes the **Layout** options:

<b>Group</b>	<b>Option</b>	<b>Description</b>
Placement	<b>Auto</b>	Let MATLAB decide placement of plot on page*
	<b>Use manual...</b>	Specify position parameters for plot on page*
	<b>Top, Left, Width, Height</b>	Standard position parameters in current units
	<b>Use defaults</b>	Revert to default position
	<b>Fill page</b>	Expand figure to fill printable area (see note below)
	<b>Fix aspect ratio</b>	Correct height/width ratio
	<b>Center</b>	Center plot on printed page
Paper	<b>Format</b>	U.S. and ISO® sheet size selector
	<b>Width, Height</b>	Sheet size in current units
Units	<b>Inches</b>	Use inches as units for dimensions and positions
	<b>Centimeters</b>	Use centimeters as units for dimensions and positions
	<b>Points</b>	Use points as units for dimensions and positions
Orientation	<b>Portrait</b>	Upright paper orientation

Group	Option	Description
	<b>Landscape</b>	Sideways paper orientation
	<b>Rotated</b>	Currently the same as <b>Landscape</b>

\* Selecting **Auto** in the Placement group sets the figure PaperPositionMode to 'auto' and disables the controls in that panel. Selecting **Use manual size and position** sets the figure PaperPositionMode to 'manual' and enables the controls. If you set PaperPositionMode programmatically, the print preview Placement controls respond accordingly.

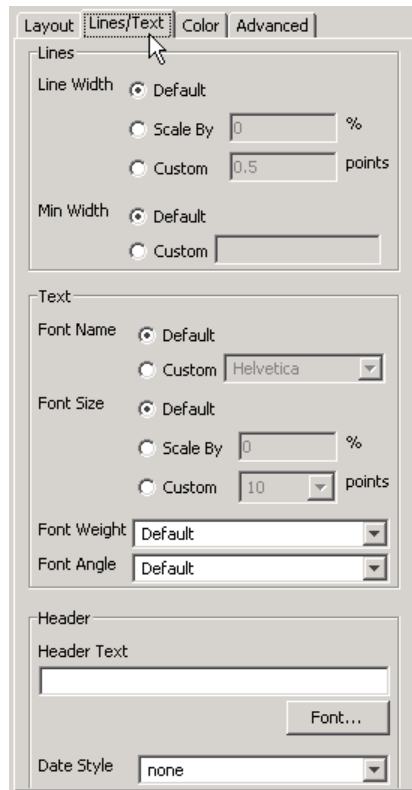

---

**Note** Selecting the **Fill page** option changes the PaperPosition property to fill the page, allowing objects in normalized units to expand to fill the space. If an object within the figure has an absolute size, for example a table, it can overflow the page when objects with normalized units expand. To avoid having objects fall off the page, do not use **Fill page** under such circumstances.

---

### The Lines/Text Tab

Use the **Lines/Text** tab, shown below, to control the line weights, font characteristics, and headers for printed pages. The following table summarizes the **Lines/Text** options:

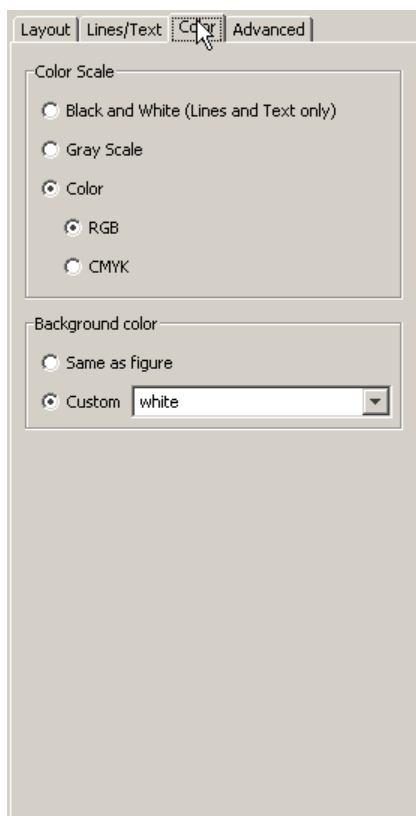

Group	Option	Description
Lines	<b>Line Width</b>	Scale all lines by a percentage from 0 upward (100 being no change), print lines at a specified point size, or default line widths used on the plot
	<b>Min Width</b>	Smallest line width (in points) to use when printing; defaults to 0.5 point
Text	<b>Font Name</b>	Select a system font for all text on plot, or default to fonts currently used on the plot

Group	Option	Description
	<b>Font Size</b>	Scale all text by a percentage from 0 upward (100 being no change), print text at a specified point size, or default to this
	<b>Font Weight</b>	Select Normal ... Bold font styling for all text from drop-down menu or default to the font weights used on the plot
	<b>Font Angle</b>	Select Normal, Italic or Oblique font styling for all text from drop-down menu or default to the font angles used on the plot
Header	<b>Header Text</b>	Type the text to appear on the header at the upper left of printed pages, or leave blank for no header
	<b>Date Style</b>	Select a date format to have today's date appear at the upper left of printed pages, or none for no date

### The Color Tab

Use the **Color** tab, shown below, to control how colors are printed for lines and backgrounds. The following table summarizes the **Color** options:

Group	Option	Description
Color Scale	<b>Black and White</b>	Select to print lines and text in black and white, but use color for patches and other objects
	<b>Gray Scale</b>	Convert colors to shades of gray on printed pages

Group	Option	Description
	<b>Color</b>	Print everything in color, matching colors on plot; select RGB (default) or CMYK color model for printing
Background Color	<b>Same as figure</b>	Print the figure's background color as it is
	<b>Custom</b>	Select a color name, or type a colorspec for the background; white (default) implies no background color, even on colored paper.

### The Advanced Tab

Use the **Advanced** tab, shown below, to control finer details of printing, such as limits and ticks, renderer, resolution, and the printing of UIControls. The following table summarizes the **Advanced** options:

Group	Option	Description
Axes limits and ticks	<b>Recompute limits and ticks</b>	Redraw $x$ - and $y$ -axes ticks and limits based on printed plot size (default)
	<b>Keep limits and ticks</b>	Use the $x$ - and $y$ -axes ticks and limits shown on the plot when printing the previewed figure
Miscellaneous	<b>Renderer</b>	Select a rendering algorithm for printing: painters, zbuffer, opengl, or auto (default)
	<b>Resolution</b>	Select resolution to print at in dots per inch: 150, 300, 600, or auto (default), or type in any other positive value
	<b>Print UIControls</b>	Print all visible UIControls in the figure (default), or uncheck to exclude them from being printed

## Alternatives

Use **File > Print Preview** on the figure window menu to access the Print Preview dialog box, described below. For details, see “Using Print Preview”.

## How To

- How to Print or Export

**Purpose**

Product of array elements

**Syntax**

```
B = prod(A)
B = prod(A,dim)
B = prod(__ ,type)
```

**Description**

`B = prod(A)` returns the product of the array elements of `A`.

- If `A` is a vector, then `prod(A)` returns the product of the elements.
- If `A` is a nonempty matrix, then `prod(A)` treats the columns of `A` as vectors and returns a row vector of the products of each column.
- If `A` is an empty 0-by-0 matrix, `prod(A)` returns 1.
- If `A` is a multidimensional array, then `prod(A)` acts along the first nonsingleton dimension and returns an array of products. The size of this dimension reduces to 1 while the sizes of all other dimensions remain the same.

`prod` computes and returns `B` as `single` if the input, `A`, is `single`. For all other numeric and logical data types, `prod` computes and returns `B` as `double`.

`B = prod(A,dim)` returns the products along dimension `dim`. For example, if `A` is a matrix, `prod(A,2)` is a column vector containing the products of each row.

`B = prod( __ ,type)` multiplies in and returns an array in the class specified by `type`, using any of the input arguments in the previous syntaxes. `type` can be `'double'` or `'native'`.

**Input Arguments****A - Input array**

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**Complex Number Support:** Yes

## dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Dimension  $dim$  indicates the dimension whose length reduces to 1. The  $size(B, dim)$  is 1, while the sizes of all other dimensions remain the same.

Consider a two-dimensional input array,  $A$ .

- If  $dim = 1$ , then  $prod(A, 1)$  returns a row vector containing the product of the elements in each column.
- If  $dim = 2$ , then  $prod(A, 2)$  returns a column vector containing the product of the elements in each row.

`prod` returns  $A$  if  $dim$  is greater than  $ndims(A)$ .

## Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**type - Output class**

'double' | 'native'

Output class, specified as 'double' or 'native', defines the data type that the operation is performed in and output in.

- If type is 'double', then prod computes and returns a double precision array, regardless of the input data type. For example, if A is single, then prod multiplies in and returns in double.
- If type is 'native', prod multiplies natively and returns an array with the same data type as the input array A. For example, if A is an 8-bit unsigned integer, prod multiplies natively and returns B with data type uint8.

**Data Types**

char

**Output Arguments****B - Product array**

scalar | vector | matrix | multidimensional array

Product array, returned as a scalar, vector, matrix, or multidimensional array.

The class of B is as follows:

- If the type argument is not used and the input is not single, then the output is double.
- If the type argument is not used and the input is single, then the output is single.
- If the type argument specifies 'double', then the output is double regardless of the input data type.
- If the type argument specifies 'native', then the output is the same data type as the input.

**Definitions****First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1.

For example:

- If  $X$  is a 1-by- $n$  row vector, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-0-by- $n$  empty array, then the second dimension is the first nonsingleton dimension of  $X$ .
- If  $X$  is a 1-by-1-by-3 array, then the third dimension is the first nonsingleton dimension of  $X$ .

## Examples

### Product of Elements in Each Column

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

A =

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each column.

```
B = prod(A)
```

B =

```
 6 120 504
```

The length of the first dimension is 1, and the length of the second dimension matches `size(A,2)`.

### Logical Input with Double Output

Create an array of logical values.

```
A = [true false; true true]
```

```
A =

 1 0
 1 1
```

Find the product of the elements in each column.

```
B = prod(A)
```

```
B =

 1 0
```

The output is double.

```
class(B)
```

```
ans =
```

```
double
```

### **Product of Elements in Each Row**

Create a 3-by-3 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9]
```

```
A =

 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each row and reduce the length of the second dimension to 1.

```
dim = 2;
B = prod(A,dim)
```

B =

```
28
80
162
```

The length of the first dimension matches `size(A,1)`, and the length of the second dimension is 1.

## Product of Elements in Each Plane

Create a 3-by-3-by-2 array whose elements correspond to their linear indices.

```
A=[1:3:7;2:3:8;3:3:9];
A(:,:,2)=[10:3:16;11:3:17;12:3:18]
```

A(:,:,1) =

```
1 4 7
2 5 8
3 6 9
```

A(:,:,2) =

```
10 13 16
11 14 17
12 15 18
```

Find the product of each element in the first plane with its corresponding element in the second plane.

```
dim = 3;
B = prod(A,dim)
```

B =

```
10 52 112
22 70 136
36 90 162
```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is 1.

### Single-Precision Input treated as Double

Create a 3-by-3 array of single-precision values.

```
A = single([1200 1500 1800; 1300 1600 1900; 1400 1700 2000])
```

A =

```
1200 1500 1800
1300 1600 1900
1400 1700 2000
```

Find the product of the elements in each row by performing the multiplication in double precision.

```
B = prod(A,2, 'double')
```

B =

```
1.0e+09 *
3.2400
3.9520
4.7600
```

The output is double precision.

```
class(B)
```

```
ans =
```

```
double
```

## Integer Data Type for Input and Output

Create a 3-by-3 array of 8-bit unsigned integers.

```
A = uint8([1:3:7;2:3:8;3:3:9])
```

```
A =
```

```
 1 4 7
 2 5 8
 3 6 9
```

Find the product of the elements in each column natively in `uint8`.

```
B = prod(A, 'native')
```

```
B =
```

```
 6 120 255
```

The result is an array of 8-bit unsigned integers.

```
class(B)
```

```
ans =
```

```
uint8
```

```

**Purpose**

Profile execution time for function

**Syntax**

```
profile on
profile -history
profile -nohistory
profile -history -historysize integer
profile -timer clock
profile -history -historysize integer -timer clock
profile off
profile resume
profile clear
profile viewer
S = profile('status')
stats = profile('info')
```

**Description**

The `profile` function helps you debug and optimize MATLAB code files by tracking their execution time. For each MATLAB function, MATLAB local function, or MEX-function in the file, `profile` records information about execution time, number of calls, parent functions, child functions, code line hit count, and code line execution time. Some people use `profile` simply to see the child functions; see also `matlab.codetools.requiredFilesAndProducts` for that purpose. To open the Profiler graphical user interface, use the `profile viewer` syntax. By default, Profiler time is CPU time. The total time reported by the Profiler is not the same as the time reported using the `tic` and `toc` functions or the time you would observe using a stopwatch.

---

**Note** If your system uses Intel multi-core chips, you may want to restrict the active number of CPUs to 1 for the most accurate and efficient profiling. See “Multi-Core Processors — Setting for Most Accurate Profiling on Windows Systems” or “Multi-Core Processors — Setting for Most Accurate Profiling on Linux Systems” for details on how to do this.

---

`profile on` starts the Profiler, clearing previously recorded profile statistics. Note the following:

- You can specify all, none, or a subset, of the `history`, `historysize` and `timer` options with the `profile on` syntax.
- You can specify options in any order, including before or after `on`.
- If the Profiler is currently on and you specify `profile` with one of the options, MATLAB software returns an error message and the option has no effect. For example, if you specify `profile timer real`, MATLAB returns the following error: The profiler has already been started. `TIMER` cannot be changed.
- To change options, first specify `profile off`, and then specify `profile on` or `profile resume` with new options.

`profile -history` records the exact sequence of function calls. The `profile` function records, by default, up to 1,000,000 function entry and exit events. For more than 1,000,000 events, `profile` continues to record other profile statistics, but not the sequence of calls. To change the number of function entry and exit events that the `profile` function records, use the `historysize` option. By default, the `history` option is not enabled.

`profile -nohistory` disables further recording of the history (exact sequence of function calls). Use the `-nohistory` option after having previously set the `-history` option. All other profiling statistics continue to be collected.

`profile -history -historysize integer` specifies the number of function entry and exit events to record. By default, `historysize` is set to 1,000,000.

`profile -timer clock` specifies the type of time to use. Valid values for `clock` are:

- `'cpu'` — The Profiler uses computer time (the default).
- `'real'` — The Profiler uses wall-clock time.

For example, `cpu` time for the `pause` function is typically small, but `real` time accounts for the actual time paused, and therefore would be larger.

`profile -history -historysize integer -timer clock` specifies all of the options. Any order is acceptable, as is a subset.

`profile off` stops the Profiler.

`profile resume` restarts the Profiler without clearing previously recorded statistics.

`profile clear` clears the statistics recorded by `profile`.

`profile viewer` stops the Profiler and displays the results in the Profiler window. For more information, see [Profiling for Improving Performance in the Desktop Tools and Development Environment documentation](#).

`S = profile('status')` returns a structure containing information about the current status of the Profiler. The table lists the fields in the order that they appear in the structure.

Field	Values	Default Value
ProfilerStatus	'on' or 'off'	off
DetailLevel	'mmex'	'mmex'
Timer	'cpu' or 'real'	'cpu'
HistoryTracking	'on' or 'off'	'off'
HistorySize	integer	1000000

`stats = profile('info')` stops the Profiler and displays a structure containing the results. Use this function to access the data generated by `profile`. The table lists the fields in the order that they appear in the structure.

# profile

---

Field	Description
FunctionTable	Structure array containing statistics about each function called
FunctionHistory	Array containing function call history
ClockPrecision	Precision of the <code>profile</code> function's time measurement
ClockSpeed	Estimated clock speed of the CPU
Name	Name of the profiler

The `FunctionTable` field is an array of structures, where each structure contains information about one of the functions or local functions called during execution. The following table lists these fields in the order that they appear in the structure.

Field	Description
CompleteName	Full path to <code>FunctionName</code> , including local functions
FunctionName	Function name; includes local functions
FileName	Full path to <code>FunctionName</code> , with file extension, excluding local functions
Type	MATLAB functions, MEX-functions, and many other types of functions including MATLAB local functions, nested functions, and anonymous functions
NumCalls	Number of times the function was called
TotalTime	Total time spent in the function and its child functions
TotalRecursiveTime	No longer used.
Children	<code>FunctionTable</code> indices to child functions
Parents	<code>FunctionTable</code> indices to parent functions

Field	Description
ExecutedLines	<p>Array containing line-by-line details for the function being profiled.</p> <p>Column 1: Number of the line that executed. If a line was not executed, it does not appear in this matrix.</p> <p>Column 2: Number of times the line was executed</p> <p>Column 3: Total time spent on that line. Note: The sum of Column 3 entries does not necessarily add up to the function's TotalTime.</p>
IsRecursive	BOOLEAN value: Logical 1 (true) if recursive, otherwise logical 0 (false)
PartialData	BOOLEAN value: Logical 1 (true) if function was modified during profiling, for example by being edited or cleared. In that event, data was collected only up until the point when the function was modified.

## Examples

### Profile, View Results, and Save Profile Data as HTML

This example profiles the MATLAB `magic` command and then displays the results in the Profiler window. The example then retrieves the profile data on which the HTML display is based and uses the `profsave` command to save the profile data in HTML form.

```
profile on
plot(magic(35))
profile viewer
p = profile('info');
profsave(p,'profile_results')
```

## Profile, Save Profile Data to a MAT-File, and View Results

Another way to save profile data is to store it in a MAT-file. This example stores the profile data in a MAT-file, clears the profile data from memory, and then loads the profile data from the MAT-file. This example also shows a way to bring the reloaded profile data into the Profiler graphical interface as live profile data, not as a static HTML page.

```
p = profile('info');
save myprofiledata p
clear p
load myprofiledata
profview(0,p)
```

## Profile and Show Results Including History

This example illustrates an effective way to view the results of profiling when the history option is enabled. The history data describes the sequence of functions entered and exited during execution. The `profile` command returns history data in the `FunctionHistory` field of the structure it returns. The history data is a 2-by-n array. The first row contains Boolean values, where 0 means entrance into a function and 1 means exit from a function. The second row identifies the function being entered or exited by its index in the `FunctionTable` field. This example reads the history data and displays it in the MATLAB Command Window.

```
profile on -history
plot(magic(4));
p = profile('info');

for n = 1:size(p.FunctionHistory,2)
 if p.FunctionHistory(1,n)==0
 str = 'entering function: ';
 else
 str = 'exiting function: ';
 end
 disp([str p.FunctionTable(p.FunctionHistory(2,n)).FunctionName])
end
```

end

# profsave

---

**Purpose** Save profile report in HTML format

**Syntax**

```
profsave
profsave(profinfo)
profsave(profinfo,dirname)
```

**Description** `profsave` executes the `profile('info')` function and saves the results in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of the structure returned by `profile`. By default, `profsave` stores the HTML files in a subfolder of the current folder named `profile_results`.

`profsave(profinfo)` saves the profiling results, `profinfo`, in HTML format. `profinfo` is a structure of profiling information returned by the `profile('info')` function.

`profsave(profinfo,dirname)` saves the profiling results, `profinfo`, in HTML format. `profsave` creates a separate HTML file for each function listed in the `FunctionTable` field of `profinfo` and stores them in the folder specified by `dirname`.

**Examples** Run profile and save the results.

```
profile on
plot(magic(5))
profile off
profsave(profile('info'),'myprofile_results')
```

**See Also** `profile`

**How To**

- [Profiling for Improving Performance](#)

**Purpose** Open Property Editor

**Syntax**  
`propedit`  
`propedit(handle_list)`

**Description** `propedit` starts the Property Editor, a graphical user interface to the properties of graphics objects. If no current figure exists, `propedit` will create one.

`propedit(handle_list)` edits the properties for the object (or objects) in `handle_list`.

Starting the Property Editor enables plot editing mode for the figure.

**See Also** `inspect` | `plottedit` | `propertyeditor`

# propedit (COM)

---

<b>Purpose</b>	Open built-in property page for control
<b>Syntax</b>	<code>h.propedit</code> <code>propedit(h)</code>
<b>Description</b>	<p><code>h.propedit</code> requests the control to display its built-in property page. Note that some controls do not have a built-in property page. For those controls, this command fails.</p> <p><code>propedit(h)</code> is an alternate syntax for the same operation.</p>
<b>Tips</b>	COM functions are available on Microsoft Windows systems only.
<b>See Also</b>	<code>inspect</code>   <code>get (COM)</code>

<b>Purpose</b>	Class property names
<b>Syntax</b>	<pre>properties('classname') properties(obj) p = properties(...)</pre>
<b>Description</b>	<p><code>properties('classname')</code> displays the names of the public properties for the MATLAB class named by <code>classname</code>. The <code>properties</code> function also displays inherited properties.</p> <p><code>properties(obj)</code> <code>obj</code> can be either a scalar object or an array of objects. When <code>obj</code> is scalar, <code>properties</code> also returns dynamic properties. See “Dynamic Properties — Adding Properties to an Instance” for information on using dynamic properties.</p> <p><code>p = properties(...)</code> returns the property names in a cell array of strings.</p>
<b>Definitions</b>	<p>A property is public when its <code>GetAccess</code> attribute value is <code>public</code> and its <code>Hidden</code> attribute value is <code>false</code> (default values for these attributes). See “Property Attributes” for a complete list of attributes.</p> <p><code>properties</code> is also a MATLAB class-definition keyword. See <code>classdef</code> for more information on class definition keywords.</p>
<b>Examples</b>	<p>Retrieve the names of the public properties of class <code>memmapfile</code> and store the result in a cell array of strings:</p> <pre>p = properties('memmapfile'); p ans =      'writable'     'offset'     'format'     'repeat'     'filename'</pre>

# properties

---

Construct an instance of the MException class and get its properties names:

```
me = MException('Msg:ID', 'MsgText');
properties(me)
Properties for class MException:
```

```
 identifier
 message

## Tutorials

- “Properties”

**Purpose** Show or hide **Property Editor**

**Syntax**

```
propertyeditor('on')
propertyeditor('off')
propertyeditor
propertyeditor(figure_handle,...)
```

**Description** `propertyeditor('on')` displays the Property Editor tool on the current figure.

`propertyeditor('off')` hides the Property Editor on the current figure.

`propertyeditor` toggles the visibility of the Property Editor on the current figure. You can also use `propertyeditor('toggle')` instead for the same functionality.

`propertyeditor(figure_handle,...)` displays or hides the Property Editor on the figure specified by *figure\_handle*.

**Tips** If you call `propertyeditor` in a MATLAB program and subsequent lines depend on the Property Editor being fully initialized, follow it by `drawnow` to ensure complete initialization.

**Alternatives** To collectively enable **Plotting Tools**, use the large Plotting Tool icon  on the figure toolbar. To collectively disable the **Plotting Tools**, use the smaller icon . Open or close the **Property Editor** tool from the figure's **View** menu. For details, see “Customize Objects in Graph”.

# propertyeditor

---

## **See Also**

`plottools` | `plotbrowser` | `figurepalette` | `inspect`

**Purpose** Custom property list for object display

**Description** Use the PropertyGroup class to create custom property display lists for class derived from matlab.mixin.CustomDisplay.

**Construction** `P = matlab.mixin.util.PropertyGroup(propertyList)` constructs a property group with the supplied `propertyList`.

`P = matlab.mixin.util.PropertyGroup(propertyList,title)` displays `title` above the list of properties.

## Input Arguments

### **propertyList**

The `propertyList` is either a cell array of property names, or a scalar struct with property name-value pairs.

### **title**

Text to display above properties.

## Properties

### **NumProperties**

The number of properties in the `PropertyList`.

### **Attributes:**

Dependent	true
GetAccess	public
GetObservable	true
SetAccess	private
Transient	true

### **PropertyList**

The list of properties to display, stored as a scalar struct or a cell array of strings.

# matlab.mixin.util.PropertyGroup

---

## Attributes:

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

## Title

An optional Title for the PropertyGroup.

## Attributes:

GetAccess	public
GetObservable	true
SetAccess	public
SetObservable	true

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Concepts

- Property Attributes

**Purpose** Psi (polygamma) function

**Syntax**  
`Y = psi(X)`  
`Y = psi(k,X)`

**Description** `Y = psi(X)` evaluates the  $\psi$  function for each element of array `X`. `X` must be real and nonnegative. The  $\psi$  function, also known as the digamma function, is the logarithmic derivative of the gamma function

$$\begin{aligned}\psi(x) &= \text{digamma}(x) \\ &= \frac{d(\log(\Gamma(x)))}{dx} \\ &= \frac{d(\Gamma(x)) / dx}{\Gamma(x)}\end{aligned}$$

`Y = psi(k,X)` evaluates the  $k$ th derivative of  $\psi$  at the elements of `X`. `psi(0,X)` is the digamma function, `psi(1,X)` is the trigamma function, `psi(2,X)` is the tetragamma function, etc.

## Examples

### Example 1

Use the `psi` function to calculate Euler's constant,  $\gamma$ .

```
format long
-psi(1)
ans =
 0.57721566490153
```

```
-psi(0,1)
ans =
 0.57721566490153
```

### Example 2

The trigamma function of 2, `psi(1,2)`, is the same as  $(\pi^2/6) - 1$ .

```
format long
psi(1,2)
```

```
ans =
 0.64493406684823
```

```
pi^2/6 - 1
ans =
 0.64493406684823
```

## Purpose

Generate view of MATLAB file in specified format

## Syntax

```
publish(file)
publish(file,format)

publish(file,Name,Value)
publish(file,options)

my_doc = publish(file, ___)
```

## Description

`publish(file)` generates a view of a MATLAB file in HTML format for sharing your code. For example, `publish('myfile.m')` executes the code in `myfile.m` using the base workspace and saves the formatted code and results in `/html/myfile.html`. The `html` subfolder is relative to the `file` folder.

When MATLAB publishes a file, it can delete existing files from the output folder that start with the same name as `file`.

`publish(file,format)` generates a view of a MATLAB file in the specified file format. The resulting files save to the `html` subfolder for all file formats.

`publish(file,Name,Value)` generates a view of the MATLAB file, `file`, with options specified by one or more name-value pair arguments.

`publish(file,options)` uses the `options` structure to customize the output, which is useful when you want to preconfigure and save your options for repeated use. The `options` structure fields and values correspond to names and values of name-value pair arguments, respectively.

`my_doc = publish(file, ___ )` generates a view of the MATLAB file `file`, and returns a string indicating the path of the resulting output file. It can include any of the input arguments in previous syntaxes.

## Input Arguments

### **file - MATLAB file**

string

Full or partial path of the MATLAB file for which you want to generate a presentation view, specified as a string.

**Example:** 'myfile.m'

### **format - Output format of published file**

'html' (default) | 'doc' | 'latex' | 'ppt' | 'xml' | 'pdf'

Output format of published MATLAB file, specified as one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

**Example:** `publish('myfile.m','ppt');`

### **options - Options for published output**

MATLAB structure

Options for published output, specified as a structure. Use the options structure instead of name-value pair arguments when you want to reuse the same configuration for publishing multiple MATLAB code files.

The `options` structure field and values correspond to names and values of the name-value pair arguments, respectively.

For example, to specify the PDF output format and the output folder `C:\myPublishedOutput`, use:

```
options = struct('format','pdf','outputDir','C:\myPublishedOutput')
```

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'format','latex','showCode',false` specifies LaTeX output file format and excludes the code from the output.

### Output Options

#### 'format' - Published output file format

`'html'` (default) | `'doc'` | `'latex'` | `'ppt'` | `'xml'` | `'pdf'`

Published output file format, specified as the comma-separated pair consisting of `'format'` and one of the following string values.

Output Format	String Value
Hypertext Markup Language	'html' (default)
Microsoft Word	'doc'
LaTeX	'latex'
Microsoft PowerPoint	'ppt'
Extensible Markup Language	'xml'
Portable Document Format	'pdf'

#### 'outputDir' - Output folder

`' '` (default) | full path

Output folder to which the published document is saved, specified as the comma-separated pair consisting of `'outputDir'` and the full path. You must specify the full path as a string, for example `'C:\myPublishedOutput'`.

The default value, `' '`, specifies the `html` subfolder of the current folder.

## **'stylesheet' - Extensible Stylesheet language (XSL) file**

`' '` (default) | full path to XSL file name

Extensible Stylesheet Language (XSL) file to use when publishing MATLAB code to HTML, XML, or LaTeX format, specified as the comma-separated pair consisting of `'stylesheet'` and the full path to the XSL file. The full path must be a string, for example, `'C:\myStylesheet\stylesheet.xml'`

The default value, `' '`, specifies the MATLAB default style sheet.

## **Figure Options**

### **'createThumbnail' - Thumbnail image creation**

`true` (default) | `false`

Thumbnail image creation for the published document, specified as the comma-separated pair consisting of `'createThumbnail'` and either `true` or `false`. You can use this thumbnail to represent your file in HTML pages.

### **'figureSnapMethod' - Published figure window appearance**

`'entireGUIWindow'` (default) | `'print'` | `'getframe'` | `'entireFigureWindow'`

Appearance of published figure windows, including window decorations and background color, specified as the comma-separated pair consisting of `'figureSnapMethod'` and one of the following string values.

String Value	Window Decorations		Background Color	
	GUIs	Figures	GUIs	Figures
<code>'entireGUIWindow'</code> (default)	Included	Excluded	Matches screen	White
<code>'print'</code>	Excluded	Excluded	White	White

**(Continued)**

'getframe'	Excluded	Excluded	Matches screen	Matches screen
'entireFigureWindow'	Included	Included	Matches screen	Matches screen

**'imageFormat' - Published image file format**

'png' | 'epsc2' | 'jpg' | ...

Published image file format, specified as the comma-separated pair consisting of 'imageFormat' and one of the following string values.

<b>'format' Value</b>	<b>Valid 'imageFormat' Value</b>	<b>Default 'imageFormat' Value</b>
'doc'	Any image format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'. If the 'figureSnapMethod' is 'print', then you can also specify 'eps', 'epsc', 'eps2', 'ill', 'meta', and 'pdf'.	'png'
'html'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'

## (Continued)

'latex'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'eps2', except when 'figureSnapMethod' is any one of the following: <ul style="list-style-type: none"><li>• 'getframe'</li><li>• 'entireFigureWindow'</li><li>• 'entireGUIWindow' and the snapped window is a GUI window</li></ul> In these cases the default is 'png'
'pdf'	'bmp' or 'jpg'.	'bmp'
'ppt'	Any format that your installed version of Microsoft Office can import, including 'png', 'jpg', 'bmp', and 'tiff'.	'png'
'xml'	Any format publishes successfully. Ensure that the tools you use to view and process the output files can display the output format you specify.	'png'

### 'maxHeight' - Maximum height of published images

[] (default) | positive integer value

Maximum height of published images that the code generates, specified as the comma-separated pair consisting of 'maxHeight' and one of the following values:

- [ ] (default)—Unrestricted height. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image height in pixels.

### **'maxWidth' - Maximum width of published images**

[ ] (default) | positive integer value

Maximum width of an image that the code generates, specified as the comma-separated pair consisting of 'maxWidth' and one of the following values:

- [ ] (default)—Unrestricted width. This value is always used when the 'format' value is 'pdf'.
- Positive integer value that specifies the image width in pixels.

### **'useNewFigure' - Create new figure**

true (default) | false

A logical value that determines if MATLAB creates a new Figure window for figures that the code generates, specified as the comma-separated pair consisting of 'useNewFigure' and one of the following:

- true (default)—If the code generates a figure, then MATLAB creates a Figure window with a white background, and at the default size before publishing.
- false—MATLAB does not create a figure window.

This value enables you to use a figure with different properties for publishing. For example, open a Figure window, change the size and background color, and then publish your code. Figures in your published document use the characteristics of the figure you opened before publishing.

## Code Options

### **'evalCode' - Option to run code**

true (default) | false

Option to evaluate code and include the MATLAB output in the published view, specified as a logical value.

### **'catchError' - Error handling during publishing**

true (default) | false

Error handling during publishing, specified as the comma-separated pair consisting of 'catchError' and one of the following logical values:

- true (default)—MATLAB continues publishing and includes the error in the published file.
- false—MATLAB displays the error at the command line and does not produce a published file.

### **'codeToEvaluate' - Additional code to evaluate during publishing**

string

Additional code to evaluate during publishing, specified as the comma-separated pair consisting of 'codeToEvaluate' and the string with the corresponding code. Use this option to specify code that does not appear in the MATLAB file, for example to set the value of an input argument for a function being published.

If this option is unspecified, MATLAB evaluates only the code in the MATLAB file you are publishing.

### **'maxOutputLines' - Maximum number of lines**

Inf (default) | nonnegative integer value

Maximum number of lines in MATLAB output per cell evaluated during publishing, specified as the comma-separated pair consisting of 'maxOutputLines' and one of the following values:

- Inf (default)—MATLAB includes all output lines in the published output.

- Nonnegative integer—MATLAB truncates the number of lines in the output at the number of lines you specify.

**'showCode' - Option to include code in published file**

true (default) | false

Option to include code in published file, specified as the comma-separated pair consisting of 'maxOutputLines' and a logical value.

**Tips**

- If 'format' is 'html', MATLAB includes the code being published at the end of the published HTML file as comments, even when you set the 'showCode' option to false. Because MATLAB includes the code as comments, this code does not display in a Web browser. This enables you to use the grabcode function to extract the MATLAB code from an HTML file, even when the file does not display the code.

**Definitions****Window Decorations**

Window decorations include window title bar, toolbar, menu bar, and window border.

**Syntax Highlighting**

Syntax highlighting colors various elements in code to help you identify these elements while reading or editing code. By default, keywords are blue, strings are purple, and unterminated strings are maroon.

MATLAB does not preserve syntax highlighting when you set 'format' to 'latex' or 'ppt'.

**Examples****Generate HTML View of MATLAB Script**

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file, fourier\_demo2.m, to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Generate an HTML view of the MATLAB file.

```
publish('fourier_demo2.m');
```

The `publish` command executes the code for each cell in `fourier_demo2.m`, and saves the file to `/html/fourier_demo2.html`.

View the HTML file.

```
web('html/fourier_demo2.html')
```

## **Generate View of MATLAB Script in Microsoft Word Format**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the file in Microsoft Word format.

```
publish('fourier_demo2.m', 'doc');
```

View the published output.

```
winopen('html/fourier_demo2.doc')
```

## **Publish MATLAB Script Using Name-Value Pairs to Customize Output**

Generate an HTML view of the code, MATLAB results, and comments in a MATLAB script. Use name-value pair arguments to include window decorations in the published output.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot, 'help', 'techdoc', ...
'matlab_env', 'examples', 'fourier_demo2.m'), '.', 'f')
```

Publish the example MATLAB file to HTML format.

```
publish('fourier_demo2.m', 'figureSnapMethod', 'entireFigureWindow')
```

The 'figureSnapMethod', 'entireFigureWindow' name-value pair argument specifies to include the window decorations in the figures, and to match the figure background color to the screen color.

View the published output.

```
web('html/fourier_demo2.html')
```

### **Customize publish Output Using Options Structure**

Generate a Microsoft Word view of the code, MATLAB results, and comments in a MATLAB script. Use a structure to customize the published output.

Specifying options as a structure is useful when you want to preconfigure and save your options for repeated use.

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Define options to customize the published output as a structure, options\_doc\_nocode.

```
options_doc_nocode.format = 'doc';
options_doc_nocode.showCode = false;
```

Publish the file, specifying the options structure.

```
publish('fourier_demo2.m',options_doc_nocode);
```

### **Save File Path of Published Script to Variable**

Generate an HTML view of a MATLAB script, and save the path of the published HTML file to a variable.

This example assumes that the current folder is C:\my\_MATLAB\_files.

# publish

---

Copy the example file to your current folder.

```
copyfile(fullfile(matlabroot,'help','techdoc',...
'matlab_env','examples','fourier_demo2.m'),'.','f')
```

Publish the MATLAB file, and save the path of the resulting published HTML file to an output variable.

```
mydoc = publish('fourier_demo2.m')
```

```
mydoc =
```

```
C:\my_MATLAB_files\html\fourier_demo2.html
```

## Concepts

- “Publishing MATLAB Code”
- “Publishing Markup”

**Purpose** Store character array in Automation server

**Syntax** **IDL Method Signature**

```
PutCharArray([in] BSTR varname, [in] BSTR workspace,
 [in] BSTR string)
```

**Microsoft Visual Basic Client**

```
PutCharArray(varname As String, workspace As String,
 string As String)
```

**MATLAB Client**

```
h.PutCharArray('varname', 'workspace', 'string')
PutCharArray(h, 'varname', 'workspace', 'string')
```

**Description**

`h.PutCharArray('varname', 'workspace', 'string')` stores the character array in `string` in the specified workspace of the server attached to handle `h`, assigning to it the variable `varname`. The workspace argument can be either `base` or `global`. The function name is case sensitive.

`PutCharArray(h, 'varname', 'workspace', 'string')` is an alternate syntax.

**Tips**

The character array specified in the `string` argument can have any dimensions. However, `PutCharArray` changes the dimensions to a 1-by-`n` column-wise representation, where `n` is the number of characters in the array. Executing the following commands in MATLAB illustrates this behavior:

```
h = actxserver('matlab.application');
chArr = ['abc'; 'def'; 'ghk']
chArr =
abc
def
ghk
```

```
h.PutCharArray('Foo', 'base', chArr)
```

# PutCharArray

---

```
tstArr = h.GetCharArray('Foo', 'base')
tstArr =
adgbehcfk
```

## Examples

### Visual Basic .NET Client

This example uses the Visual Basic `MsgBox` command to control flow between MATLAB and the Visual Basic Client.

```
Dim Matlab As Object
Try
 Matlab = GetObject(, "matlab.application")
Catch e As Exception
 Matlab = CreateObject("matlab.application")
End Try
MsgBox("MATLAB window created; now open it...")
```

Open the MATLAB window, then click **Ok**.

```
Matlab.PutCharArray("str", "base", _
 "He jests at scars that never felt a wound.")
MsgBox("In MATLAB, type" & vbCrLf _
 & "str")
```

In the MATLAB window type `str`; MATLAB displays:

```
str =
He jests at scars that never felt a wound.
```

Click **Ok**.

```
MsgBox("closing MATLAB window...")
```

Click **Ok** to close and terminate MATLAB.

```
Matlab.Quit()
```

## See Also

[GetCharArray](#) | [PutWorkspaceData](#) | [GetWorkspaceData](#) | [Execute](#)

**Purpose** Matrix in Automation server workspace

**Syntax** **IDL Method Signature**

```
PutFullMatrix([in] BSTR varname, [in] BSTR workspace,
[in] SAFEARRAY(double) xreal, [in] SAFEARRAY(double) ximag)
```

**Microsoft Visual Basic Client**

```
PutFullMatrix([in] varname As String, [in] workspace As String,
[in] xreal As Double, [in] ximag As Double)
```

**MATLAB Client**

```
h.PutFullMatrix('varname', 'workspace', xreal, ximag)
PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)
```

**Description**

`h.PutFullMatrix('varname', 'workspace', xreal, ximag)` stores a matrix in the specified workspace of the server attached to handle `h` and assigns it to variable `varname`. Use `xreal` and `ximag` for the real and imaginary parts of the matrix. The matrix cannot be a scalar, an empty array, or have more than two dimensions. The values for *workspace* are *base* or *global*.

`PutFullMatrix(h, 'varname', 'workspace', xreal, ximag)` is an alternate syntax.

For VBScript clients, use the `GetWorkspaceData` and `PutWorkspaceData` functions to pass numeric data to and from the MATLAB workspace. These functions use the variant data type instead of `safearray` which is not supported by VBScript.

**Examples**

This example uses a Visual Basic .NET client to write a matrix to the base workspace of the server:

```
Dim MatLab As Object
Dim XReal(4, 4) As Double
Dim XImag(4, 4) As Double
Dim ZReal(4, 4) As Double
Dim ZImag(4, 4) As Double
```

# PutFullMatrix

---

```
Dim i, j As Integer

For i = 0 To 4
 For j = 0 To 4
 XReal(i, j) = Rnd() * 6
 XImag(i, j) = 0
 Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("M", "base", XReal, XImag)
MatLab.GetFullMatrix("M", "base", ZReal, ZImag)
```

---

Use a Visual Basic .NET client to write a matrix to the global workspace of the server:

```
Dim MatLab As Object
Dim XReal(1,2) As Double
Dim XImag(1,2) As Double
Dim result As String
Dim i,j As Integer

For i = 0 To 1
 For j = 0 To 2
 XReal(i,j) = (j * 2 + 1) + i
 XImag(i,j) = 1
 Next j
Next i

Matlab = CreateObject("matlab.application")
MatLab.PutFullMatrix("X", "global", XReal, XImag)
result = Matlab.Execute("whos global")
MsgBox(result)
```

## See Also

[GetFullMatrix](#) | [PutWorkspaceData](#) | [Execute](#)

## How To

- “Exchanging Data with the Server”

# PutWorkspaceData

---

**Purpose** Data in Automation server workspace

**Syntax** **IDL Method Signature**

```
PutWorkspaceData([in] BSTR varname, [in] BSTR workspace,
[in] VARIANT data)
```

**Microsoft Visual Basic Client**

```
PutWorkspaceData(varname As String, workspace As String,
data As Object)
```

**MATLAB Client**

```
h.PutWorkspaceData('varname', 'workspace', data)
PutWorkspaceData(h, 'varname', 'workspace', data)
```

**Description**

h.PutWorkspaceData('varname', 'workspace', data) stores data in the workspace of the server attached to handle h and assigns it to varname. The values for *workspace* are base or global.

PutWorkspaceData(h, 'varname', 'workspace', data) is an alternate syntax.

Use PutWorkspaceData to pass numeric and character array data respectively to the server. Do *not* use PutWorkspaceData on sparse arrays, structures, or function handles. Use the Execute method for these data types.

The GetWorkspaceData and PutWorkspaceData functions pass numeric data as a variant data type. These functions are especially useful for VBScript clients as VBScript does not support the safearray data type used by GetFullMatrix and PutFullMatrix.

**Examples**

Create an array in a Visual Basic .NET client and put it in the base workspace of the MATLAB Automation server:

- 1 Create the Visual Basic application. Use the MsgBox command to control flow between MATLAB and the application:

```
Dim Matlab As Object
```

```
Dim data(6) As Double
Dim i As Integer
MatLab = CreateObject("matlab.application")
For i = 0 To 6
 data(i) = i * 15
Next i
MatLab.PutWorkspaceData("A","base",data)
MsgBox("In MATLAB, type" & vbCrLf & "A")
```

**2** Open the MATLAB window and type A. MATLAB displays:

```
A =
 0 15 30 45 60 75 90
```

**3** Click **Ok** to close and terminate MATLAB.

## See Also

## How To

- “Executing Commands in the MATLAB Server”
- “Exchanging Data with the Server”

# pwd

---

**Purpose** Identify current folder

**Syntax** `pwd`  
`currentFolder = pwd`

**Description** `pwd` displays the MATLAB current folder.  
`currentFolder = pwd` returns the current folder as a string to `currentFolder`.

**Alternatives**

- Use the Current Folder toolbar.

**See Also** `cd` | `dir`

**Purpose** Quasi-minimal residual method

**Syntax**

```
x = qmr(A,b)
qmr(A,b,tol)
qmr(A,b,tol,maxit)
qmr(A,b,tol,maxit,M)
qmr(A,b,tol,maxit,M1,M2)
qmr(A,b,tol,maxit,M1,M2,x0)
[x,flag] = qmr(A,b,...)
[x,flag,relres] = qmr(A,b,...)
[x,flag,relres,iter] = qmr(A,b,...)
[x,flag,relres,iter,resvec] = qmr(A,b,...)
```

**Description** `x = qmr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and should be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x, 'notransp')` returns  $A*x$  and `afun(x, 'transp')` returns  $A'*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `qmr` converges, a message to that effect is displayed. If `qmr` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`qmr(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `qmr` uses the default,  $1e-6$ .

`qmr(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `qmr` uses the default,  $\min(n,20)$ .

`qmr(A,b,tol,maxit,M)` and `qmr(A,b,tol,maxit,M1,M2)` use preconditioners  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(M)*A*x = \text{inv}(M)*b$  for  $x$ . If  $M$  is `[]` then `qmr` applies no

preconditioner.  $M$  can be a function handle  $mfun$  such that  $mfun(x, 'notransp')$  returns  $M \setminus x$  and  $mfun(x, 'transp')$  returns  $M' \setminus x$ .

`qmr(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x0$  is `[]`, then `qmr` uses the default, an all zero vector.

`[x,flag] = qmr(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>qmr</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>qmr</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	The method stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>qmr</code> became too small or too large to continue computing.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = qmr(A,b,...)` also returns the relative residual norm  $\|b - A \cdot x\| / \|b\|$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = qmr(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = qmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\|b - A \cdot x_0\|$ .

## Examples

### Using `qmr` with a Matrix Input

This example shows how to use `qmr` with a matrix input. The code:

```
n = 100;
on = ones(n,1);
```

```

A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8; maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = qmr(A,b,tol,maxit,M1,M2);

```

displays the message:

```

qmr converged at iteration 9 to a solution...
with relative residual
5.6e-009

```

### Using qmr with a Function Handle

This example replaces the matrix A in the previous example with a handle to a matrix-vector product function `afun`. The example is contained in a file `run_qmr` that

- Calls `qmr` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_qmr` are available to `afun`.

The following shows the code for `run_qmr`:

```

function x1 = run_qmr
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = qmr(@afun,b,tol,maxit,M1,M2);

function y = afun(x,transp_flag)
 if strcmp(transp_flag,'transp')
 y = 4 * x;
 % y = A'*x

```

```
 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 y(2:n) = y(2:n) - x(1:n-1);
 elseif strcmp(transp_flag,'notransp') % y = A*x
 y = 4 * x;
 y(2:n) = y(2:n) - 2 * x(1:n-1);
 y(1:n-1) = y(1:n-1) - x(2:n);
 end
end
end
```

When you enter

```
x1=run_qmr;
```

MATLAB software displays the message

```
qmr converged at iteration 9 to a solution with relative residual
5.6e-009
```

### **Using qmr with a Preconditioner**

This example demonstrates the use of a preconditioner.

Load A = west0479, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define b so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12; maxit = 20;
```

Use qmr to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = qmr(A,b,tol,maxit);
```

`f10` is 1 because `qmr` does not converge to the requested tolerance  $1e-12$  within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB stores the residual history in `rv0`.

Plot the behavior of `qmr`.

```
semilogy(0:maxit,rv0/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using `ilu`

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the `'udiag'` option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = qmr(A,b,tol,maxit,L,U);
```

f11 is 0 because qmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

You can follow the progress of qmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

`minres` | `pcg` | `symmlq` | `mldivide`

**Purpose** Orthogonal-triangular decomposition

**Syntax**

```
[Q,R] = qr(A)
[Q,R] = qr(A,0)
[Q,R,E] = qr(A)
[Q,R,E] = qr(A,'matrix')
[Q,R,e] = qr(A,'vector')
[Q,R,e] = qr(A,0)
X = qr(A)
X = qr(A,0)
R = qr(A)
R = qr(A,0)
[C,R] = qr(A,B)
[C,R,E] = qr(A,B)
[C,R,E] = qr(A,B,'matrix')
[C,R,e] = qr(A,B,'vector')
[C,R] = qr(A,B,0)
[C,R,e] = qr(A,B,0)
```

**Description**  $[Q,R] = \text{qr}(A)$ , where  $A$  is  $m$ -by- $n$ , produces an  $m$ -by- $n$  upper triangular matrix  $R$  and an  $m$ -by- $m$  unitary matrix  $Q$  so that  $A = Q \cdot R$ .

$[Q,R] = \text{qr}(A,0)$  produces the economy-size decomposition. If  $m > n$ , only the first  $n$  columns of  $Q$  and the first  $n$  rows of  $R$  are computed. If  $m \leq n$ , this is the same as  $[Q,R] = \text{qr}(A)$ .

If  $A$  is full:

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A \cdot E = Q \cdot R$ . The column permutation  $E$  is chosen so that  $\text{abs}(\text{diag}(R))$  is decreasing.

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:, e) = Q \cdot R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:, e) = Q \cdot R$ .

$X = \text{qr}(A)$  and  $X = \text{qr}(A,0)$  return a matrix  $X$  such that  $\text{triu}(X)$  is the upper triangular factor  $R$ .

If  $A$  is sparse:

$R = \text{qr}(A)$  computes a Q-less QR decomposition and returns the upper triangular factor  $R$ . Note that  $R = \text{chol}(A' * A)$ . Since  $Q$  is often nearly full, this is preferred to  $[Q,R] = \text{QR}(A)$ .

$R = \text{qr}(A,0)$  produces economy-size  $R$ . If  $m > n$ ,  $R$  has only  $n$  rows. If  $m \leq n$ , this is the same as  $R = \text{qr}(A)$ .

$[Q,R,E] = \text{qr}(A)$  or  $[Q,R,E] = \text{qr}(A, 'matrix')$  produces unitary  $Q$ , upper triangular  $R$  and a permutation matrix  $E$  so that  $A * E = Q * R$ . The column permutation  $E$  is chosen to reduce fill-in in  $R$ .

$[Q,R,e] = \text{qr}(A, 'vector')$  returns the permutation information as a vector instead of a matrix. That is,  $e$  is a row vector such that  $A(:, e) = Q * R$ .

$[Q,R,e] = \text{qr}(A,0)$  produces an economy-size decomposition in which  $e$  is a permutation vector, so that  $A(:, e) = Q * R$ .

$[C,R] = \text{qr}(A,B)$ , where  $B$  has as many rows as  $A$ , returns  $C = Q' * B$ . The least-squares solution to  $A * X = B$  is  $X = R \setminus C$ .

$[C,R,E] = \text{qr}(A,B)$  or  $[C,R,E] = \text{qr}(A,B, 'matrix')$ , also returns a fill-reducing ordering. The least-squares solution to  $A * X = B$  is  $X = E * (R \setminus C)$ .

$[C,R,e] = \text{qr}(A,B, 'vector')$  returns the permutation information as a vector instead of a matrix. That is, the least-squares solution to  $A * X = B$  is  $X(e, :) = R \setminus C$ .

$[C,R] = \text{qr}(A,B,0)$  produces economy-size results. If  $m > n$ ,  $C$  and  $R$  have only  $n$  rows. If  $m \leq n$ , this is the same as  $[C,R] = \text{qr}(A,B)$ .

$[C,R,e] = \text{qr}(A,B,0)$  additionally produces a fill-reducing permutation vector  $e$ . In this case, the least-squares solution to  $A * X = B$  is  $X(e, :) = R \setminus C$ .

## Examples

Find the least squares approximate solution to  $A*x = b$  with the Q-less QR decomposition and one step of iterative refinement:

```
if issparse(A), R = qr(A);
else R = triu(qr(A)); end
x = R\(R\'\'(A'*b));
r = b - A*x;
err = R\'\'(A'*r);
x = x + err;
```

**Purpose** Remove column or row from QR factorization

**Syntax**

```
[Q1,R1] = qrdelete(Q,R,j)
[Q1,R1] = qrdelete(Q,R,j,'col')
[Q1,R1] = qrdelete(Q,R,j,'row')
```

**Description**

`[Q1,R1] = qrdelete(Q,R,j)` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the column `A(:,j)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

`[Q1,R1] = qrdelete(Q,R,j,'col')` is the same as `qrdelete(Q,R,j)`.

`[Q1,R1] = qrdelete(Q,R,j,'row')` returns the QR factorization of the matrix `A1`, where `A1` is `A` with the row `A(j,:)` removed and `[Q,R] = qr(A)` is the QR factorization of `A`.

**Examples**

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
[Q1,R1] = qrdelete(Q,R,j,'row');
```

```
Q1 =
 0.5274 -0.5197 -0.6697 -0.0578
 0.7135 0.6911 0.0158 0.1142
 0.3102 -0.1982 0.4675 -0.8037
 0.3413 -0.4616 0.5768 0.5811
```

```
R1 =
 32.2335 26.0908 19.9482 21.4063 23.3297
 0 -19.7045 -10.9891 0.4318 -1.4873
 0 0 22.7444 5.8357 -3.1977
 0 0 0 -14.5784 3.7796
```

returns a valid QR factorization, although possibly different from

```
A2 = A;
A2(j,:) = [];
[Q2,R2] = qr(A2)
```

# qrdelete

---

```
Q2 =
 -0.5274 0.5197 0.6697 -0.0578
 -0.7135 -0.6911 -0.0158 0.1142
 -0.3102 0.1982 -0.4675 -0.8037

 0 0 -22.7444 -5.8357 3.1977
 0 0 0 -14.5784 3.7796
```

## Algorithms

The `qrdelete` function uses a series of Givens rotations to zero out the appropriate elements of the factorization.

## See Also

`planerot` | `qr` | `qrinsert`

**Purpose** Insert column or row into QR factorization

**Syntax**

```
[Q1,R1] = qrinsert(Q,R,j,x)
[Q1,R1] = qrinsert(Q,R,j,x,'col')
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

**Description** [Q1,R1] = qrinsert(Q,R,j,x) returns the QR factorization of the matrix A1, where A1 is  $A = Q \cdot R$  with the column x inserted before  $A(:,j)$ . If A has n columns and  $j = n+1$ , then x is inserted after the last column of A.

[Q1,R1] = qrinsert(Q,R,j,x,'col') is the same as qrinsert(Q,R,j,x).

[Q1,R1] = qrinsert(Q,R,j,x,'row') returns the QR factorization of the matrix A1, where A1 is  $A = Q \cdot R$  with an extra row, x, inserted before  $A(j,:)$ .

## Examples

```
A = magic(5);
[Q,R] = qr(A);
j = 3;
x = 1:5;
[Q1,R1] = qrinsert(Q,R,j,x,'row')
```

```

## Algorithms

The `qrinsert` function inserts the values of `x` into the `j`th column (row) of `R`. It then uses a series of Givens rotations to zero out the nonzero elements of `R` on and below the diagonal in the `j`th column (row).

`planerot` | `qr` | `qrdelete`

**Purpose** Rank 1 update to QR factorization

**Syntax** `[Q1,R1] = qrupdate(Q,R,u,v)`

**Description** `[Q1,R1] = qrupdate(Q,R,u,v)` when `[Q,R] = qr(A)` is the original QR factorization of A, returns the QR factorization of  $A + u \cdot v'$ , where u and v are column vectors of appropriate lengths.

**Tips** qrupdate works only for full matrices.

**Examples** The matrix

```
mu = sqrt(eps)
```

```
mu =
```

```
1.4901e-08
```

```
A = [ones(1,4); mu*eye(4)];
```

is a well-known example in least squares that indicates the dangers of forming  $A' \cdot A$ . Instead, we work with the QR factorization – orthonormal Q and upper triangular R.

```
[Q,R] = qr(A);
```

As we expect, R is upper triangular.

```
R =
```

```
-1.0000 -1.0000 -1.0000 -1.0000
 0 0.0000 0.0000 0.0000
 0 0 0.0000 0.0000
 0 0 0 0.0000
 0 0 0 0
```

# qrupdate

---

In this case, the upper triangular entries of R, excluding the first row, are on the order of  $\sqrt{\text{eps}}$ .

Consider the update vectors

$$u = [-1 \ 0 \ 0 \ 0 \ 0]'; \quad v = \text{ones}(4,1);$$

Instead of computing the rather trivial QR factorization of this rank one update to A from scratch with

$$[QT,RT] = \text{qr}(A + u*v')$$

QT =

$$\begin{bmatrix} 0 & 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 \end{bmatrix}$$

RT =

$$1.0\text{e-}007 * \begin{bmatrix} -0.1490 & 0 & 0 & 0 \\ 0 & -0.1490 & 0 & 0 \\ 0 & 0 & -0.1490 & 0 \\ 0 & 0 & 0 & -0.1490 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

we may use `qrupdate`.

$$[Q1,R1] = \text{qrupdate}(Q,R,u,v)$$

Q1 =

$$\begin{bmatrix} -0.0000 & -0.0000 & -0.0000 & -0.0000 & 1.0000 \\ 1.0000 & -0.0000 & -0.0000 & -0.0000 & 0.0000 \end{bmatrix}$$

```

 0.0000 1.0000 -0.0000 -0.0000 0.0000
 0.0000 0.0000 1.0000 -0.0000 0.0000
 -0.0000 -0.0000 -0.0000 1.0000 0.0000

```

R1 =

```

1.0e-007 *
0.1490 0.0000 0.0000 0.0000
 0 0.1490 0.0000 0.0000
 0 0 0.1490 0.0000
 0 0 0 0.1490
 0 0 0 0

```

Note that both factorizations are correct, even though they are different.

## Algorithms

qrupdate uses the algorithm in section 12.5.1 of the third edition of *Matrix Computations* by Golub and van Loan. qrupdate is useful since, if we take  $N = \max(m, n)$ , then computing the new QR factorization from scratch is roughly an  $O(N^3)$  algorithm, while simply updating the existing factors in this way is an  $O(N^2)$  algorithm.

cholupdate | qr

# quad

---

**Purpose** Numerically evaluate integral, adaptive Simpson quadrature

**Compatibility** quad will be removed in a future release. Use `integral` instead.

**Syntax**

```
q = quad(fun,a,b)
q = quad(fun,a,b,tol)
q = quad(fun,a,b,tol,trace)
[q,fcnt] = quad(...)
```

**Description** *Quadrature* is a numerical method used to find the area under the graph of a function, that is, to compute a definite integral.

$$q = \int_a^b f(x) dx$$

`q = quad(fun,a,b)` tries to approximate the integral of function `fun` from `a` to `b` to within an error of `1e-6` using recursive adaptive Simpson quadrature. `fun` is a function handle. Limits `a` and `b` must be finite. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, the integrand evaluated at each element of `x`.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quad(fun,a,b,tol)` uses an absolute error tolerance `tol` instead of the default which is `1.0e-6`. Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results. In MATLAB version 5.3 and earlier, the `quad` function used a less reliable algorithm and a default relative tolerance of `1.0e-3`.

`q = quad(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q]` during the recursion.

`[q,fcnt] = quad(...)` returns the number of function evaluations.

The function `quadl` may be more efficient with high accuracies and smooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function may be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function may be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

To compute the integral

$$\int_0^2 \frac{1}{x^3 - 2x - 5} dx,$$

write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

# quad

---

Then pass `@myfun`, a function handle to `myfun`, to `quad`, along with the limits of integration, 0 to 2:

```
Q = quad(@myfun,0,2)
```

```
Q =
```

```
-0.4605
```

Alternatively, you can pass the integrand to `quad` as an anonymous function handle `F`:

```
F = @(x)1./(x.^3-2*x-5);
```

```
Q = quad(F,0,2);
```

## Algorithms

`quad` implements a low order method using an adaptive recursive Simpson's rule.

## Diagnostics

`quad` may issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

`quad2d` | `dblquad` | `quadgk` | `quadl` | `quadv` | `trapz` | `triplequad` | `function_handle` | `integral` | `integral2` | `integral3`

**How To**

- “Anonymous Functions”

# quad2d

---

**Purpose** Numerically evaluate double integral, tiled method

**Syntax**  
`q = quad2d(fun,a,b,c,d)`  
`[q,errbnd] = quad2d(...)`  
`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)`

**Description** `q = quad2d(fun,a,b,c,d)` approximates the integral of `fun(x,y)` over the planar region  $a \leq x \leq b$  and  $c(x) \leq y \leq d(x)$ . `fun` is a function handle, `c` and `d` may each be a scalar or a function handle. All input functions must be vectorized. The function `Z=fun(X,Y)` must accept 2-D matrices `X` and `Y` of the same size and return a matrix `Z` of corresponding values. The functions `ymin=c(X)` and `ymax=d(X)` must accept matrices and return matrices of the same size with corresponding values.

`[q,errbnd] = quad2d(...)`. `errbnd` is an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`q = quad2d(fun,a,b,c,d,param1,val1,param2,val2,...)` performs the integration as above with specified values of optional parameters:

<code>AbsTol</code>	absolute error tolerance
<code>RelTol</code>	relative error tolerance

`quad2d` attempts to satisfy  $ERRBND \leq \max(AbsTol, RelTol * |Q|)$ . This is absolute error control when  $|Q|$  is sufficiently small and relative error control when  $|Q|$  is larger. A default tolerance value is used when a tolerance is not specified. The default value of `AbsTol` is  $1e-5$ . The default value of `RelTol` is  $100 * \text{eps}(\text{class}(Q))$ . This is also the minimum value of `RelTol`. Smaller `RelTol` values are automatically increased to the default value.

<code>MaxFunEvals</code>	Maximum allowed number of evaluations of <code>fun</code> reached.
--------------------------	--------------------------------------------------------------------

The `MaxFunEvals` parameter limits the number of vectorized calls to `fun`. The default is 2000.

<code>FailurePlot</code>	Generate a plot if <code>MaxFunEvals</code> is reached.
--------------------------	---------------------------------------------------------

Setting `FailurePlot` to `true` generates a graphical representation of the regions needing further refinement when `MaxFunEvals` is reached. No plot is generated if the integration succeeds before reaching `MaxFunEvals`. These (generally) 4-sided regions are mapped to rectangles internally. Clusters of small regions indicate the areas of difficulty. The default is `false`.

<code>Singular</code>	Problem may have boundary singularities
-----------------------	-----------------------------------------

With `Singular` set to `true`, `quad2d` will employ transformations to weaken boundary singularities for better performance. The default is `true`. Setting `Singular` to `false` will turn these transformations off, which may provide a performance benefit on some smooth problems.

## Examples

### Example 1

Integrate  $y\sin(x) + x\cos(y)$  over  $\pi \leq x \leq 2\pi$ ,  $0 \leq y \leq \pi$ . The true value of the integral is  $-\pi^2$ .

```
Q = quad2d(@(x,y) y.*sin(x)+x.*cos(y),pi,2*pi,0,pi)
```

### Example 2

Integrate  $[(x+y)^{1/2}(1+x+y)^2]^{-1}$  over the triangle  $0 \leq x \leq 1$  and  $0 \leq y \leq 1-x$ . The integrand is infinite at  $(0,0)$ . The true value of the integral is  $\pi/4 - 1/2$ .

```
fun = @(x,y) 1./(sqrt(x + y) .* (1 + x + y).^2)
```

In Cartesian coordinates:

```
ymax = @(x) 1 - x;
```

# quad2d

---

```
Q = quad2d(fun,0,1,0,ymax)
```

In polar coordinates:

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
rmax = @(theta) 1./(sin(theta) + cos(theta));
Q = quad2d(polarfun,0,pi/2,0,rmax)
```

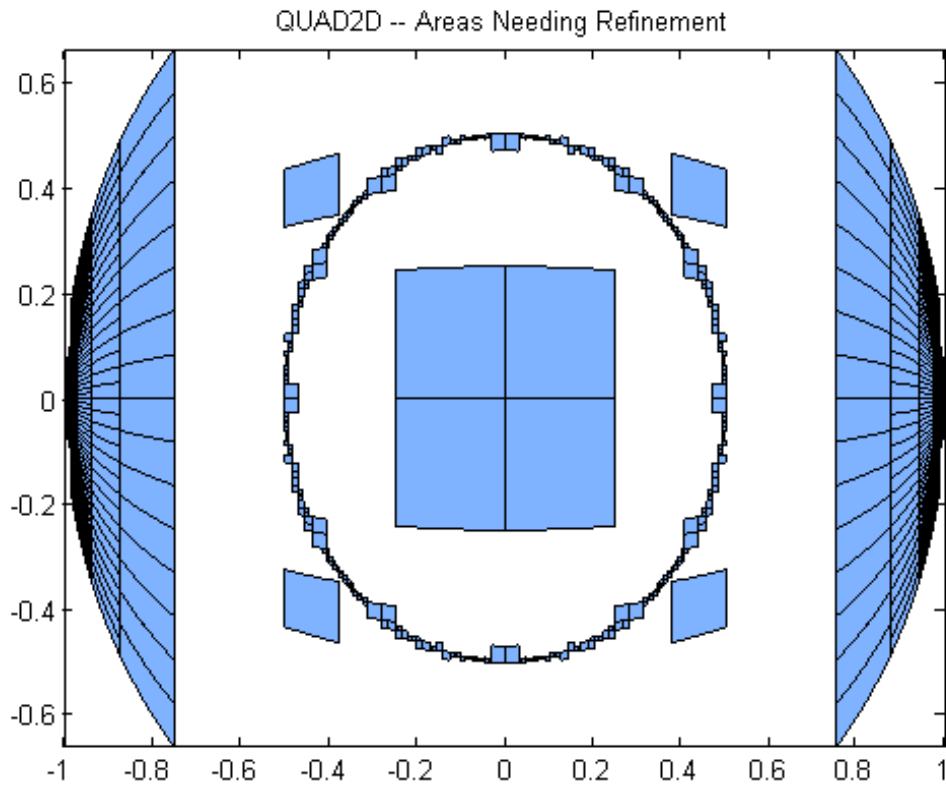

## Limitations

quad2d begins by mapping the region of integration to a rectangle. Consequently, it may have trouble integrating over a region that does not have four sides or has a side that cannot be mapped smoothly to a straight line. If the integration is unsuccessful, some helpful tactics are leaving `Singular` set to its default value of `true`, changing between Cartesian and polar coordinates, or breaking the region of integration into pieces and adding the results of integration over the pieces.

For instance:

```
fun = @(x,y)abs(x.^2 + y.^2 - 0.25);
c = @(x)-sqrt(1 - x.^2);
d = @(x)sqrt(1 - x.^2);
quad2d(fun,-1,1,c,d,'AbsTol',1e-8,...
 'FailurePlot',true,'Singular',false);
```

Warning: Reached the maximum number of function evaluations (2000). The r fails the global error test.

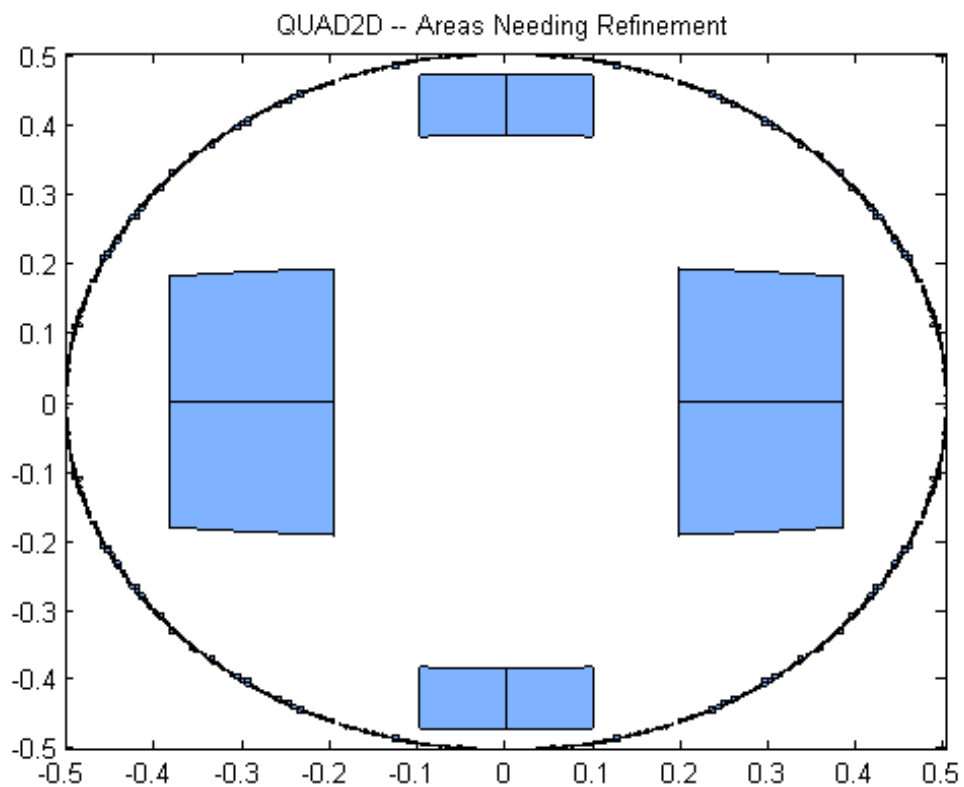

The failure plot shows two areas of difficulty, near the points  $(-1, 0)$  and  $(1, 0)$  and near the circle  $x^2 + y^2 = 0.25$ .

Changing the value of `Singular` to `true` will cope with the geometric singularities at  $(-1, 0)$  and  $(1, 0)$ . The larger shaded areas may need refinement but are probably not areas of difficulty.

```
Q = quad2d(fun, -1, 1, c, d, 'AbsTol', 1e-8, ...
 'FailurePlot', true, 'Singular', true);
```

# quad2d

Warning: Reached the maximum number of function evaluations (2000). The result passes the global error test.

From here you can take advantage of symmetry:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-8,...
 'Singular',true,'FailurePlot',true)
```

Q =

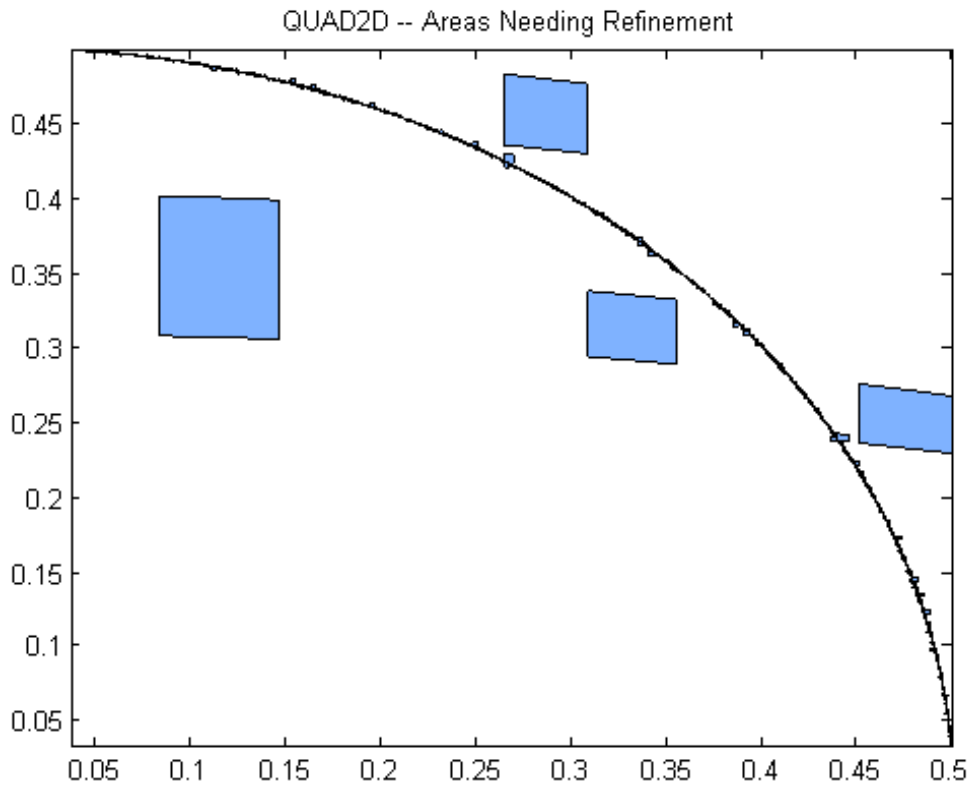

0.9817

However, the code is still working very hard near the singularity. It may not be able to provide higher accuracy:

```
Q = 4*quad2d(fun,0,1,0,d,'Abstol',1e-10,...
 'Singular',true,'FailurePlot',true);
```

Warning: Reached the maximum number of function evaluations (2000). The result does not pass the global error test.

# quad2d

At higher accuracy, a change in coordinates may work better.

```
polarfun = @(theta,r) fun(r.*cos(theta),r.*sin(theta)).*r;
Q = 4*quad2d(polarfun,0,pi/2,0,1,'AbsTol',1e-10);
```

It is best to put the singularity on the boundary by splitting the region of integration into two parts:

```
Q1 = 4*quad2d(polarfun,0,pi/2,0,0.5,'AbsTol',5e-11);
Q2 = 4*quad2d(polarfun,0,pi/2,0.5,1,'AbsTol',5e-11);
```

$Q = Q1 + Q2;$

## How To

- “Anonymous Functions”

# quadgk

**Purpose** Numerically evaluate integral, adaptive Gauss-Kronrod quadrature

**Syntax**  
`q = quadgk(fun,a,b)`  
`[q,errbnd] = quadgk(fun,a,b)`  
`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)`

**Description** `q = quadgk(fun,a,b)` attempts to approximate the integral of a scalar-valued function `fun` from `a` to `b` using high-order global adaptive quadrature and default error tolerances. The function `y = fun(x)` should accept a vector argument `x` and return a vector result `y`, where `y` is the integrand evaluated at each element of `x`. `fun` must be a function handle. Limits `a` and `b` can be `-Inf` or `Inf`. If both are finite, they can be complex. If at least one is complex, the integral is approximated over a straight line path from `a` to `b` in the complex plane.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`[q,errbnd] = quadgk(fun,a,b)` returns an approximate upper bound on the absolute error,  $|Q - I|$ , where `I` denotes the exact value of the integral.

`[q,errbnd] = quadgk(fun,a,b,param1,val1,param2,val2,...)` performs the integration with specified values of optional parameters. The available parameters are

Parameter	Description	
'AbsTol'	Absolute error tolerance.  The default value of 'AbsTol' is 1.e-10 (double), 1.e-5 (single).	quadgk attempts to satisfy $errbnd \leq \max(AbsTol, RelTol *  Q )$ . This is absolute error control when $ Q $ is sufficiently small and relative error control

Parameter	Description	
'RelTol'	<p>Relative error tolerance.</p> <p>The default value of 'RelTol' is 1.e-6 (double), 1.e-4 (single).</p>	<p>when <math> Q </math> is larger. For pure absolute error control use 'AbsTol' &gt; 0 and 'RelTol' = 0. For pure relative error control use 'AbsTol' = 0. Except when using pure absolute error control, the minimum relative tolerance is 'RelTol' <math>\geq 100 \cdot \text{eps}(\text{class}(Q))</math>.</p>
'Waypoints'	<p>Vector of integration waypoints.</p>	<p>If <math>\text{fun}(x)</math> has discontinuities in the interval of integration, the locations should be supplied as a Waypoints vector. When a, b, and the waypoints are all real, only the waypoints between a and b are used, and they are used in sorted order. Note that waypoints are not intended for singularities in <math>\text{fun}(x)</math>. Singular points should be handled by making them endpoints of separate integrations and adding the results.</p> <p>If a, b, or any entry of the waypoints vector is complex, the integration is performed over a</p>

# quadgk

Parameter	Description	
		sequence of straight line paths in the complex plane, from a to the first waypoint, from the first waypoint to the second, and so forth, and finally from the last waypoint to b.
'MaxIntervalCount'	Maximum number of intervals allowed. The default value is 650.	The 'MaxIntervalCount' parameter limits the number of intervals that quadgk uses at any one time after the first iteration. A warning is issued if quadgk returns early because of this limit. Routinely increasing this value is not recommended, but it may be appropriate when errbnd is small enough that the desired accuracy has nearly been achieved.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The quad function may be most efficient for low accuracies with nonsmooth integrands.
- The quadl function may be more efficient than quad at higher accuracies with smooth integrands.

- The `quadgk` function may be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

### Integrand with a singularity at an integration end point

Write a function `myfun` that computes the integrand:

```
function y = myfun(x)
y = exp(x).*log(x);
```

Then pass `@myfun`, a function handle to `myfun`, to `quadgk`, along with the limits of integration, 0 to 1:

```
q = quadgk(@myfun,0,1)
```

```
q =
```

```
-1.3179
```

Alternatively, you can pass the integrand to `quadgk` as an anonymous function handle `F`:

# quadgk

---

```
f = @(x)exp(x).*log(x);
q = quadgk(f,0,1);
```

## Oscillatory integrand on a semi-infinite interval

Integrate over a semi-infinite interval with specified tolerances, and return the approximate error bound:

```
f = @(x)x.^5.*exp(-x).*sin(x);
[q,errbnd] = quadgk(f,0,inf,'RelTol',1e-8,'AbsTol',1e-12)
```

```
q =
```

```
-15.0000
```

```
errbnd =
```

```
9.4386e-009
```

## Contour integration around a pole

Use Waypoints to integrate around a pole using a piecewise linear contour:

```
f = @(z)1./(2*z - 1);
q = quadgk(f,-1-i,-1-i,'Waypoints',[1-i,1+i,-1+i])
```

```
q =
```

```
0.0000 + 3.1416i
```

## Algorithms

quadgk implements adaptive quadrature based on a Gauss-Kronrod pair (15<sup>th</sup> and 7<sup>th</sup> order formulas).

## Diagnostics

quadgk may issue one of the following warnings:

'Minimum step size reached' indicates that interval subdivision has produced a subinterval whose length is on the order of roundoff

error in the length of the original interval. A nonintegrable singularity is possible.

'Reached the limit on the maximum number of intervals in use' indicates that the integration was terminated before meeting the tolerance requirements and that continuing the integration would require more than `MaxIntervalCount` subintervals. The integral may not exist, or it may be difficult to approximate numerically. Increasing `MaxIntervalCount` usually does not help unless the tolerance requirements were nearly met when the integration was previously terminated.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- “Anonymous Functions”

# quadl

---

## Purpose

Numerically evaluate integral, adaptive Lobatto quadrature  
quadl will be removed in a future release. Use `integral` instead.

## Syntax

```
q = quadl(fun,a,b)
q = quadl(fun,a,b,tol)
quadl(fun,a,b,tol,trace)
[q,fcnt] = quadl(...)
```

## Description

`q = quadl(fun,a,b)` approximates the integral of function `fun` from `a` to `b`, to within an error of  $10^{-6}$  using recursive adaptive Lobatto quadrature. `fun` is a function handle. It accepts a vector `x` and returns a vector `y`, the function `fun` evaluated at each element of `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = quadl(fun,a,b,tol)` uses an absolute error tolerance of `tol` instead of the default, which is  $1.0e-6$ . Larger values of `tol` result in fewer function evaluations and faster computation, but less accurate results.

`quadl(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a q]` during the recursion.

`[q,fcnt] = quadl(...)` returns the number of function evaluations.

Use array operators `.*`, `./` and `.^` in the definition of `fun` so that it can be evaluated with a vector argument.

The function `quad` might be more efficient with low accuracies or nonsmooth integrands.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.
- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.

- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued `fun`.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of `fun(x)` to exist, `fun(x)` must decay as `x` approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if `fun(x)` decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint `c` like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

Pass the function handle, `@myfun`, to `quadl`:

```
Q = quadl(@myfun,0,2);
```

where the function `myfun.m` is:

```
function y = myfun(x)
y = 1./(x.^3-2*x-5);
```

Pass anonymous function handle `F` to `quadl`:

```
F = @(x) 1./(x.^3-2*x-5);
Q = quadl(F,0,2);
```

## Algorithms

`quadl` implements a high order method using an adaptive Gauss/Lobatto quadrature rule.

# quadl

---

## Diagnostics

quadl might issue one of the following warnings:

'Minimum step size reached' indicates that the recursive interval subdivision has produced a subinterval whose length is on the order of roundoff error in the length of the original interval. A nonintegrable singularity is possible.

'Maximum function count exceeded' indicates that the integrand has been evaluated more than 10,000 times. A nonintegrable singularity is likely.

'Infinite or Not-a-Number function value encountered' indicates a floating point overflow or division by zero during the evaluation of the integrand in the interior of the interval.

## How To

- "Anonymous Functions"

**Purpose**

Vectorized quadrature

quadv will be removed in a future release. Use `integral` with the 'ArrayValued' option instead.

**Syntax**

```
Q = quadv(fun,a,b)
Q = quadv(fun,a,b,tol)
Q = quadv(fun,a,b,tol,trace)
[Q,fcnt] = quadv(...)
```

**Description**

`Q = quadv(fun,a,b)` approximates the integral of the complex array-valued function `fun` from `a` to `b` to within an error of  $1.e-6$  using recursive adaptive Simpson quadrature. `fun` is a function handle. The function `Y = fun(x)` should accept a scalar argument `x` and return an array result `Y`, whose components are the integrands evaluated at `x`. Limits `a` and `b` must be finite.

“Parameterizing Functions” explains how to provide addition parameters to the function `fun`, if necessary.

`Q = quadv(fun,a,b,tol)` uses the absolute error tolerance `tol` for all the integrals instead of the default, which is  $1.e-6$ .

---

**Note** The same tolerance is used for all components, so the results obtained with `quadv` are usually not the same as those obtained with `quad` on the individual components.

---

`Q = quadv(fun,a,b,tol,trace)` with non-zero `trace` shows the values of `[fcnt a b-a Q(1)]` during the recursion.

`[Q,fcnt] = quadv(...)` returns the number of function evaluations.

The list below contains information to help you determine which quadrature function in MATLAB to use:

- The `quad` function might be most efficient for low accuracies with nonsmooth integrands.

- The `quadl` function might be more efficient than `quad` at higher accuracies with smooth integrands.
- The `quadgk` function might be most efficient for high accuracies and oscillatory integrands. It supports infinite intervals and can handle moderate singularities at the endpoints. It also supports contour integration along piecewise linear paths.
- The `quadv` function vectorizes `quad` for an array-valued fun.
- If the interval is infinite,  $[a, \text{Inf})$ , then for the integral of  $\text{fun}(x)$  to exist,  $\text{fun}(x)$  must decay as  $x$  approaches infinity, and `quadgk` requires it to decay rapidly. Special methods should be used for oscillatory functions on infinite intervals, but `quadgk` can be used if  $\text{fun}(x)$  decays fast enough.
- The `quadgk` function will integrate functions that are singular at finite endpoints if the singularities are not too strong. For example, it will integrate functions that behave at an endpoint  $c$  like  $\log|x-c|$  or  $|x-c|^p$  for  $p \geq -1/2$ . If the function is singular at points inside  $(a,b)$ , write the integral as a sum of integrals over subintervals with the singular points as endpoints, compute them with `quadgk`, and add the results.

## Examples

For the parameterized array-valued function `myarrayfun`, defined by

```
function Y = myarrayfun(x,n)
Y = 1./((1:n)+x);
```

the following command integrates `myarrayfun`, for the parameter value  $n = 10$  between  $a = 0$  and  $b = 1$ :

```
Qv = quadv(@(x)myarrayfun(x,10),0,1);
```

The resulting array `Qv` has 10 elements estimating  $Q(k) = \log((k+1)/(k))$ , for  $k = 1:10$ .

The entries in `Qv` are slightly different than if you compute the integrals using `quad` in a loop:

```
for k = 1:10
 Qs(k) = quadv(@(x)myscalarfun(x,k),0,1);
end
```

where `myscalarfun` is:

```
function y = myscalarfun(x,k)
y = 1./(k+x);
```

# matlab.unittest.qualifications

---

## Purpose

Summary of classes in MATLAB Qualifications Interface

## Description

Qualifications are methods for testing values and responding to failures. Qualification failures might or might not correspond to a test failure, and they might or might not continue execution in the test when one is encountered. To determine which qualification to use, see “Types of Qualifications”.

matlab.unittest.qualifications.AssertionQualification  
Qualification to validate preconditions of a test

matlab.unittest.qualifications.AssumptionQualification  
Qualification to filter test content

matlab.unittest.qualifications.FatalAssertionQualification  
Qualification to abort test execution

matlab.unittest.qualifications.VerificationQualification  
Qualification to produce soft-failure conditions

The package contains the following event data classes:

matlab.unittest.qualifications.ExceptionEventData  
ExceptionThrown event listeners

matlab.unittest.qualifications.QualificationEventData  
Qualification event listeners

The package contains the following exception handling classes:

matlab.unittest.qualifications.AssertionFailedException  
Exception for assertion failures

matlab.unittest.qualifications.AssumptionFailedException  
Exception for assumption failures

matlab.unittest.qualifications.FatalAssertionFailedException  
Exception for fatal assertion failures

## Purpose

Qualification to validate preconditions of a test

## Description

The `Assertable` class provides a qualification to validate preconditions of a test. Apart from actions performed for failures, the `Assertable` class works the same as other `matlab.unittest` qualifications.

Upon an assertion failure, the `Assertable` class throws an `AssertionFailedException` to inform the testing framework of the failure. This is most useful when a failure at the assertion point renders the rest of the current test method invalid, yet does not prevent proper execution of other test methods. Often, you use assertions to ensure that preconditions of the current test are not violated or that fixtures are set up correctly. Make sure the test content is “Exception Safe” on page 1-5301. If you cannot make the fixture teardown exception safe or if you cannot recover it after failure, use fatal assertions instead.

Use assertions to allow remaining test methods to receive coverage when preconditions are violated in a test and all fixture states are restorable. Assertions also reduce the noise level of failures by not performing later verifications that fail due the precondition failures. In the event of a failure, however, the test framework marks the full content of the test method that failed as incomplete. Therefore, if the failure does not affect the preconditions of the test or cause problems with fixture setup or teardown, use verifications, which give the added information for added information that the full test content was run.

## Methods

<code>assertClass</code>	Assert exact class of specified value
<code>assertEmpty</code>	Assert value is empty
<code>assertEqual</code>	Assert value is equal to specified value
<code>assertError</code>	Assert function throws specified exception

# matlab.unittest.qualifications.Assertable

---

<code>assertFail</code>	Produce unconditional assertion failure
<code>assertFalse</code>	Assert value is false
<code>assertGreaterThan</code>	Assert value is greater than specified value
<code>assertGreaterThanOrEqual</code>	Assert value is greater than or equal to specified value
<code>assertInstanceOf</code>	Assert value is object of specified type
<code>assertLength</code>	Assert value has specified length
<code>assertLessThan</code>	Assert value is less than specified value
<code>assertLessThanOrEqual</code>	Assert value is less than or equal to specified value
<code>assertMatches</code>	Assert string matches specified regular expression
<code>assertNotEmpty</code>	Assert value is not empty
<code>assertNotEqual</code>	Assert value is not equal to specified value
<code>assertNotSameHandle</code>	Assert value is not handle to specified instance
<code>assertNumElements</code>	Assert value has specified element count
<code>assertReturnsTrue</code>	Assert function returns true when evaluated
<code>assertSameHandle</code>	Assert two values are handles to same instance
<code>assertSize</code>	Assert value has specified size

<code>assertSubstring</code>	Assert string contains specified string
<code>assertThat</code>	Assert that value meets specified constraint
<code>assertTrue</code>	Assert value is true
<code>assertWarning</code>	Assert function issues specified warning
<code>assertWarningFree</code>	Assert function issues no warnings

## Events

<code>AssertionFailed</code>	Triggered upon failing assertion. A <code>QualificationEventData</code> object is passed to listener callback functions.
<code>AssertionPassed</code>	Triggered upon passing assertion. A <code>QualificationEventData</code> object is passed to listener callback functions.

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

# matlab.unittest.qualifications.Assertable

---

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Test for Preconditions Using Assertions

Use assertable qualifications to test for preconditions. This example will create a test case to write a polynomial to a MAT-file.

Create `DocPolynomSaveLoadTest` Test Case. Refer to the following `DocPolynomSaveLoadTest` test case in the subsequent steps in this example. The steps highlight specific code in the `testSaveLoad` function; the code statements are not intended to be executed outside the context of the class definition file.

### DocPolynomSaveLoadTest Class Definition File

```
classdef DocPolynomSaveLoadTest < matlab.unittest.TestCase

 methods (TestClassSetup)
 function addDocPolynomClassToPath(testCase)
 origPath = path;
 testCase.addTeardown(@path, origPath);
 end
 end
end
```

# matlab.unittest.qualifications.Assertable

---

```
 addpath(fullfile(matlabroot, ...
 'help', 'techdoc', 'matlab_oop', 'examples'));
 end
end

methods (Test)
 function testSaveLoad(testCase)

 import matlab.unittest.diagnostics.Diagnostic;

 %% Phase 1: Setup
 % Create a temporary working folder
 tempFolder = tempname;
 [success, message] = mkdir(tempFolder);
 testCase.assertTrue(success, ...
 Diagnostic.join('Could not create temporary folder.',
 message));
 testCase.addTeardown(@() testCase.cleanUpTemporaryFolder(
 tempFolder));

 % Change to the temporay folder and register the
 % teardown, which restores the original folder
 origFolder = pwd;
 testCase.addTeardown(@cd, origFolder);
 cd(tempFolder);

 %% Phase 2: Exercise
 % Save the instance to a mat file.
 p = DocPolynom([1, 0, 1]);
 save('DocPolynomFile', 'p');

 % Validate Precondition. Save resulted in valid .mat file
 testCase.assertEqual(exist('DocPolynomFile.mat', 'file'),
 2, Diagnostic.join(...
 'mat file was not saved correctly.', @() dir(pwd)));

 loaded = load('DocPolynomFile');
```

# matlab.unittest.qualifications.Assertable

---

```
%% Phase 3: Verify
testCase.verifyEqual(loaded.p, p,...
 'Loaded polynomial did not equal original polynomial.');
```

```
%% Phase 4: Teardown
% Done inline via calls to addTeardown at the points
% at which the state was changed.
```

```
end
end

methods(Access=private)
function cleanUpTemporaryFolder(testCase,tempFolder)
 % Clean up the temporary folder and fatally assert
 % that it was correctly cleaned up.

 import matlab.unittest.diagnostics.Diagnostic;

 [success, message] = rmdir(tempFolder, 's');
 testCase.fatalAssertTrue(success, ...
 Diagnostic.join('Could not remove temporary folder.',...
 message));
end
end

end
```

To execute the MATLAB commands in “Run DocPolynomSaveLoadTest Test Case”, add the DocPolynomSaveLoadTest.m file to a folder on your MATLAB path.

The testSaveLoad function consists of the following phases:

- Phase 1: Setup — Create and verify precondition code.
- Phase 2: Exercise — Create a DocPolynom object and save it to a MAT-file.
- Phase 3: Verify — Test that object was successfully saved.
- Phase 4: Teardown — Execute teardown code.

Define phase 1 precondition. For this test, use a temporary folder for creating a DocPolynom object. The precondition for continuing with this test is that the following commands execute successfully.

```
tempFolder = tempname;
[success, message] = mkdir(tempFolder);
```

Test the results of the `mkdir` function. Use the `assertTrue` method to test the `mkdir` `success` argument for errors. If an assertion occurs, the remainder of the `testSaveLoad` test method is invalid, and the test is marked Incomplete.

```
testCase.assertTrue(success, ...
 Diagnostic.join('Could not create the temporary folder.', ...
 message));
```

If the `mkdir` function fails, MATLAB displays the diagnostic message, `Could not create the temporary folder`, as well as the contents of the `mkdir` `message` argument.

Add teardown fixture code. Creating a temporary folder is setup code, which requires a corresponding call to the `rmdir` function to restore MATLAB to the original state. Use the `addTeardown` method to ensure the teardown code executes even when an exception is thrown in the middle of the test method. This makes the test Exception Safe.

```
testCase.addTeardown(@() testCase.cleanupTemporaryFolder(tempFolder));
```

Place teardown code in the helper function. Although the `addTeardown` statement occurs in the same code block as the `mkdir` setup statement,

# matlab.unittest.qualifications.Assertable

---

the `cleanUpTemporaryFolder` code is executed in phase 4 of the test method.

In the `DocPolynomSaveLoadTest` test case, the helper function, `cleanUpTemporaryFolder`, executes the `rmdir` function.

Define the precondition for creating valid MAT-File. A precondition for verifying that the `DocPolynom` object was correctly saved and loaded is that the MAT-file, `DocPolynomFile.mat`, was successfully created. The following code in the `Phase 2: Exercise` block tests this condition. If an assertion occurs, the remainder of the `testSaveLoad` test method is invalid, and the test is marked `Failed` and `Incomplete`.

```
testCase.assertEqual(exist('DocPolynomFile.mat','file'), 2, ...
 Diagnostic.join('The mat file was not saved correctly.', ...
 @() dir(pwd)));
```

If the file was not created, MATLAB displays the diagnostic message, `The mat file was not saved correctly`, as well as the contents of the temporary folder.

Run `DocPolynomSaveLoadTest` Test Case.

```
tc = DocPolynomSaveLoadTest;
run(tc);
```

```
Running DocPolynomSaveLoadTest
.
Done DocPolynomSaveLoadTest
```

## Concepts

# matlab.unittest.qualifications.Assertable.assertClass

## Purpose

Assert exact class of specified value

## Syntax

```
assertClass(assertable,actual,className)
assertClass(assertable,actual,metaClass)
assertClass(___,diagnostic)
```

## Description

`assertClass(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertClass(assertable,actual,metaClass)` asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assertInstanceOf` to assert inclusion in a class hierarchy.

`assertClass( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
assertable.assertThat(actual, IsOfClass(className));
assertable.assertThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Assertable.assertClass

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyClass`.

## **See Also**

`assertThat` | `assertInstanceOf`

# matlab.unittest.qualifications.Assertable.assertEmpty

<b>Purpose</b>	Assert value is empty
<b>Syntax</b>	<pre>assertEmpty(assertable,actual) assertEmpty(assertable,actual,diagnostic)</pre>
<b>Description</b>	<p><code>assertEmpty(assertable,actual)</code> asserts that <code>actual</code> is an empty MATLAB value.</p> <p><code>assertEmpty(assertable,actual,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsEmpty; assertable.assertThat(actual, IsEmpty());</pre><p>This method is a convenience method. There exists more functionality when using the <code>IsEmpty</code> constraint directly via <code>assertThat</code>.</p></li></ul>
<b>Input Arguments</b>	<p><b>assertable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>string</li><li>function handle</li><li><code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul> <p>Diagnostic values can be nonscalar. # matlab.unittest.qualifications.Assertable.assertEmpty

---

**Examples**      See examples for `verifyEmpty`.

**See Also**      `assertThat` | `assertNotEmpty` | `isempty`

# matlab.unittest.qualifications.Assertable.assertEqual

## Purpose

Assert value is equal to specified value

## Syntax

```
assertEqual(assertable,actual,expected)
assertEqual(____,Name,Value)
assertEqual(____,diagnostic)
```

## Description

`assertEqual(assertable,actual,expected)` asserts that `actual` is strictly equal to `expected`.

`assertEqual( ____,Name,Value)` asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`assertEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assertable.assertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol))
```

# matlab.unittest.qualifications.Assertable.assertEqual

---

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

**'RelTol'**

# matlab.unittest.qualifications.Assertable.assertEqual

---

**Examples**      See examples for `verifyEqual`.

**See Also**      `assertThat` | `assertNotEqual`

# matlab.unittest.qualifications.Assertable.assertError

---

**Purpose** Assert function throws specified exception

**Syntax** `assertError(assertable,actual,identifier)`  
`assertError(assertable,actual,metaClass)`  
`assertError(___,diagnostic)`

**Description** `assertError(assertable,actual,identifier)` asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assertError(assertable,actual,metaClass)` asserts that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assertError(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips** • This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
assertable.assertThat(actual, Throws(identifier));
assertable.assertThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **identifier**

# matlab.unittest.qualifications.Assertable.assertError

---

Error identifier, specified as a string.

## **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyError`.

## **See Also**

`assertThat` | `assertWarning` | `MException` | `error`

# matlab.unittest.qualifications.Assertable.assertFail

---

**Purpose** Produce unconditional assertion failure

**Syntax** `assertFail(assertable)`  
`assertFail(assertable,diagnostic)`

**Description** `assertFail(assertable)` produces an unconditional assertion failure when encountered.

`assertFail(assertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyFail`.

# matlab.unittest.qualifications.Assertable.assertFalse

## Purpose

Assert value is false

## Syntax

```
assertFalse(assertable,actual)
assertFalse(assertable,actual,diagnostic)
```

## Description

`assertFalse(assertable,actual)` asserts that `actual` is a scalar logical with the value of false.

`assertFalse(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
assertable.assertThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `assertThat`.

- Unlike `assertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assertTrue`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assertable.assertFalse

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** For examples, see `verifyFalse`.

**See Also** `assertThat` | `assertTrue`

# matlab.unittest.qualifications.Assertable.assertGreaterThan

## Purpose

Assert value is greater than specified value

## Syntax

```
assertGreaterThan(assertable,actual,floor)
assertGreaterThan(assertable,actual,floor,diagnostic)
```

## Description

`assertGreaterThan(assertable,actual,floor)` asserts that all elements of `actual` are greater than all the elements of `floor`.

`assertGreaterThan(assertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThan;
assertable.assertThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertGreaterThan

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThan`.

## See Also

`assertThat` | `assertGreaterThanOrEqual` |  
`assertLessThan` | `assertLessThanOrEqual` | `gt` |  
`matlab.unittest.constraints.IsGreaterThan` |  
`matlab.unittest.diagnostics.Diagnostic`

# matlab.unittest.qualifications.Assertable.assertGreaterThanOrEqualTo

## Purpose

Assert value is greater than or equal to specified value

## Syntax

```
assertGreaterThanOrEqualTo(assertable,actual,floor)
assertGreaterThanOrEqualTo(assertable,actual,floor,diagnostic)
```

## Description

`assertGreaterThanOrEqualTo(assertable,actual,floor)` asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assertGreaterThanOrEqualTo(assertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
assertable.assertThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assertable.assertGreaterThanOrEqualTo

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThanOrEqualTo`.

## See Also

`assertThat` | `assertGreaterThan` |  
`assertLessThanOrEqualTo` | `assertLessThan` | `ge` |  
`matlab.unittest.constraints.IsGreaterThanOrEqualTo` |  
`matlab.unittest.diagnostics.Diagnostic`

# matlab.unittest.qualifications.Assertable.assertInstanceOf

## Purpose

Assert value is object of specified type

## Syntax

```
assertInstanceOf(assertable,actual,className)
assertInstanceOf(assertable,actual,metaClass)
assertInstanceOf(___,diagnostic)
```

## Description

`assertInstanceOf(assertable,actual,className)` asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`assertInstanceOf(assertable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assertInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
assertable.assertThat(actual, IsInstanceOf(className));
assertable.assertThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of `meta.class`.

# matlab.unittest.qualifications.Assertable.assertInstanceOf

---

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`.

## **See Also**

`assertThat` | `assertClass` | `isa`

# matlab.unittest.qualifications.Assertable.assertLength

---

## Purpose

Assert value has specified length

## Syntax

```
assertLength(assertable,actual,expectedLength)
assertLength(assertable,actual,expectedLength,diagnostic)
```

## Description

`assertLength(assertable,actual,expectedLength)` that `actual` is a MATLAB array whose length is `expectedLength`.

`assertLength(assertable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
assertable.assertThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertLength

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLength`.

## See Also

`assertThat` | `assertSize` | `assertNumElements` | `length`

# matlab.unittest.qualifications.Assertable.assertLessThan

---

## Purpose

Assert value is less than specified value

## Syntax

```
assertLessThan(assertable,actual,ceiling)
assertLessThan(assertable,actual,ceiling,diagnostic)
```

## Description

`assertLessThan(assertable,actual,ceiling)` asserts that all elements of `actual` are less than all the elements of `ceiling`.

`assertLessThan(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assertable.assertThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertLessThan

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThan`.

## See Also

`assertGreaterThan` | `assertGreaterThanOrEqual` |  
`lt` | `matlab.unittest.constraints.IsLessThan` |  
`matlab.unittest.diagnostics.Diagnostic`

# matlab.unittest.qualifications.Assertable.assertLessThanOrEqual

## Purpose

Assert value is less than or equal to specified value

## Syntax

```
assertLessThanOrEqual(assertable,actual,ceiling)
assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)
```

## Description

`assertLessThanOrEqual(assertable,actual,ceiling)` asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assertLessThanOrEqual(assertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
assertable.assertThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThanOrEqualTo`.

## See Also

`assertThat` | `assertLessThan` | `assertGreaterThan`  
| `assertGreaterThanOrEqualTo` | `le` |  
`matlab.unittest.constraints.IsLessThanOrEqualTo` |  
`matlab.unittest.diagnostics.Diagnostic`

# matlab.unittest.qualifications.Assertable.assertMatches

## Purpose

Assert string matches specified regular expression

## Syntax

```
assertMatches(assertable,actual,expression)
assertMatches(assertable,actual,expression,diagnostic)
```

## Description

`assertMatches(assertable,actual,expression)` asserts that `actual` is a string that matches the regular expression defined by `expression`.

`assertMatches(assertable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
assertable.assertThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expression**

The value to match, specified as a regular expression.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertMatches

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyMatches`.

**See Also** `assertThat` | `assertSubstring` | `regexp`

# matlab.unittest.qualifications.Assertable.assertNotEmpty

---

## Purpose

Assert value is not empty

## Syntax

```
assertNotEmpty(assertable,actual)
assertNotEmpty(assertable,actual,diagnostic)
```

## Description

`assertNotEmpty(assertable,actual)` asserts that `actual` is a non-empty MATLAB value.

`assertNotEmpty(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assertable.assertThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

# matlab.unittest.qualifications.Assertable.assertNotEmpty

---

**Examples**      See examples for `verifyNotEmpty`.

**See Also**      `assertThat` | `assertEmpty` | `isempty`

# matlab.unittest.qualifications.Assertable.assertNotEqual

---

## Purpose

Assert value is not equal to specified value

## Syntax

```
assertNotEqual(assertable, actual, notExpected)
assertNotEqual(assertable, actual, notExpected, diagnostic)
```

## Description

`assertNotEqual(assertable, actual, notExpected)` asserts that `actual` is not equal to `notExpected`.

`assertNotEqual(assertable, actual, notExpected, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
assertable.assertThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assertable.assertNotEqual

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples**      See examples for `verifyNotEqual`.

**See Also**      `assertThat` | `assertEqual`

# matlab.unittest.qualifications.Assertable.assertNotSameHandle

---

## Purpose

Assert value is not handle to specified instance

## Syntax

```
assertNotSameHandle(assertable,actual,notExpectedHandle)
assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)
```

## Description

`assertNotSameHandle(assertable,actual,notExpectedHandle)` asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assertNotSameHandle(assertable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assertable.assertThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`.

## See Also

`assertThat` | `assertSameHandle`

# matlab.unittest.qualifications.Assertable.assertNumElements

## Purpose

Assert value has specified element count

## Syntax

```
assertNumElements(assertable,actual,expectedElementCount)
assertNumElements(assertable,actual,expectedElementCount,diagnostic)
```

## Description

`assertNumElements(assertable,actual,expectedElementCount)` asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assertNumElements(assertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assertable.assertThat(actual, HasElementCount(expectedElementCount))
```

There exists more functionality when using the `HasElementCount` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedElementCount**

The expected number of elements in the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertNumElements

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`.

## See Also

`assertThat` | `assertSize` | `assertLength` | `numel`

# matlab.unittest.qualifications.Assertable.assertReturnsTrue

**Purpose** Assert function returns true when evaluated

**Syntax** `assertReturnsTrue(assertable,actual)`  
`assertReturnsTrue(assertable,actual,diagnostic)`

**Description** `assertReturnsTrue(assertable,actual)` asserts that `actual` is a function handle that returns a scalar logical whose value is true.  
`assertReturnsTrue(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assertTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
assertable.assertThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assertable.assertReturnsTrue

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`.

## See Also

`assertThat` | `assertTrue`

# matlab.unittest.qualifications.Assertable.assertSameHandle

## Purpose

Assert two values are handles to same instance

## Syntax

```
assertSameHandle(assertable,actual,expectedHandle)
assertSameHandle(assertable,actual,expectedHandle,diagnostic)
```

## Description

`assertSameHandle(assertable,actual,expectedHandle)` asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assertSameHandle(assertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assertable.assertThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertSameHandle

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`.

## See Also

`assertThat` | `assertNotSameHandle` | `handle`

# matlab.unittest.qualifications.Assertable.assertSize

---

<b>Purpose</b>	Assert value has specified size
<b>Syntax</b>	<pre>assertSize(assertable,actual,expectedSize) assertSize(assertable,actual,expectedSize,diagnostic)</pre>
<b>Description</b>	<p><code>assertSize(assertable,actual,expectedSize)</code> asserts that <code>actual</code> is a MATLAB array whose size is <code>expectedSize</code>.</p> <p><code>assertSize(assertable,actual,expectedSize,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• This method is functionally equivalent to: <pre>import matlab.unittest.constraints.HasSize; assertable.assertThat(actual, HasSize(expectedSize));</pre><p>There exists more functionality when using the <code>HasSize</code> constraint directly via <code>assertThat</code>.</p></li></ul>
<b>Input Arguments</b>	<p><b>assertable</b> The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assertion in conjunction with the test running framework.</p> <p><b>actual</b> The value to test.</p> <p><b>expectedSize</b> The expected sizes of each dimension the array.</p> <p><b>diagnostic</b> Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

# matlab.unittest.qualifications.Assertable.assertSize

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifySize`.

**See Also** `assertThat` | `assertLength` | `assertNumElements` | `size`

# matlab.unittest.qualifications.Assertable.assertSubstring

---

## Purpose

Assert string contains specified string

## Syntax

```
assertSubstring(assertable,actual,substring)
assertSubstring(assertable,actual,substring,diagnostic)
```

## Description

`assertSubstring(assertable,actual,substring)` asserts that `actual` is a string that contains `substring`.

`assertSubstring(assertable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
assertable.assertThat(actual, ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **substring**

The value to match, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assertable.assertSubstring

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifySubstring`.

**See Also** `assertThat` | `assertMatches` | `strfind`

# matlab.unittest.qualifications.Assertable.assertThat

---

## Purpose

Assert that value meets specified constraint

## Syntax

```
assertThat(assertable, actual, constraint)
assertThat(assertable, actual, constraint, diagnostic)
```

## Description

`assertThat(assertable, actual, constraint)` asserts that `actual` is a value that satisfies the `constraint` provided.

If the `constraint` is not satisfied, an assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`assertThat(assertable, actual, constraint, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **constraint**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

# matlab.unittest.qualifications.Assertable.assertThat

---

## **Examples**

See examples for `verifyThat`.

# matlab.unittest.qualifications.Assertable.assertTrue

## Purpose

Assert value is true

## Syntax

```
assertTrue(assertable, actual)
assertTrue(assertable, actual, diagnostic)
```

## Description

`assertTrue(assertable, actual)` asserts that `actual` is a scalar logical with the value of true.

`assertTrue(assertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and non-zero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
assertable.assertThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `assertThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `assertReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

# matlab.unittest.qualifications.Assertable.assertTrue

---

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`.

## **See Also**

`assertThat` | `assertFalse` | `assertReturnsTrue`

# matlab.unittest.qualifications.Assertable.assertWarning

## Purpose

Assert function issues specified warning

## Syntax

```
assertWarning(assertable,actual,warningID)
assertWarning(assertable,actual,warningID,diagnostic)
[output1,...,outputN] = assertWarning(___)
```

## Description

`assertWarning(assertable,actual,warningID)` asserts that `actual` issues a warning with the identifier `warningID`.

`assertWarning(assertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
assertable.assertThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assertable.assertWarning

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`.

## See Also

`assertThat` | `assertError` | `assertWarningFree` | `warning`

# matlab.unittest.qualifications.Assertable.assertWarningFree

## Purpose

Assert function issues no warnings

## Syntax

```
assertWarningFree(assertable,actual)
assertWarningFree(assertable,actual,diagnostic)
[output1,...,outputN] = assertWarningFree(___)
```

## Description

`assertWarningFree(assertable,actual)` asserts that `actual` is a function handle that issues no warnings.

`assertWarningFree(assertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
assertable.assertThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assertThat`.

## Input Arguments

### **assertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assertable.assertWarningFree

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### `output1,...,outputN`

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`.

## See Also

`assertThat` | `assertWarning` | `warning`

# matlab.unittest.qualifications.AssertionFailedException

---

**Purpose** Exception used for assertion failures

**Description** The `AssertionFailedException` class provides an exception used for assertion failures. This class is used exclusively by the `Assertable` qualification type.

**See Also** `Assertable` | `MException`

# matlab.unittest.qualifications.Assumable

---

**Purpose** Qualification to filter test content

**Description** The `Assumable` class provides a qualification to filter test content. Apart from actions performed in the event of failures, the `Assumable` class works the same as other `matlab.unittest` qualifications.

Upon an assumption failure, the `Assumable` class informs the testing framework of the failure by throwing an `AssumptionFailedException`. The test framework then marks the test content as filtered and continues testing. Often, assumptions are used to ensure that the test is run only when certain preconditions are met. However, running the test without satisfying the preconditions does not produce a test failure. Ensure that the test content is “Exception Safe” on page 1-5361. If the failure condition is meant to produce a test failure, use assertions or verifications instead of assumptions.

The attributes specified in the `TestCase` method definition determine which tests are filtered. The following behavior occurs when the test framework encounters an assumption failure inside of a `TestCase` method:

- If you define the `TestCase` method using the `Test` attribute, the framework marks the entire method as filtered and runs subsequent test methods.
- If you define the `TestCase` method using the `TestMethodSetup` or `TestMethodTeardown` attributes, the test framework marks the method to run for that instance as filtered.
- If you define the `TestCase` method using the `TestClassSetup` or `TestClassTeardown` attributes, the test framework filters the entire `TestCase` class.

Filtering test content using assumptions does not produce test failures. Therefore, dead test code can result. Avoid this by monitoring filtered tests.

## Methods

<code>assumeClass</code>	Assume exact class of specified value
<code>assumeEmpty</code>	Assume value is empty
<code>assumeEqual</code>	Assume value is equal to specified value
<code>assumeError</code>	Assume function throws specified exception
<code>assumeFail</code>	Produce unconditional assumption failure
<code>assumeFalse</code>	Assume value is false
<code>assumeGreaterThan</code>	Assume value is greater than specified value
<code>assumeGreaterThanOrEqual</code>	Assume value is greater than or equal to specified value
<code>assumeInstanceOf</code>	Assume value is object of specified type
<code>assumeLength</code>	Assume value has specified length
<code>assumeLessThan</code>	Assume value is less than specified value
<code>assumeLessThanOrEqual</code>	Assume value is less than or equal to specified value
<code>assumeMatches</code>	Assume string matches specified regular expression
<code>assumeNotEmpty</code>	Assume value is not empty
<code>assumeNotEqual</code>	Assume value is not equal to specified value
<code>assumeNotSameHandle</code>	Assume value is not handle to specified instance

# matlab.unittest.qualifications.Assumable

---

<code>assumeNumElements</code>	Assume value has specified element count
<code>assumeReturnsTrue</code>	Assume function returns true when evaluated
<code>assumeSameHandle</code>	Assume two values are handles to same instance
<code>assumeSize</code>	Assume value has specified size
<code>assumeSubstring</code>	Assume string contains specified string
<code>assumeThat</code>	Assume value meets specified constraint
<code>assumeTrue</code>	Assume value is true
<code>assumeWarning</code>	Assume function issues specified warning
<code>assumeWarningFree</code>	Assume function issues no warnings

## Events

<code>AssumptionFailed</code>	Triggered upon failing assumption. A <code>QualificationEventData</code> object is passed to listener callback functions.
<code>AssumptionPassed</code>	Triggered upon passing assumption. A <code>QualificationEventData</code> object is passed to listener callback functions.

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
close(f);
```

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.assertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `assertEqual`.

```
% Not exception safe
f = figure;
testCase.assertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Write TestClassSetup Method Using Assumptions

Assumptions assure that a test runs only when certain preconditions are satisfied and when such an event should not produce a test failure. When an assumption failure occurs, the test is marked as filtered.

# matlab.unittest.qualifications.Assumable

---

Create `IsSupportedTest` test case. Refer to the following `IsSupportedTest` test case in the subsequent steps in this example, which highlight specific functions in the file.

## IsSupportedTest Class Definition File

```
classdef IsSupportedTest < matlab.unittest.TestCase
 methods(TestClassSetup)
 function TestPlatform(testcase)
 testcase.assumeFalse(ispc,...
 'Do not run any of these tests on Windows.');
```

end

```
 end
 end
 methods(Test)
 function test1(testcase)
 %write test code here
 end
 end
end
```

To execute the MATLAB commands in this example, add the `IsSupportedTest.m` file to a folder on your MATLAB path.

Write `Test to Verify Platform`. All tests in this test case must run on UNIX platforms only. The `TestPlatform` function uses the `assumeFalse` method to test if MATLAB is running on a Windows platform. If it is, the test fails.

```
function TestPlatform(testcase)
 testcase.assumeFalse(ispc,...
 'Do not run any of these tests on Windows.');
```

end

Make `TestPlatform` a `TestClassSetup` Test. To make the `TestPlatform` test a precondition, add it inside the `methods (TestClassSetup)` block.

Run the test case. Create a test case object and run the tests on a Windows platform.

```
tc = IsSupportedTest;
res = tc.run;
```

Running IsSupportedTest

```
=====
All tests in IsSupportedTest were filtered.
 Test Diagnostic: Do not run any of these tests on Windows.
 Details
=====
```

Done IsSupportedTest

Failure Summary:

Name	Failed	Incomplete	Reason(s)
IsSupportedTest/test1		X	Filtered by assumption

The test(s) were filtered, and did not run (marked Incomplete).

For more information, click the [Details link](#).

```
=====
The TestClassSetup or TestClassTeardown for IsSupportedTest was filtered.
All tests in this class were also filtered as a result.
```

```

Test Diagnostic:
```

```

Do not run any of these tests on Windows.
```

```

Framework Diagnostic:
```

# matlab.unittest.qualifications.Assumable

---

```

assumeFalse failed.
--> The value must evaluate to "false".

Actual Value:
 1

Stack Information:

In C:\Program Files\MATLAB\R2013a\toolbox\matlab\testframework\+matlab\unittest\qualifications\Assumable.m (Assumable.assumeFalse) at 4
In c:\work\IsSupportedTest.m (IsSupportedTest.TestPlatform) at 4

## Concepts

- “Dynamically Filtered Tests”

# matlab.unittest.qualifications.Assumable.assumeClass

## Purpose

Assume exact class of specified value

## Syntax

```
assumeClass(assumable,actual,className)
assumeClass(assumable,actual,metaClass)
assumeClass(____,diagnostic)
```

## Description

`assumeClass(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeClass(assumable,actual,metaClass)` assumes that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. See `assumeInstanceOf` to assume inclusion in a class hierarchy.

`assumeClass( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
assumable.assumeThat(actual, IsOfClass(className));
assumable.assumeThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Assumable.assumeClass

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyClass`.

## **See Also**

`assumeThat` | `assumeInstanceOf`

# matlab.unittest.qualifications.Assumable.assumeEmpty

---

## Purpose

Assume value is empty

## Syntax

```
assumeEmpty(assumable,actual)
assumeEmpty(assumable,actual,diagnostic)
```

## Description

`assumeEmpty(assumable,actual)` assumes that `actual` is an empty MATLAB value.

`assumeEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assumable.assumeThat(actual, IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assumable.assumeEmpty

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyEmpty`.

**See Also** `assumeThat` | `assumeNotEmpty` | `isempty`

# matlab.unittest.qualifications.Assumable.assumeEqual

## Purpose

Assume value is equal to specified value

## Syntax

```
assumeEqual(assumable,actual,expected)
assumeEqual(____,Name,Value)
assumeEqual(____,diagnostic)
```

## Description

`assumeEqual(assumable,actual,expected)` assumes that `actual` is strictly equal to `expected`.

`assumeEqual( ____,Name,Value)` assumes equality with additional options specified by one or more `Name,Value` pair arguments.

`assumeEqual( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
assumable.assumeThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol))
```

# matlab.unittest.qualifications.Assumable.assumeEqual

---

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'AbsTol'**

**'RelTol'**

# matlab.unittest.qualifications.Assumable.assumeEqual

---

**Examples**      See examples for `verifyEqual`.

**See Also**      `assumeThat` | `assumeNotEqual`

# matlab.unittest.qualifications.Assumable.assumeError

---

**Purpose** Assume function throws specified exception

**Syntax**

```
assumeError(assumable,actual,identifier)
assumeError(assumable,actual,metaClass)
assumeError(____,diagnostic)
```

**Description** `assumeError(assumable,actual,identifier)` assumes that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`assumeError(assumable,actual,metaClass)` assumes that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`assumeError( ____,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
assumable.assumeThat(actual, Throws(identifier));
assumable.assumeThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **identifier**

# matlab.unittest.qualifications.Assumable.assumeError

---

Error identifier, specified as a string.

## **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyError`.

## **See Also**

`assumeThat` | `assumeWarning` | `MException` | `error`

# matlab.unittest.qualifications.Assumable.assumeFail

---

<b>Purpose</b>	Produce unconditional assumption failure
<b>Syntax</b>	<code>assumeFail(assumable)</code> <code>assumeFail(assumable,diagnostic)</code>
<b>Description</b>	<code>assumeFail(assumable)</code> produces an unconditional assumption failure when encountered.  <code>assumeFail(assumable,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.
<b>Input Arguments</b>	<p><b>assumable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assumption in conjunction with the test running framework.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul> <p>Diagnostic values can be nonscalar. <b>Examples</b>	See examples for <code>verifyFail</code> .

# matlab.unittest.qualifications.Assumable.assumeFalse

## Purpose

Assume value is false

## Syntax

```
assumeFalse(assumable, actual)
assumeFalse(assumable, actual, diagnostic)
```

## Description

`assumeFalse(assumable, actual)` assumes that `actual` is a scalar logical with the value of false.

`assumeFalse(assumable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
assumable.assumeThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `assumeThat`.

- Unlike `assumeTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `assumeTrue`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

# matlab.unittest.qualifications.Assumable.assumeFalse

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

For examples, see `verifyFalse`.

## See Also

`assumeThat` | `assumeTrue`

# matlab.unittest.qualifications.Assumable.assumeGreaterThan

---

## Purpose

Assume value is greater than specified value

## Syntax

```
assumeGreaterThan(assumable,actual,floor)
assumeGreaterThan(assumable,actual,floor,diagnostic)
```

## Description

`assumeGreaterThan(assumable,actual,floor)` assumes that all elements of `actual` are greater than all the elements of `floor`.

`assumeGreaterThan(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThan;
assumable.assumeThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeGreaterThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThan`.

## See Also

`assumeThat` | `assumeGreaterThanOrEqual` |  
`assumeLessThanOrEqual` | `assumeLessThan` | `gt` |  
`matlab.unittest.constraints.IsGreaterThan` |  
`matlab.unittest.diagnostics.Diagnostic`

## Purpose

Assume value is greater than or equal to specified value

## Syntax

```
assumeGreaterThanOrEqual(assumable,actual,floor)
assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)
```

## Description

`assumeGreaterThanOrEqual(assumable,actual,floor)` assumes that all elements of `actual` are greater than or equal to all the elements of `floor`.

`assumeGreaterThanOrEqual(assumable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
assumable.assumeThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThanOrEqual`.

## See Also

# matlab.unittest.qualifications.Assumable.assumeInstanceOf

**Purpose** Assume value is object of specified type

**Syntax**

```
assumeInstanceOf(assumable,actual,className)
assumeInstanceOf(assumable,actual,metaClass)
assumeInstanceOf(___,diagnostic)
```

**Description**

`assumeInstanceOf(assumable,actual,className)` assumes that `actual` is a MATLAB value whose class is the class specified by `className`.

`assumeInstanceOf(assumable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`assumeInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
assumable.assumeThat(actual, IsInstanceOf(className));
assumable.assumeThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.Assumable.assumeInstanceOf

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`.

## **See Also**

# matlab.unittest.qualifications.Assumable.assumeLength

---

## Purpose

Assume value has specified length

## Syntax

```
assumeLength(assumable,actual,expectedLength)
assumeLength(assumable,actual,expectedLength,diagnostic)
```

## Description

`assumeLength(assumable,actual,expectedLength)` assumes that `actual` is a MATLAB array whose length is `expectedLength`.

`assumeLength(assumable,actual,expectedLength,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
assumable.assumeThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeLength

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLength`.

## See Also

`assumeThat` | `assumeSize` | `assumeNumElements` | `length`

## Purpose

Assume value is less than specified value

## Syntax

```
assumeLessThan(assumable,actual,ceiling)
assumeLessThan(assumable,actual,ceiling,diagnostic)
```

## Description

`assumeLessThan(assumable,actual,ceiling)` assumes that all elements of `actual` are less than all the elements of `ceiling`.

`assumeLessThan(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assumable.assumeThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeLessThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

`matlab.unittest.diagnostics.Diagnostic`

## Purpose

Assume value is less than or equal to specified value

## Syntax

```
assumeLessThanOrEqualTo(assumable,actual,ceiling)
assumeLessThanOrEqualTo(assumable,actual,ceiling,diagnostic)
```

## Description

`assumeLessThanOrEqualTo(assumable,actual,ceiling)` assumes that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`assumeLessThanOrEqualTo(assumable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
assumable.assumeThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThanOrEqual`.

## See Also

`assumeThat` | `assumeLessThan` | `assumeGreaterThan`  
| `assumeGreaterThanOrEqual` | `le` |  
`matlab.unittest.constraints.IsLessThanOrEqualTo` |  
`matlab.unittest.diagnostics.Diagnostic`

# matlab.unittest.qualifications.Assumable.assumeMatches

---

## Purpose

Assume string matches specified regular expression

## Syntax

```
assumeMatches(assumable,actual,expression)
assumeMatches(assumable,actual,expression,diagnostic)
```

## Description

`assumeMatches(assumable,actual,expression)` assumes that `actual` is a string that matches the regular expression defined by `expression`.

`assumeMatches(assumable,actual,expression,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
assumable.assumeThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The string to test.

### **expression**

The value to match, specified as a regular expression.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeMatches

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyMatches`.

## See Also

`assumeThat` | `assumeSubstring` | `regexp`

**Purpose** Assume value is not empty

**Syntax** `assumeNotEmpty(assumable,actual)`  
`assumeNotEmpty(assumable,actual,diagnostic)`

**Description** `assumeNotEmpty(assumable,actual)` assumes that `actual` is a non-empty MATLAB value.  
`assumeNotEmpty(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips** • This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
assumable.assumeThat(actual, ~IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.Assumable.assumeNotEmpty

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyNotEmpty`.

**See Also** `assumeThat` | `assumeEmpty` | `isempty`

## Purpose

Assume value is not equal to specified value

## Syntax

```
assumeNotEqual(assumable,actual,notExpected)
assumeNotEqual(assumable,actual,notExpected,diagnostic)
```

## Description

`assumeNotEqual(assumable,actual,notExpected)` assumes that `actual` is not equal to `notExpected`.

`assumeNotEqual(assumable,actual,notExpected,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
assumable.assumeThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assumable.assumeNotEqual

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyNotEqual`.

**See Also** `assumeThat` | `assumeEqual`

# matlab.unittest.qualifications.Assumable.assumeNotSame

---

## Purpose

Assume value is not handle to specified instance

## Syntax

```
assumeNotSameHandle(actual,notExpectedHandle)
assumeNotSameHandle(actual,notExpectedHandle,diagnostic)
```

## Description

`assumeNotSameHandle(actual,notExpectedHandle)` assumes that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`assumeNotSameHandle(actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assumable.assumeThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeNotSameHandle

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`.

## See Also

`assumeThat` | `assumeSameHandle`

# matlab.unittest.qualifications.Assumable.assumeNumElements

---

## Purpose

Assume value has specified element count

## Syntax

```
assumeNumElements(assumable,actual,expectedElementCount)
assumeNumElements(assumable,actual,expectedElementCount,diagnostic)
```

## Description

`assumeNumElements(assumable,actual,expectedElementCount)` assumes that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`assumeNumElements(assumable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
assumable.assumeThat(actual, HasElementCount(expectedElementCount))
```

There exists more functionality when using the `HasElementCount` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedElementCount**

The expected number of elements in the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeNumElements

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`.

## See Also

`assumeThat` | `assumeSize` | `assumeLength` | `numel`

# matlab.unittest.qualifications.Assumable.assumeReturnsTrue

## Purpose

Assume function returns true when evaluated

## Syntax

```
assumeReturnsTrue(assumable,actual)
assumeReturnsTrue(assumable,actual,diagnostic)
```

## Description

`assumeReturnsTrue(assumable,actual)` assumes that `actual` is a function handle that returns a scalar logical whose value is true.

`assumeReturnsTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `assumeTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `assumeTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
assumable.assumeThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.Assumable.assumeReturnsTrue

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`.

## See Also

`assumeThat` | `assumeTrue`

# matlab.unittest.qualifications.Assumable.assumeSameHandle

## Purpose

Assume two values are handles to same instance

## Syntax

```
assumeSameHandle(assumable,actual,expectedHandle)
assumeSameHandle(assumable,actual,expectedHandle,diagnostic)
```

## Description

`assumeSameHandle(assumable,actual,expectedHandle)` assumes that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`assumeSameHandle(assumable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
assumable.assumeThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeSameHandle

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`.

## See Also

`assumeThat` | `assumeNotSameHandle` | `handle`

# matlab.unittest.qualifications.Assumable.assumeSize

## Purpose

Assume value has specified size

## Syntax

```
assumeSize(assumable,actual,expectedSize)
assumeSize(assumable,actual,expectedSize,diagnostic)
```

## Description

`assumeSize(assumable,actual,expectedSize)` assumes that `actual` is a MATLAB array whose size is `expectedSize`.

`assumeSize(assumable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
assumable.assumeThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedSize**

The expected sizes of each dimension the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assumable.assumeSize

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySize`.

## See Also

`assumeThat` | `assumeLength` | `assumeNumElements` | `size`

**Purpose** Assume string contains specified string

**Syntax** `assumeSubstring(assumable,actual,substring)`  
`assumeSubstring(assumable,actual,substring,diagnostic)`

**Description** `assumeSubstring(assumable,actual,substring)` assumes that `actual` is a string that contains `substring`.  
`assumeSubstring(assumable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips** • This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
assumable.assumeThat(actual, ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The value to test.

### **substring**

The value to match, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Assumable.assumeSubstring

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySubstring`.

# matlab.unittest.qualifications.Assumable.assumeThat

---

<b>Purpose</b>	Assume value meets specified constraint
<b>Syntax</b>	<code>assumeThat(assumable,actual,constraint)</code> <code>assumeThat(assumable,actual,constraint,diagnostic)</code>
<b>Description</b>	<p><code>assumeThat(assumable,actual,constraint)</code> assumes that <code>actual</code> is a value that satisfies the <code>constraint</code> provided.</p> <p>If the constraint is not satisfied, an assumption failure is produced utilizing only the framework diagnostic generated by the <code>constraint</code>.</p> <p><code>assumeThat(assumable,actual,constraint,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p> <p>When using this signature, both the diagnostic information contained within <code>diagnostic</code> is used in addition to the diagnostic information provided by the <code>constraint</code>.</p>
<b>Input Arguments</b>	<p><b>assumable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the assumption in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>constraint</b></p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

# matlab.unittest.qualifications.Assumable.assumeThat

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyThat`.

# matlab.unittest.qualifications.Assumable.assumeTrue

## Purpose

Assume value is true

## Syntax

```
assumeTrue(assumable,actual)
assumeTrue(assumable,actual,diagnostic)
```

## Description

`assumeTrue(assumable,actual)` assumes that `actual` is a scalar logical with the value of true.

`assumeTrue(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
assumable.assumeThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `assumeThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `assumeReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

# matlab.unittest.qualifications.Assumable.assumeTrue

---

## **actual**

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`.

## **See Also**

`assumeThat` | `assumeFalse` | `assumeReturnsTrue`

# matlab.unittest.qualifications.Assumable.assumeWarning

## Purpose

Assume function issues specified warning

## Syntax

```
assumeWarning(assumable,actual,warningID)
assumeWarning(assumable,actual,warningID,diagnostic)
[output1,...,outputN] = assumeWarning(___)
```

## Description

`assumeWarning(assumable,actual,warningID)` assumes that `actual` issues a warning with the identifier `warningID`.

`assumeWarning(assumable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarning( ___ )` also return the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
assumable.assumeThat(actual, IssuesWarnings({warningID}));
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

# matlab.unittest.qualifications.Assumable.assumeWarning

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`.

## See Also

`assumeThat` | `assumeError` | `assumeWarningFree` | `warning`

# matlab.unittest.qualifications.Assumable.assumeWarning

## Purpose

Assume function issues no warnings

## Syntax

```
assumeWarningFree(assumable,actual)
assumeWarningFree(assumable,actual,diagnostic)
[output1,...,outputN] = assumeWarningFree(___)
```

## Description

`assumeWarningFree(assumable,actual)` assumes that `actual` is a function handle that issues no warnings.

`assumeWarningFree(assumable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = assumeWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
assumable.assumeThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `assumeThat`.

## Input Arguments

### **assumable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the assumption in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Assumable.assumeWarningFree

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`.

# matlab.unittest.qualifications.AssumptionFailedException

---

**Purpose** Exception used for assumption failures

**Description** The AssumptionFailedException class provides an exception used for assumption failures. This class is used exclusively by the Assumable qualification type.

**See Also** Assumable | MException

# matlab.unittest.qualifications.ExceptionEventData

---

**Purpose** Event data for ExceptionThrown event listeners

**Description** The ExceptionEventData class holds event data for ExceptionThrown event listeners. ExceptionThrown event listeners are callback functions that you register with the testing framework to listen for the TestRunner to encounter an error during execution of test content. Typically, authors of custom plugins use this class. Only the test framework constructs this class directly.

**Properties** **Exception**  
Unexpected exception caught by TestRunner during its execution of test content

**See Also** [matlab.unittest.TestRunner](#) | [matlab.unittest.plugins.TestRunnerPlugin](#) | [MException](#)

**Concepts**

## Purpose

Qualification to abort test execution

## Description

The `FatalAssertable` class provides a qualification to abort test execution. Apart from actions performed for failures, the `FatalAssertable` class works the same as `matlab.unittest` qualifications.

Upon a fatal assertion failure, the `FatalAssertable` class informs the testing framework of the failure by throwing a `FatalAssertionFailedException`. The test running framework then displays diagnostic information for the failure and aborts the entire test session. This is useful when the software under test contains so many errors that it does not make sense to continue the test session. Also, you can use fatal assertions in fixture teardown to guarantee the fixture state is restored correctly. If it is not restored, the full testing session will aborts and indicates to restart MATLAB before you resume testing. This allows later tests to run in a consistent MATLAB state. If you can recover the fixture teardown and make it “Exception Safe” on page 1-5419 for failures, use assertions instead.

Fatal assertions prevent false test failures due to the failure of a fundamental test. They also prevent false test failures when a prior test failed to restore test fixtures. If the test framework cannot properly tear down fixtures, restart MATLAB to ensure testing can resume in a clean state.

## Methods

<code>fatalAssertClass</code>	Fatally assert exact class of specified value
<code>fatalAssertEmpty</code>	Fatally assert value is empty
<code>fatalAssertEqual</code>	Fatally assert value is equal to specified value
<code>fatalAssertError</code>	Fatally assert function throws specified exception

# matlab.unittest.qualifications.FatalAssertable

---

<code>fatalAssertFail</code>	Produce unconditional fatal assertion failure
<code>fatalAssertFalse</code>	Fatally assert value is false
<code>fatalAssertGreaterThanOrEqual</code>	Fatally assert value is greater than or equal to specified value
<code>fatalAssertInstanceOf</code>	Fatally assert value is object of specified type
<code>fatalAssertLength</code>	Fatally assert value has specified length
<code>fatalAssertLessThan</code>	Fatally assert value is less than specified value
<code>fatalAssertLessThanOrEqual</code>	Fatally assert value is less than or equal to specified value
<code>fatalAssertMatches</code>	Fatally assert string matches specified regular expression
<code>fatalAssertNotEmpty</code>	Fatally assert value is not empty
<code>fatalAssertNotEqual</code>	Fatally assert value is not equal to specified value
<code>fatalAssertNotSameHandle</code>	Fatally assert value is not handle to specified instance
<code>fatalAssertNumElements</code>	Fatally assert value has specified element count
<code>fatalAssertReturnsTrue</code>	Fatally assert function returns true when evaluated
<code>fatalAssertSameHandle</code>	Fatally assert two values are handles to same instance
<code>fatalAssertSize</code>	Fatally assert value has specified size
<code>fatalAssertSubstring</code>	Fatally assert string contains specified string

<code>fatalAssertThat</code>	Fatally assert value meets specified constraint
<code>fatalAssertTrue</code>	Fatally assert value is true
<code>fatalAssertWarning</code>	Fatally assert function issues specified warning
<code>fatalAssertWarningFree</code>	Fatally assert function issues no warnings

## Events

<code>FatalAssertionFailed</code>	Triggered upon failing fatal assertion. A <code>QualificationEventData</code> object is passed to listener callback functions.
<code>FatalAssertionPassed</code>	Triggered upon passing fatal assertion. A <code>QualificationEventData</code> object is passed to listener callback functions.

## Definitions

### Exception Safe

Test content is *exception safe* when all fixture teardown is performed with `addTeardown` or through the appropriate object destructors when a failure occurs. This ensures that the failure does not affect later testing due to stale fixtures.

This code is not exception safe. After an assertion failure, the test framework does not close the figure.

```
% Not exception safe
f = figure;
testCase.fatalAssertEqual(actual, expected);
close(f);
```

# matlab.unittest.qualifications.FatalAssertable

---

This code is exception safe because the test framework closes the figure in all cases.

```
% Exception safe
f = figure;
testCase.addTeardown(@close, f);
testCase.fatalAssertEqual(actual, expected);
```

However, tearing down a fixture using `addTeardown` does not guarantee code is exception safe. This code shows a failure in `fatalAssertEqual`.

```
% Not exception safe
f = figure;
testCase.fatalAssertEqual(actual, expected);
testCase.addTeardown(@close, f);
```

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Write Helper Function Using Fatal Assertions

A fatal assertion renders the remainder of the current test method invalid because the state is unrecoverable. A *helper function* is a function in the `TestCase` class but not located within any of the methods block statement. Execution of these functions is not controlled by the `matlab.unittest` framework.

Add the `DocPolynomSaveLoadTest.m` file to a folder on your MATLAB path. Refer to the helper function, `cleanupTemporaryFolder`, in the `DocPolynomSaveLoadTest` test case.

### DocPolynomSaveLoadTest Class Definition File

```
classdef DocPolynomSaveLoadTest < matlab.unittest.TestCase

 methods (TestClassSetup)
 function addDocPolynomClassToPath(testCase)
 origPath = path;
```

# matlab.unittest.qualifications.FatalAssertable

---

```
 testCase.addTeardown(@path, origPath);
 addpath(fullfile(matlabroot, ...
 'help', 'techdoc', 'matlab_oop', 'examples'));
 end
end

methods (Test)
 function testSaveLoad(testCase)

 import matlab.unittest.diagnostics.Diagnostic;

 %% Phase 1: Setup
 % Create a temporary working folder
 tempFolder = tempname;
 [success, message] = mkdir(tempFolder);
 testCase.assertTrue(success, ...
 Diagnostic.join('Could not create temporary folder.',
 message));
 testCase.addTeardown(@() testCase.cleanupTemporaryFolder(
 tempFolder));

 % Change to the temporary folder and register the
 % teardown, which restores the original folder
 origFolder = pwd;
 testCase.addTeardown(@cd, origFolder);
 cd(tempFolder);

 %% Phase 2: Exercise
 % Save the instance to a mat file.
 p = DocPolynom([1, 0, 1]);
 save('DocPolynomFile', 'p');

 % Validate Precondition. Save resulted in valid .mat file
 testCase.assertEqual(exist('DocPolynomFile.mat', 'file'),
 2, Diagnostic.join(...
 'mat file was not saved correctly.', @() dir(pwd)));
 end
end
```

# matlab.unittest.qualifications.FatalAssertable

---

```
loaded = load('DocPolynomFile');

%% Phase 3: Verify
testCase.verifyEqual(loaded.p, p,...
 'Loaded polynom did not equal original polynom.');
```

%% Phase 4: Teardown  
% Done inline via calls to addTeardown at the points  
% at which the state was changed.

```
end
end

methods(Access=private)
function cleanUpTemporaryFolder(testCase,tempFolder)
 % Clean up the temporary folder and fatally assert
 % that it was correctly cleaned up.

 import matlab.unittest.diagnostics.Diagnostic;

 [success, message] = rmdir(tempFolder, 's');
 testCase.fatalAssertTrue(success, ...
 Diagnostic.join('Could not remove temporary folder.',...
 message));
end
end
```

end

Make the `cleanUpTemporaryFolder` function a helper function by placing it inside a separate `methods` block.

```
methods(Access=private)
function cleanUpTemporaryFolder(testCase, tempFolder)
```

```
 % code
 end
end
```

Use the `fatalAssertTrue` method to test the `rmdir` `SUCCESS` argument for errors. If a fatal assertion occurs, the test run is aborted.

```
function cleanUpTemporaryFolder(testCase, tempFolder)

 import matlab.unittest.diagnostics.Diagnostic;

 [success, message] = rmdir(tempFolder, 's');
 testCase.fatalAssertTrue(success, ...
 Diagnostic.join('Could not remove the temporary folder.',...
 message));
end
```

If the `rmdir` function fails, then this test has failed to restore the state of MATLAB and the machine at initial startup. Aborting prevents subsequent tests to fail because MATLAB is left in an unexpected state by this test.

## Concepts

# matlab.unittest.qualifications.FatalAssertable.fatalAssertClass

**Purpose**                      Fataally assert exact class of specified value

**Syntax**

```
fatalAssertClass(fatalAssertable,actual,className)
fatalAssertClass(fatalAssertable,actual,metaClass)
fatalAssertClass(___,diagnostic)
```

**Description**                `fatalAssertClass(fatalAssertable,actual,className)` fataally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertClass(fatalAssertable,actual,metaClass)` fataally asserts that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertClass(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- The method is functionally equivalent to:

```
import matlab.unittest.constraints.IsOfClass;
fatalAssertable.fatalAssertThat(actual, IsOfClass(className));
fatalAssertable.fatalAssertThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyClass`.

## **See Also**

`fatalAssertThat` | `fatalAssertInstanceOf`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertEmpty

## Purpose

Fatally assert value is empty

## Syntax

```
fatalAssertEmpty(fatalAssertable,actual)
fatalAssertEmpty(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertEmpty(fatalAssertable,actual)` fatally asserts that `actual` is an empty MATLAB value.

`fatalAssertEmpty(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEmpty;
fatalAssertable.fatalAssertThat(actual, IsEmpty());
```

There exists more functionality when using the `IsEmpty` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyEmpty`.

**See Also** `fatalAssertThat` | `fatalAssertNotEmpty` | `isempty`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertEqual

## Purpose

Fatally assert value is equal to specified value

## Syntax

```
fatalAssertEqual(fatalAssertable,actual,expected)
fatalAssertEqual(__,Name,Value)
fatalAssertEqual(__,diagnostic)
```

## Description

`fatalAssertEqual(fatalAssertable,actual,expected)` fatally asserts that `actual` is strictly equal to `expected`.

`fatalAssertEqual(__,Name,Value)` fatally asserts equality with additional options specified by one or more `Name,Value` pair arguments.

`fatalAssertEqual(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
fatalAssertable.fatalAssertThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'AbsTol'**

**'RelTol'**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertEqual

---

**Examples**      See examples for `verifyEqual`.

**See Also**      `fatalAssertThat` | `fatalAssertNotEqual`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertE

## Purpose

Fatally assert function throws specified exception

## Syntax

```
fatalAssertError(fatalAssertable,actual,identifier)
fatalAssertError(fatalAssertable,actual,metaClass)
fatalAssertError(___,diagnostic)
```

## Description

`fatalAssertError(fatalAssertable,actual,identifier)` fatally asserts that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`fatalAssertError(fatalAssertable,actual,metaClass)` fatally asserts that `actual` is a function handle that throws an exception whose type is defined by the `metaClass` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class..

`fatalAssertError(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
fatalAssertable.fatalAssertThat(actual, Throws(identifier));
fatalAssertable.fatalAssertThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **identifier**

Error identifier, specified as a string.

### **metaClass**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertError

---

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyError`.

## **See Also**

`fatalAssertThat` | `fatalAssertWarning` | `MException` | `error`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertFail

---

## Purpose

Produce unconditional fatal assertion failure

## Syntax

```
fatalAssertFail(fatalAssertable)
fatalAssertFail(fatalAssertable,diagnostic)
```

## Description

`fatalAssertFail(fatalAssertable)` produces an unconditional fatal assertion failure when encountered.

`fatalAssertFail(fatalAssertable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyFail`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertFalse

## Purpose

Fatally assert value is false

## Syntax

```
fatalAssertFalse(fatalAssertable,actual)
fatalAssertFalse(fatalAssertable,actual,diagnostic)
```

## Description

`fatalAssertFalse(fatalAssertable,actual)` fatally asserts that `actual` is a scalar logical with the value of false.

`fatalAssertFalse(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
fatalAssertable.fatalAssertThat(actual, IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `fatalAssertThat`.

- Unlike `fatalAssertTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `fatalAssertTrue`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyFalse`.

## See Also

# matlab.unittest.qualifications.FatalAssertable.fatalAssertGreater

## Purpose

Fatally assert value is greater than or equal to specified value

## Syntax

```
fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor)
fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor,
 diagnostic)
```

## Description

`fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor)` fatally asserts that all elements of `actual` are greater than or equal to all the elements of `floor`.

`fatalAssertGreaterThanOrEqualTo(fatalAssertable,actual,floor,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
fatalAssertable.fatalAssertThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyGreaterThanOrEqualTo`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertInstance

## Purpose

Fatally assert value is object of specified type

## Syntax

```
fatalAssertInstanceOf(fatalAssertable,actual,className)
fatalAssertInstanceOf(fatalAssertable,actual,metaClass)
fatalAssertInstanceOf(___,diagnostic)
```

## Description

`fatalAssertInstanceOf(fatalAssertable,actual,className)` fatally asserts that `actual` is a MATLAB value whose class is the class specified by `className`.

`fatalAssertInstanceOf(fatalAssertable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`fatalAssertInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(className));
fatalAssertable.fatalAssertThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of `meta.class`.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyInstanceOf`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertLessThan

## Purpose

Fatally assert value is less than specified value

## Syntax

```
fatalAssertLessThan(fatalAssertable,actual,ceiling)
fatalAssertLessThan(fatalAssertable,actual,ceiling,diagnostic)
```

## Description

`fatalAssertLessThan(fatalAssertable,actual,ceiling)` fatally asserts that all elements of `actual` are less than all the elements of `ceiling`.

`fatalAssertLessThan(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
assertable.assertThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `assertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyLessThan`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertLessThanOrEqual

## Purpose

Fatally assert value is less than or equal to specified value

## Syntax

```
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)
fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,diagnostic)
```

## Description

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling)` fatally asserts that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`fatalAssertLessThanOrEqual(fatalAssertable,actual,ceiling,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
fatalAssertable.fatalAssertThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **actual**

The value to test.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

# matlab.unittest.qualifications.FatalAssertable.fatalAssertMatches

<b>Purpose</b>	Fatally assert string matches specified regular expression
<b>Syntax</b>	<code>fatalAssertMatches(fatalAssertable,actual,expression)</code> <code>fatalAssertMatches(fatalAssertable,actual,expression,diagnostic)</code>
<b>Description</b>	<code>fatalAssertMatches(fatalAssertable,actual,expression)</code> fatally asserts that <code>actual</code> is a string that matches the regular expression defined by <code>expression</code> . <code>fatalAssertMatches(fatalAssertable,actual,expression,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.
<b>Tips</b>	<ul style="list-style-type: none"><li>This method is functionally equivalent to: <pre>import matlab.unittest.constraints.Matches; fatalAssertable.fatalAssertThat(actual, Matches(expression));</pre> There exists more functionality when using the <code>Matches</code> constraint directly via <code>fatalAssertThat</code>.</li></ul>
<b>Input Arguments</b>	<p><b>fatalAssertable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>expression</b></p> <p>The value to match, specified as a regular expression.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>string</li></ul>

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyMatches`.

`fatalAssertThat` | `fatalAssertSubstring` | `regexp`

<b>Purpose</b>	Fatally assert value is not empty
<b>Syntax</b>	<pre>fatalAssertNotEmpty(fatalAssertable,actual) fatalAssertNotEmpty(fatalAssertable,actual,diagnostic)</pre>
<b>Description</b>	<p><code>fatalAssertNotEmpty(fatalAssertable,actual)</code> fatally asserts that <code>actual</code> is a non-empty MATLAB value.</p> <p><code>fatalAssertNotEmpty(fatalAssertable,actual,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsEmpty; fatalAssertable.fatalAssertThat(actual, ~IsEmpty());</pre><p>There exists more functionality when using the <code>IsEmpty</code> constraint directly via <code>fatalAssertThat</code>.</p></li></ul>
<b>Input Arguments</b>	<p><b>fatalAssertable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

**Examples** See examples for `verifyNotEmpty`.

**See Also** `fatalAssertThat` | `fatalAssertEmpty` | `isempty`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertNotEqual

## Purpose

Fatally assert value is not equal to specified value

## Syntax

```
fatalAssertNotEqual(fatalAssertable, actual, notExpected)
fatalAssertNotEqual(fatalAssertable, actual, notExpected, diagnostic)
```

## Description

`fatalAssertNotEqual(fatalAssertable, actual, notExpected)` fatally asserts that `actual` is not equal to `notExpected`.

`fatalAssertNotEqual(fatalAssertable, actual, notExpected, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsEqualTo;
fatalAssertable.fatalAssertThat(actual, ~IsEqualTo(notExpected));
```

There exists more functionality when using the `IsEqualTo` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpected**

Value to compare.

## Examples

See examples for `verifyNotEqual`.

## See Also

`fatalAssertThat` | `fatalAssertEqual`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertNotSameHandle

## Purpose

Fatally assert value is not handle to specified instance

## Syntax

```
fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle)
fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle,
 diagnostic)
```

## Description

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle)` fatally asserts that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`fatalAssertNotSameHandle(fatalAssertable,actual,notExpectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
fatalAssertable.fatalAssertThat(actual, ~IsSameHandleAs(notExpectedHandleArray));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNotSameHandle`.

## See Also

`fatalAssertThat` | `fatalAssertSameHandle`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertNumElements

## Purpose

Fatally assert value has specified element count

## Syntax

```
fatalAssertNumElements(fatalAssertable,actual,expectedElementCount)
fatalAssertNumElements(fatalAssertable,actual,expectedElementCount,
 diagnostic)
```

## Description

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount)` fatally asserts that `actual` is a MATLAB array with `expectedElementCount` number of elements.

`fatalAssertNumElements(fatalAssertable,actual,expectedElementCount,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasElementCount;
fatalAssertable.fatalAssertThat(actual, HasElementCount(expectedElementCount))
```

There exists more functionality when using the `HasElementCount` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedElementCount**

The expected number of elements in the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyNumElements`.

## See Also

`fatalAssertThat` | `fatalAssertSize` | `fatalAssertLength` | `numel`

## Purpose

Fatally assert function returns true when evaluated

## Syntax

```
fatalAssertReturnsTrue(fatalAssertable, actual)
fatalAssertReturnsTrue(fatalAssertable, actual, diagnostic)
```

## Description

`fatalAssertReturnsTrue(fatalAssertable, actual)` fatally asserts that `actual` is a function handle that returns a scalar logical whose value is true.

`fatalAssertReturnsTrue(fatalAssertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `fatalAssertTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `fatalAssertTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
fatalAssertable.fatalAssertThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyReturnsTrue`.

## See Also

`fatalAssertThat` | `fatalAssertTrue`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertS

## Purpose

Fatally assert two values are handles to same instance

## Syntax

```
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)
fatalAssertSameHandle(fatalAssertable,actual,expectedHandle,
 diagnostic)
```

## Description

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle)` fatally asserts that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`fatalAssertSameHandle(fatalAssertable,actual,expectedHandle,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
fatalAssertable.fatalAssertThat(actual, IsSameHandleAs(expectedHandl
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

# matlab.unittest.qualifications.FatalAssertable.fatalAssertSame

---

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySameHandle`.

## See Also

`fatalAssertThat` | `fatalAssertNotSameHandle` | `handle`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertSize

## Purpose

Fatally assert value has specified size

## Syntax

```
fatalAssertSize(fatalAssertable,actual,expectedSize)
fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)
```

## Description

`fatalAssertSize(fatalAssertable,actual,expectedSize)` fatally asserts that `actual` is a MATLAB array whose size is `expectedSize`.  
`fatalAssertSize(fatalAssertable,actual,expectedSize,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasSize;
fatalAssertable.fatalAssertThat(actual, HasSize(expectedSize));
```

There exists more functionality when using the `HasSize` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedSize**

The expected sizes of each dimension the array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.FatalAssertable.fatalAssertSize

---

- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySize`.

## See Also

`fatalAssertThat` | `fatalAssertLength` | `fatalAssertNumElements`  
| `size`

## Purpose

Fatally assert string contains specified string

## Syntax

```
fatalAssertSubstring(fatalAssertable,actual,substring)
fatalAssertSubstring(fatalAssertable,actual,substring,diagnostic)
```

## Description

`fatalAssertSubstring(fatalAssertable,actual,substring)` fatally asserts that `actual` is a string that contains `substring`.

`fatalAssertSubstring(fatalAssertable,actual,substring,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ContainsSubstring;
fatalAssertable.fatalAssertThat(actual,...
 ContainsSubstring(substring));
```

There exists more functionality when using the `ContainsSubstring` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **substring**

The value to match, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.FatalAssertable.fatalAssertSubstr

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifySubstring`.

## See Also

`fatalAssertThat` | `fatalAssertMatches` | `strfind`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertThat

---

## Purpose

Fatally assert value meets specified constraint

## Syntax

```
fatalAssertThat(fatalAssertable, actual, constraint)
fatalAssertThat(fatalAssertable, actual, constraint, diagnostic)
```

## Description

`fatalAssertThat(fatalAssertable, actual, constraint)` fatally asserts that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a fatal assertion failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`fatalAssertThat(fatalAssertable, actual, constraint, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The value to test.

### **constraint**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

# matlab.unittest.qualifications.FatalAssertable.fatalAssertThat

---

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

See examples for `verifyThat`.

# matlab.unittest.qualifications.FatalAssertable.fatalAssertT

---

## Purpose

Fatally assert value is true

## Syntax

```
fatalAssertTrue(fatalAssertable, actual)
fatalAssertTrue(fatalAssertable, actual, diagnostic)
```

## Description

`fatalAssertTrue(fatalAssertable, actual)` fatally asserts that `actual` is a scalar logical with the value of true.

`fatalAssertTrue(fatalAssertable, actual, diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
fatalAssertable.fatalAssertThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `fatalAssertThat`.

However, this method is optimized for performance and does not construct a new `IsTrue` constraint for each call. Sometimes such use can come at the expense of less diagnostic information. Use the `fatalAssertReturnsTrue` method for a similar approach which may provide better diagnostic information.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

# matlab.unittest.qualifications.FatalAssertable.fatalAssertTrue

---

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

See examples for `verifyTrue`.

## **See Also**

`fatalAssertThat` | `fatalAssertFalse` | `fatalAssertReturnsTrue`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertWarning

## Purpose

Fatally assert function issues specified warning

## Syntax

```
fatalAssertWarning(fatalAssertable,actual,warningID)
fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)
[output1,...,outputN] = fatalAssertWarning(___)
```

## Description

`fatalAssertWarning(fatalAssertable,actual,warningID)` fatally asserts that `actual` issues a warning with the identifier `warningID`.

`fatalAssertWarning(fatalAssertable,actual,warningID,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarning( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesWarnings;
fatalAssertable.fatalAssertThat(actual, IssuesWarnings({warningID}))
```

There exists more functionality when using the `IssuesWarnings` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **warningID**

Warning ID, specified as a string.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

**output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarning`.

## See Also

`fatalAssertThat` | `fatalAssertError` | `fatalAssertWarningFree` | `warning`

# matlab.unittest.qualifications.FatalAssertable.fatalAssertV

---

## Purpose

Fatally assert function issues no warnings

## Syntax

```
fatalAssertWarningFree(fatalAssertable,actual)
fatalAssertWarningFree(fatalAssertable,actual,diagnostic)
[output1,...,outputN] = fatalAssertWarningFree(___)
```

## Description

`fatalAssertWarningFree(fatalAssertable,actual)` fatally asserts that `actual` is a function handle that issues no warnings.

`fatalAssertWarningFree(fatalAssertable,actual,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

`[output1,...,outputN] = fatalAssertWarningFree( ___ )` also returns the output arguments `output1,...,outputN` that are produced when invoking `actual`.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IssuesNoWarnings;
fatalAssertable.fatalAssertThat(actual, IssuesNoWarnings());
```

There exists more functionality when using the `IssuesNoWarnings` constraint directly via `fatalAssertThat`.

## Input Arguments

### **fatalAssertable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the fatal assertion in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

See examples for `verifyWarningFree`.

# matlab.unittest.qualifications.FatalAssertionFailedException

---

**Purpose** Exception used for fatal assertion failures

**Description** The FatalAssertionFailedException class provides an exception used for fatal assertion failures. This class is used exclusively by the FatalAssertable qualification type.

**See Also** FatalAssertable | MException

# matlab.unittest.qualifications.QualificationEventData

---

## Purpose

Event data for qualification event listeners

## Description

The `QualificationEventData` class holds event data for qualification event listeners. Qualification event listeners are callback functions that you register with the testing framework to listen for passing and/or failing qualifications. Qualifications can be assertions, fatal assertions, assumptions or verifications performed on test content. The corresponding qualification classes define these events. Typically, authors of custom plugins use this class. Only the test framework constructs this class directly.

## Properties

### ActualValue

Value tested to satisfy the qualification logic of the Constraint

### Constraint

Instance of `matlab.unittest.constraints.Constraint` used for the qualification

When you use a qualification method on a `TestCase` or `Fixture` object, the `Constraint` property contains the underlying constraint used for the qualification. For example, if you use the `verifyEqual` method, the underlying constraint is the `IsEqualTo` constraint. Therefore, if you invoke the constraint's `getDiagnosticFor` method, the diagnostic result can appear different than what the test framework displays.

### TestDiagnostic

Diagnostic specified in the qualification, represented as a string, function handle, or instance of the `Diagnostic` class

### TestDiagnosticResult

Result of diagnostic specified in the qualification, represented as a character array

### FrameworkDiagnosticResult

Result of diagnostic from constraint used for the qualification, represented as a character array

## **Stack**

Function call stack leading up to the qualification event, represented as a structure array

## **Concepts**

# matlab.unittest.qualifications.Verifiable

---

**Purpose** Qualification to produce soft-failure conditions

**Description** The `Verifiable` class provides a qualification to produce soft-failure conditions. Apart from actions performed for failures, the `Verifiable` class works the same as other `matlab.unittest` qualifications.

Upon a verification failure, the `Verifiable` class informs the testing framework of the failure, including all diagnostic information associated with the failure, but continues to execute the currently running test without throwing an `MException`. This is most useful when a failure at the verification point is not fatal to the remaining test content. Often, you use verifications as the primary verification of a Four-Phase Test. Use other qualification types, such as assertions, fatal assertions, and assumptions, to test for violation of preconditions or incorrect test setup.

Since verifications do not throw `MExceptions`, all test content runs to completion even when verification failures occur. This helps you understand how close a piece of software is to meeting the test suite requirements. Qualification types that throw exceptions do not provide this insight, since once an exception is thrown an arbitrary amount of code remains that is not reached or exercised. Verifications also provide more testing coverage in failure conditions. However, when you overuse verifications, they can produce excess noise for a single failure condition. If a failure condition will cause later qualification points to also fail, use assertions or fatal assertions instead.

## Methods

<code>verifyClass</code>	Verify exact class of specified value
<code>verifyEmpty</code>	Verify value is empty
<code>verifyEqual</code>	Verify value is equal to specified value
<code>verifyError</code>	Verify function throws specified exception

<code>verifyFail</code>	Produce unconditional verification failure
<code>verifyFalse</code>	Verify value is false
<code>verifyGreaterThan</code>	Verify value is greater than specified value
<code>verifyGreaterThanOrEqual</code>	Verify value is greater than or equal to specified value
<code>verifyInstanceOf</code>	Verify value is object of specified type
<code>verifyLength</code>	Verify value has specified length
<code>verifyLessThan</code>	Verify value is less than specified value
<code>verifyLessThanOrEqual</code>	Verify value is less than or equal to specified value
<code>verifyMatches</code>	Verify string matches specified regular expression
<code>verifyNotEmpty</code>	Verify value is not empty
<code>verifyNotEqual</code>	Verify value is not equal to specified value
<code>verifyNotSameHandle</code>	Verify value is not handle to specified instance
<code>verifyNumElements</code>	Verify value has specified element count
<code>verifyReturnsTrue</code>	Verify function returns true when evaluated
<code>verifySameHandle</code>	Verify two values are handles to same instance
<code>verifySize</code>	Verify value has specified size

# matlab.unittest.qualifications.Verifiable

---

<code>verifySubstring</code>	Verify string contains specified string
<code>verifyThat</code>	Verify value meets given constraint
<code>verifyTrue</code>	Verify value is true
<code>verifyWarning</code>	Verify function issues specified warning
<code>verifyWarningFree</code>	Verify function issues no warnings

## Events

<code>VerificationFailed</code>	Triggered upon failing verification. A <code>QualificationEventData</code> object is passed to listener callback functions.
<code>VerificationPassed</code>	Triggered upon passing verification. A <code>QualificationEventData</code> object is passed to listener callback functions.

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Write Test Methods Using Verifications

Verifications produce and record failures without throwing an exception, meaning the currently running test runs to completion. This example creates a test case to verify arithmetic operations on objects of the `DocPolynom` example class.

Create the DocPolynomTest Test Case. Refer to the following DocPolynomTest test case in the subsequent steps in this example, which highlight specific functions in the file.

## DocPolynomTest Class Definition File

```
classdef DocPolynomTest < matlab.unittest.TestCase
 % Tests the DocPolynom class.

 properties
 msgEqn = 'Equation under test: ';
 end

 methods (TestClassSetup)
 function addDocPolynomClassToPath(testCase)
 testCase.addTeardown(@path,addpath(fullfile(matlabroot,...
 'help', 'techdoc', 'matlab_oop', 'examples')));
 end
 end

 methods (Test)
 function testConstructor(testCase)
 p = DocPolynom([1, 0, 1]);
 testCase.verifyClass(p, ?DocPolynom);
 end

 function testAddition(testCase)
 p1 = DocPolynom([1, 0, 1]);
 p2 = DocPolynom([5, 2]);

 actual = p1 + p2;
 expected = DocPolynom([1, 5, 3]);

 msg = [testCase.msgEqn,...
 '(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3'];
 testCase.verifyEqual(actual, expected, msg);
 end
 end
end
```

# matlab.unittest.qualifications.Verifiable

---

```
function testMultiplication(testCase)
 p1 = DocPolynom([1, 0, 3]);
 p2 = DocPolynom([5, 2]);

 actual = p1 * p2;
 expected = DocPolynom([5, 2, 15, 6]);

 msg = [testCase.msgEqn,...
 '(x^2 + 3) * (5*x + 2) = 5*x^3 + 2*x^2 + 15*x + 6'];
 testCase.verifyEqual(actual, expected, msg);
end

end
end
```

To execute the MATLAB commands in this example, add the `DocPolynomTest.m` file to a folder on your MATLAB path.

Write Test to Verify Constructor. Create a function, `testConstructor`, using the `verifyClass` method to test the `DocPolynom` class constructor.

```
function testConstructor(testCase)
 p = DocPolynom([1, 0, 1]);
 testCase.verifyClass(p, ?DocPolynom);
end
```

Write Tests to Verify Operations. In the `testAddition` function, use the `verifyEqual` method to test the equation  $(x^2 + 1) + (5x + 2) = x^2 + 5x + 3$ . The `verifyEqual` method includes this equation in the diagnostic argument.

```
function testAddition(testCase)
 p1 = DocPolynom([1, 0, 1]);
 p2 = DocPolynom([5, 2]);

 actual = p1 + p2;
```

```
expected = DocPolynom([1, 5, 3]);

msg = [testCase.msgEqn,...
 '(x^2 + 1) + (5*x + 2) = x^2 + 5*x + 3'];
testCase.verifyEqual(actual, expected, msg);
end
```

The function, `testMultiplication`, tests multiplication operations.

Run the tests in the `DocPolynomTest` test case.

```
tc = DocPolynomTest;
ts = matlab.unittest.TestSuite.fromClass(?DocPolynomTest);
res = run(ts);
```

```
Running DocPolynomTest
...
Done DocPolynomTest
```

---

All tests passed.

# matlab.unittest.qualifications.Verifiable.verifyClass

---

**Purpose** Verify exact class of specified value

**Syntax**

```
verifyClass(verifiable,actual,className)
verifyClass(verifiable,actual,metaClass)
verifyClass(__,diagnostic)
```

**Description**

`verifyClass(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyClass(verifiable,actual,metaClass)` verifies that `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`. The instance must be an exact class match. Use `verifyInstanceOf` to verify inclusion in a class hierarchy.

`verifyClass(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- The method is functionally equivalent to the following methods:

```
import matlab.unittest.constraints.IsOfClass;
verifiable.verifyThat(actual, IsOfClass(className));
verifiable.verifyThat(actual, IsOfClass(metaClass));
```

There exists more functionality when using the `IsOfClass` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test a Class**

These interactive tests verify the class of the number, 5.

Create a TestCase object and the value to test.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
actvalue = 5;
```

Verify class of actvalue is double.

```
verifyClass(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify class of actvalue is char.

```
verifyClass(testCase, actvalue, 'char');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

# matlab.unittest.qualifications.Verifiable.verifyClass

---

```
verifyClass failed.
--> The value's class is incorrect.
```

```
Actual Class:
 double
Expected Class:
 char
```

```
Actual Value:
 5
```

Test fails.

## Test a Function Handle

These interactive tests verify function handles, specified as a meta.class instance, ?function\_handle.

Create a TestCase object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a function handle.

```
fh = @sin;
verifyClass(testCase, fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
verifyClass(testCase, fh, ?function_handle);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyClass failed.
--> The value's class is incorrect.
```

```
Actual Class:
 char
Expected Class:
 function_handle
```

```
Actual Value:
 sin
```

Test fails.

## **Test a Derived Class**

Verify that a derived class is not the same class as its base class.

Create a class, BaseExample.

```
classdef BaseExample
end
```

Create a derived class, DerivedExample.

```
classdef DerivedExample < BaseExample
end
```

Verify the classes are not equal.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyClass(testCase, DerivedExample(), ?BaseExample);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyClass failed.
--> The value's class is incorrect.
```

# matlab.unittest.qualifications.Verifiable.verifyClass

---

```
Actual Class:
 DerivedExample
Expected Class:
 BaseExample
```

```
Actual Value:
 DerivedExample with no properties.
```

Test fails.

## Test Class of Output Value

Use `verifyClass` to test the `add5` function returns a double value.

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.');
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
 methods (Test)
 function testDoubleOut(testCase)
 actOutput = add5(1);
 testCase.verifyClass(actOutput,'double');
```

Create a test suite from the Add5Test class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');

result = run(suite);
```

```
Running Add5Test
```

```
..
```

```
Done Add5Test
```

---

# matlab.unittest.qualifications.Verifiable.verifyEmpty

---

<b>Purpose</b>	Verify value is empty
<b>Syntax</b>	<pre>verifyEmpty(verifiable,actual) verifyEmpty( __,diagnostic)</pre>
<b>Description</b>	<p><code>verifyEmpty(verifiable,actual)</code> verifies that <code>actual</code> is an empty MATLAB value.</p> <p><code>verifyEmpty( __,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsEmpty; verifiable.verifyThat(actual, IsEmpty());</pre><p>There exists more functionality when using the <code>IsEmpty</code> constraint directly via <code>verifyThat</code>.</p></li></ul>
<b>Input Arguments</b>	<p><b>verifiable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the verification in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li><li>• <code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples **Test for Empty Strings**

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, '');
```

```
Interactive verification passed.
```

## **Test for Empty Arrays**

An array with any zero dimension is empty.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, ones(2, 5, 0, 3));
```

```
Interactive verification passed.
```

```
verifyEmpty(testCase, [2 3], 'Array is not empty.');
```

```
Interactive verification failed.
```

```

Test Diagnostic:
```

```

Array is not empty.
```

```

Framework Diagnostic:
```

```

verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1 2].
```

```
Actual Value:
```

# matlab.unittest.qualifications.Verifiable.verifyEmpty

---

2 3

Test failed.

## Test for Empty Cell Arrays

Test empty cell array, {}.

```
matlab.unittest.TestCase.forInteractiveUse;
verifyEmpty(testCase, {}, 'Cell array is not empty.');
```

Interactive verification passed.

A cell array of empty arrays is not empty.

```
verifyEmpty(testCase, {[], [], []}, 'Cell array is not empty.');
```

Interactive verification failed.

```

Test Diagnostic:

Cell array is not empty.
```

```

Framework Diagnostic:

verifyEmpty failed.
--> The value must be empty.
--> The value has a size of [1 3].
```

```
Actual Value:
 [] [] []
```

Test failed.

## Test for Empty Test Suite

Test for empty object, emptyTestSuite.

# matlab.unittest.qualifications.Verifiable.verifyEmpty

---

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
emptyTestSuite = matlab.unittest.TestSuite.empty;
verifyEmpty(testCase, emptyTestSuite);
```

Interactive verification passed.

## See Also

```
matlab.unittest.constraints | matlab.unittest.qualifications
| verifyThat | verifyNotEmpty | isempty
| matlab.unittest.constraints.IsEmpty |
matlab.unittest.diagnostics.Diagnostic
```

# matlab.unittest.qualifications.Verifiable.verifyEqual

---

**Purpose** Verify value is equal to specified value

**Syntax** `verifyEqual(verifyable,actual,expected)`  
`verifyEqual( ___,Name,Value)`  
`verifyEqual( ___,diagnostic)`

**Description** `verifyEqual(verifyable,actual,expected)` verifies that `actual` is strictly equal to `expected`.

`verifyEqual( ___,Name,Value)` verifies equality with additional options specified by one or more `Name,Value` pair arguments.

`verifyEqual( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure

**Tips** • This method is functionally equivalent to any of the following:

```
import matlab.unittest.constraints.IsEqualTo;
verifyable.verifyThat(actual, IsEqualTo(expected));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
verifyable.verifyThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.RelativeTolerance;
verifyable.verifyThat(actual, IsEqualTo(expected, ...
 'Within', RelativeTolerance(reltol)));
```

```
import matlab.unittest.constraints.IsEqualTo;
import matlab.unittest.constraints.AbsoluteTolerance;
import matlab.unittest.constraints.RelativeTolerance;
verifyable.verifyThat(actual, IsEqualTo(expected, ...
 'Within', AbsoluteTolerance(abstol) | RelativeTolerance(reltol)));
```

There exists more functionality when using the `IsEqualTo`, `RelativeTolerance`, and `IsEqualTo` constraints directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **expected**

Expected value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'AbsTol'**

**'RelTol'**

## Examples

### Comparing Numeric Values

Numeric values are equivalent if they are of the same class with equivalent size, complexity, and sparsity.

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

A value is equal to itself.

```
verifyEqual(testCase, 5, 5);
```

Interactive verification passed.

Values must have equal sizes.

```
verifyEqual(testCase, [5 5], 5);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyEqual failed.
--> NumericComparator failed.
 --> Sizes do not match.
```

```
Actual double size:
 1 2
Expected double size:
 1 1
```

```
Actual Value:
 5 5
Expected Value:
 5
```

Test failed.

## Test Classes

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, int8(5), int16(5));
```

Interactive verification failed.

```

Framework Diagnostic:

verifyEqual failed.
--> NumericComparator failed.
 --> Classes do not match.
```

```
Actual Class:
 int8
Expected Class:
 int16
```

```
Actual Value:
 5
Expected Value:
 5
```

Test failed.

## Test Cell Arrays

Each element of a cell array must be equal in value, class, and size.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

Interactive verification passed.

## Test Numeric Tolerances

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyEqual(testCase, 4.95, 5);
```

# matlab.unittest.qualifications.Verifiable.verifyEqual

---

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
4.95 is not equal to 5
```

```

Framework Diagnostic:

```

```
verifyEqual failed.
```

```
--> NumericComparator failed.
```

```
 --> The values are not equal using "isequaln".
```

```
Actual Value:
```

```
 4.9500000000000000
```

```
Expected Value:
```

```
 5
```

```
Test failed.
```

```
verifyEqual(testCase, 1.5, 2, 'AbsTol', 1)
```

```
Interactive verification passed.
```

```
verifyEqual(testCase, 1.5, 2, 'RelTol', 0.1, ...
```

```
 'Difference between actual and expected exceeds relative tolerance')
```

```
Interactive verification failed.
```

```

Test Diagnostic:

```

```
Difference between actual and expected exceeds relative tolerance
```

```

```

```
Framework Diagnostic:

verifyEqual failed.
--> NumericComparator failed.
 --> The values are not equal using "isequaln".
 --> RelativeTolerance failed.
 --> The value was not within relative tolerance.

 Tolerance Definition:
 abs(expected - actual) <= tolerance .* abs(expected)
 Tolerance Value:
 0.10000000000000000

Actual Value:
 1.5000000000000000
Expected Value:
 2
```

Test failed.

```

# matlab.unittest.qualifications.Verifiable.verifyError

---

**Purpose** Verify function throws specified exception

**Syntax**

```
verifyError(verifiable,actual,identifier)
verifyError(verifiable,actual,metaClass)
verifyError(__,diagnostic)
```

**Description** `verifyError(verifiable,actual,identifier)` verifies that `actual` is a function handle that throws an exception with an error identifier that is equal to `identifier`.

`verifyError(verifiable,actual,metaClass)` verifies that `actual` is a function handle that throws an exception whose type is defined by the `meta.class` instance specified in `metaClass`. This method does not require the instance to be an exact class match, but rather it must be in the specified class hierarchy, and that hierarchy must include the `MException` class.

`verifyError(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Throws;
verifiable.verifyThat(actual, Throws(identifier));
verifiable.verifyThat(actual, Throws(metaClass));
```

There exists more functionality when using the `Throws` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **identifier**

Error identifier, specified as a string.

## metaClass

An instance of meta.class.

## diagnostic

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Error IDs

```
testCase = matlab.unittest.TestCase.forInteractiveUse;

% Passing scenarios
%%
verifyError(testCase, @() error('SOME:error:id','Error!'), 'SOME:error:
verifyError(testCase, @testCase.assertFail, ...
 ?matlab.unittest.qualifications.AssertionFailedException);

% Failing scenarios
%%
verifyError(testCase, 5, 'some:id', '5 is not a function handle');
verifyError(testCase, @testCase.verifyFail, ...
 ?matlab.unittest.qualifications.AssertionFailedException, ...
 'Verifications dont throw exceptions. ');
verifyError(testCase, @() error('SOME:id'), 'OTHER:id', 'Wrong id');
verifyError(testCase, @() error('whoops'), ...
 ?matlab.unittest.qualifications.AssertionFailedException, ...
 'Wrong type of exception thrown');
```

# matlab.unittest.qualifications.Verifiable.verifyError

---

## Test Error Condition

Create `testNonNumericInput` to test if function throws expected error message, `add5:InputMustBeNumeric`, for unexpected condition, input is char.

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.');
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
 methods (Test)
 function testDoubleOut(testCase)
 actOutput = add5(1);
 testCase.verifyClass(actOutput,'double');
 end
 function testNonNumericInput(testCase)
 testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
```

Create a test suite from the `Add5Test` class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');
```

```
result = run(suite);
```

```
Running Add5Test
```

```
..
Done Add5Test
```

---

# matlab.unittest.qualifications.Verifiable.verifyFail

---

**Purpose** Produce unconditional verification failure

**Syntax** `verifyFail(verifiable)`  
`verifyFail(verifiable,diagnostic)`

**Description** `verifyFail(verifiable)` produces an unconditional verification failure when encountered.

`verifyFail(verifiable,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### **Test for Failure Condition**

An example of where this method may be used is in a callback function that should not be executed in a given scenario. A test can confirm this does not occur by unconditionally performing a failure if the code path is reached.

Create a handle class, `MyHandle`, with a `SomethingHappened` event.

```
classdef MyHandle < handle
 events
 SomethingHappened
 end
end
```

Create a file, `ListenerTest`, on your MATLAB path that contains the following `TestCase` class.

```
classdef ListenerTest < matlab.unittest.TestCase
 methods(Test)
 function testDisabledListeners(testCase)
 h = MyHandle;

 % Add a listener to a test helper method
 listener = h.addlistener('SomethingHappened', ...
 @testCase.shouldNotGetCalled);

 % Passing scenario (code path is not reached)
 %%%%%%%%%%%
 % Disabled listener should not invoke callbacks
 listener.Enabled = false;
 h.notify('SomethingHappened');

 % Failing scenario (code path is reached)
 %%%%%%%%%%%
 % Enabled listener invoke callback and fail
 listener.Enabled = true;
 h.notify('SomethingHappened');
 end
 end

 methods
 function shouldNotGetCalled(testCase, ~, ~)
 % A test helper callback method that should not execute
 testCase.verifyFail('This listener callback should not have
 end
```

# matlab.unittest.qualifications.Verifiable.verifyFail

---

```
end
```

```
end
```

From the command prompt, run the test.

```
run(ListenerTest);
```

```
Running ListenerTest
```

```
=====
Verification failed in ListenerTest/testDisabledListeners.
```

```

# matlab.unittest.qualifications.Verifiable.verifyFalse

---

## Purpose

Verify value is false

## Syntax

```
verifyFalse(verifiable,actual)
verifyFalse(__ ,diagnostic)
```

## Description

`verifyFalse(verifiable,actual)` verifies that `actual` is a scalar logical with the value of false.

`verifyFalse( __ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of false. Therefore, entities such as empty arrays, false valued arrays, and zero doubles produce failures when used in this method, despite these entities exhibiting "false-like" behavior such as bypassing the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsFalse;
verifiable.verifyThat(actual,.IsFalse());
```

There exists more functionality when using the `IsFalse` constraint directly via `verifyThat`.

- Unlike `verifyTrue`, this method may create a new constraint for each call. For performance critical uses, consider using `verifyTrue`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **diagnostic**

# matlab.unittest.qualifications.Verifiable.verifyFalse

---

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test MATLAB Logical Functions

Create a TestCase object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test true.

```
verifyFalse(testCase, true);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyFalse failed.
```

```
--> The value must evaluate to "false".
```

```
Actual Value:
```

```
 1
```

Test failed.

Test false.

```
verifyFalse(testCase, false);
```

Interactive verification passed.

## Test the Value 0

The number 0 is a double value, not a logical value.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyFalse(testCase, 0);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyFalse failed.
--> The value must be logical. It is of type "double".
```

```
Actual Value:
 0
```

Test failed.

## Test Array of Logical Values

To be false, the value must be scalar.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyFalse(testCase, [false false false]);
```

Interactive verification failed.

```

Framework Diagnostic:

verifyFalse failed.
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:
 0 0 0
```

# matlab.unittest.qualifications.Verifiable.verifyFalse

---

Test failed.

Test an array of mixed logical values.

```
verifyFalse(testCase, [false true false], ...
 'A mixed array of logicals is not the one false value');
```

Interactive verification failed.

-----

Test Diagnostic:

-----

A mixed array of logicals is not the one false value

-----

Framework Diagnostic:

-----

verifyFalse failed.

--> The value must be scalar. It has a size of [1 3].

Actual Value:

0 1 0

Test failed.

## See Also

```
verifyThat | verifyTrue |
matlab.unittest.diagnostics.Diagnostic
| matlab.unittest.constraints.IsFalse |
matlab.unittest.constraints | matlab.unittest.qualifications
```

**Purpose** Verify value is greater than specified value

**Syntax** `verifyGreaterThan(verifiable,actual,floor)`  
`verifyGreaterThan(__,diagnostic)`

**Description** `verifyGreaterThan(verifiable,actual,floor)` verifies that all elements of `actual` are greater than all the elements of `floor`.  
`verifyGreaterThan(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
matlab.unittest.constraints.IsGreaterThan;
verifiable.verifyThat(actual, IsGreaterThan(floor));
```

There exists more functionality when using the `IsGreaterThan` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Verifiable.verifyGreaterThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 3 is greater than 2.

```
verifyGreaterThan(testCase, 3, 2);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
verifyGreaterThan(testCase, 5, 9);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyGreaterThan failed.
```

```
--> The value must be greater than the minimum value.
```

```
Actual Value:
```

```
5
```

```
Minimum Value (Exclusive):
```

```
9
```

```
Test failed.
```

## Compare an Array to a Scalar

Test if each element is greater than the FLOOR value, 2.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThan(testCase, [5 6 7], 2);
```

```
Interactive verification passed.
```

Test if value 5 is greater than each element in the FLOOR array, [1 2 3].

```
verifyGreaterThan(testCase, 5, [1 2 3]);
```

```
Interactive verification passed.
```

Test if each element in the matrix is greater than the FLOOR value, 4.

```
verifyGreaterThan(testCase, [1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyGreaterThan failed.
```

```
--> Each element must be greater than the minimum value.
```

```
Failing Indices:
```

```
 1 2 3 5
```

```
Actual Value:
```

```
 1 2 3
 4 5 6
```

```
Minimum Value (Exclusive):
```

```
 4
```

```
Test failed.
```

## Compare Arrays

Test if each element is greater than each corresponding element of the FLOOR array, [4 -9 0].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThan(testCase, [5 -3 2], [4 -9 0]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyGreaterThan(testCase, eye(2), eye(2));
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyGreaterThan failed.

--> Each element must be greater than each corresponding element of the m

Failing Indices:

1	2	3	4
---	---	---	---

Actual Value:

1	0
0	1

Minimum Value (Exclusive):

1	0
0	1

Test failed.

## Purpose

Verify value is greater than or equal to specified value

## Syntax

```
verifyGreaterThanOrEqualTo(verifiable,actual,floor)
verifyGreaterThanOrEqualTo(___,diagnostic)
```

## Description

`verifyGreaterThanOrEqualTo(verifiable,actual,floor)` that all elements of `actual` are greater than or equal to all the elements of `floor`.

`verifyGreaterThanOrEqualTo( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsGreaterThanOrEqualTo;
verifiable.verifyThat(actual, IsGreaterThanOrEqualTo(floor));
```

There exists more functionality when using the `IsGreaterThanOrEqualTo` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `floor` unless either one is scalar, at which point scalar expansion occurs.

### **floor**

Minimum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 3 is greater than 2.

```
verifyGreaterThanOrEqualTo(testCase, 3, 2);
```

```
Interactive verification passed.
```

Verify 3 is greater than or equal to 3.

```
verifyGreaterThanOrEqualTo(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if 5 is greater than 9.

```
verifyGreaterThanOrEqualTo(testCase, 5, 9);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyGreaterThanOrEqualTo failed.
```

```
--> The value must be greater than or equal to the minimum value.
```

```
Actual Value:
```

```
5
```

```
Minimum Value (Inclusive):
 9
```

Test failed.

## Compare an Array to a Scalar

Test if each element is greater than or equal to the FLOOR value, 2.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThanOrEqualTo(testCase, [5 2 7], 2);
```

Interactive verification passed.

Test if each element in the matrix is greater than or equal to the FLOOR value, 4.

```
verifyGreaterThanOrEqualTo(testCase, [1 2 3; 4 5 6], 4);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifyGreaterThanOrEqualTo failed.
```

```
--> Each element must be greater than or equal to the minimum value.
```

```
Failing Indices:
```

```
 1 3 5
```

```
Actual Value:
```

```
 1 2 3
 4 5 6
```

```
Minimum Value (Inclusive):
```

```
 4
```

## Compare Arrays

Test if each element is greater than or equal to each corresponding element of the FLOOR array, [4 -3 0].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyGreaterThanOrEqualTo(testCase, [5 -3 2], [4 -3 0]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyGreaterThanOrEqualTo(testCase, eye(2), eye(2));
```

Interactive verification passed.

# matlab.unittest.qualifications.Verifiable.verifyInstanceOf

## Purpose

Verify value is object of specified type

## Syntax

```
verifyInstanceOf(verifiable,actual,className)
verifyInstanceOf(verifiable,actual,metaClass)
verifyInstanceOf(___,diagnostic)
```

## Description

`verifyInstanceOf(verifiable,actual,className)` verifies that `actual` is a MATLAB value whose class is the class specified by `className`.

`verifyInstanceOf(verifiable,actual,metaClass)` `actual` is a MATLAB value whose class is the class specified by the `meta.class` instance `metaClass`.

`verifyInstanceOf(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsInstanceOf;
verifiable.verifyThat(actual, IsInstanceOf(className));
verifiable.verifyThat(actual, IsInstanceOf(metaClass));
```

There exists more functionality when using the `IsInstanceOf` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **className**

Name of class, specified as a string.

### **metaClass**

An instance of meta.class.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test a Class**

These interactive tests verify the class of the number, 5.

Create a TestCase object and the value to test.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
actvalue = 5;
```

Verify actvalue is an instance of class double.

```
verifyInstanceOf(testCase, actvalue, 'double');
```

```
Interactive verification passed.
```

Verify if actvalue is an instance of char.

```
verifyInstanceOf(testCase, 5, 'char');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyInstanceOf failed.
```

# matlab.unittest.qualifications.Verifiable.verifyInstanceOf

```
--> The value must be an instance of the expected type.
```

```
Actual Class:
 double
Expected Type:
 char
```

```
Actual Value:
 5
```

Test failed.

## Test a Function Handle

These tests verify function handles, specified as a meta.class instance, ?function\_handle.

Create a function handle.

```
fh = @sin;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyInstanceOf(testCase, fh, ?function_handle);
```

```
Interactive verification passed.
```

Test the function name.

```
fh = 'sin';
verifyInstanceOf(testCase, fh, ?function_handle);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyInstanceOf failed.
```

```
--> The value must be an instance of the expected type.
```

```
Actual Class:
```

```
char
Expected Type:
function_handle
```

```
Actual Value:
sin
```

Test failed.

## Test a Derived Class

Verify that a derived class is not the same class as its base class.

Create a class, BaseExample.

```
classdef BaseExample
end
```

Create a derived class, DerivedExample.

```
classdef DerivedExample < BaseExample
end
```

Verify DerivedExample is an instance of BaseExample.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
testCase.verifyInstanceOf(DerivedExample(), ?BaseExample);
```

```
Interactive verification passed.
```

Verify BaseExample is not an instance of DerivedExample.

```
testCase.verifyInstanceOf(BaseExample(), ?DerivedExample);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

# matlab.unittest.qualifications.Verifiable.verifyInstanceOf

---

```
verifyInstanceOf failed.
--> The value must be an instance of the expected type.
```

```
Actual Class:
 BaseExample
Expected Type:
 DerivedExample
```

```
Actual Value:
 BaseExample with no properties.
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyLength

---

## Purpose

Verify value has specified length

## Syntax

```
verifyLength(verifiable,actual,expectedLength)
verifyLength(___,diagnostic)
```

## Description

`verifyLength(verifiable,actual,expectedLength)` verifies that `actual` is a MATLAB array whose length is `expectedLength`.

`verifyLength( ___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.HasLength;
verifiable.verifyThat(actual, HasLength(expectedLength));
```

There exists more functionality when using the `HasLength` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedLength**

The length of an array is defined as the largest dimension of that array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Verifiable.verifyLength

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Array Lengths

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify length of array is the expected value, 5.

```
verifyLength(testCase, ones(2, 5, 3), 5, 'User diagnostic');
```

```
Interactive verification passed.
```

Length of array is not the expected value, 3.

```
verifyLength(testCase, [2 3], 3);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyLength failed.
```

```
--> The array has an incorrect length.
```

```
Actual Length:
```

```
2
```

```
Expected Length:
```

```
3
```

```
Actual Array:
```

```
2 3
```

Test failed.

The length of a 2x3 array is 3.

```
verifyLength(testCase, [1 2 3; 4 5 6], 3);
```

Interactive verification passed.

Verify the length of a 2x3 array is not the number of elements, 6.

```
verifyLength(testCase, [1 2 3; 4 5 6], 6);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifyLength failed.
```

```
--> The array has an incorrect length.
```

```
Actual Length:
```

```
3
```

```
Expected Length:
```

```
6
```

```
Actual Array:
```

```
1 2 3
4 5 6
```

Test failed.

```
verifyLength(testCase, eye(2), 4);
```

Interactive verification failed.

```

Framework Diagnostic:

```

# matlab.unittest.qualifications.Verifiable.verifyLength

---

```
verifyLength failed.
--> The array has an incorrect length.
```

```
Actual Length:
 2
Expected Length:
 4
```

```
Actual Array:
 1 0
 0 1
```

## Test Cell Array Lengths

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLength(testCase, {'somestring', 'someotherstring'}, 2);
```

```
Interactive verification passed.
```

```

# matlab.unittest.qualifications.Verifiable.verifyLessThan

## Purpose

Verify value is less than specified value

## Syntax

```
verifyLessThan(verifiable,actual,ceiling)
verifyLessThan(___,diagnostic)
```

## Description

`verifyLessThan(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than all the elements of `ceiling`.

`verifyLessThan(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThan;
verifiable.verifyThat(actual, IsLessThan(ceiling));
```

There exists more functionality when using the `IsLessThan` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test. `actual` must be the same size as `ceiling` unless either one is scalar, at which point scalar expansion occurs.

### **ceiling**

Maximum value, exclusive.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

# matlab.unittest.qualifications.Verifiable.verifyLessThan

---

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 2 is less than 3.

```
verifyLessThan(testCase, 2, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
verifyLessThan(testCase, 9, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyLessThan failed.
```

```
--> The value must be less than the maximum value.
```

```
Actual Value:
```

```
 9
```

```
Maximum Value (Exclusive):
```

```
 5
```

```
Test failed.
```

## Compare an Array to a Scalar

Test if each element is less than the CEILING value, 9.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThan(testCase, [5 6 7], 9);
```

```
Interactive verification passed.
```

Test if each element in the matrix is less than the CEILING value, 4.

```
verifyLessThan(testCase, [1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyLessThan failed.
```

```
--> Each element must be less than the maximum value.
```

```
Failing Indices:
```

```
 2 4 6
```

```
Actual Value:
```

```
 1 2 3
 4 5 6
```

```
Maximum Value (Exclusive):
```

```
 4
```

```
Test failed.
```

## Compare Arrays

Test if each element is less than each corresponding element of the CEILING array, [7 -1 8].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThan(testCase, [5 -3 2], [7 -1 8]);
```

# matlab.unittest.qualifications.Verifiable.verifyLessThan

---

Interactive verification passed.

Compare an array to itself.

```
verifyLessThan(testCase, eye(2), eye(2));
```

Interactive verification failed.

```

Framework Diagnostic:

```

verifyLessThan failed.

--> Each element must be less than each corresponding element of the maximum value.

Failing Indices:

```
 1 2 3 4
```

Actual Value:

```
 1 0
 0 1
```

Maximum Value (Exclusive):

```
 1 0
 0 1
```

Test failed.

## See Also

```
verifyThat | verifyLessThanOrEqual |
verifyGreaterThan | verifyGreaterThanOrEqual
| lt | matlab.unittest.constraints.IsLessThan
| matlab.unittest.diagnostics.Diagnostic |
matlab.unittest.constraints | matlab.unittest.qualifications
```

## Purpose

Verify value is less than or equal to specified value

## Syntax

```
verifyLessThanOrEqualTo(verifiable,actual,ceiling)
verifyLessThanOrEqualTo(___,diagnostic)
```

## Description

`verifyLessThanOrEqualTo(verifiable,actual,ceiling)` verifies that all elements of `actual` are less than or equal to all the elements of `ceiling`.

`verifyLessThanOrEqualTo(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsLessThanOrEqualTo;
verifiable.verifyThat(actual, IsLessThanOrEqualTo(ceiling));
```

There exists more functionality when using the `IsLessThanOrEqualTo` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **ceiling**

Maximum value.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Two Numbers

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify 2 is less than 3.

```
verifyLessThanOrEqual(testCase, 2, 3);
```

```
Interactive verification passed.
```

Verify 3 is less than or equal to 3.

```
verifyLessThanOrEqual(testCase, 3, 3);
```

```
Interactive verification passed.
```

Test if 9 is less than 5.

```
verifyLessThanOrEqual(testCase, 9, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyLessThanOrEqual failed.
```

```
--> The value must be less than or equal to the maximum value.
```

```
Actual Value:
```

```
 9
```

```
Maximum Value (Inclusive):
 5
```

Test failed.

## Compare an Array to a Scalar

Test if each element is less than or equal to the ceiling value, 7.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThanOrEqual(testCase, [5 2 7], 7);
```

```
Interactive verification passed.
```

Test if each element in the matrix is less than or equal to the ceiling value, 4.

```
verifyLessThanOrEqual(testCase, [1 2 3; 4 5 6], 4);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyLessThanOrEqual failed.
--> Each element must be less than or equal to the maximum value.
```

```
Failing Indices:
 4 6
```

```
Actual Value:
```

```
 1 2 3
 4 5 6
```

```
Maximum Value (Inclusive):
 4
```

Test failed.

## Compare Arrays

Test if each element is less than or equal to each corresponding element of the ceiling array, [5 -3 8].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyLessThanOrEqualTo(testCase, [5 -3 2], [5 -3 8]);
```

Interactive verification passed.

Compare an array to itself.

```
verifyLessThanOrEqualTo(testCase, eye(2), eye(2));
```

Interactive verification passed.

## See Also

| matlab.unittest.diagnostics.Diagnostic |
matlab.unittest.constraints | matlab.unittest.qualifications
```

# matlab.unittest.qualifications.Verifiable.verifyMatches

## Purpose

Verify string matches specified regular expression

## Syntax

```
verifyMatches(verifiable,actual,expression)
verifyMatches(___,diagnostic)
```

## Description

`verifyMatches(verifiable,actual,expression)` that `actual` is a string that matches the regular expression defined by `expression`.

`verifyMatches(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.Matches;
verifiable.verifyThat(actual, Matches(expression));
```

There exists more functionality when using the `Matches` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The string to test.

### **expression**

The value to match, specified as a regular expression.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle

# matlab.unittest.qualifications.Verifiable.verifyMatches

---

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for String Matches

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify that strings matches a regular expression.

```
verifyMatches(testCase, 'Some String', 'Some [Ss]tring', ...
 'My result should have matched the expression');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another string', '(Some |An)other');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, 'Another 3 strings', '^Another \d+ strings?$');
```

```
Interactive verification passed.
```

```
verifyMatches(testCase, '3 more strings', '\d+ strings?');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyMatches failed.
```

```
--> The string did not match the regular expression.
```

```
Actual String:
```

```
 3 more strings
```

Regular Expression:  
`\d+ strings?`

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyNotEmpty

<b>Purpose</b>	Verify value is not empty
<b>Syntax</b>	<pre>verifyNotEmpty(verifiable,actual) verifyNotEmpty( ____,diagnostic)</pre>
<b>Description</b>	<p><code>verifyNotEmpty(verifiable,actual)</code> verifies that <code>actual</code> is a non-empty MATLAB value.</p> <p><code>verifyNotEmpty( ____,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsEmpty; verifiable.verifyThat(actual, ~IsEmpty());</pre></li></ul> <p>There exists more functionality when using the <code>IsEmpty</code> constraint directly via <code>verifyThat</code>.</p>
<b>Input Arguments</b>	<p><b>verifiable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the verification in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>string</li><li>function handle</li><li><code>matlab.unittest.diagnostics.Diagnostic</code> object</li></ul>

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Non-Empty Strings

Create a `TestCase` object.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;

verifyNotEmpty(testCase, '');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [0 0].
```

```
Actual Value:
 ''
```

Test failed.

### Test for Non-Empty Arrays

An array with any zero dimension is empty.

Test array [2 3].

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, [2 3]);
```

```
Interactive verification passed.
```

Test array with a zero dimension.

```
verifyNotEmpty(testCase, ones(2, 5, 0, 3));
```

# matlab.unittest.qualifications.Verifiable.verifyNotEmpty

---

```
Interactive verification failed.

Framework Diagnostic:

verifyNotEmpty failed.
--> The value must not be empty.
--> The value has a size of [2 5 0 3].

Actual Value:
 Empty array: 2-by-5-by-0-by-3
```

Test failed.

## Test for Non-Empty Cell Arrays

A cell array of empty arrays is not empty.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, {[], [], []}, '');
```

```
Interactive verification passed.
```

## Test for Non-Empty Test Suite

Test an empty object, emptyTestSuite.

```
emptyTestSuite = matlab.unittest.TestSuite.empty;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEmpty(testCase, emptyTestSuite);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyNotEmpty failed.
--> The value must not be empty.
```

# matlab.unittest.qualifications.Verifiable.verifyNotEmpty

---

--> The value has a size of [0 0].

Actual Value:

0x0 TestCase array with no properties.

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyNotEqual

<b>Purpose</b>	Verify value is not equal to specified value
<b>Syntax</b>	<pre>verifyNotEqual(verifiable,actual,notExpected) verifyNotEqual( ____,diagnostic)</pre>
<b>Description</b>	<p><code>verifyNotEqual(verifiable,actual,notExpected)</code> verifies that <code>actual</code> is not equal to <code>notExpected</code>.</p> <p><code>verifyNotEqual( ____,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• This method is functionally equivalent to: <pre>import matlab.unittest.constraints.IsEqualTo; verifiable.verifyThat(actual, ~IsEqualTo(notExpected));</pre><p>There exists more functionality when using the <code>IsEqualTo</code> constraint directly via <code>verifyThat</code>.</p></li></ul>
<b>Input Arguments</b>	<p><b>verifiable</b> The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the verification in conjunction with the test running framework.</p> <p><b>actual</b> The value to test.</p> <p><b>notExpected</b> Value to compare.</p> <p><b>diagnostic</b> Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li><li>• function handle</li></ul>

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Compare Numeric Values

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Compare a value to itself.

```
verifyNotEqual(testCase, 5, 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyNotEqual failed.
--> NumericComparator passed.
```

```
Actual Value:
 5
Prohibited Value:
 5
```

Test failed.

Compare different number values.

```
verifyNotEqual(testCase, 4.95, 5, '4.95 should be different from 5');
```

```
Interactive verification passed.
```

Values 4.95 and 5 are not equal.

# matlab.unittest.qualifications.Verifiable.verifyNotEqual

---

Compare values of different sizes.

```
verifyNotEqual(testCase, [5 5], 5, '[5 5] is not equal to 5');
```

```
Interactive verification passed.
```

Values are not equal.

## Compare Classes

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEqual(testCase, int8(5), int16(5), 'Classes dont match');
```

```
Interactive verification passed.
```

## Compare Cell Arrays

Test a cell array by comparing each element.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNotEqual(testCase, {'cell', struct, 5}, {'cell', struct, 5});
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyNotEqual failed.
--> CellComparator passed.
```

```
Actual Value:
 'cell' [1x1 struct] [5]
Prohibited Value:
 'cell' [1x1 struct] [5]
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyNotSameHandle

**Purpose** Verify value is not handle to specified instance

**Syntax** `verifyNotSameHandle(verifyable,actual,notExpectedHandle)`  
`verifyNotSameHandle( __ ,diagnostic)`

**Description** `verifyNotSameHandle(verifyable,actual,notExpectedHandle)` verifies that `actual` is a different size and/or does not contain the same instances as the `notExpectedHandle` handle array.

`verifyNotSameHandle( __ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
verifyable.verifyThat(actual, ~IsSameHandleAs(notExpectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

## Input Arguments

### **verifyable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **notExpectedHandle**

The handle array to compare.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Handles point to different objects.

```
verifyNotSameHandle(testCase, h1, h2);
```

```
Interactive verification passed.
```

Show matching handle combinations.

```
verifyNotSameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

```

verifyNotSameHandle failed.
```

# matlab.unittest.qualifications.Verifiable.verifyNotSameHandle

---

--> The two handles must not refer to the same handle, or should have different sizes.

Actual Value:

1x3 ExampleHandle array with no properties.

Handle Object:

1x3 ExampleHandle array with no properties.

Test failed.

The order of the handle arguments matters.

```
verifyNotSameHandle(testCase, [h1 h2], [h2 h1]);
```

Interactive verification passed.

Test a handle with itself.

```
verifyNotSameHandle(testCase, h1, h1);
```

Interactive verification failed.

-----  
Framework Diagnostic:  
-----

verifyNotSameHandle failed.

--> The two handles must not refer to the same handle, or should have different sizes.

Actual Value:

ExampleHandle with no properties.

Handle Object:

ExampleHandle with no properties.

Test failed.

Variables are not same size.

```
verifyNotSameHandle(testCase, h2, [h2 h2]);
```

```
Interactive verification passed.
```

```
Variables are the same size.
```

```
verifyNotSameHandle(testCase, [h1 h1], [h1 h1]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNotSameHandle failed.
```

```
--> The two handles must not refer to the same handle, or should have
different sizes.
```

```
Actual Value:
```

```
 1x2 ExampleHandle array with no properties.
```

```
Handle Object:
```

```
 1x2 ExampleHandle array with no properties.
```

```
Test failed.
```

# matlab.unittest.qualifications.Verifiable.verifyNumElements

<b>Purpose</b>	Verify value has specified element count
<b>Syntax</b>	<pre>verifyNumElements(verifiable,actual,expectedElementCount) verifyNumElements(___,diagnostic)</pre>
<b>Description</b>	<p><code>verifyNumElements(verifiable,actual,expectedElementCount)</code> verifies that <code>actual</code> is a MATLAB array with <code>expectedElementCount</code> number of elements.</p> <p><code>verifyNumElements(___,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p>

- Tips**
- This method is functionally equivalent to:  

```
import matlab.unittest.constraints.HasElementCount;
verifiable.verifyThat(actual, HasElementCount(expectedElementCount));
```

There exists more functionality when using the `HasElementCount` constraint directly via `verifyThat`.

<b>Input Arguments</b>	<p><b>verifiable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the verification in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The value to test.</p> <p><b>expectedElementCount</b></p> <p>The expected number of elements in the array.</p> <p><b>diagnostic</b></p> <p>Diagnostic information to display upon a failure, specified as one of the following:</p> <ul style="list-style-type: none"><li>• string</li></ul>
------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Matrices

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
n = 7;
verifyNumElements(testCase, eye(n), n^2);
```

```
Interactive verification passed.
```

```
verifyNumElements(testCase, 3, 1);
```

```
Interactive verification passed.
```

```
verifyNumElements(testCase, [1 2 3; 4 5 6], 5);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifyNumElements failed.
```

```
--> The value did not have the correct number of elements.
```

```
Actual Number of Elements:
```

```
6
```

```
Expected Number of Elements:
```

```
5
```

```
Actual Value:
```

# matlab.unittest.qualifications.Verifiable.verifyNumElements

---

```
1 2 3
4 5 6
```

Test failed.

## Test Cell Array

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNumElements(testCase, {'SomeString', 'SomeOtherString'}, 2);
```

Interactive verification passed.

## Test Structure

```
s.Field1 = 1;
s.Field2 = 2;
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyNumElements(testCase, s, 2);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifyNumElements failed.
```

```
--> The value did not have the correct number of elements.
```

```
Actual Number of Elements:
```

```
1
```

```
Expected Number of Elements:
```

```
2
```

```
Actual Value:
```

```
Field1: 1
```

```
Field2: 2
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifyReturnsTrue

**Purpose** Verify function returns true when evaluated

**Syntax** `verifyReturnsTrue(verifiable,actual)`  
`verifyReturnsTrue(___,diagnostic)`

**Description** `verifyReturnsTrue(verifiable,actual)` verifies that `actual` is a function handle that returns a scalar logical whose value is true.  
`verifyReturnsTrue(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- It is a shortcut for quick custom comparison functionality that can be defined quickly, and possibly inline. It can be preferable over simply evaluating the function directly and using `verifyTrue` because the function handle will be shown in the diagnostics, thus providing more insight into the failure condition which is lost when using `verifyTrue`.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.ReturnsTrue;
verifiable.verifyThat(actual, ReturnsTrue());
```

There exists more functionality when using the `ReturnsTrue` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The function handle to test.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test if Condition is True

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyReturnsTrue(testCase, @true);
```

```
Interactive verification passed.
```

Verify that it is true that two numbers are equal.

```
verifyReturnsTrue(testCase, @() isequal(1,1));
```

```
Interactive verification passed.
```

Verify that it is true that two letters are not the same.

```
verifyReturnsTrue(testCase, @() ~strcmp('a','b'));
```

```
Interactive verification passed.
```

Cause verification to fail by trying to verify that “false” evaluates to “true”.

```
verifyReturnsTrue(testCase, @false);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

# matlab.unittest.qualifications.Verifiable.verifyReturnsTrue

---

```

verifyReturnsTrue failed.
--> The function handle should have evaluated to "true".
--> Returned value:
 0
```

```
Actual Function Handle:
 @false
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a vector of logical values not a scalar logical value.

```
verifyReturnsTrue(testCase, @() strcmp('a',{ 'a','a'}));
```

Interactive verification failed.

```

Framework Diagnostic:

verifyReturnsTrue failed.
--> The function handle should have returned a scalar. The return value h
--> Returned value:
 1 1
```

```
Actual Function Handle:
 @()strcmp('a',{ 'a','a'})
```

Test failed.

Cause verification to fail by having the test specified in the function handle return a double not a logical.

```
verifyReturnsTrue(testCase, @() exist('exist'));
```

Interactive verification failed.

```

Framework Diagnostic:

verifyReturnsTrue failed.
--> The function handle should have returned a logical value. It was c
--> Returned value:
 5
```

```
Actual Function Handle:
 @()exist('exist')
```

Test failed.

# matlab.unittest.qualifications.Verifiable.verifySameHandle

**Purpose** Verify two values are handles to same instance

**Syntax** `verifySameHandle(verifiable,actual,expectedHandle)`  
`verifySameHandle(___,diagnostic)`

**Description** `verifySameHandle(verifiable,actual,expectedHandle)` verifies that `actual` is the same size and contains the same instances as the `expectedHandle` handle array.

`verifySameHandle(___,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

**Tips**

- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsSameHandleAs;
verifiable.verifyThat(actual, IsSameHandleAs(expectedHandle));
```

There exists more functionality when using the `IsSameHandleAs` constraint directly via `verifyThat`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **expectedHandle**

The expected handle array.

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string

- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test Handles from Same Class

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Create a handle class, `ExampleHandle`.

```
classdef ExampleHandle < handle
end
```

Create two handle variables.

```
h1 = ExampleHandle;
h2 = ExampleHandle;
```

Show matching handle combinations.

```
verifySameHandle(testCase, h1, h1);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h1], [h1 h1]);
```

```
Interactive verification passed.
```

```
verifySameHandle(testCase, [h1 h2 h1], [h1 h2 h1]);
```

```
Interactive verification passed.
```

Handles must point to same object.

# matlab.unittest.qualifications.Verifiable.verifySameHandle

---

```
verifySameHandle(testCase, h1, h2);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySameHandle failed.
--> Values do not refer to the same handle.
```

```
Actual Value:
 ExampleHandle with no properties.
Expected Handle Object:
 ExampleHandle with no properties.
```

Test failed.

Size of handle objects must match.

```
verifySameHandle(testCase, [h1 h1], h1);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySameHandle failed.
--> Sizes do not match.
 Actual Value Size : [1 2]
 Expected Handle Object Size : [1 1]
```

```
Actual Value:
 1x2 ExampleHandle array with no properties.
Expected Handle Object:
 ExampleHandle with no properties.
```

Test failed.

Order of arguments is important.

```
verifySameHandle(testCase, [h1 h2], [h2 h1]);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifySameHandle failed.
```

```
--> Some elements in the handle array refer to the wrong handle.
```

Actual Value:

```
 1x2 ExampleHandle array with no properties.
```

Expected Handle Object:

```
 1x2 ExampleHandle array with no properties.
```

Test failed.

## Examples

### Test Arrays

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

```
verifySize(testCase, ones(2, 5, 3), [2 5 3]);
```

```
Interactive verification passed.
```

```
verifySize(testCase, [1 2 3; 4 5 6], [2 3]);
```

```
Interactive verification passed.
```

```
verifySize(testCase, [2 3], [3 2]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

```

```
verifySize failed.
```

```
--> The value had an incorrect size.
```

```
Actual Size:
```

```
1 2
```

```
Expected Size:
```

```
3 2
```

```
Actual Value:
```

```
2 3
```

```
Test failed.
```

# matlab.unittest.qualifications.Verifiable.verifySize

---

Number of elements is not the same as size.

```
verifySize(testCase, [1 2 3; 4 5 6], [6 1]);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifySize failed.
```

```
--> The value had an incorrect size.
```

```
Actual Size:
```

```
 2 3
```

```
Expected Size:
```

```
 6 1
```

```
Actual Value:
```

```
 1 2 3
```

```
 4 5 6
```

Test failed.

```
verifySize(testCase, eye(2), [4 1]);
```

Interactive verification failed.

```

Framework Diagnostic:

```

```
verifySize failed.
```

```
--> The value had an incorrect size.
```

```
Actual Size:
```

```
 2 2
```

```
Expected Size:
```

```
 4 1
```

Actual Value:

```
 1 0
 0 1
```

Test failed.

## Test Cell Array

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifySize(testCase, {'SomeString', 'SomeOtherString'}, [1 2]);
```

Interactive verification passed.

---

- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples

### Test for Substrings

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test that a substring is contained in a string.

```
verifySubstring(testCase, 'SomeLongString', 'Long');
```

```
Interactive verification passed.
```

Show that case matters.

```
verifySubstring(testCase, 'SomeLongString', 'lonG');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifySubstring failed.
--> The string must contain the substring.
```

```
Actual String:
 SomeLongString
Expected Substring:
 lonG
```

Test failed.

Cause the verification to fail by testing a substring that isn't contained in the actual string.

# matlab.unittest.qualifications.Verifiable.verifySubstring

---

```
verifySubstring(testCase, 'SomeLongString', 'OtherString');
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

```

```

```
verifySubstring failed.
```

```
--> The string must contain the substring.
```

```
Actual String:
```

```
 SomeLongString
```

```
Expected Substring:
```

```
 OtherString
```

```
Test failed.
```

Show that the verification will fail if the substring is longer than the actual string.

```
verifySubstring(testCase, 'SomeLongString', 'SomeLongStringThatIsLonger')
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

```

```

```
verifySubstring failed.
```

```
--> The string must contain the substring.
```

```
Actual String:
```

```
 SomeLongString
```

```
Expected Substring:
```

```
 SomeLongStringThatIsLonger
```

```
Test failed.
```

# matlab.unittest.qualifications.Verifiable.verifySubstring

`matlab.unittest.constraints` | `matlab.unittest.qualifications`

# matlab.unittest.qualifications.Verifiable.verifyThat

---

**Purpose** Verify value meets given constraint

**Syntax** `verifyThat(verifiable,actual,constraint)`  
`verifyThat( __ ,diagnostic)`

**Description** `verifyThat(verifiable,actual,constraint)` verifies that `actual` is a value that satisfies the `constraint` provided.

If the constraint is not satisfied, a verification failure is produced utilizing only the framework diagnostic generated by the `constraint`.

`verifyThat( __ ,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

When using this signature, both the diagnostic information contained within `diagnostic` is used in addition to the diagnostic information provided by the `constraint`.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

### **actual**

The value to test.

### **constraint**

### **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- `matlab.unittest.diagnostics.Diagnostic` object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Examples **Test Conditions Using Constraints**

```
testCase = matlab.unittest.TestCase.forInteractiveUse;

% Passing scenarios
%%
import matlab.unittest.constraints.IsTrue;
verifyThat(testCase, true, IsTrue);

import matlab.unittest.constraints.IsEqualTo;
verifyThat(testCase, 5, IsEqualTo(5), '5 should be equal to 5');

import matlab.unittest.constraints.IsGreaterThan;
import matlab.unittest.constraints.HasNaN;
verifyThat(testCase, [5 NaN], IsGreaterThan(10) | HasNaN, ...
 'The value was not greater than 10 or NaN');

% Failing scenarios
%%
import matlab.unittest.constraints.AnyCellof;
import matlab.unittest.constraints.ContainsSubstring;
verifyThat(testCase, AnyCellof({'cell', 'of', 'strings'}), ...
 ContainsSubstring('char'), 'Test description');

import matlab.unittest.constraints.HasSize;
verifyThat(testCase, zeros(10,4,2), HasSize([10,5,2]), ...
 @() disp('A function handle diagnostic.'));

import matlab.unittest.constraints.IsEmpty;
verifyThat(testCase, 5, IsEmpty);
```

# matlab.unittest.qualifications.Verifiable.verifyThat

[matlab.unittest.constraints.Constraint](#) |  
[matlab.unittest.constraints](#) | [matlab.unittest.qualifications](#)

# matlab.unittest.qualifications.Verifiable.verifyTrue

---

## Purpose

Verify value is true

## Syntax

```
verifyTrue(verifiable,actual)
verifyTrue(__,diagnostic)
```

## Description

`verifyTrue(verifiable,actual)` verifies that `actual` is a scalar logical with the value of true.

`verifyTrue(__,diagnostic)` also displays the diagnostic information in `diagnostic` upon a failure.

## Tips

- This method passes if and only if the actual value is a scalar logical with a value of true. Therefore, entities such as true valued arrays and nonzero doubles produce qualification failures when used in this method, despite these entities exhibiting "true-like" behavior such as triggering the execution of code inside of "if" statements.
- This method is functionally equivalent to:

```
import matlab.unittest.constraints.IsTrue;
verifiable.verifyThat(actual, IsTrue());
```

There exists more functionality when using the `IsTrue` constraint directly via `verifyThat`.

Use of this method for performance benefits can come at the expense of less diagnostic information, and may not provide the same level of strictness adhered to by other constraints such as `IsEqualTo`. A similar approach that is generally less performant but can provide slightly better diagnostic information is the use of `verifyReturnsTrue`, which at least shows the display of the function evaluated to generate the failing result.

## Input Arguments

### **verifiable**

The `matlab.unittest.TestCase` instance which is used to pass or fail the verification in conjunction with the test running framework.

# matlab.unittest.qualifications.Verifiable.verifyTrue

---

## **actual**

The value to test.

## **diagnostic**

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## **Examples**

### **Test MATLAB Logical Functions**

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test true.

```
verifyTrue(testCase, true);
```

```
Interactive verification passed.
```

Test false.

```
verifyTrue(testCase, false);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyTrue failed.
```

```
--> The value must evaluate to "true".
```

```
Actual Value:
```

```
 0
```

```
Test failed.
```

## Test the Value 1

```
The number 1 is a double value, not a logical value.
```

```
A double value of 1 is not true.
```

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyTrue(testCase, 1);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

```

verifyTrue failed.
```

```
--> The value must be logical. It is of type "double".
```

```
Actual Value:
```

```
 1
```

```
Test failed.
```

## Test Array of Logical Values

```
To be true, the value must be scalar.
```

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyTrue(testCase, [true true true]);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:
```

# matlab.unittest.qualifications.Verifiable.verifyTrue

---

```

verifyTrue failed.
--> The value must be scalar. It has a size of [1 3].
```

```
Actual Value:
 1 1 1
```

Test failed.

Optimized comparison that trades speed for less diagnostics.

```
verifyTrue(testCase, ~isempty(strfind('string', 'ring')), ...
 'Could not find expected string');
```

# matlab.unittest.qualifications.Verifiable.verifyWarning

<b>Purpose</b>	Verify function issues specified warning
<b>Syntax</b>	<pre>verifyWarning(verifiable,actual,warningID) verifyWarning( ____,diagnostic) [output1,...,outputN] = verifyWarning( ____ )</pre>
<b>Description</b>	<p><code>verifyWarning(verifiable,actual,warningID)</code> verifies that <code>actual</code> issues a warning with the identifier <code>warningID</code>.</p> <p><code>verifyWarning( ____,diagnostic)</code> also displays the diagnostic information in <code>diagnostic</code> upon a failure.</p> <p><code>[output1,...,outputN] = verifyWarning( ____ )</code> also returns the output arguments <code>output1,...,outputN</code> that are produced when invoking <code>actual</code>.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>This method is functionally equivalent to:<pre>import matlab.unittest.constraints.IssuesWarnings; verifiable.verifyThat(actual, IssuesWarnings({warningID}));</pre>There exists more functionality when using the <code>IssuesWarnings</code> constraint directly via <code>verifyThat</code>.</li></ul>
<b>Input Arguments</b>	<p><b>verifiable</b></p> <p>The <code>matlab.unittest.TestCase</code> instance which is used to pass or fail the verification in conjunction with the test running framework.</p> <p><b>actual</b></p> <p>The function handle to test.</p> <p><b>warningID</b></p> <p>Warning ID, specified as a string.</p> <p><b>diagnostic</b></p>

# matlab.unittest.qualifications.Verifiable.verifyWarning

Diagnostic information to display upon a failure, specified as one of the following:

- string
- function handle
- matlab.unittest.diagnostics.Diagnostic object

Diagnostic values can be nonscalar. For more information, see `matlab.unittest.diagnostics.Diagnostic`.

## Output Arguments

### `output1,...,outputN`

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

### Test warning Function

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Verify `actual` warning ID is the same as input warning ID.

```
verifyWarning(testCase, @() warning('SOME:warning:id','Warning!'), ...
 'SOME:warning:id');
```

```
Interactive verification passed.
```

```
verifyWarning(testCase, @() warning('SOME:other:id', 'Warning message'), ...
 'SOME:warning:id', 'Did not issue specified warning');
```

```
Warning: Warning message
```

```
> In @()warning('SOME:other:id','Warning message')
 In FunctionHandleConstraint>FunctionHandleConstraint.invoke at 43
 In WarningQualificationConstraint>WarningQualificationConstraint.invoke
 In IssuesWarnings>IssuesWarnings.invoke at 364
```

# matlab.unittest.qualifications.Verifiable.verifyWarning

---

```
In IssuesWarnings>IssuesWarnings.issuesExpectedWarnings at 411
In IssuesWarnings>IssuesWarnings.satisfiedBy at 240
In QualificationDelegate>QualificationDelegate.qualifyThat at 90
In QualificationDelegate>QualificationDelegate.qualifyWarning at 190
In Verifiable>Verifiable.verifyWarning at 701
Interactive verification failed.
```

```

Test Diagnostic:

Did not issue specified warning
```

```

Framework Diagnostic:

verifyWarning failed.
--> The function handle did not issue a correct warning profile.
 The expected warning profile ignores:
 Set
 Count
 Order
--> The function handle did not issue the correct warnings.
```

```
Missing Warnings:
 SOME:warning:id
```

```
Actual Warning Profile:
 SOME:other:id
Expected Warning Profile:
 SOME:warning:id
```

```
Evaluated Function:
 @()warning('SOME:other:id','Warning message')
```

## Test a Function Without Warnings

Test the true function, which does not issue warnings.

# matlab.unittest.qualifications.Verifiable.verifyWarning

---

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
verifyWarning(testCase, @true, 'SOME:warning:id', ...
 '@true did not issue any warning');

Interactive verification failed.

Test Diagnostic:

@true did not issue any warning

Framework Diagnostic:

verifyWarning failed.
--> The function handle did not issue a correct warning profile.
 The expected warning profile ignores:
 Set
 Count
 Order
--> The function handle did not issue any warnings.

Expected Warning Profile:
 SOME:warning:id

Evaluated Function:
 @true

Test failed.
```

## Test Function With Output Arguments

Create a helper function that generates a warning and returns output.

```
function varargout = helper()
 warning('SOME:warning:id', 'Warning!');
 varargout = {123, 'abc'};
end
```

# matlab.unittest.qualifications.Verifiable.verifyWarning

---

Call helper.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
[actualOut1, actualOut2] = verifyWarning(testCase, @helper, ...
 'SOME:warning:id');
```

Interactive verification passed.

## Output Arguments

### **output1,...,outputN**

Output arguments, 1 through n (if any), from `actual`, returned as any type. The argument type is specified by the `actual` argument list.

## Examples

### **Test for Warnings from MATLAB Functions**

Create a `TestCase` object for interactive testing.

```
testCase = matlab.unittest.TestCase.forInteractiveUse;
```

Test the `why` function.

```
verifyWarningFree(testCase, @why);
```

```
The bald and not excessively bald and not excessively smart hamster of
Interactive verification passed.
```

This is a randomly-generated message.

Test the `true` function.

```
verifyWarningFree(testCase, @true);
```

```
Interactive verification passed.
```

Test the `false` function.

```
actualOutputFromFalse = verifyWarningFree(testCase, @false);
```

```
Interactive verification passed.
```

# matlab.unittest.qualifications.Verifiable.verifyWarningFree

Test a value that is not a function handle.

```
verifyWarningFree(testCase, 5, 'diagnostic');
```

Interactive verification failed.

```

Test Diagnostic:

```

```
diagnostic
```

```

Framework Diagnostic:

```

```
verifyWarningFree failed.
```

```
--> The value must be an instance of the expected type.

# questdlg

---

**Purpose** Create and open question dialog box

**Syntax**

```
button = questdlg('qstring')
button = questdlg('qstring','title')
button = questdlg('qstring','title',default)
button = questdlg('qstring','title','str1','str2',default)
button =
questdlg('qstring','title','str1','str2','str3',default)
button = questdlg('qstring','title', ..., options)
```

**Description** `button = questdlg('qstring')` displays a modal dialog box presenting the question 'qstring'. The dialog has three default buttons, **Yes**, **No**, and **Cancel**. If the user presses one of these three buttons, `button` is set to the name of the button pressed. If the user presses the close button on the dialog without making a choice, `button` is set to the empty string. If the user presses the **Return** key, `button` is set to 'Yes'. 'qstring' is a cell array or a string that automatically wraps to fit within the dialog box.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`button = questdlg('qstring','title')` displays a question dialog with 'title' displayed in the dialog's title bar.

`button = questdlg('qstring','title',default)` specifies which push button is the default in the event that the **Return** key is pressed. '*default*' must be 'Yes', 'No', or 'Cancel'.

`button = questdlg('qstring','title','str1','str2',default)` creates a question dialog box with two push buttons labeled 'str1' and 'str2'. *default* specifies the default button selection and must be 'str1' or 'str2'.

```
button =
questdlg('qstring','title','str1','str2','str3',default)
creates a question dialog box with three push buttons labeled 'str1',
'str2', and 'str3'. default specifies the default button selection and
must be 'str1', 'str2', or 'str3'.
```

When *default* is specified, but is not set to one of the button names, pressing the **Enter** key displays a warning and the dialog remains open.

```
button = questdlg('qstring','title', ..., options) replaces
the string default with a structure, options. The structure specifies
which button string is the default answer, and whether to use TeX to
interpret the question string, qstring. Button strings and dialog titles
cannot use TeX interpretation. The options structure must include the
fields Default and Interpreter, both strings. It can include other
fields, but questdlg does not use them. You can set Interpreter to
'none' or 'tex'. If the Default field does not contain a valid button
name, a command window warning is issued and the dialog box does
not respond to pressing the Enter key.
```

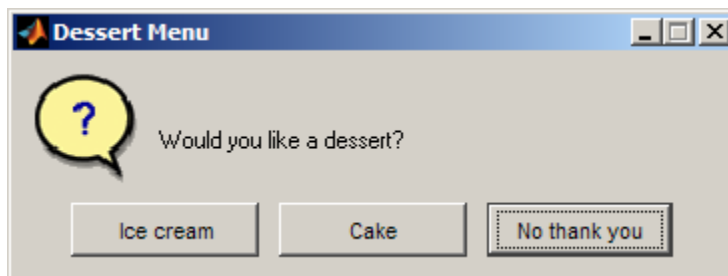

## Examples

### Example 1

Create a dialog that requests a dessert preference and encode the resulting choice as an integer.

```
% Construct a questdlg with three options
choice = questdlg('Would you like a dessert?', ...
'Dessert Menu', ...
'Ice cream','Cake','No thank you','No thank you');
% Handle response
switch choice
case 'Ice cream'
 disp([choice ' coming right up.'])
 dessert = 1;
case 'Cake'
 disp([choice ' coming right up.'])
 dessert = 2;
case 'No thank you'
 disp('I'll bring you your check.')
```

```
 dessert = 0;
end
```

To access the return value assigned to `dessert`, save the example as a function, for example `choosedessert`, by inserting this line on top:

```
function dessert = choosedessert
```

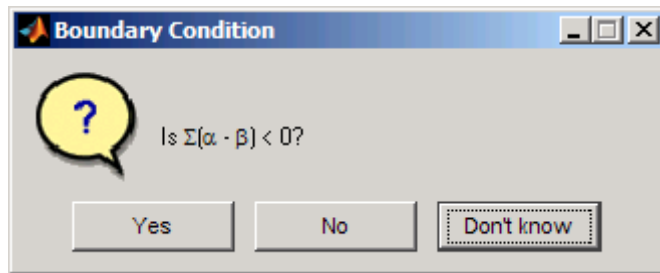

You can generalize the function by providing the cases as string or cell array calling arguments.

As the example shows, case statements can contain white space (but are case-sensitive).

## Example 2

Specify an options structure to use the TeX interpreter to format a question.

```
options.Interpreter = 'tex';
% Include the desired Default answer
options.Default = 'Don''t know';
% Create a TeX string for the question
qstring = 'Is $\Sigma(\alpha - \beta) < 0$?';
choice = questdlg(qstring,'Boundary Condition',...
 'Yes','No','Don''t know',options)
```

# quit

---

**Purpose** Terminate MATLAB program

**Alternatives** As an alternative to the quit function, use the Close box in the MATLAB desktop.

**Syntax**

```
quit
quit cancel
quit force
```

**Description** quit displays a confirmation dialog box if the confirm upon quitting preference is selected, and if confirmed or if the confirmation preference is not selected, terminates MATLAB after running `finish.m`, if `finish.m` exists. The workspace is not automatically saved by quit. To save the workspace or perform other actions when quitting, create a `finish.m` file to perform those actions. For example, you can display a custom dialog box to confirm quitting using a `finish.m` file—see the following examples for details. If an error occurs while `finish.m` is running, quit is canceled so that you can correct your `finish.m` file without losing your workspace.

quit **cancel** is for use in `finish.m` and cancels quitting. It has no effect anywhere else.

quit **force** bypasses `finish.m` and terminates MATLAB. Use this to override `finish.m`, for example, if an errant `finish.m` will not let you quit.

**Tips** When using Handle Graphics objects in `finish.m`, use `uiwait`, `waitfor`, or `drawnow` so that figures are visible. See the reference pages for these functions for more information.

If you want MATLAB to display the following confirmation dialog box after running quit, select **Preferences** in the **Environment** section on the **Home** tab. Then select the check box for Confirm before exiting MATLAB, and click **OK**.

## Examples

Two sample `finish.m` files are included with MATLAB. Use them to help you create your own `finish.m`, or rename one of the files to `finish.m` to use it.

- `finishesav.m`—Saves the workspace to a MAT-file when MATLAB quits.
- `finishdlg.m`—Displays a dialog allowing you to cancel quitting; it uses `quit cancel` and contains the following code:

```
button = questdlg('Ready to quit?', ...
 'Exit Dialog', 'Yes', 'No', 'No');
switch button
 case 'Yes',
 disp('Exiting MATLAB');
 %Save variables to matlab.mat
 save
 case 'No',
 quit cancel;
end
```

## See Also

`exit` | `save` | `finish` | `startup`

## How To

- “Stop Execution”

# Quit (COM)

---

**Purpose** Terminate MATLAB Automation server

**Syntax** **IDL Method Signature**

`void Quit(void)`

**Microsoft Visual Basic Client**

`Quit`

**MATLAB Client**

`h.Quit`

`Quit(h)`

**Description** `h.Quit` terminates the MATLAB server session attached to handle `h`. The MATLAB object is active until all references have been released, such as when the variable in a function call goes out of scope.

The function name is case-sensitive.

`Quit(h)` is an alternate syntax.

**Purpose**

Quiver or velocity plot

**Syntax**

```
quiver(x,y,u,v)
quiver(u,v)
quiver(...,scale)
quiver(...,LineStyle)
quiver(...,LineStyle,'filled')
quiver(...,'PropertyName',PropertyValue,...)
quiver(axes_handle,...)
h = quiver(...)
```

**Description**

A quiver plot displays velocity vectors as arrows with components  $(u, v)$  at the points  $(x, y)$ .

For example, the first vector is defined by components  $u(1), v(1)$  and is displayed at the point  $x(1), y(1)$ .

`quiver(x,y,u,v)` plots vectors as arrows at the coordinates specified in each corresponding pair of elements in  $x$  and  $y$ . The matrices  $x$ ,  $y$ ,  $u$ , and  $v$  must all be the same size and contain corresponding position and velocity components. However,  $x$  and  $y$  can also be vectors, as explained in the next section. By default, the arrows are scaled to just not overlap, but you can scale them to be longer or shorter if you want.

`quiver(u,v)` draws vectors specified by  $u$  and  $v$  at equally spaced points in the  $x$ - $y$  plane.

`quiver(...,scale)` automatically scales the arrows to fit within the grid and then stretches them by the factor `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves the length. Use `scale = 0` to plot the velocity vectors without automatic scaling. You can also tune the length of arrows after they have been drawn by choosing the **Plot**

**Edit**  tool, selecting the quivergroup object, opening the Property Editor, and adjusting the **Length** slider.

`quiver(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver` draws the markers at the origin of the vectors.

`quiver(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the quivergroup objects the function creates.

`quiver(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver(...)` returns the handle to the quivergroup object.

## Expanding x- and y-Coordinates

MATLAB expands `x` and `y` if they are not matrices. This expansion is equivalent to calling `meshgrid` to generate matrices from vectors:

```
[x,y] = meshgrid(x,y);
quiver(x,y,u,v)
```

In this case, the following must be true:

`length(x) = n` and `length(y) = m`, where `[m,n] = size(u) = size(v)`.

The vector `x` corresponds to the columns of `u` and `v`, and vector `y` corresponds to the rows of `u` and `v`.

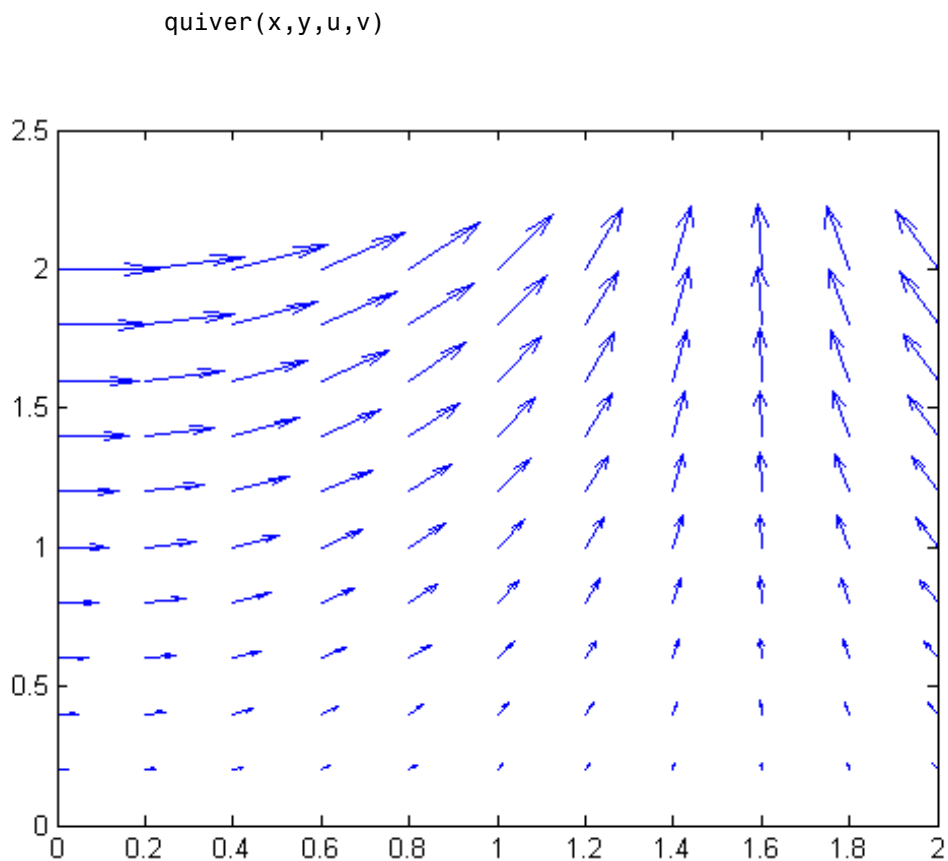

## Examples

### Plot Vector Velocities

Use `quiver` to display an arrow at each data point in `x` and `y` such that the arrow direction and length represent the corresponding values in `u` and `v`.

```
[x,y] = meshgrid(0:0.2:2,0:0.2:2);
u = cos(x).*y;
v = sin(x).*y;
```

figure

### Show Gradient with Quiver Plot

Plot the gradient of the function  $z = xe^{-x^2-y^2}$ .

```
[X,Y] = meshgrid(-2:.2:2);
Z = X.*exp(-X.^2 - Y.^2);
[DX,DY] = gradient(Z,.2,.2);
```

# quiver

```
figure
contour(X,Y,Z)
hold on
quiver(X,Y,DX,DY)
hold off
```

## See Also

[contour](#) | [LineSpec](#) | [plot](#) | [quiver3](#)

## How To

- “Display Quiver Plot Over Contour Plot”

**Purpose** 3-D quiver or velocity plot

**Syntax**

```
quiver3(x,y,z,u,v,w)
quiver3(z,u,v,w)
quiver3(...,scale)
quiver3(...,LineStyle)
quiver3(...,LineStyle,'filled')
quiver3(...,'PropertyName',PropertyValue,...)
quiver3(axes_handle,...)
h = quiver3(...)
```

**Description** A three-dimensional quiver plot displays vectors with components  $(u,v,w)$  at the points  $(x,y,z)$ , where  $u,v,w,x,y$ , and  $z$  all have real (non-complex) values.

`quiver3(x,y,z,u,v,w)` plots vectors with directions determined by components  $(u,v,w)$  at points determined by  $(x,y,z)$ . The matrices  $x,y,z,u,v,w$  must all be the same size and contain the corresponding position and vector components.

`quiver3(z,u,v,w)` plots vectors with directions determined by components  $(u,v,w)$  at equally spaced points along the surface  $z$ . For each vector  $(u(i,j),v(i,j),w(i,j))$ , the column index  $j$  determines the  $x$ -value of the point on the surface, the row index  $i$  determines the  $y$ -value, and  $z(i,j)$  determines the  $z$ -value. That is, `quiver3` locates the vector at the point on the surface  $(j,i,z(i,j))$ . The `quiver3` function automatically scales the vectors to prevent overlapping based on the distance between them.

`quiver3(...,scale)` automatically scales the vectors to prevent them from overlapping, and then multiplies them by `scale`. `scale = 2` doubles their relative length, and `scale = 0.5` halves them. Use `scale = 0` to plot the vectors without the automatic scaling.

# quiver3

---

`quiver3(...,LineStyle)` specifies line style, marker symbol, and color using any valid `LineStyle`. `quiver3` draws the markers at the origin of the vectors.

`quiver3(...,LineStyle,'filled')` fills markers specified by `LineStyle`.

`quiver3(...,'PropertyName',PropertyValue,...)` specifies property name and property value pairs for the `quivergroup` object the function creates.

`quiver3(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes (`gca`).

`h = quiver3(...)` returns a handle to the `quivergroup` object.

## Examples

### Create 3-D Quiver Plot

Define the data.

```
x = -3:0.5:3;
y = -3:0.5:3;
[X,Y] = meshgrid(x, y);
Z = Y.^2 - X.^2;
[U,V,W] = surfnorm(Z);
```

Plot vectors with components  $(U,V,W)$  at points that are equally spaced in the  $x$ -direction and  $y$ -direction with heights determined by  $Z$ .

```
figure
quiver3(Z,U,V,W)
view(-35,45)
```

### Plot Surface Normals

Plot the surface normals of the function  $z = xe^{-x^2-y^2}$ .

```
[X,Y] = meshgrid(-2:0.25:2,-1:0.2:1);
Z = X.* exp(-X.^2 - Y.^2);
[U,V,W] = surfnorm(X,Y,Z);
```

```
figure
quiver3(X,Y,Z,U,V,W,0.5);
```

# quiver3

```
hold on
surf(X,Y,Z);
view(-35,45)
axis ([-2 2 -1 1 -.6 .6])
hold off
```

**How To**

- “Projectile Path Over Time”

# Quivergroup Properties

---

**Purpose** Define quivergroup properties

**Modifying Properties** You can set and query graphics object properties using the set and get commands or the Property Editor (propertyeditor).

Note that you cannot define default properties for quivergroup objects. See Plot Objects for more information on quivergroup objects.

**Quivergroup Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation

hg.Annotation object (read-only)

*Control the display of quivergroup objects in legends.* Specifies whether this quivergroup object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the quivergroup object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the quivergroup object in a legend as one entry, but not its children objects
off	Do not include the quivergroup or its children in a legend (default)
children	Include only the children of the quivergroup as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

### AutoScale

{on} | off

*Autoscale arrow length.* Based on average spacing in the  $x$  and  $y$  directions, `AutoScale` scales the arrow length to fit within the grid-defined coordinate data and keeps the arrows from overlapping. After autoscaling, `quiver` applies the `AutoScaleFactor` to the arrow length.

### AutoScaleFactor

scalar (default = 0.9)

*User-specified scale factor.* When `AutoScale` is on, the `quiver` function applies this user-specified autoscale factor to the arrow length. A value of 2 doubles the length of the arrows; 0.5 halves the length.

### BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

# Quivergroup Properties

---

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Children

array of graphics object handles

*Children of the quivergroup object.* An array containing the handles of all line objects parented to this object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

# Quivergroup Properties

---

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is [0 0 0] (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

## `CreateFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see `Function Handle Callbacks`.

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcb0`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the quivergroup object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.

# Quivergroup Properties

---

- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object’s color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

# Quivergroup Properties

---

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and

the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the quiver plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on` | `{off}`

*Select the object by clicking lines or area of extent.* Select plot objects by:

- Clicking quiver arrows (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the quiver lines (excluding the baseline) to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the arrows).

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

# Quivergroup Properties

---

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a *drawnow*, *figure*, *getframe*, *waitfor*, or *pause* command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the *gca* or *gcf* command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of quivergroup object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

### LineWidth

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

### Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk

# Quivergroup Properties

---

Specifier	Marker Type
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MaxHeadSize`  
scalar (default = 0.2)

*Maximum size of arrowhead.* A value determining the maximum size of the arrowhead relative to the length of the arrow.

`Parent`  
handle of parent axes, `hggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hggroup`, or `hgtransform` object that contains the object.

`Selected`  
`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object

# Quivergroup Properties

---

is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

ShowArrowHead  
{on} | off

*Display arrowheads on vectors.* When this property is on, MATLAB draws arrowheads on the vectors displayed by quiver. When you set this property to off, quiver draws the vectors as lines without arrowheads.

Tag  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the Tag property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use findobj to find the object's handle. The following statement changes the FaceColor property of the object whose Tag is area1.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stem objects, `Type` is `'hggroup'`. This statement finds all the `hggroup` objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

## UData

matrix

# Quivergroup Properties

---

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components UData(1),VData(1),WData(1).

UDataSource  
string (MATLAB variable)

*Link UData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the UData. The default value is an empty array.

```
set(h, 'UDataSource', 'Udatavariablename')
```

MATLAB requires a call to refreshdata when you set this property. Changing workspace variables used as an object's UDataSource does not change the object's UData values, but you can use refreshdata to force an update of the object's data. refreshdata also lets you specify that the data source variable be evaluated in the workspace of a function from which you call refreshdata.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

VData  
matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components UData(1),VData(1),WData(1).

## VDataSource

MATLAB variable, as a string

*Link VData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the VData. The default value is an empty array.

```
set(h,'VDataSource','Vdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's VDataSource does not change the object's VData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## WData

matrix

*One dimension of 2-D or 3-D vector components.* UData, VData and WData (for 3-D) together specify the components of the vectors displayed as arrows in the quiver graph. For example, the first vector is defined by components `UData(1),VData(1),WData(1)`.

## WDataSource

MATLAB variable, as a string

*Link WData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the WData. The default value is an empty array.

# Quivergroup Properties

---

```
set(h, 'WDataSource', 'WDatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `WDataSource` does not change the object's `WData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## XData

vector | matrix

*X-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *x*-axis location in the `XData` array. `XData` can be either a matrix equal in size to all other data properties or for 2-D, a vector equal in length to the number of columns in `UData` or `VData`. That is, `length(XData) == size(UData,2)`.

If you do not specify `XData` (which is the input argument `X`), the `quiver` function uses the indices of `UData` to create the quiver graph. See the `XDataMode` property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the input argument `X`), the `quiver` function sets this property to `manual`.

If you set `XDataMode` to `auto` after having specified `XData`, the `quiver` function resets the  $x$  tick-mark labels to the indices of the `U`, `V`, and `W` data, overwriting any previous values.

## `XDataSource`

MATLAB variable, as a string

*Link `XData` to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatabasename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## `YData`

vector | matrix

*Y-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each  $y$ -axis location in the `YData` array. `YData` can be either a matrix equal in size to all other data properties or for 2-D, a vector equal in length to the number of rows in `UData` or `VData`. That is, `length(YData) == size(UData,1)`.

# Quivergroup Properties

---

If you do not specify `YData` (which is the input argument `Y`), the `quiver` function uses the indices of `VData` to create the quiver graph. See the `YDataMode` property for related information.

The input argument `Y` in the `quiver` function calling syntax assigns values to `YData`.

`YDataMode`  
{auto} | manual

*Use automatic or user-specified y-axis values.* If you specify `YData` (by setting the `YData` property or specifying the input argument `Y`), MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the `y` tick-mark labels to the indices of the `U`, `V`, and `W` data, overwriting any previous values.

`YDataSource`  
MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector | matrix

*Z-axis coordinates of arrows.* The `quiver` function draws an individual arrow at each *z*-axis location in the `ZData` array. `ZData` must be a matrix equal in size to `XData` and `YData`.

The input argument `Z` in the `quiver3` function calling syntax assigns values to `ZData`.

**Purpose** QZ factorization for generalized eigenvalues

**Syntax**  
 $[AA, BB, Q, Z] = \text{qz}(A, B)$   
 $[AA, BB, Q, Z, V, W] = \text{qz}(A, B)$   
 $\text{qz}(A, B, \text{flag})$

**Description** The `qz` function gives access to intermediate results in the computation of generalized eigenvalues.

$[AA, BB, Q, Z] = \text{qz}(A, B)$  for square matrices  $A$  and  $B$ , produces upper quasitriangular matrices  $AA$  and  $BB$ , and unitary matrices  $Q$  and  $Z$  such that  $Q^*A^*Z = AA$ , and  $Q^*B^*Z = BB$ . For complex matrices,  $AA$  and  $BB$  are triangular.

$[AA, BB, Q, Z, V, W] = \text{qz}(A, B)$  also produces matrices  $V$  and  $W$  whose columns are generalized eigenvectors.

$\text{qz}(A, B, \text{flag})$  for real matrices  $A$  and  $B$ , produces one of two decompositions depending on the value of `flag`:

'complex' Produces a possibly complex decomposition with a triangular  $AA$ . For compatibility with earlier versions, 'complex' is the default.

'real' Produces a real decomposition with a quasitriangular  $AA$ , containing 1-by-1 and 2-by-2 blocks on its diagonal.

If  $AA$  is triangular, the diagonal elements of  $AA$  and  $BB$ ,  $\alpha = \text{diag}(AA)$  and  $\beta = \text{diag}(BB)$ , are the generalized eigenvalues that satisfy

$$A * V * \beta = B * V * \alpha$$
$$\beta' * W' * A = \alpha' * W' * B$$

The eigenvalues produced by

$$\lambda = \text{eig}(A, B)$$

---

are the ratios of the  $\alpha$ s and  $\beta$ s.

$$\lambda = \alpha / \beta$$

If  $AA$  is not triangular, it is necessary to further reduce the 2-by-2 blocks to obtain the eigenvalues of the full system.

**See Also**

eig

# rand

---

**Purpose** Uniformly distributed pseudorandom numbers

**Syntax**

```
r = rand
r = rand(n)
r = rand(sz1, ..., szN)
r = rand(sz)

r = rand(classname)
r = rand(n,classname)
r = rand(sz1, ..., szN,classname)
r = rand(sz,classname)

r = rand('like',p)
r = rand(n,'like',p)
r = rand(sz1, ..., szN,'like',p)
r = rand(sz,'like',p)
```

**Description** `r = rand` returns a pseudorandom scalar drawn from the standard uniform distribution on the open interval (0,1).

`r = rand(n)` returns an n-by-n matrix of pseudorandom uniform values.

`r = rand(sz1, ..., szN)` returns a sz1-by-...-by-szN array of pseudorandom uniform values where `sz1, ..., szN` indicates the size of each dimension. For example, `rand(3,4)` returns a 3-by-4 array of pseudorandom values.

`r = rand(sz)` is an array of pseudorandom uniform values where the size vector, `sz`, defines `size(r)`. For example, `rand([3,4])` returns a 3-by-4 array of pseudorandom values.

---

**Note** The size inputs `sz1, ..., szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

---

`r = rand(classname)` returns a pseudorandom uniform value where the string, `classname`, specifies the data type. `classname` can be either 'single' or 'double'.

`r = rand(n,classname)` returns an `n`-by-`n` array of pseudorandom uniform values of data type `classname`.

`r = rand(sz1, ..., szN,classname)` returns a `sz1`-by-...-by-`szN` array of pseudorandom uniform values of data type `classname`.

`r = rand(sz,classname)` returns an array of pseudorandom uniform values where the size vector, `sz`, defines `size(r)` and `classname` defines `class(r)`.

`r = rand('like',p)` returns a pseudorandom uniform value of the same data type as the numeric variable, `p`.

`r = rand(n, 'like', p)` returns an `n`-by-`n` array of pseudorandom uniform values like `p`.

`r = rand(sz1, ..., szN, 'like', p)` returns a `sz1`-by-...-by-`szN` array of pseudorandom uniform values like `p`

`r = rand(sz, 'like', p)` returns an array of pseudorandom uniform values like `p` where the size vector, `sz`, defines `size(r)`.

# rand

---

The sequence of numbers produced by `rand` is determined by the internal settings of the uniform random number generator that underlies `rand`, `randi`, and `randn`. You can control that shared random number generator using `rng`.

---

**Note** Use the `rng` function instead of `rand` or `randn` with the `'seed'`, `'state'`, or `'twister'` inputs. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”

---

## Examples

### Example 1

Generate values from the uniform distribution on the interval `[a, b]`:

```
r = a + (b-a).*rand(100,1);
```

### Example 2

Use the `randi` function, instead of `rand`, to generate integer values from the uniform distribution on the set `1:100`:

```
r = randi(100,1,5);
```

### Example 3

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `rand` produces the same random numbers as if you restarted MATLAB:

```
rng('default')
rand(1,5)
ans =
 0.8147 0.9058 0.1270 0.9134 0.6324
```

### Example 4

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `rand`, restore the settings, and repeat those values:

```
s = rng;
u1 = rand(1,5)
u1 =
 0.0975 0.2785 0.5469 0.9575 0.9649

rng(s);
u2 = rand(1,5)
u2 =
 0.0975 0.2785 0.5469 0.9575 0.9649
```

u2 contains exactly the same values as u1.

### Example 5

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `rand` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
rng('shuffle');
rand(1,5);
```

# rand (RandStream)

---

**Purpose** Uniformly distributed random numbers

**Class** RandStream

**Syntax**

```
r = rand(s,n)
r = rand(s,m,n)
r = rand(s,[m,n])
r = rand(s,m,n,p,...)
r = rand(s,[m,n,p,...])
r = rand(s)
r = rand(s,size(A))
r = rand(..., 'double')
r = rand(..., 'single')
```

**Description**

`r = rand(s,n)` returns an  $n$ -by- $n$  matrix containing pseudorandom values drawn from the standard uniform distribution on the open interval  $(0,1)$ . The values are drawn from the random stream `s`.

`r = rand(s,m,n)` or `r = rand(s,[m,n])` returns an  $m$ -by- $n$  matrix.

`r = rand(s,m,n,p,...)` or `r = rand(s,[m,n,p,...])` returns an  $m$ -by- $n$ -by- $p$ -by-... array.

`r = rand(s)` returns a scalar.

`r = rand(s,size(A))` returns an array the same size as `A`.

`r = rand(..., 'double')` or `r = rand(..., 'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `rand` is determined by the internal state of the random number stream `s`. Resetting that stream to the same fixed state allows computations to be repeated. Setting

the stream to different states leads to unique computations, however, it does not improve any statistical properties.

randperm (RandStream)

# randi

---

**Purpose** Uniformly distributed pseudorandom integers

**Syntax**

```
r = randi(imax)
r = randi(imax,n)
r = randi(imax,sz1,...,szN)
r = randi(imax,sz)

r = randi(imax,classname)
r = randi(imax,n,classname)
r = randi(imax,sz1,...,szN,classname)
r = randi(imax,sz,classname)

r = randi(imax,'like',p)
r = randi(imax,n,'like',p)
r = randi(imax,sz1,...,szN,'like',p)
r = randi(imax,sz,'like',p)

r = randi([imin,imax], ___)
```

**Description** `r = randi(imax)` returns a pseudorandom scalar between 1 and `imax`. This is the same as `r = randi(imax,1)`.

`r = randi(imax,n)` returns an `n`-by-`n` matrix containing pseudorandom integers drawn from the discrete uniform distribution on the interval `[1,imax]`.

`r = randi(imax,sz1,...,szN)` returns a `sz1`-by-...-by-`szN` array of pseudorandom integers where `sz1,...,szN` indicates the size of each dimension. For example, `randi(10,3,4)` returns a 3-by-4 array of pseudorandom integers between 1 and 10.

`r = randi(imax,sz)` returns an array of pseudorandom integers where the size vector, `sz`, defines `size(r)`. For example, `randi(10,[3,4])` returns a 3-by-4 array of pseudorandom integers between 1 and 10.

---

**Note** The size inputs  $sz_1, \dots, sz_N$ , as well as the elements of the size vector  $sz$ , should be nonnegative integers. Negative integers are treated as 0.

---

$r = \text{randi}(\text{imax}, \text{classname})$  returns a pseudorandom integer where the string, `classname` specifies the data type. `classname` can be 'single', 'double', 'int8', 'uint8', 'int16', 'uint16', 'int32', or 'uint32'.

$r = \text{randi}(\text{imax}, n, \text{classname})$  returns an  $n$ -by- $n$  array of pseudorandom integers of data type `classname`.

$r = \text{randi}(\text{imax}, sz_1, \dots, sz_N, \text{classname})$  returns a  $sz_1$ -by- $\dots$ -by- $sz_N$  array of pseudorandom integers of data type `classname`.

$r = \text{randi}(\text{imax}, sz, \text{classname})$  returns an array of pseudorandom integers where the size vector, `sz`, defines `size(r)` and `classname` defines `class(r)`.

$r = \text{randi}(\text{imax}, \text{'like'}, p)$  returns a pseudorandom integer of the same data type as the numeric variable, `p`.

$r = \text{randi}(\text{imax}, n, \text{'like'}, p)$  returns an  $n$ -by- $n$  array of pseudorandom integers like `p`.

$r = \text{randi}(\text{imax}, sz_1, \dots, sz_N, \text{'like'}, p)$  returns a  $sz_1$ -by- $\dots$ -by- $sz_N$  array of pseudorandom integers like `p`.

$r = \text{randi}(\text{imax}, sz, \text{'like'}, p)$  returns an array of pseudorandom integers like `p` where the size vector, `sz`, defines `size(r)`.

`r = randi([imin,imax], ___)` returns an array containing integers drawn from the discrete uniform distribution on the interval `[imin,imax]` using any of the above syntaxes.

If you specify a distribution range using two numbers, `[imin,imax]`, both numbers must be integers that satisfy  $imin \leq imax$ . If you specify the range using only the upper bound, `imax`, it must be a positive integer (greater than zero).

The sequence of numbers produced by `randi` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. `randi` uses one uniform random value to create each integer random value. You can control that shared random number generator using `rng`.

## Examples

### Example 1

Generate a 100-by-1 array of integer values from the uniform distribution on the set 1:10:

```
r = randi(10,100,1);
```

### Example 2

Generate a 100-by-1 array of integers drawn uniformly from 1:10:

```
r = randi(10,100,1,'uint32');
```

### Example 3

Generate a 100-by-1 array of integer values drawn uniformly from -10:10:

```
r = randi([-10 10],100,1);
```

### Example 4

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `randi` produces the same random numbers as if you restarted MATLAB:

```
rng('default');
```

```
randi(10,1,5)

ans =
 9 10 2 10 7
```

### Example 5

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `randi`, restore the settings, and repeat those values:

```
s = rng;
i1 = randi(10,1,5)
i1 =
 1 3 6 10 10
rng(s);
i2 = randi(10,1,5)
i2 =
 1 3 6 10 10
```

`i2` contains exactly the same values as `i1`.

### Example 6

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `randi` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session:

```
rng('shuffle');
randi(10,1,5);
```

### Tips

- The arrays returned by `randi` might contain repeated integer values. This behavior is sometimes referred to as sampling with replacement. Use `randperm` if you require all unique values.

# randi

---

## **Related Examples**

- “Random Integers”

## **Concepts**

- “Class Support for Array-Creation Functions”

**Purpose** Uniformly distributed pseudorandom integers

**Class** RandStream

**Syntax**

```
r = randi(s,imax,n)
r = randi(s,imax,m,n)
r = randi(s,imax,[m,n])
r = randi(s,imax,m,n,p,...)
r = randi(s,imax,[m,n,p,...])
r = randi(s,imax)
r = randi(s,imax,size(A))
r = randi(s,[imin,imax],...)
r = randi(...,classname)
```

**Description** `r = randi(s,imax,n)` returns an n-by-n matrix containing pseudorandom integer values drawn from the discrete uniform distribution on `1:imax`. `randi` draws those values from the random stream `s`.

`r = randi(s,imax,m,n)` or `r = randi(s,imax,[m,n])` returns an m-by-n matrix.

`r = randi(s,imax,m,n,p,...)` or `r = randi(s,imax,[m,n,p,...])` returns an m-by-n-by-p-by-... array.

`r = randi(s,imax)` returns a scalar.

`r = randi(s,imax,size(A))` returns an array the same size as `A`.

`r = randi(s,[imin,imax],...)` returns an array containing integer values drawn from the discrete uniform distribution on `imin:imax`.

`r = randi(...,classname)` returns an array of integer values of class `classname`. `classname` does not support 64-bit integers.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

## randi (RandStream)

---

The arrays returned by `randi` might contain repeated integer values. This is sometimes referred to as sampling with replacement. To get unique integer values, sometimes referred to as sampling without replacement, use `randperm (RandStream)`.

The sequence of numbers produced by `randi` is determined by the internal state of the random stream `s`. `randi` uses one uniform value from `s` to generate each integer value. Resetting `s` to the same fixed state allows computations to be repeated. Setting the stream to different states leads to unique computations, however, it does not improve any statistical properties.

### See Also

`randi` | `RandStream` | `rand (RandStream)` | `randn (RandStream)` | `randperm (RandStream)`

**Purpose**

Normally distributed pseudorandom numbers

**Syntax**

```
r = randn
r = randn(n)
r = randn(sz1,...,szN)
r = randn(sz)

r = randn(classname)
r = randn(n,classname)
r = randn(sz1,...,szN,classname)
r = randn(sz,classname)

r = randn('like',p)
r = randn(n,'like',p)
r = randn(sz1,...,szN,'like',p)
r = randn(sz,'like',p)
```

**Description**

`r = randn` returns a pseudorandom scalar drawn from the standard normal distribution.

`r = randn(n)` returns an  $n$ -by- $n$  matrix containing pseudorandom normal values.

`r = randn(sz1,...,szN)` returns a  $sz1$ -by-...-by- $szN$  array of pseudorandom normal values where  $sz1, \dots, szN$  indicates the size of each dimension. For example, `randn(3,4)` returns a 3-by-4 array of pseudorandom values.

`r = randn(sz)` returns an array of pseudorandom normal values where the size vector, `sz`, defines `size(r)`. For example, `randn([3,4])` returns a 3-by-4 array of pseudorandom values.

---

**Note** The size inputs `sz1, ..., szN`, as well as the elements of the size vector `sz`, should be nonnegative integers. Negative integers are treated as 0.

---

`r = randn(classname)` returns a pseudorandom normal value where the string, `classname`, specifies the data type. `classname` can be either 'single' or 'double'.

`r = randn(n,classname)` returns an `n`-by-`n` array of pseudorandom normal values of data type `classname`.

`r = randn(sz1, ..., szN,classname)` returns a `sz1`-by-...-by-`szN` array of pseudorandom normal values of data type `classname`.

`r = randn(sz,classname)` returns an array of pseudorandom normal values where the size vector, `sz`, defines `size(r)` and `classname` defines `class(r)`.

`r = randn('like',p)` returns a pseudorandom normal value of the same data type as the numeric variable, `p`.

`r = randn(n, 'like', p)` returns an `n`-by-`n` array of pseudorandom normal values like `p`.

`r = randn(sz1, ..., szN, 'like', p)` returns a `sz1`-by-...-by-`szN` array of pseudorandom normal values like `p`

`r = randn(sz, 'like', p)` returns an array of pseudorandom normal values like `p` where the size vector, `sz`, defines `size(r)`.

The sequence of numbers produced by `randn` is determined by the settings of the uniform random number generator that underlies `rand`, `randn`, and `randi`. `randn` uses one or more uniform random values to create each normal random value. You can control that shared random number generator using `rng`.

---

**Note** Use the `rng` function instead of `rand` or `randn` with the 'seed', 'state', or 'twister' inputs. For more information, see “Replace Discouraged Syntaxes of `rand` and `randn`”

---

## Examples

### Example 1

Generate values from a normal distribution with mean 1 and standard deviation 2:

```
r = 1 + 2.*randn(100,1);
```

### Example 2

Generate values from a bivariate normal distribution with specified mean vector and covariance matrix:

```
mu = [1 2];
Sigma = [1 .5; .5 2]; R = chol(Sigma);
z = repmat(mu,100,1) + randn(100,2)*R;
```

### Example 3

Reset the random number generator used by `rand`, `randi`, and `randn` to its default startup settings, so that `randn` produces the same random numbers as if you restarted MATLAB:

```
rng('default');
randn(1,5)
ans =
 0.5377 1.8339 -2.2588 0.8622 0.3188
```

## Example 4

Save the settings for the random number generator used by `rand`, `randi`, and `randn`, generate 5 values from `randn`, restore the settings, and repeat those values:

```
s = rng;
z1 = randn(1,5)
z1 =
 -1.3077 -0.4336 0.3426 3.5784 2.7694
rng(s);
z2 = randn(1,5)
z2 =
 -1.3077 -0.4336 0.3426 3.5784 2.7694
```

`z2` contains exactly the same values as `z1`.

## Example 5

Reinitialize the random number generator used by `rand`, `randi`, and `randn` with a seed based on the current time. `randn` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session:

```
rng('shuffle');
randn(1,5)
```

## See Also

`rand` | `randi` | `rng` | `@RandStream` | `randn` (`RandStream`)

## Related Examples

- “Random Numbers from Normal Distribution with Specific Mean and Variance”

## Concepts

- “Class Support for Array-Creation Functions”

**Purpose** Normally distributed pseudorandom numbers

**Class** RandStream

**Syntax**

```
r = randn(s,m,n)
r = randn(s,[m,n])
r = randn(s,m,n,p,...)
r = randn(s,[m,n,p,...])
r = randn(s)
r = randn(s,size(A))
r = randn(...,'double')
r = randn(...,'single')
```

**Description**

`r = randn(s,n)` returns an n-by-n matrix containing pseudorandom values drawn from the standard normal distribution. `randn` draws those values from the random stream `s`.

`r = randn(s,m,n)` or `r = randn(s,[m,n])` returns an m-by-n matrix.

`r = randn(s,m,n,p,...)` or `r = randn(s,[m,n,p,...])` returns an m-by-n-by-p-by-... array.

`r = randn(s)` returns a scalar.

`r = randn(s,size(A))` returns an array the same size as `A`.

`r = randn(...,'double')` or `r = randn(...,'single')` returns an array of uniform values of the specified class.

---

**Note** The size inputs `m`, `n`, `p`, ... should be nonnegative integers. Negative integers are treated as 0.

---

The sequence of numbers produced by `randn` is determined by the internal state of the random stream `s`. `randn` uses one or more uniform values from `s` to generate each normal value. Resetting that stream to the same fixed state allows computations to be repeated. Setting the

## randn (RandStream)

---

stream to different states leads to unique computations, however, it does not improve any statistical properties.

### **See Also**

`randn` | `RandStream` | `rand (RandStream)` | `randi (RandStream)`

**Purpose** Random permutation

**Syntax**  
`p = randperm(n)`  
`p = randperm(n,k)`

**Description**  
`p = randperm(n)` returns a row vector containing a random permutation of the integers from 1 to *n* inclusive.  
`p = randperm(n,k)` returns a row vector containing *k* unique integers selected randomly from 1 to *n* inclusive.

**Tips**  
For `p = randperm(n,k)`, `p` contains *k* *unique* values. `randperm` performs *k*-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(n,1,k)`.  
`randperm` uses the same random number generator as `rand`, `randi`, and `randn`. You control this generator with `rng`.

**Examples**  
`randperm(6)`  
might be the vector  
`[3 2 6 4 1 5]`

or it might be some other permutation of the integers from 1 to 6, depending on the state of the random number generator. Two successive calls to `randperm` would in most cases return two different vectors:

```
randperm(6)
ans =
 5 2 6 4 1 3
```

```
randperm(6)
ans =
 4 1 6 2 3 5
```

---

# randperm

---

`randperm(6,3)`

might be the vector

`[4 2 5]`

or it might be some other permutation of any three integers from 1 to 6 inclusive, depending on the state of the random number generator.

## **See Also**

`permute` | `nchoosek` | `randi` | `randperm(RandStream)` | `perms` | `rng`

**Purpose** Random permutation

**Class** RandStream

**Syntax**  
`p = randperm(s,n)`  
`p = randperm(s,n,k)`

**Description** `p = randperm(s,n)` returns a row vector containing a random permutation of integers from 1 to *n* inclusive. `randperm(s,n)` uses random values drawn from the random stream *s*.

`p = randperm(s,n,k)` returns a row vector containing *k* unique integers selected randomly from 1 to *n* inclusive.

**Tips** For `p = randperm(s,n,k)`, *p* contains *k* *unique* values. `randperm` performs *k*-permutations (sampling without replacement). To allow repeated values in the output (sampling with replacement), use `randi(s,n,1,k)`.

**Examples** Create a random stream *s* and generate a random permutation of the integers from 1 to 6 based on *s*:

```
s = RandStream('mt19937ar','Seed',0);
randperm(s,6)
```

MATLAB returns the vector

```
[6 3 5 1 2 4]
```

Use the random stream *s* to generate three integers between 1 and 10:

```
randperm(s,10,3)
ans =
 1 8 9
```

**See Also** `permute` | `randperm` | `nchoosek` | `perms` | `rand` | `randi` (RandStream)

# RandStream

---

**Purpose** Random number stream

**Constructor** RandStream

**Description** Pseudorandom numbers in MATLAB come from one or more random number streams. The simplest way to generate arrays of random numbers is to use `rand`, `randn`, or `randi`. These functions all rely on the same stream of uniform random numbers, known as the *global stream*. You can create other streams that act separately from the global stream, and you can use their `rand`, `randi`, or `randn` methods to generate arrays of random numbers. You can also create a random number stream and make it the global stream.

To create a single random number stream, use the `RandStream` constructor. To create multiple independent random number streams, use `RandStream.create`. The `rng` function provides a simple interface to create a new global stream.

`stream = RandStream.getGlobalStream` returns the global random number stream, that is, the one currently used by the `rand`, `randi`, and `randn` functions.

`prevstream = RandStream.setGlobalStream(stream)` designates the random number stream `stream` as the new global stream to be used by the `rand`, `randi`, and `randn` functions, and returns the previous global stream.

A random number stream `s` has properties that control its behavior. Access or assign to a property using `p = s.Property` or `s.Property = p`. The following table lists defined properties:

## Properties

Property	Description
Type	(Read-only) Generator algorithm used by the stream. The list of possible generators is given by <code>RandStream.list</code> .
Seed	(Read-only) Seed value used to create the stream.
NumStreams	(Read-only) Number of streams in the group in which the current stream was created.
StreamIndex	(Read-only) Index of the current stream from among the group of streams with which it was created.
State	<p>Internal state of the generator. You should not depend on the format of this property. The value you assign to <code>S.State</code> must be a value read from <code>S.State</code> previously. Use <code>reset</code> to return a stream to a predictable state without having previously read from the <code>State</code> property.</p> <p>The sequence of random numbers produced by a random number stream <code>s</code> is determined by the internal state of its random number generator. Saving and restoring the generator's internal state with the <code>State</code> property allows you to reproduce a sequence of random numbers.</p>

# RandStream

---

Property	Description
Substream	Index of the substream to which the stream is currently set. The default is 1. Multiple substreams are not supported by all generator types; the multiplicative lagged Fibonacci generator ( <code>m1fg6331_64</code> ) and combined multiple recursive generator ( <code>mrg32k3a</code> ) support substreams.
NormalTransform	Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.
Antithetic	Logical value indicating whether <code>S</code> generates antithetic pseudorandom values, that is, the usual values subtracted from 1. The default is false.
FullPrecision	Logical value indicating whether <code>S</code> generates values using its full precision. Some generators can create pseudorandom values faster, but with fewer random bits, if <code>FullPrecision</code> is false. The default is true.

## Methods

Method	Description
<code>RandStream</code>	Create a random number stream.
<code>RandStream.create</code>	Create multiple independent random number streams.
<code>get</code>	Get the properties of a random stream object.

Method	Description
list	List available random number generator algorithms.
set	Set random stream property.
RandStream.getGlobalStream	Get the global random number stream.
RandStream.setGlobalStream	Set global random number stream.
reset	Reset a stream to its initial internal state
rand	Pseudorandom numbers from a uniform distribution
randn	Pseudorandom numbers from a standard normal distribution
randi	Pseudorandom integers from a uniform discrete distribution
randperm	Random permutation of a set of values

## Examples

### Example 1

Create a single stream and designate it as the current global stream:

```
s = RandStream('mt19937ar','Seed',1);
RandStream.setGlobalStream(s);
```

### Example 2

Create three independent streams:

```
[s1,s2,s3] = RandStream.create('mrg32k3a','NumStreams',3);
r1 = rand(s1,100000,1);
r2 = rand(s2,100000,1);
r3 = rand(s3,100000,1);
corrcoef([r1,r2,r3])
```

## Example 3

Create only one stream from a set of three independent streams, and designate it as the current global stream:

```
s2 = RandStream.create('mrg32k3a','NumStreams',3,...
 'StreamIndices',2);
RandStream.setGlobalStream(s2);
```

## Example 4

Reset the global random number stream that underlies `rand`, `randi`, and `randn` back to its beginning, to reproduce previous results:

```
stream = RandStream.getGlobalStream;
reset(stream);
```

## Example 5

Save and restore the current global stream's state to reproduce the output of `rand`:

```
stream = RandStream.getGlobalStream;
savedState = stream.State;
u1 = rand(1,5)
u1 =
 0.8147 0.9058 0.1270 0.9134 0.6324

stream.State = savedState;
u2 = rand(1,5)
u2 =
 0.8147 0.9058 0.1270 0.9134 0.6324
```

`u2` contains exactly the same values as `u1`.

## Example 6

Reset the global random number stream to its initial settings. This causes `rand`, `randi`, and `randn` to start over, as if in a new MATLAB session:

```
s = RandStream('mt19937ar','Seed',0);
```

```
RandStream.setGlobalStream(s);
```

## Example 7

Reinitialize the global random number stream using a seed based on the current time. This causes `rand`, `randi`, and `randn` to return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

## Example 8

Change the transformation algorithm that `randn` uses to create normal pseudorandom values from uniform values. This does not replace or reset the global stream.

```
stream = RandStream.getGlobalStream;
stream.NormalTransform = 'inversion'
```

## See Also

# RandStream constructor

---

**Purpose** Random number stream

**Class** RandStream

**Syntax**  
`s = RandStream('gentype')`  
`s = RandStream('gentype',Name,Value)`

**Description** `s = RandStream('gentype')` creates a random number stream that uses the uniform pseudorandom number generator algorithm specified by `gentype`. `RandStream.list` returns all possible values for `gentype`, or see “Choosing a Random Number Generator” for details on generator algorithms.

`s = RandStream('gentype',Name,Value)` allows you to specify one or more optional `Name,Value` pairs to control creation of the stream.

Once you have created a random, you can use `RandStream.setGlobalStream` to make it the global stream, so that the functions `rand`, `randi`, and `randn` draw values from it.

Parameters for `RandStream` are:

Parameter	Description
Seed	Nonnegative scalar integer with which to initialize all streams. Seeds must be an integer between 0 and $2^{32} - 1$ or 'shuffle' to create a seed based on the current time. Default is 0.
NormalTransform	Transformation algorithm used by <code>randn(s, ...)</code> to generate normal pseudorandom values. Possible values are 'Ziggurat', 'Polar', or 'Inversion'.

## Examples

### Example 1

Create a random number stream, make it the global stream, and save and restore its state to reproduce the output of `randn`:

```
s = RandStream('mrg32k3a');
RandStream.setGlobalStream(s);
savedState = s.State;
z1 = randn(1,5)
z1 =
 -0.1894 -1.4426 -0.3592 0.8883 -0.4337
s.State = savedState;
z2 = randn(1,5)
z2 =
 -0.1894 -1.4426 -0.3592 0.8883 -0.4337
```

`z2` contains exactly the same values as `z1`.

### Example 2

Return `rand`, `randi`, and `randn` to their default startup settings:

```
s = RandStream('mt19937ar','Seed',0)
RandStream.setGlobalStream(s);
```

### Example 3

Replace the current global random number stream with a stream whose seed is based on the current time, so `rand`, `randi`, and `randn` will return different values in different MATLAB sessions. It is usually not desirable to do this more than once per MATLAB session as it may affect the statistical properties of the random numbers MATLAB produces:

```
s = RandStream('mt19937ar','Seed','shuffle');
RandStream.setGlobalStream(s);
```

## Tips

- Streams created using `RandStream` might not be independent from each other. Use `RandStream.create` to create multiple streams that are independent.

# RandStream constructor

# rat

---

**Purpose** Rational fraction approximation

**Syntax**  
`R = rat(X)`  
`R = rat(X,tol)`

`[N,D] = rat( ___ )`

**Description** `R = rat(X)` returns the rational fraction approximation of `X` to within the default tolerance,  $1e-6 \cdot \text{norm}(X(:), 1)$ . The approximation is a string containing the truncated continued fractional expansion.

`R = rat(X,tol)` approximates `X` to within the tolerance, `tol`.

`[N,D] = rat( ___ )` returns two arrays, `N` and `D`, such that `N./D` approximates `X`, using any of the above syntaxes.

## Input Arguments

### **X - Input array**

numeric array

Input array, specified as a numeric array of class `single` or `double`.

### **Data Types**

`single` | `double`

**Complex Number Support:** Yes

### **tol - Tolerance**

scalar

Tolerance, specified as a scalar. `N` and `D` approximate `X`, such that  $N./D - X < \text{tol}$ . The default tolerance is  $1e-6 \cdot \text{norm}(X(:), 1)$ .

## Output Arguments

### **R - Continued fraction**

string

Continued fraction, returned as a string. The accuracy of the rational approximation via continued fractions increases with the number of terms.

**N - Numerator**

numeric array

Numerator, returned as a numeric array. N./D approximates X.

**D - Denominator**

numeric array

Denominator, returned as a numeric array. N./D approximates X.

**Examples****Approximate Value of**

Approximate the value of  $\pi$  using a rational representation of the quantity pi.

The mathematical quantity  $\pi$  is not a rational number, but the quantity pi that approximates it is a rational number since all floating-point numbers are rational.

Find the rational representation of pi.

```
format rat
pi
```

```
ans =
```

```
355/113
```

The resulting expression is a string. You also can use `rats(pi)` to get the same answer.

Use `rat` to see the continued fractional expansion of pi.

```
R = rat(pi)
```

```
R =
```

```
3 + 1/(7 + 1/(16))
```

The resulting string is an approximation by continued fractional expansion. If you consider the first two terms of the expansion, you get

the approximation  $3 + \frac{1}{7} = \frac{22}{7}$ , which only agrees with pi to 2 decimals.

However, if you consider all three terms printed by rat, you can recover the value 355/113, which agrees with pi to 6 decimals.

$$3 + \frac{1}{7 + \frac{1}{16}} = \frac{355}{113}.$$

Specify a tolerance for additional accuracy in the approximation.

```
R = rat(pi,1e-7)
```

```
R =
```

```
3 + 1/(7 + 1/(16 + 1/(-294)))
```

The resulting approximation, 104348/33215, agrees with pi to 9 decimals.

### **Express Array Elements as Ratios**

Create a 4-by-4 matrix.

```
format short;
X = hilb(4)
```

```
X =
```

```
 1.0000 0.5000 0.3333 0.2500
 0.5000 0.3333 0.2500 0.2000
 0.3333 0.2500 0.2000 0.1667
 0.2500 0.2000 0.1667 0.1429
```

Express the elements of X as ratios of small integers using rat.

```
[N,D] = rat(X)
```

```
N =
```

```

1 1 1 1
1 1 1 1
1 1 1 1
1 1 1 1
```

```
D =
```

```

1 2 3 4
2 3 4 5
3 4 5 6
4 5 6 7
```

The two matrices, N and D, approximate X with  $N./D$ .

View the elements of X as ratios using `format rat`.

```
format rat
```

```
X
```

```
X =
```

```

1 1/2 1/3 1/4
1/2 1/3 1/4 1/5
1/3 1/4 1/5 1/6
1/4 1/5 1/6 1/7
```

In this form, it is clear that N contains the numerators of each fraction and D contains the denominators.

## Algorithms

Even though all floating-point numbers are rational numbers, it is sometimes desirable to approximate them by simple rational numbers, which are fractions whose numerator and denominator are

small integers. Rational approximations are generated by truncating continued fraction expansions.

The `rat` function approximates each element of `X` by a continued fraction of the form

$$\frac{N}{D} = D_1 + \frac{1}{D_2 + \frac{1}{\left( D_3 + \dots + \frac{1}{D_k} \right)}}$$

The  $D_s$  are obtained by repeatedly picking off the integer part and then taking the reciprocal of the fractional part. The accuracy of the approximation increases exponentially with the number of terms and is worst when  $X = \text{sqrt}(2)$ . For  $X = \text{sqrt}(2)$ , the error with  $k$  terms is about  $2.68 * (.173)^k$ , so each additional term increases the accuracy by less than one decimal digit. It takes 21 terms to get full floating-point accuracy.

## See Also

`rats` | `format`

**Purpose**

Rational output

**Syntax**

```
S = rats(X)
S = rats(X, strlen)
```

**Description**

`S = rats(X)` returns a string containing the rational approximations to the elements of `X` using the default string length of 13. The rational output is the same as that produced by `format rat`.

`rats` returns asterisks for elements that cannot be printed in the allotted space, but which are not negligible compared to the other elements in `X`.

`S = rats(X, strlen)` returns a string of length `strlen`. The rational approximation uses a tolerance that is inversely proportional to string length.

**Input Arguments****X - Input array**

numeric array

Input array, specified as a numeric array of class `single` or `double`.

**Data Types**

`single` | `double`

**strlen - String length**

positive integer

String length, specified as a positive integer. The default string length is 13, which allows for 6 elements in 78 spaces.

**Output Arguments****S - Rational output**

string

Rational output, returned as a string.

## Examples

### Rational Representation of Matrix

Create a 4-by-4 matrix.

```
format short
X = hilb(4)
```

X =

1.0000	0.5000	0.3333	0.2500
0.5000	0.3333	0.2500	0.2000
0.3333	0.2500	0.2000	0.1667
0.2500	0.2000	0.1667	0.1429

View the rational representation of the matrix using rats.

```
R = rats(X)
```

R =

1	1/2	1/3	1/4
1/2	1/3	1/4	1/5
1/3	1/4	1/5	1/6
1/4	1/5	1/6	1/7

The result is the same as using `format rat`.

### Adjust Output String Length

Find the rational representation of pi with the default string length and approximation tolerance.

```
rats(pi)
```

ans =

```
355/113
```

The result is the same as using `format rat`.

---

Adjust the string length of the output, which also adjusts the approximation tolerance.

```
rats(pi,20)

ans =

 104348/33215
```

The resulting rational approximation has greater accuracy. As the string length increases, the tolerance decreases.

Adjust the string length again to achieve greater accuracy.

```
rats(pi,25)

ans =

 1146408/364913
```

The resulting approximation agrees with pi to 10 decimal places.

## Algorithms

The format `rat` command uses the same internal algorithm, with the default `strlen`, as `rats`.

`rats` obtains rational approximations with  $[N,D] = \text{rat}(X, \text{tol})$ , where  $\text{tol}$  is  $\min(10^{-(\text{strlen}-1)/2} * \text{norm}(X(\text{isfinite}(X)), 1), .1)$ . Thus, the tolerance is inversely proportional to the string length, `strlen`.

## See Also

`rat` | `format`

# rbbox

---

**Purpose** Create rubberband box for area selection

**Syntax**

```
rbbox
rbbox(initialRect)
rbbox(initialRect, fixedPoint)
rbbox(initialRect, fixedPoint, stepSize)
finalRect = rbbox(...)
```

**Description** `rbbox` initializes and tracks a rubberband box in the current figure. It sets the initial rectangular size of the box to 0, anchors the box at the figure's `CurrentPoint`, and begins tracking from this point.

`rbbox(initialRect)` specifies the initial location and size of the rubberband box as `[x y width height]`, where `x` and `y` define the lower left corner, and `width` and `height` define the size. `initialRect` is in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. The corner of the box closest to the pointer position follows the pointer until `rbbox` receives a button-up event.

`rbbox(initialRect, fixedPoint)` specifies the corner of the box that remains fixed. All arguments are in the units specified by the current figure's `Units` property, and measured from the lower left corner of the figure window. `fixedPoint` is a two-element vector, `[x y]`. The tracking point is the corner diametrically opposite the anchored corner defined by `fixedPoint`.

`rbbox(initialRect, fixedPoint, stepSize)` specifies how frequently the rubberband box is updated. When the tracking point exceeds `stepSize` figure units, `rbbox` redraws the rubberband box. The default stepsize is 1.

`finalRect = rbbox(...)` returns a four-element vector, `[x y width height]`, where `x` and `y` are the `x` and `y` components of the lower left corner of the box, and `width` and `height` are the dimensions of the box.

**Tips**

rbbox is useful for defining and resizing a rectangular region:

- For box definition, `initialRect` is `[x y 0 0]`, where `(x,y)` is the figure's `CurrentPoint`.
- For box resizing, `initialRect` defines the rectangular region that you resize (e.g., a legend). `fixedPoint` is the corner diametrically opposite the tracking point.

rbbox returns immediately if a button is not currently pressed. Therefore, you use rbbox with `waitforbuttonpress` so that the mouse button is down when rbbox is called. rbbox returns when you release the mouse button.

**Examples**

Assuming the current view is `view(2)`, use the current axes' `CurrentPoint` property to determine the extent of the rectangle in dataspace units:

```
f = figure;
a = axes('Parent',f);
k = waitforbuttonpress;
point1 = get(a,'CurrentPoint'); % button down detected
finalRect = rbbox; % return figure units

# rcond

---

<b>Purpose</b>	Reciprocal condition number
<b>Syntax</b>	<code>C = rcond(A)</code>
<b>Description</b>	<code>C = rcond(A)</code> returns an estimate for the reciprocal condition of A in 1-norm. If A is well conditioned, <code>rcond(A)</code> is near 1.0. If A is badly conditioned, <code>rcond(A)</code> is near 0.
<b>Input Arguments</b>	<b>A - Input matrix</b> square numeric matrix  Input matrix, specified as a square numeric matrix.  <b>Data Types</b> single   double
<b>Output Arguments</b>	<b>C - Reciprocal condition number</b> scalar  Reciprocal condition number, returned as a scalar. The data type of C is the same as A.  The reciprocal condition number is a scale-invariant measure of how close a given matrix is to the set of singular matrices. <ul style="list-style-type: none"><li>• If C is near 0, the matrix is nearly singular and badly conditioned.</li><li>• If C is near 1.0, the matrix is well conditioned.</li></ul>
<b>Examples</b>	<b>Sensitivity of Badly Conditioned Matrix</b>  Examine the sensitivity of a badly conditioned matrix.  A notable matrix that is symmetric and positive definite, but badly conditioned, is the Hilbert matrix. The elements of the Hilbert matrix are $H(i,j) = 1/(i + j - 1)$ .  Create a 10-by-10 Hilbert matrix.  <code>A = hilb(10);</code>

Find the reciprocal condition number of the matrix.

```
C = rcond(A)
```

```
C =
```

```
2.8286e-14
```

The reciprocal condition number is small, so  $A$  is badly conditioned.

The condition of  $A$  has an effect on the solutions of similar linear systems of equations. To see this, compare the solution of  $Ax = b$  to that of the perturbed system,  $Ax = b + 0.01$ .

Create a column vector of ones and solve  $Ax = b$ .

```
b = ones(10,1);
```

```
x = A\b;
```

Now change  $b$  by 0.01 and solve the perturbed system.

```
b1 = b + 0.01;
```

```
x1 = A\b1;
```

Compare the solutions,  $x$  and  $x1$ .

```
norm(x-x1)
```

```
ans =
```

```
1.1250e+05
```

Since  $A$  is badly conditioned, a small change in  $b$  produces a very large change (on the order of  $1e5$ ) in the solution to  $x = A \setminus b$ . The system is sensitive to perturbations.

### Find Condition of Identity Matrix

Examine why the reciprocal condition number is a more accurate measure of singularity than the determinant.

Create a 5-by-5 multiple of the identity matrix.

```
A = eye(5)*0.01;
```

This matrix is full rank and has five equal singular values, which you can confirm by calculating `svd(A)`.

Calculate the determinant of A.

```
det(A)
```

```
ans =
```

```
1.0000e-10
```

Although the determinant of the matrix is close to zero, A is actually very well conditioned and *not* close to being singular.

Calculate the reciprocal condition number of A.

```
rcond(A)
```

```
ans =
```

```
1
```

The matrix has a reciprocal condition number of 1 and is, therefore, very well conditioned. Use `rcond(A)` or `cond(A)` rather than `det(A)` to confirm singularity of a matrix.

## Tips

- `rcond` is a more efficient but less reliable method of estimating the condition of a matrix compared to the condition number, `cond`.

## See Also

`cond` | `condest` | `norm` | `normest` | `rank` | `svd`

<b>Purpose</b>	Right array division
<b>Syntax</b>	$x = A ./ B$ <code>x = rdivide(A,B)</code>
<b>Description</b>	<p><math>x = A ./ B</math> divides each element of <i>A</i> by the corresponding element of <i>B</i>. Inputs <i>A</i> and <i>B</i> must have the same size unless one is a scalar value. A scalar value is expanded into an array of the same size as the other input.</p> <p><code>x = rdivide(A,B)</code> is an alternative way to divide <i>A</i> by <i>B</i>, but is rarely used. It enables operator overloading for classes.</p>
<b>Input Arguments</b>	<p><b>A - Numerator</b> numeric array   sparse numeric array</p> <p>Numerator, specified as a full or sparse numeric array. If <i>B</i> is an integer data type, <i>A</i> must be the same integer type or a scalar double.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>Complex Number Support:</b> Yes</p> <p><b>B - Denominator</b> numeric array   sparse numeric array</p> <p>Denominator, specified as a full or sparse numeric array. If <i>A</i> is an integer data type, <i>B</i> must be the same integer type or a scalar double.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64</p> <p><b>Complex Number Support:</b> Yes</p>

# rdivide, ./

---

## Output Arguments

### x - Solution

numeric array | sparse numeric array

Solution, returned as a full or sparse numeric array. If either A or B is an integer data type, then x is that same integer data type.

## Examples

### Divide Two Numeric Arrays

Create two numeric arrays, A and B, and divide the second array, B, into the first, A.

```
A = [2 4 6 8; 3 5 7 9];
B = 10*ones(2,4);
x = A./B
```

x =

```
 0.2000 0.4000 0.6000 0.8000
 0.3000 0.5000 0.7000 0.9000
```

### Integer Division

Divide an int16 scalar value by each element of an int16 vector.

```
a = int16(10);
b = int16([3 4 6]);
x = a./b
```

x =

```
 3 3 2
```

MATLAB rounds the results when dividing integer data types.

### Divide Scalar by Array

Create an array and divide it into a scalar.

```
C = 5;
D = magic(3);
```

```
x = C./D
```

```
x =
```

```
 0.6250 5.0000 0.8333
 1.6667 1.0000 0.7143
 1.2500 0.5556 2.5000
```

When you specify a scalar value to be divided by an array, the scalar value expands into an array of the same size, then element-by-element division is performed.

## Tips

- When dividing integers, use `idivide` for more rounding options.
- MATLAB does not support complex integer division.

## See Also

# VideoReader.read

---

**Purpose** Read video frame data from file

**Syntax**

```
video = read(obj)
video = read(obj,index)
video = read(__,'native')
```

**Description**

`video = read(obj)` reads in all video frames from the file associated with `obj`. The `read` method returns a H-by-W-by-B-by-F matrix, `video`, where H is the image frame height, W is the image frame width, B is the number of bands in the image (for example, 3 for RGB), and F is the number of frames read.

`video = read(obj,index)` reads only the specified frames. `index` can be a single number or a two-element array representing an index range of the video stream.

`video = read(__,'native')` returns data in the format specified by the `VideoFormat` property, and can include any of the input arguments in the previous syntaxes.

## Input Arguments

### **obj**

Name of multimedia object created with `VideoReader`.

### **index**

Frames to read, where the first frame number is 1. Use `Inf` to represent the last frame of the file.

For example:

```
video = read(obj, 1); % first frame only
video = read(obj, [1 10]); % first 10 frames
video = read(obj, Inf); % last frame only
video = read(obj, [50 Inf]); % frame 50 thru end
```

MATLAB cannot determine the number of frames in a variable frame rate file until you read the last frame. If the requested *index* extends beyond the end of the file, `read` returns either a

warning or an error. For more information, see “Read Variable Frame Rate Video”.

**Default:** [1 Inf]

## Output Arguments

### video

Array of data representing video frames, returned in a format dependent on the VideoFormat property of obj. For most files, the data type and dimensions of video are as follows. Note that when the VideoFormat property of obj is 'Indexed', the data type and dimensions of video depend on whether you call read with the 'native' argument.

Value of obj.VideoFormat	Data Type of video	Dimensions of video	Description
'RGB24'	uint8	H-by-W-by-3-by-F	RGB24 image
'Grayscale', without specifying 'native'	uint8	H-by-W-by-1-by-F	Grayscale image
'Indexed', without specifying 'native'	uint8	H-by-W-by-3-by-F	RGB24 image
'Grayscale' or 'Indexed', specifying 'native'	struct	1-by-F	MATLAB movie, which is an array of frame structure arrays, each containing the fields cdata and colormap.

# VideoReader.read

---

H is the image frame height, W is the image frame width, and F is the number of frames read.

For Motion JPEG 2000 files, the data type and dimensions of video are as follows.

Value of obj.VideoFormat	Data Type of video	Dimensions of video	Description
'Mono8'	uint8	H-by-W-by-1-by-F	Mono image
'Mono8 Signed'	int8	H-by-W-by-1-by-F	Mono signed image
'Mono16'	uint16	H-by-W-by-1-by-F	Mono image
'Mono16 Signed'	int16	H-by-W-by-1-by-F	Mono signed image
'RGB24'	uint8	H-by-W-by-3-by-F	RGB24 image
'RGB24 Signed'	uint8	H-by-W-by-3-by-F	RGB24 signed image
'RGB48'	uint16	H-by-W-by-3-by-F	RGB48 image
'RGB48 Signed'	int16	H-by-W-by-3-by-F	RGB48 signed image

## Examples

### Read and Play Back Movie File

Read and play back the movie file xylophone.mp4.

```
xyloObj = VideoReader('xylophone.mp4');
```

```
nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;
```

Preallocate the movie structure.

```
mov(1:nFrames) = ...
```

```
struct('cdata',zeros(vidHeight,vidWidth, 3,'uint8'),...
 'colormap',[]);
```

Read one frame at a time.

```
for k = 1 : nFrames
 mov(k).cdata = read(xyloObj,k);
end
```

Size a figure based on the video's width and height.

```
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])
```

Play back the movie once at the video's frame rate.

```
movie(hf, mov, 1, xyloObj.FrameRate);
```

## How To

- [“Read Video Files”](#)

# Tiff.read

---

**Purpose** Read entire image

**Syntax**  
`imageData = tiffobj.read()`  
`[Y,Cb,Cr] = tiffobj.read()`

**Description** `imageData = tiffobj.read()` reads the image data from the current image file directory (IFD) in the TIFF file associated with the `Tiff` object, `tiffobj`.

`[Y,Cb,Cr] = tiffobj.read()` reads the YCbCr component data from the current directory in the TIFF file. Depending upon the values of the `YCbCrSubSampling` tag, the size of the Cb and Cr channels might differ from the Y channel.

**Examples** Open a `Tiff` object and read data from the TIFF file:

```
t = Tiff('example.tif','r');
imageData = t.read();
t.close();
```

**See Also** `Tiff.write` | `imread`

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

<b>Purpose</b>	Read data asynchronously from device
<b>Syntax</b>	<code>readasync(obj)</code> <code>readasync(obj, size)</code>
<b>Description</b>	<p><code>readasync(obj)</code> initiates an asynchronous read operation on the serial port object, <code>obj</code>.</p> <p><code>readasync(obj, size)</code> asynchronously reads, at most, the number of bytes given by <code>size</code>. If <code>size</code> is greater than the difference between the <code>InputBufferSize</code> property value and the <code>BytesAvailable</code> property value, an error is returned.</p>
<b>Tips</b>	<p>Before you can read data, you must connect <code>obj</code> to the device with the <code>open</code> function. A connected serial port object has a <code>Status</code> property value of <code>open</code>. An error is returned if you attempt to perform a read operation while <code>obj</code> is not connected to the device.</p> <p>Only use <code>readasync</code> to configure the <code>ReadAsyncMode</code> property to <code>manual</code>. <code>readasync</code> is ignored if used when <code>ReadAsyncMode</code> is <code>continuous</code>.</p> <p>The <code>TransferStatus</code> property indicates if an asynchronous read or write operation is in progress. You can write data while an asynchronous read is in progress because serial ports have separate read and write pins. You can stop asynchronous read and write operations with the <code>stopasync</code> function.</p> <p>You can monitor the amount of data stored in the input buffer with the <code>BytesAvailable</code> property. Additionally, you can use the <code>BytesAvailableFcn</code> property to execute a callback function when the terminator or the specified amount of data is read.</p> <p><b>Rules for Completing an Asynchronous Read Operation</b></p> <p>An asynchronous read operation with <code>readasync</code> completes when one of these conditions is met:</p> <ul style="list-style-type: none"><li>• The terminator specified by the <code>Terminator</code> property is read.</li><li>• The time specified by the <code>Timeout</code> property passes.</li></ul>

# readasync

---

- The specified number of bytes is read.
- The input buffer is filled (if size is not specified).

Because `readasync` checks for the terminator, this function can be slow. To increase speed, you might want to configure `ReadAsyncMode` to `continuous` and continuously return data to the input buffer as soon as it is available from the device.

## Examples

This example creates the serial port object `s` on a Windows platform. It connects `s` to a Tektronix TDS 210 oscilloscope, configures `s` to read data asynchronously only if `readasync` is issued, and configures the instrument to return the peak-to-peak value of the signal on channel 1.

```
s = serial('COM1');
fopen(s)
s.ReadAsyncMode = 'manual';
fprintf(s, 'Measurement:Meas1:Source CH1')
fprintf(s, 'Measurement:Meas1:Type Pk2Pk')
fprintf(s, 'Measurement:Meas1:Value?')
```

Begin reading data asynchronously from the instrument using `readasync`. When the read operation is complete, return the data to the MATLAB workspace using `fscanf`.

```
readasync(s)
s.BytesAvailable

ans =
 15

out = fscanf(s)

out =
2.03999999619E0

fclose(s)
```

# Tiff.readEncodedStrip

---

**Purpose** Read data from specified strip

**Syntax**  
`stripData = tiffobj.readEncodedStrip(stripNumber)`  
`[Y,Cb,Cr] = tiffobj.readEncodedStrip(stripNumber)`

**Description** `stripData = tiffobj.readEncodedStrip(stripNumber)` reads data from the strip specified by `stripNumber`. Strip numbers are one-based numbers.

`[Y,Cb,Cr] = tiffobj.readEncodedStrip(stripNumber)` reads YCbCr component data from the specified strip. The size of the chrominance components Cb and Cr might differ from the size of the luminance component Y depending on the value of the YCbCrSubSampling tag.

`readEncodeStrip` clips the last strip, if the strip extends past the `ImageLength` boundary.

## Examples **Read a Strip**

Read the first strip in the second image of a TIFF file.

Create a Tiff object associated with the example file, `example.tif`, and make the second image the current directory.

```
t = Tiff('example.tif','r');
t.setDirectory(2);
```

Read the data in the first strip. Then, close the Tiff object.

```
data = t.readEncodedStrip(1);
t.close();
```

**References** This method corresponds to the `TIFFReadEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# Tiff.readEncodedTile

---

**Purpose** Read data from specified tile

**Syntax**  
`tileData = tiffobj.readEncodedTile(tileNumber)`  
`[Y,Cb,Cr] = tiffobj.readEncodedTile(tileNumber)`

**Description**  
`tileData = tiffobj.readEncodedTile(tileNumber)` reads data from the tile specified by `tileNumber`. Tile numbers are one-based numbers.  
`[Y,Cb,Cr] = tiffobj.readEncodedTile(tileNumber)` reads YCbCr component data from the specified tile. The size of the chrominance components Cb and Cr might differ from the size of the luminance component Y, depending on the value of the YCbCrSubSampling tag.  
`readEncodedTile` clips tiles on the last row or right-most column of an image if the tile extends past the `ImageLength` and `ImageLength` boundaries.

## Examples **Read a Tile**

Create a Tiff object associated with the example file, `example.tif`. Then, read the first tile of data.

```
t = Tiff('example.tif','r');
data = t.readEncodedTile(1);
t.close();
```

## References

This method corresponds to the `TIFFReadEncodedTile` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

`Tiff.readRGBATile` | `Tiff.readRGBAImage`

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Read tile data using RGBA interface

**Syntax** `[RGB,alpha] = readRGBATile(row,col)`

**Description** `[RGB,alpha] = readRGBATile(row,col)` reads a tile using the RGBA interface. `row` and `col` are the one-based row and column numbers of any pixel in the requested tile. `RGB` consists of an `m`-by-`n`-by-3 colormetric image, where `m` and `n` are the height and width of the tile, respectively. `alpha` is the associated alpha matting. If the image does not have associated alpha matting, then `alpha` is a matrix with all values set to 255 (transparent).

The tile is clipped if the tile boundaries extend past the edges of the image.

The pixel values may be transformed depending upon the values of the following tags:

PhotometricInterpretation

BitsPerSample

SamplesPerPixel

Orientation

ExtraSamples

ColorMap

**Examples** Open a Tiff object and read the first tile using the RGBA interface.

```
t = Tiff('example.tif','r');
t.setDirectory(1);
[RGB,A] = t.readRGBATile(1,1);
t.close();
```

**References** This method corresponds to the `TIFFReadRGBATile` function in the LibTIFF C API.

## Purpose

Create timeseries object

## Description

Time series are data vectors sampled over time, in order, often at regular intervals. They are distinguished from randomly sampled data that form the basis of many other data analyses. Time series represent the time-evolution of a dynamic population or process. The linear ordering of time series gives them a distinctive place in data analysis, with a specialized set of techniques. Time series analysis is concerned with:

- Identifying patterns
- Modeling patterns
- Forecasting values

## Construction

`ts = timeseries` creates an empty time-series object.

`ts = timeseries(tsname)` creates an empty time-series object using the name, `tsname`, for the time-series object. This name can differ from the time-series variable name.

`ts = timeseries(data)` creates the time-series object using the specified data.

`ts = timeseries(data,time)` creates the time-series object using the specified data and time.

`ts = timeseries(data,time,quality)` specifies quality in terms of codes defined by `QualityInfo.Code`.

`ts = timeseries(data,'Name',tsname)` creates the time-series object using the specified data and the name, `tsname`.

`ts = timeseries(data,time,'Name',tsname)` creates the time-series object using the specified data, time, and the name, `tsname`.

`ts = timeseries(data,time,quality,'Name',tsname)` uses the specified quality and the name, `tsname`.

## Input Arguments

### data

The time-series data, which can be an array of samples

### tsname

Time-series name specified as a string

**Default:** ''

### time

The time vector.

When time values are date strings, you must specify `Time` as a cell array of date strings. When the time vector contains duplicate values:

- Duplicated values must occupy contiguous elements.
- Time values must not be decreasing.

Interpolating time-series data using methods like `resample` and `synchronize` can produce different results depending on whether the input `timeseries` contains duplicate times.

**Default:** A time vector that ranges from 0 to N-1 with a 1-second interval, where N is the number of samples.

### quality

An integer vector with values -128 to 127 that specifies the quality in terms of codes defined by `QualityInfo.Code`

When `Quality` is a vector:

- `Quality` must have the same length as the time vector.
- Each `Quality` value applies to the corresponding data sample.

When `Quality` is an array:

- `Quality` must have the same size as the data array.
- Each `Quality` value applies to the corresponding data value of the `ts.data` array.

## Properties

### Data

Time-series data, where each data sample corresponds to a specific time

The data can be a scalar, a vector, or a multidimensional array. Either the first or last dimension of the data must align with `Time`.

By default, NaNs represent missing or unspecified data. Set the `TreatNaNasMissing` property to determine how missing data is treated in calculations.

#### Attributes:

Dependent	true
-----------	------

### DataInfo

Contains fields for storing contextual information about `Data`:

- `Unit` — String that specifies data units
- `Interpolation` — A `tsdata.interpolation` object that specifies the interpolation method for this `timeseries` object.

Fields of the `tsdata.interpolation` object include:

- `Fhandle` — Function handle to a user-defined interpolation function
- `Name` — String that specifies the name of the interpolation method. Predefined methods include `'linear'` and `'zoh'` (zero-order hold). `'linear'` is the default.
- `UserData` — Any user-defined information entered as a string

## Events

An array of `tsdata.event` objects that stores event information for this `timeseries` object.

You add events by using the `addevent` method. Fields of the `tsdata.event` object include the following:

- `EventData` — Any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number or a date string
- `Units` — Time units
- `StartDate` — A reference date specified in MATLAB date-string format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

## IsTimeFirst

Logical value (`true` or `false`) specifies whether the time vector is aligned with the first or last dimension of the `Data` array. The value is `false` for 3-D and higher dimensional data and `true` otherwise.

- `true` — The first dimension of the data array is aligned with the time vector. For example, `ts = timeseries(rand(3,3),1:3);`
- `false` — The last dimension of the data array is aligned with the time vector. For example: `ts = timeseries(rand(3,4,5),1:5);`

## Attributes:

<code>Dependent</code>	<code>true</code>
<code>SetAccess</code>	<code>'protected'</code>

## Length

Length of the time vector in the `timeseries` object

**Attributes:**

Dependent	true
SetAccess	'protected'

**Name**

The `timeseries` object name entered as a string, `tsname`.

This name can differ from the name of the `timeseries` variable in the MATLAB workspace.

**Quality**

An integer vector or array containing values -128 to 127 that specify the quality in terms of codes defined by `QualityInfo.Code`.

When `Quality` is a vector, it must have the same length as the time vector. In this case, each `Quality` value applies to a corresponding data sample.

When `Quality` is an array, it must have the same size as the data array. In this case, each `Quality` value applies to the corresponding value of the data array.

**Attributes:**

Dependent	true
-----------	------

**QualityInfo**

Provides a lookup table that converts numerical `Quality` codes to readable descriptions.

`QualityInfo` fields include the following:

- **Code** — Integer vector containing values -128 to 127 that define the “dictionary” of quality codes. You can assign one of these integer values to each `Data` value by using the `Quality` property.

- **Description** — Cell vector of strings, where each element provides a readable description of the associated quality Code.
- **UserData** — Stores any additional user-defined information.

Lengths of Code and Description must match.

## **Time**

Array of time values.

When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to 0 in specified units. When `TimeInfo.StartDate` is defined, the time values are date strings measured relative to the `StartDate` in specified units.

The length of `Time` must be the same as either the first or the last dimension of `Data`. When the data contains three or more dimensions, the length of `Time` matches the size of the last data dimension. Otherwise, the length of `Time` matches the size of the first data dimension.

### **Attributes:**

Dependent	true
-----------	------

## **TimeInfo**

Uses the following fields for storing contextual information about `Time`:

- **Units** — Time units having any of following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', or 'nanoseconds'
- **Start** — Start time
- **End** — End time (read only)
- **Increment** — Interval between two subsequent time values
- **Length** — Length of the time vector (read only)

- **Format** — String defining the date string display format. See the MATLAB `datestr` function reference page for more information.
- **StartDate** — Date string defining the reference date. See the MATLAB `setabstime` function reference page for more information.
- **UserData** — Stores any additional user-defined information

### **TreatNaNasMissing**

Logical value that specifies how to treat NaN values in `Data`:

- **true** — (Default) Treats all NaN values as missing data except during statistical calculations.
- **false** — Includes NaN values in statistical calculations, in which case NaN values are propagated to the result.

### **UserData**

Generic field for data of any class that you want to add to the object.

**Default:** []

## **Methods**

### **Time-Series Methods**

- [Methods to Query and Set Object Properties and Plot the Data on page 5702](#)
- [Methods to Manipulate Data and Time on page 5702](#)
- [Event Methods on page 5703](#)
- [Methods to Arithmetically Combine `timeseries` Objects on page 5704](#)
- [Methods to Calculate Descriptive Statistics for a `timeseries` Object on page 5705](#)

## Methods to Query and Set Object Properties and Plot the Data

<code>get</code>	Query <code>timeseries</code> object property values.
<code>getdatasamplesize</code>	Return the size of each data sample in a <code>timeseries</code> object.
<code>getqualitydesc</code>	Return data quality descriptions based on the <code>Quality</code> property values assigned to a <code>timeseries</code> object.
<code>plot</code>	Plot the <code>timeseries</code> object.
<code>set</code>	Set <code>timeseries</code> property values.

## Methods to Manipulate Data and Time

<code>addsample</code>	Add a data sample to a <code>timeseries</code> object.
<code>append</code>	Concatenate <code>timeseries</code> objects in the time dimension.
<code>ctranspose</code>	Transpose a <code>timeseries</code> object.
<code>delsample</code>	Delete a sample from a <code>timeseries</code> object.
<code>detrend</code>	Subtract the mean or best-fit line and remove all NaNs from time-series data.
<code>filter</code>	Shape frequency content of time-series data using a 1-D digital filter.
<code>getabstime</code>	Extract a date-string time vector from a <code>timeseries</code> object into a cell array.
<code>getdatasamples</code>	Extract a subset of data samples from an existing <code>timeseries</code> object into an array using a subscripted indexed array.
<code>getsamples</code>	Extract a subset of data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object using a subscript indexed array.

**(Continued)**

<code>getinterpmethod</code>	Get the interpolation method for a <code>timeseries</code> object.
<code>getsamplingsingtime</code>	Extract data samples from an existing <code>timeseries</code> object into a new <code>timeseries</code> object based on specified start and end time values.
<code>idealfilter</code>	Apply an ideal pass or notch (noncausal) filter to a <code>timeseries</code> object.
<code>resample</code>	Select or interpolate data in a <code>timeseries</code> object using a new time vector.
<code>setabstime</code>	Set the time values in the time vector as date strings.
<code>setinterpmethod</code>	Set interpolation method for a <code>timeseries</code> object.
<code>setuniformtime</code>	Assign uniform time vector to <code>timeseries</code> object.
<code>synchronize</code>	Synchronize and resample two <code>timeseries</code> objects using a common time vector.
<code>transpose</code>	Transpose a <code>timeseries</code> object.

**Event Methods**

To construct an event object, use the constructor `tsdata.event`. For an example of defining events for a time-series object, see “Defining Events”.

<code>addevent</code>	Add one or more events to a <code>timeseries</code> object.
<code>delevent</code>	Delete one or more events from a <code>timeseries</code> object.

## (Continued)

<code>gettsafteratevent</code>	Create a new <code>timeseries</code> object by extracting the samples from an existing time series that occur after or at a specified event.
<code>gettsafterevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur after a specified event from an existing time series.
<code>gettsatevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur at the same time as a specified event from an existing time series.
<code>gettsbeforeatevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur before or at a specified event from an existing time series.
<code>gettsbeforeevent</code>	Create a new <code>timeseries</code> object by extracting the samples that occur before a specified event from an existing time series.
<code>gettsbetweenevents</code>	Create a new <code>timeseries</code> object by extracting the samples that occur between two specified events from an existing time series.

## **Methods to Arithmetically Combine timeseries Objects**

<code>+</code>	Addition of the corresponding data values of <code>timeseries</code> objects.
<code>-</code>	Subtraction of the corresponding data values of <code>timeseries</code> objects.
<code>.*</code>	Element-by-element multiplication of <code>timeseries</code> data.

## (Continued)

<code>*</code>	Matrix-multiply <code>timeseries</code> data.
<code>./</code>	Right element-by-element division of <code>timeseries</code> data.
<code>/</code>	Right matrix division of <code>timeseries</code> data.
<code>.\</code>	Element-by-element left-array divide of <code>timeseries</code> data.
<code>\</code>	Left matrix division of <code>timeseries</code> data.

## Methods to Calculate Descriptive Statistics for a `timeseries` Object

<code>iqr</code>	Return the interquartile range of <code>timeseries</code> data.
<code>max</code>	Return the maximum value of <code>timeseries</code> data.
<code>mean</code>	Return the mean of <code>timeseries</code> data.
<code>median</code>	Return the median of <code>timeseries</code> data.
<code>min</code>	Return the minimum of <code>timeseries</code> data.
<code>std</code>	Return the standard deviation of <code>timeseries</code> data.
<code>sum</code>	Return the sum of <code>timeseries</code> data.
<code>var</code>	Return the variance of <code>timeseries</code> data.

## Definitions

### `timeseries`

The time-series object, called `timeseries`, is a MATLAB variable that contains time-indexed data and properties in a single, coherent structure. For example, in addition to data and time values, you can also use the time-series object to store events, descriptive information about data and time, data quality, and the interpolation method.

## Data Sample

A time-series *data sample* consists of one or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

For example, suppose that `ts.data` has the size 3-by-4-by-5 and the time vector has the length 5. Then, the number of samples is 5 and the total number of data values is  $3 \times 4 \times 5 = 60$ .

## Time Vector

A time vector of a `timeseries` object can be either numerical (double) values or valid MATLAB date strings.

When the `timeseries` `TimeInfo.StartDate` property is empty, the numerical time values are measured relative to 0 (or another numerical value) in specified units. In this case, the time vector is described as *relative* (that is, it contains time values that are not associated with a specific start date).

When `TimeInfo.StartDate` is nonempty, the time values are date strings measured relative to `StartDate` in specified units. In this case, the time vector is described as *absolute* (that is, it contains time values that are associated with a specific calendar date).

MATLAB supports the following date-string formats for time-series applications.

Date-String Format	Usage Example
dd-mmm-yyyy HH:MM:SS	01-Mar-2000 15:45:17
dd-mmm-yyyy	01-Mar-2000
mm/dd/yy	03/01/00
mm/dd	03/01
HH:MM:SS	15:45:17
HH:MM:SS PM	3:45:17 PM
HH:MM	15:45

Date-String Format	Usage Example
HH:MM PM	3:45 PM
mmm.dd,yyyy HH:MM:SS	Mar.01,2000 15:45:17
mmm.dd,yyyy	Mar.01,2000
mm/dd/yyyy	03/01/2000

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

Create a `timeseries` object called 'LaunchData' that contains four data sets, each stored as a column of length 5 and using the default time vector:

```
b = timeseries(rand(5, 4), 'Name', 'LaunchData')
```

Create a `timeseries` object containing a single data set of length 5 and a time vector starting at 1 and ending at 5:

```
b = timeseries(rand(5,1), [1 2 3 4 5])
```

Create a `timeseries` object called 'FinancialData' containing five data points at a single time point:

```
b = timeseries(rand(1,5), 1, 'Name', 'FinancialData')
```

## How To

- “MATLAB Objects”

# timeseries.addsample

---

**Purpose** Add data sample to timeseries object

**Syntax**

```
ts1 = addsample(ts, s)
ts1 = addsample(ts, 'Data', data-value,
 'Time', time-value, ..., Name,
 Value)
```

**Description** `ts1 = addsample(ts, s)` adds one or more new data samples stored in a structure `s` to the timeseries object `ts`.

`ts1 = addsample(ts, 'Data', data-value, 'Time', time-value, ..., Name, Value)` adds one or more data samples to the timeseries object `ts` along with additional options specified by one or more `Name, Value` pair arguments.

**Tips**

- If `N` is the number of data samples, you can get the sample size of each time with `SampleSize = getsamplesize(ts)`.

When `ts.IsTimeFirst` is true, the size of the data is `N-by-SampleSize`. When `ts.IsTimeFirst` is false, the size of the data is `SampleSize-by-N`.

## Input Arguments

**s**

A structure that you must define before passing as an argument to `addsample`. It consists of the following optional fields:

- `s.data`
- `s.time`
- `s.quality`
- `s.overwriteflag`

### **data-value**

A numeric data value.

### **time-value**

A valid time vector.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Quality'**

Array of data quality codes.

**Default:** []

### **'OverwriteFlag'**

Logical value that controls whether to overwrite a data sample at the same time with the new sample you are adding to your `timeseries` object. When set to `true`, the new sample overwrites the old sample at the same time.

**Default:** `false`

## **Output Arguments**

**ts1**

The `timeseries` object that results when you add the specified samples to the original `timeseries` object.

## **Definitions**

### **data sample**

One or more values recorded at a specific time. The number of data samples in a time series is the same as the length of the time vector.

## **Examples**

Add a data value of 420 at time 3:

```
ts = ts.addsample('Time',3,'Data',420);
```

---

# timeseries.addsample

---

Add a data value of 420 at time 3 and specify quality code 1 for this data value. Set the `OverwriteFlag` to overwrite an existing value at time 3.

```
ts = ts.addsample('Data',3.2,'Quality',1,'OverwriteFlag',...
 true,'Time',3);
```

## See Also

[timeseries](#) | [delsample](#) | [getdatasamples](#)

<b>Purpose</b>	Concatenate time series objects in time dimension
<b>Syntax</b>	<code>ts = append(ts1,ts2, ... tsn)</code>
<b>Description</b>	<code>ts = append(ts1,ts2, ... tsn)</code> creates a new <code>timeseries</code> object by concatenating <code>timeseries</code> <code>ts1</code> , <code>ts2</code> , and so on, along the time dimension.
<b>Tips</b>	<ul style="list-style-type: none"><li>• A single overlapping time between each input time series is valid, as long as the overlapping samples are identical.</li><li>• The time vectors must not overlap by a nonzero amount. That is, the last time in <code>ts1</code> must be earlier than or equal to the first time in <code>ts2</code>.</li><li>• The sample size of the time series must be the same.</li></ul>
<b>Input Arguments</b>	<p><b>ts1</b> The first <code>timeseries</code> object that you want to append.</p> <p><b>ts2</b> The second <code>timeseries</code> object that you want to append.</p> <p><b>tsn</b> The <code>n</code>th <code>timeseries</code> object that you want to append.</p>
<b>Output Arguments</b>	<p><b>ts</b> The <code>timeseries</code> object that results from appending the input <code>timeseries</code> objects.</p>
<b>Examples</b>	<p>After creating <code>timeseries</code> objects, <code>ts1</code> and <code>ts2</code>, append them:</p> <pre>ts1 = timeseries(rand(5,1),[1 2 3 4 5]); ts2 = timeseries(rand(5,1),[6 7 8 9 10]); ts3 = append(ts1, ts2)</pre>
<b>See Also</b>	<code>timeseries</code>

# timeseries.ctranspose

---

**Purpose** Transpose timeseries object

**Syntax** `ts1 = ctranspose(ts)`

**Description** `ts1 = ctranspose(ts)` returns a new timeseries object `ts1` with the `IsTimeFirst` value set to opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector as a result of this operation.

- Tips**
- The overloaded `ctranspose` method for timeseries objects does not transpose the data. Instead, this method changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, you must transpose the `Data` property of the timeseries object. For example, you can use the syntax `ctranspose(ts.Data)` or `(ts.Data)'`. The `Data` property value must be a 2-D array.
  - Consider a timeseries object with 10 samples with the property `IsTimeFirst = True`. When you transpose this object, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes the size for `Data` property of the timeseries object (up to three dimensions) before and after transposing.

## Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

## Input Arguments

**ts**

The timeseries object you want to transpose.

## Output Arguments

**ts1**

The transposed timeseries object.

## Examples

Suppose that a timeseries object `ts` has `ts.data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is set to `true`, which means that the first dimension of the data is aligned with the time vector. `ctranspose(ts)` modifies `ts`, such that the last dimension of the data is now aligned with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

## See Also

`timeseries` | `transpose`

# timeseries.delsample

---

**Purpose** Remove sample from timeseries object

**Syntax** `ts1 = delsample(ts,Name,Value)`

**Description** `ts1 = delsample(ts,Name,Value)` deletes samples from the timeseries object `ts` based on the specified `Name,Value` pair arguments.

**Input Arguments**

**ts**  
A timeseries object.

**Name-Value Pair Arguments** Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Index**

The indices of the time vector that correspond to the samples you want to delete.

**Value**

The time values that correspond to the samples you want to delete.

**Output Arguments**

**ts1**  
The timeseries object that results from removing the specified samples.

**Examples** Create a timeseries object, and then remove samples:

```
ts = timeseries(rand(5,1),[10 20 30 40 50]);

% Remove data sample at time index 1

ts1 = delsample(ts,'Index', 1)
```

```
% Remove data sample at time value 20:
ts2 = delsample(ts, 'Value', [20])
```

## See Also

set | timeseries

# timeseries.detrend

---

**Purpose** Subtract mean or best-fit line and all NaNs from `timeseries` object

**Syntax**

```
ts1 = detrend(ts, method)
ts1 = detrend(ts, method, index)
```

**Description** `ts1 = detrend(ts, method)` subtracts either a mean or a best-fit line from time-series data, using the specified `method`. Usually for FFT processing.

`ts1 = detrend(ts, method, index)` uses the optional `index` to specify the columns or rows to detrend.

**Tips**

- You cannot apply `detrend` to `timeseries` data with more than two dimensions.

**Input Arguments**

**ts**

The `timeseries` object from which you want to subtract the mean or best-fit line and all NaNs.

**method**

A string that specifies one of the following `detrend` methods:

- 'constant' — Subtracts the mean.
- 'linear' — Subtracts the best-fit line.

**index**

An integer array that specifies the columns or rows to detrend when `ts.IsTimeFirst` is true.

**Output Arguments**

**ts1**

The `timeseries` object resulting from detrending the input `timeseries` object.

**See Also** `timeseries`

**Purpose**

Shape frequency content of time-series

**Syntax**

```
ts1 = filter(ts, numerator, denominator)
ts1=filter(ts, numerator, denominator, index)
```

**Description**

`ts1 = filter(ts, numerator, denominator)` applies the transfer function filter  $b(z^{-1})/a(z^{-1})$  to the data in the timeseries object `ts`. `b` and `a` are the coefficient arrays of the transfer function numerator and denominator, respectively.

`ts1=filter(ts, numerator, denominator, index)` uses the optional `index` integer array to specify either the columns or rows to filter, depending on the value of `ts.IsTimeFirst`.

**Tips**

- The time-series data must be uniformly sampled to use this filter.
- The following function

```
y = filter(b,a,x)
```

creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.

- The `filter` function is a general tapped delay-line filter, described by the difference equation:

$$a(1)y(n) = b(1)x(n) + b(2)x(n - 1) + \dots + b(nb)x(n - nb + 1) - a(2)y(n - 1) - \dots - a(N_a)y(n - N_b + 1).$$

Here,  $n$  is the index of the current sample,  $N_a$  is the order of the polynomial described by vector `a`, and  $N_b$  is the order of the polynomial described by vector `b`. The output  $y(n)$  is a linear combination of current and previous inputs,  $x(n) x(n - 1)\dots$ , and previous outputs,  $y(n - 1) y(n - 2)\dots$ .

- You use the discrete filter to shape the data by applying a transfer function to the input signal.

# timeseries.filter

---

Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

- In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in  $z^{-1}$  and to order the numerator and denominator terms in ascending powers of  $z^{-1}$ .

Taking the z-transform of the difference equation

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \dots + b(nb)x(n-nb+1) - a(2)y(n-1) - \dots - a(na)y(na+1),$$

results in the transfer function

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + \dots + b(nb)z^{-nb+1}}{a(1) + a(2)z^{-1} + \dots + a(na)z^{-na+1}} X(z),$$

where  $Y(z)$  is the z-transform of the filtered output  $y(n)$ . The coefficients  $b$  and  $a$  are unchanged by the z-transform.

## Input Arguments

### **ts**

The first `timeseries` object for which you want to shape the frequency content.

### **numerator**

The coefficient array of the transfer function numerator.

### **denominator**

The coefficient array of the transfer function denominator.

### **index**

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

**Output Arguments****ts1**

The timeseries object that results from filtering the input timeseries object.

**Examples****Apply Transfer Function to Time Series Data**

This example applies the following transfer function to the data in count.dat:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

Load the matrix count into the workspace:

```
load count.dat;
```

Create a time-series object based on this matrix:

```
count1=timeseries(count(:,1),[1:24]);
```

Enter the coefficients of the denominator ordered in ascending powers of  $z^{-1}$  to represent  $1 + 0.2z^{-1}$ :

```
a = [1 0.2];
```

Enter the coefficients of the numerator to represent  $2 - 3z^{-1}$ :

```
b = [2 3];
```

Call the filter method:

```
filter_count = filter(count1, b, a);
```

Compare the original data and the shaped data with an overlaid plot of the two curves:

```
plot(count1,'-.'), grid on, hold on
plot(filter_count,'-')
```

# timeseries.filter

---

```
legend('Original Data','Shaped Data',2)
```

**See Also** [timeseries | idealfilter](#)

<b>Purpose</b>	Query <code>timeseries</code> object property values
<b>Syntax</b>	<pre>get(ts) value = get(ts, PropertyName)</pre>
<b>Description</b>	<p><code>get(ts)</code> displays all properties and values of the <code>timeseries</code> object, <code>ts</code>.</p> <p><code>value = get(ts, PropertyName)</code> returns the property value for the specified <code>timeseries</code> object. The following syntax is equivalent:</p> <pre>value = ts.PropertyName</pre>
<b>Input Arguments</b>	<p><b>ts</b> A <code>timeseries</code> object.</p> <p><b>PropertyName</b> String specifying the name of a <code>timeseries</code> property. For a list of <code>timeseries</code> properties, see <code>timeseries</code>.</p>
<b>Output Arguments</b>	<p><b>value</b> String containing the value associated with the specified property.</p>
<b>Examples</b>	<p>Create a <code>timeseries</code> object, and then get the name. This example gets the name three different ways:</p> <pre>ts1 = timeseries(rand(5,1),[1 2 3 4 5], 'Name', 'MyTimeseries'); get(ts1) get(ts1, 'Name') value = ts1.Name</pre>
<b>See Also</b>	<code>timeseries</code>   <code>set</code>

# timeseries.getabstime

---

**Purpose** Extract date-string time vector into cell array

**Syntax** `getabstime(ts)`

**Description** `getabstime(ts)` extracts the time vector from the `timeseries` object `ts` as a cell array of date strings.

**Tips**

- To define the time vector relative to a calendar date, set the `TimeInfo.StartDate` property of the `timeseries` object. When the `TimeInfo.StartDate` format is a valid `datestr` format, the output strings from `getabstime` have the same format.

**Input Arguments**

**ts**

The `timeseries` object from which you want to extract the time vector.

**Examples**

The following example extracts a time vector as a cell array of date strings from a `timeseries` object.

First, create a `timeseries` object.

```
ts = timeseries([3 6 8 0 10]);
```

The default time vector for `ts` is `[0 1 2 3 4]`, which starts at 0 and increases in 1-second increments. The length of the time vector is equal to the length of the data.

Next, set the `StartDate` property.

```
ts.TimeInfo.StartDate = '10/27/2005 07:05:36';
```

Extract the time vector.

```
getabstime(ts)
```

MATLAB returns:

```
'27-Oct-2005 07:05:36'
```

```
'27-Oct-2005 07:05:37'
'27-Oct-2005 07:05:38'
'27-Oct-2005 07:05:39'
'27-Oct-2005 07:05:40'
```

Change the date-string format of the time vector, and then extract the time vector with the new date-string format:

```
ts.TimeInfo.Format = 'mm/dd/yy';
getabstime(ts)
```

MATLAB returns:

```
'10/27/05'
'10/27/05'
'10/27/05'
'10/27/05'
'10/27/05'
```

# timeseries.getdatasamples

---

**Purpose** Returns subset of time series samples using subscripted index array

**Syntax** `datasamples = getdatasamples(ts, i)`

**Description** `datasamples = getdatasamples(ts, i)` returns an array corresponding to the samples indicated by the array, `i`.

**Input Arguments**

**ts**  
The timeseries object from which you want to extract samples.

**i**  
An array of linear indices or logical values that specifies the time value or values for which you want to extract the corresponding samples.

**Output Arguments**

**datasamples**  
The array that results from extracting the samples corresponding to the time value or values, `ts.time(i)`.

**Examples**

After creating a timeseries object, `ts`, extract the second and third data samples into an array:

```
ts = timeseries(rand(5,1),[1 2 3 4 5]);
samples = getdatasamples(ts, [2 3])
```

**See Also**

`timeseries` | `getsamples` | `resample`

<b>Purpose</b>	Size of data sample in <code>timeseries</code> object
<b>Syntax</b>	<code>getdatasamplesize(ts)</code>
<b>Description</b>	<code>getdatasamplesize(ts)</code> returns the size of each data sample in a <code>timeseries</code> object.
<b>Input Arguments</b>	<b>ts</b> String specifying the name of a <code>timeseries</code> object.
<b>Definitions</b>	<b>data sample</b> One or more scalar values recorded at a specific time. The number of data samples is the same as the length of the time vector.
<b>Examples</b>	<p>After loading data and creating a <code>timeseries</code> object, get the size of a data sample:</p> <pre>% Load a 24-by-3 data array: load count.dat  % Create a timeseries object with 24 time values: count_ts = timeseries(count,[1:24], 'Name', 'VehicleCount')  % Get the size of the data sample for this timeseries object: getdatasamplesize(count_ts)</pre> <p>MATLAB returns the following, which indicates that the size of each data sample in <code>count_ts</code> is 1-by-3. In other words, MATLAB stores each data sample as a row with three values.</p> <pre>ans =       1     3</pre>
<b>See Also</b>	<code>timeseries</code>   <code>set</code>

# timeseries.getinterpmethod

---

**Purpose** Interpolation method for `timeseries` object

**Syntax** `getinterpmethod(ts)`

**Description** `getinterpmethod(ts)` returns the interpolation method that the `timeseries` object `ts`, uses as a string.

**Input Arguments** **ts**  
The `timeseries` object from which you want to extract the interpolation method.

**Definitions** **interpolation method**  
Predefined interpolation methods are zero-order hold, `zoh`, and linear interpolation, `linear`. Linear interpolation is the default.

**Examples** Create a `timeseries` object, and then get its interpolation method:

```
ts = timeseries(rand(5));
getinterpmethod(ts)
```

MATLAB returns:

```
linear
```

**See Also** `timeseries` | `setinterpmethod`

<b>Purpose</b>	Data quality descriptions
<b>Syntax</b>	<code>getqualitydesc(ts)</code>
<b>Description</b>	<code>getqualitydesc(ts)</code> returns a cell array of data quality descriptions based on the <code>Quality</code> values you assigned to a <code>timeseries</code> object, <code>ts</code> .
<b>Input Arguments</b>	<b>ts</b> A <code>timeseries</code> object.
<b>Examples</b>	<p>Create a <code>timeseries</code> object, and then get the data quality description strings for <code>ts</code>:</p> <pre>% Create a timeseries object, ts, with Data, Time, and Quality % values, respectively:  ts = timeseries([3; 4.2; 5; 6.1; 8], 1:5, [1; 0; 1; 0; 1]);  % Set the QualityInfo property, including Code and Description:  ts.QualityInfo.Code = [0 1]; ts.QualityInfo.Description = {'good' 'bad'};  % Get the data quality description strings for ts: getqualitydesc(ts)</pre> <p>MATLAB returns:</p> <pre>ans =      'bad'     'good'     'bad'     'good'     'bad'</pre>

# timeseries.getqualitydesc

---

## See Also

[timeseries](#)

<b>Purpose</b>	Subset of time series samples using subscripted index array
<b>Syntax</b>	<code>ts1 = getsamples(ts, i)</code>
<b>Description</b>	<code>ts1 = getsamples(ts, i)</code> returns a new <code>timeseries</code> object by extracting samples from <code>timeseries</code> <code>ts</code> corresponding to the time or times indicated by the subscripted index array, <code>i</code> .
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The <code>timeseries</code> object from which you want to exact samples.</p> <p><b>i</b></p> <p>A subscripted index array that specifies the time value or values for which you want to extract the corresponding samples.</p>
<b>Output Arguments</b>	<p><b>ts1</b></p> <p>The <code>timeseries</code> object that results from extracting the samples corresponding to the time value or values <code>ts.time(i)</code> .</p>
<b>Examples</b>	<p>After creating a <code>timeseries</code> object, <code>ts</code>, extract the data samples at times 2 and 3 into a new <code>timeseries</code> object, <code>ts1</code>:</p> <pre>ts = timeseries(rand(5,1),[1 2 3 4 5]); ts1 = getdatasamples(ts, ts.time([2 3]))</pre>
<b>See Also</b>	<code>timeseries</code>   <code>getdatasamples</code>   <code>resample</code>

# timeseries.getsampleusingtime

---

**Purpose** Extract data samples into new timeseries object

**Syntax**  
`ts1 = getsampleusingtime(ts, time)`  
`ts1 = getsampleusingtime(ts, starttime, endtime)`

**Description**  
`ts1 = getsampleusingtime(ts, time)` returns a new timeseries object, `ts1`, with a single sample corresponding to specified `time` in `ts`.  
`ts1 = getsampleusingtime(ts, starttime, endtime)` returns a new timeseries object, `ts1`, with samples between the times `starttime` and `endtime` in `ts`.

**Tips**

- If the time vector in `ts` is not relative to a calendar date, then `starttime` and `endtime` must be numeric.
- If the time vector in `ts` is relative to a calendar date, then `starttime` and `endtime` values must be dates—either strings or `datetime` values.

**Input Arguments**

**ts**  
The timeseries object from which you want to extract data samples.

**time**  
The time corresponding to data sample you want to extract.

**starttime**  
The time corresponding to the first data sample you want to extract.

**endtime**  
The time corresponding to the last data sample you want to extract.

**Output Arguments**

**ts1**  
A timeseries object that contains the subset of data samples from the original timeseries object.

**See Also** [timeseries](#)

# timeseries.idealfilter

---

**Purpose** Apply ideal (noncausal) filter to timeseries object

**Syntax**  
`ts1 = idealfilter(ts, interval, filtertype)`  
`ts1 = idealfilter(ts, interval, filtertype, index)`

**Description** `ts1 = idealfilter(ts, interval, filtertype)` applies an ideal filter of `filtertype` to one or more frequency intervals that `interval` specifies for the timeseries object, `ts`.

`ts1 = idealfilter(ts, interval, filtertype, index)` applies an ideal filter and uses the optional `index` integer array to specify the columns or rows to filter.

- Tips**
- Ideal filters require data to have a mean of zero and prepare the data by subtracting its mean. You can restore the filtered signal amplitude by adding the mean of the input data to the filter output values.
  - Use the ideal *notch* filter when you want to remove variations in a specific frequency range. Alternatively, use the ideal *pass* filter to allow only the variations in a specific frequency range.
  - If the time-series data is sampled nonuniformly, filtering resamples this data on a uniform time vector.
  - All NaNs in the time series are interpolated before filtering, using the interpolation method you assigned to the timeseries object.

## Input Arguments

**ts**  
The timeseries object to which you want to apply an ideal filter.

**interval**  
The frequency interval (specified in cycles per time unit) at which you want the ideal filter applied. To specify several frequency intervals, use an n-by-2 array of start and end frequencies, where n represents the number of intervals.

**filtertype**

A string specifying the type of filter you want to apply, either pass or notch.

## index

An integer array that specifies the columns or rows to filter when `ts.IsTimeFirst` is true.

## Output Arguments

### ts1

The `timeseries` object that results when you apply an ideal filter to the original `timeseries` object.

## Definitions

### ideal filter

Filters are *ideal* in the sense that they are *not realizable*. An ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

## Examples

### Apply Ideal Notch and Pass Filters

This example first applies an ideal notch filter to the data in `count.dat`. Then, it applies a pass filter to the data.

Load the count matrix into the workspace:

```
load count.dat;
```

Create a `timeseries` object from column one of this matrix. Specify a time vector that ranges from 1 to 24 s in 1-s intervals.

```
count1=timeseries(count(:,1),1:24);
```

Obtain the mean of the data:

```
countmean = mean(count1);
```

Enter the frequency interval, in hertz, for filtering the data:

```
interval=[0.08 0.2];
```

## timeseries.idealfilter

---

Invoke an ideal notch filter:

```
idealfilter_countn = idealfilter(count1, interval, 'notch');
```

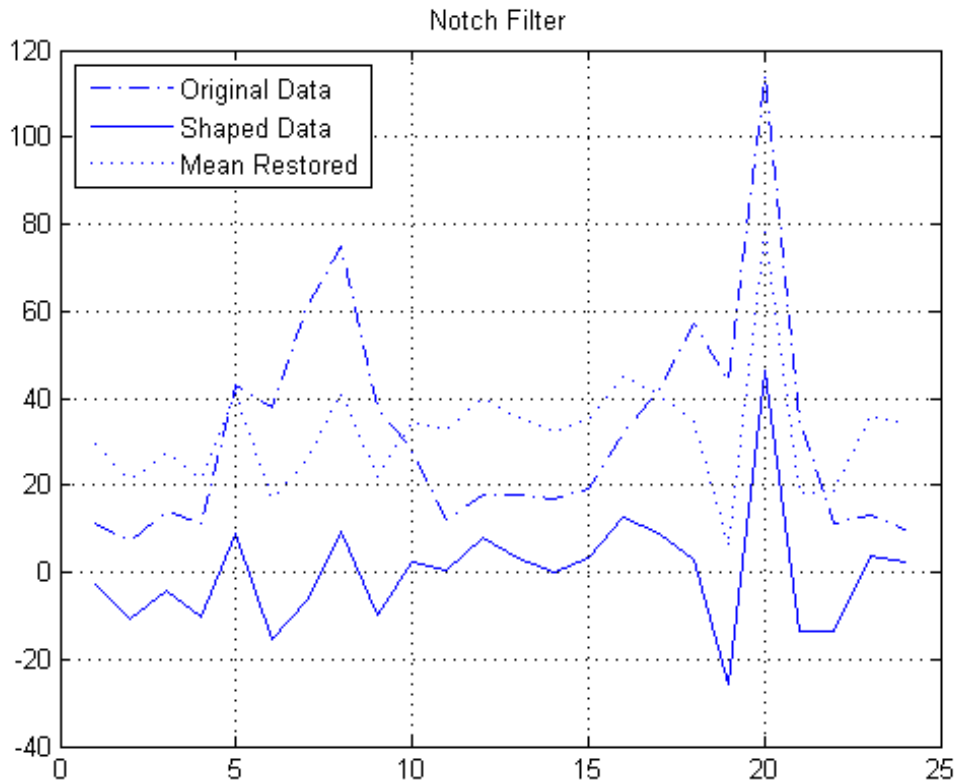

Compare the original data and the shaped data on a line plot:

```
plot(count1, '-. '), grid on, hold on
plot(idealfilter_countn, '-')
```

Restore the mean to the filtered data and show it on the line plot, adding a legend and a title:

```
countn_restored = idealfilter_countn + countmean;
plot(countn_restored, ':');
title('Notch Filter')
legend('Original Data', 'Shaped Data', 'Mean Restored', ...
 'Location', 'NorthWest')
```

Close the Figure window:

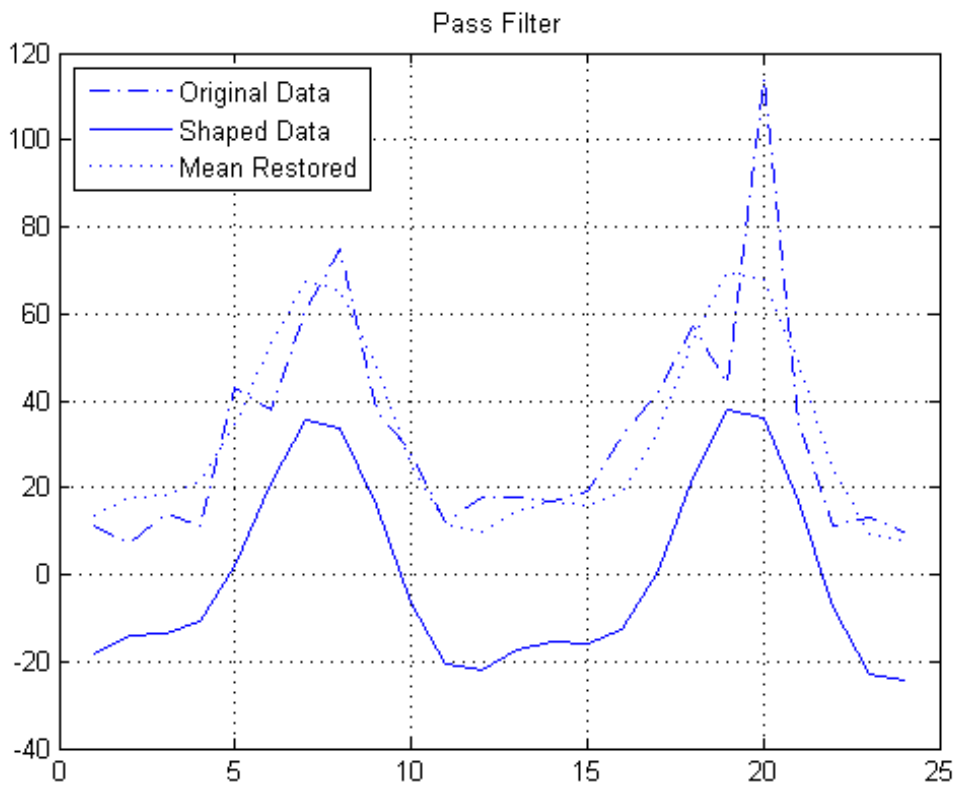

```
close
```

Then, repeat the process using a pass rather than a notch filter:

```
figure
plot(count1,'-.'), grid on, hold on
idealfilter_countp = idealfilter(count1, interval, 'pass');
plot(idealfilter_countp, '-')
```

# timeseries.idealfilter

```
countp_restored = idealfilter_countp + countmean;
plot(countp_restored, ':');
title('Pass Filter')
legend('Original Data', 'Shaped Data', 'Mean Restored', ...
 'Location', 'NorthWest')
```

**See Also** [timeseries | filter](#)

<b>Purpose</b>	Interquartile range of <code>timeseries</code> data
<b>Syntax</b>	<pre>ts_iqr = iqr(ts) iqr(ts, Name, Value)</pre>
<b>Description</b>	<p><code>ts_iqr = iqr(ts)</code> returns the interquartile range of <code>ts.Data</code>.</p> <p><code>iqr(ts, Name, Value)</code> reruns the interquartile range of <code>ts.Data</code> with the specified <code>Name, Value</code> pairs.</p>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The <code>timeseries</code> object for which you want the interquartile range of <code>timeseries</code> data.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name, Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1, Value1, ..., NameN, ValueN</code>.</p> <p><b>'MissingData'</b></p> <p>A string specifying one of two possible values, <code>remove</code> or <code>interpolate</code>, indicating how to treat missing data during the calculation.</p> <p><b>Default:</b> <code>remove</code></p> <p><b>'Quality'</b></p> <p>A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).</p>
<b>Output Arguments</b>	<p><b>ts_iqr</b></p> <p>The interquartile range of <code>ts.Data</code>, as follows:</p>

# timeseries.iqr

---

- When `ts.Data` is a vector, `ts_iqr` is the difference between the 75th and the 25th percentiles of the `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_iqr` is a row vector containing the interquartile range of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `iqr` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Create a time series with a missing value, represented by `NaN`, and then calculate the interquartile range of `ts.Data` after removing the missing value from the calculation:

```
ts = timeseries([3.0 NaN 5 6.1 8], 1:5);
iqr(ts, 'MissingData', 'remove')
```

MATLAB returns:

```
3.0500
```

## See Also

`max` | `mean` | `median` | `min` | `std` | `sum` | `timeseries` | `var`

**Purpose** Maximum value of timeseries data

**Syntax**  
`ts_max = max(ts)`  
`ts_max = max(ts,Name,Value)`

**Description** `ts_max = max(ts)` returns the maximum value in the timeseries data.

`ts_max = max(ts,Name,Value)` returns the maximum value in the timeseries data with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**

**ts**  
The timeseries object for which you want to determine the maximum data value.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

**'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

# timeseries.max

---

## Output Arguments

### **ts\_max**

The maximum data value in the specified timeseries object, as follows:

- When `ts.Data` is a vector, `ts_max` is the maximum value of `ts.Data` values.
- When `ts.Data` is a matrix, `IsTimeFirst` is true, and the first dimension of `ts` is aligned with time, then `ts_max` is a row vector containing the maximum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `max` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example illustrates how to find the maximum values in multivariate time-series data:

```
% Load a 24-by-3 data array:
load count.dat

% Create a timeseries object with 24 time values:
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond')

% Find the maximum in each data column for this timeseries object:

max(count_ts)
```

MATLAB returns:

```
114 145 257
```

## See Also

`iqr` | `mean` | `median` | `min` | `std` | `sum` | `timeseries` | `var`

**Purpose** Mean value of timeseries data

**Syntax**  
`ts_mn = mean(ts)`  
`ts_mn = mean(ts,Name,Value)`

**Description**  
`ts_mn = mean(ts)` returns the mean value of `ts.Data`.  
`ts_mn = mean(ts,Name,Value)` returns the mean value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**  
**ts**  
The timeseries object for which you want the mean value of data.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

#### **'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

#### **'Weighting'**

# timeseries.mean

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

**ts\_mn**

The mean value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_mn` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is true and the first dimension of `ts` is aligned with time, then `ts_mn` is a row vector containing the mean value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `mean` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Find the mean values in multivariate time-series data:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond')
```

```
% Find the mean of each data column for this timeseries object:
```

```
mean(count_ts)
```

MATLAB returns:

```
32.0000 46.5417 65.5833
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

## See Also

`timeseries` | `timeseries.iqr` | `timeseries.max` |  
`timeseries.median` | `timeseries.min` | `timeseries.std` |  
`timeseries.sum` | `timeseries.var`

# timeseries.median

---

**Purpose** Median value of timeseries data

**Syntax**  
`ts_med = median(ts)`  
`ts_med = method(ts,Name,Value)`

**Description** `ts_med = median(ts)` returns the median value of `ts.Data`.  
`ts_med = method(ts,Name,Value)` returns the median value of `ts.Data` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments** **ts**  
The timeseries object for which you want the median data value.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

### **'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

### **'Weighting'**

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_med`

The median value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_med` is the mean value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_med` is a row vector containing the median value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `median` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the median values in multivariate time-series data. MATLAB finds the median independently for each data column in the `timeseries` object:

```
% Load a 24-by-3 data array:

load count.dat

% Create a timeseries object with 24 time values:

count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond');

% Find the median of each data column for this timeseries object:

median(count_ts)

MATLAB returns:

23.5000 36.0000 39.0000
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# timeseries.min

---

## Output Arguments

### `ts_min`

The minimum value of `ts.Data`, as follows:

- When `ts.Data` is a vector, `ts_min` is the minimum value of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_min` is a row vector containing the minimum value of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `min` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the minimum values in multivariate time-series data. MATLAB finds the minimum independently for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,[1:24],'Name','CountPerSecond');
```

```
% Find the minimum in each data column for this timeseries object:
```

```
min(count_ts)
```

```
MATLAB returns:
```

```
7 9 7
```

## See Also

`iqr` | `max` | `mean` | `median` | `std` | `sum` | `timeseries` | `var`

**Purpose**

Plot time series

**Syntax**

```
plot(ts)
plot(tsc.tsname)
plot(ts,linespec)
plot(tsc.tsname,linespec)
plot(ts,Name, Value)
plot(tsc.tsname,Name, Value)
```

**Description**

`plot(ts)` plots the timeseries data `ts` against time and interpolates values between samples by using either zero-order-hold ('zoh') or linear interpolation (the default). The plot displays in the current axes. MATLAB creates a title and axes, if none exists.

`plot(tsc.tsname)` plots the timeseries object, `tsname` that is part of the `tscollection`, `tsc`.

`plot(ts,linespec)` plots the timeseries data using a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(tsc.tsname,linespec)` plots the timeseries object that is part of a timeseries collection as a line graph and applies the specified `linespec` to lines, markers, or both.

`plot(ts,Name, Value)` plots a line graph of the time series data using the values specified for `lineseries` properties.

`plot(tsc.tsname,Name, Value)` plots a line graph of the timeseries object that is part of the specified timeseries collection using the values specified for `lineseries` properties.

**Tips**

- The `timeseries/plot` method generates titles and axis labels automatically. These labels are:
  - Plot Title — 'Time Series Plot: <name>'  
where <name> is the string assigned to `ts.Name`, or by default, 'unnamed'
  - X-Axis Label — 'Time (<units>)'

# timeseries.plot

---

where `<units>` is the value of the `ts.TimeInfo.Units` field, which defaults to `'seconds'`

▪ Y-Axis Label — `'<name>'`

where `<name>` is the string assigned to `ts.Name`, or by default, `'unnamed'`

- You can place new time series data on a time series plot (by setting `hold on`, for example, and issuing another `timeseries/plot` command). When you add data to a plot, the title and axis labels become blank strings to avoid labeling confusion. You can add your own labels after plotting using the `title`, `xlabel`, and `ylabel` commands.
- Time series events, when defined, are marked in the plot with a circular marker with red fill. You can also specify markers for all data points using a `linespec` or `name/value` syntax in addition to any event markers your data defines. The event markers plot on top of the markers you define.
- The value assigned to `ts.DataInfo.Interpolation.Name` controls the type of interpolation the plot method uses when plotting and resampling time series data. Invoke the `timeseries` method `setinterpmethod` to change default linear interpolation to zero-order hold interpolation (staircase). This method creates a new `timeseries` object, with which you can overwrite the original one if you want. For example, to cause time series `ts` to use zero-order hold interpolation, type the following:

```
ts = ts.setinterpmethod('zoh');
```

## Input Arguments

**ts**  
A `timeseries` object.

**tsc**  
A `tscollection`.

**tsname**

The name of a timeseries object within the tscollection .

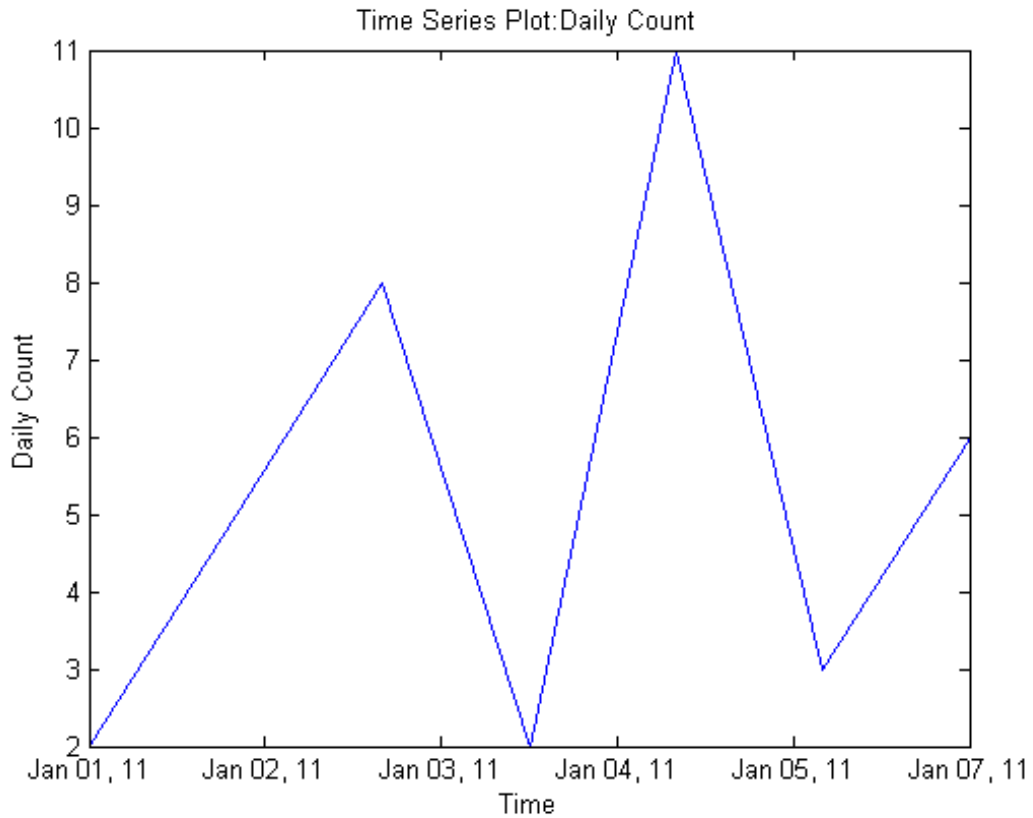

## Examples

### Plot Time Series Object with Specified Start Date

Create a time series object, set the start date, and then plot the time vector relative to the start date.

```
x = [2 5 8 2 11 3 6];
ts1 = timeseries(x,1:7);
ts1.Name = 'Daily Count';
ts1.TimeInfo.Units = 'days';
ts1.TimeInfo.StartDate='01-Jan-2011'; % Set start date.
ts1.TimeInfo.Format = 'mmm dd, yy'; % Set format for display on x-axis
ts1.Time=ts1.Time-ts1.Time(1); % Express time relative to the start date
plot(ts1)
```

# timeseries.plot

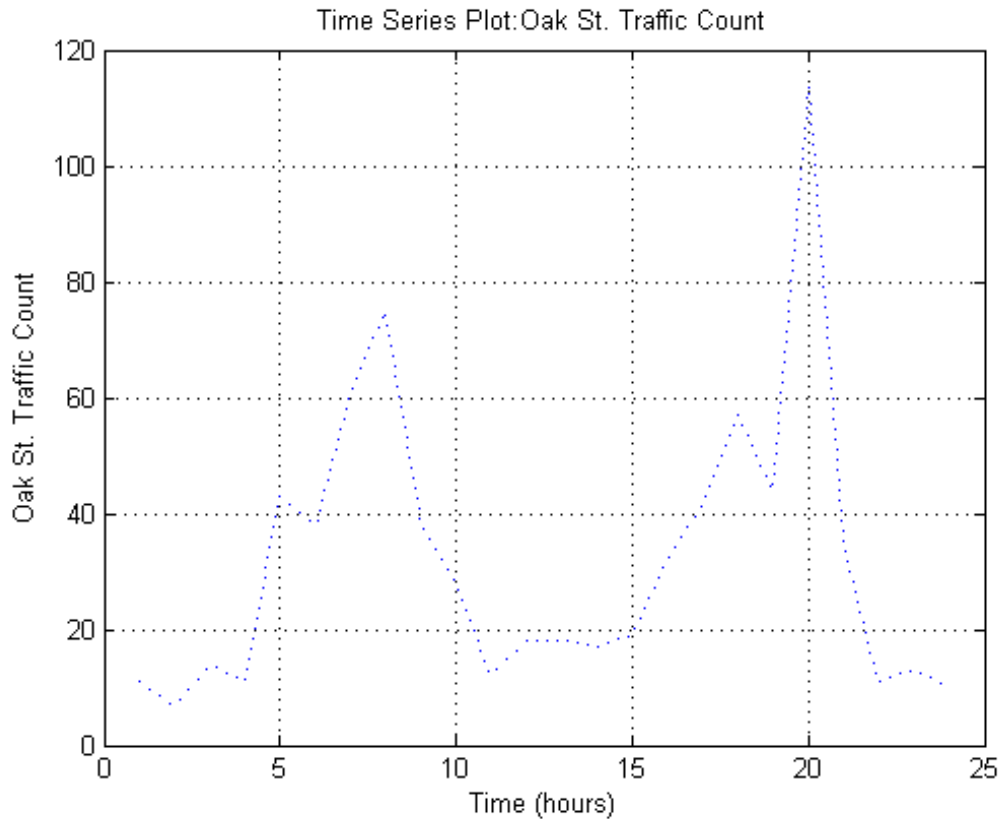

## Plot Two Time Series Objects on the Same Axes

Create two time series objects from traffic count data, and then plot them in sequence on the same axes. Add an event to one series, which is automatically displayed with a red marker.

```
load count.dat;
count1=timeseries(count(:,1),1:24);
count1.Name = 'Oak St. Traffic Count';
count1.TimeInfo.Units = 'hours';
```

```
plot(count1,':b'), grid on
```

Obtain time of maximum value and add it as an event:

```
[~,index] = max(count1.Data);
max_event = tsdata.event('peak',count1.Time(index));
max_event.Units = 'hours';
```

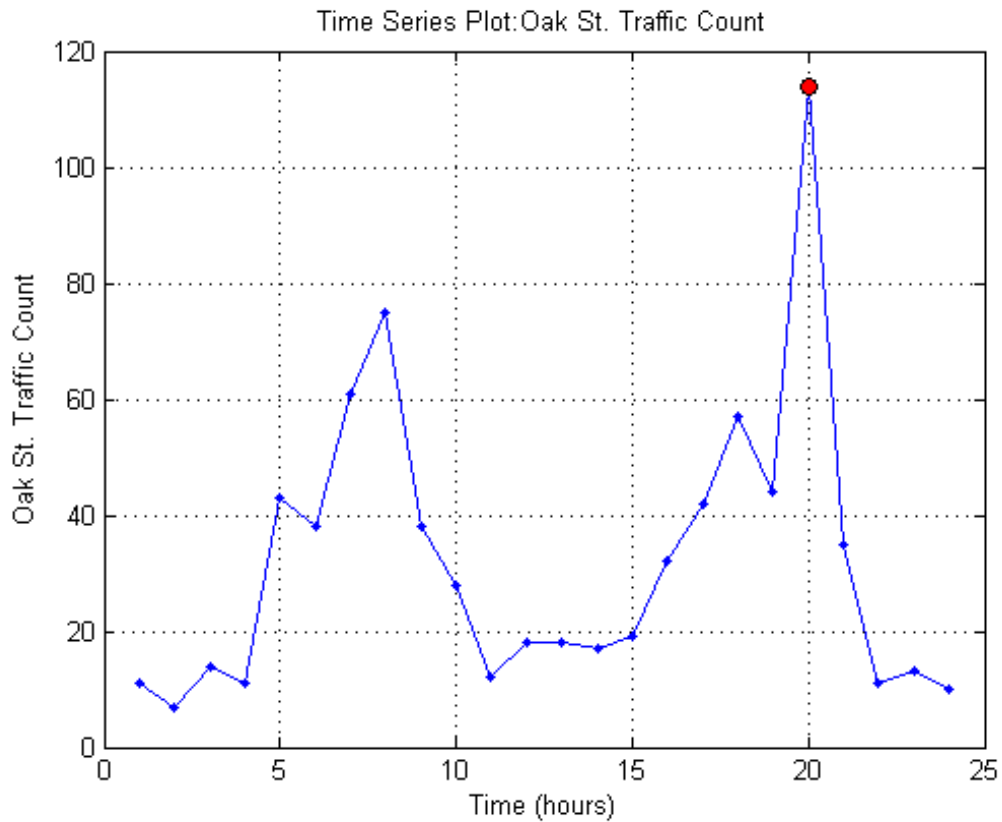

Add the event to the time series:

# timeseries.plot

```
count1 = addevent(count1,max_event);
```

Replace plot with new one showing the event:

```
plot(count1,'.-b'), grid on
```

Make a new time series object from column 2 of the same data source:

```
count2=timeseries(count(:,2),1:24);
count2.Name = 'Maple St. Traffic Count';
```

```
count2.TimeInfo.Units = 'Hours';
```

Turn hold on to add the new data to the plot:

```
hold on
```

The plot method does not add labels to a held plot. Use property/value pairs to customize markers:

```
plot(count2, 's-m', 'MarkerSize', 6),
```

# timeseries.plot

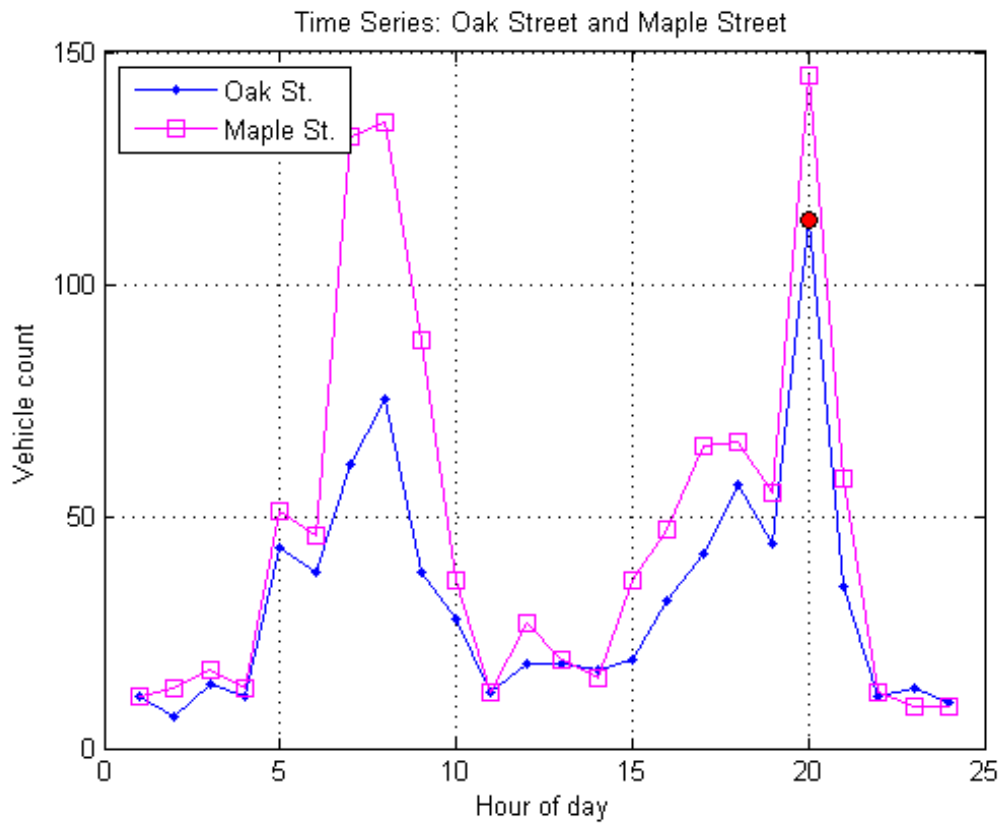

Labels are erased, so generate them manually:

```
title('Time Series: Oak Street and Maple Street')
xlabel('Hour of day')
ylabel('Vehicle count')
```

Add a legend in the upper left:

```
legend('Oak St.', 'Maple St.', 'Location', 'northwest')
```

`timeseries` | `setinterpmethod` | `tscollection` | `tsdata.event`  
| `plot`

# timeseries.resample

---

**Purpose** Select or interpolate timeseries data using new time vector

**Syntax**

```
ts1 = resample(ts, time)
ts1 = resample(ts, time, interp_method)
ts1 = resample(ts, time, interp_method, code)
```

**Description** `ts1 = resample(ts, time)` resamples the timeseries object, `ts`, using the new `time` vector. The `resample` method uses the default interpolation method, which you can view by using the `getinterpmethod(ts)` syntax.

`ts1 = resample(ts, time, interp_method)` resamples the timeseries object `ts` using the specified interpolation method, `interp_method`.

`ts1 = resample(ts, time, interp_method, code)` resamples the timeseries object `ts` using the interpolation method given by the string `interp_method`. MATLAB applies the `code` to all samples.

## Input Arguments

**ts**  
The timeseries object that you want to resample.

**time**  
The time vector you want to use to resample the timeseries object.  
When `ts` uses date strings and `time` is numeric, then `time` is treated as specified relative to the `ts.TimeInfo.StartDate` property and in the same units that `ts` uses.

**interp\_method**  
A string specifying the interpolation method. Valid interpolation methods are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

**code**

An integer value that specifies the user-defined Quality code for resampling. MATLAB applies this Quality code to all samples.

## Output Arguments

**ts1**

The `timeseries` object that results when you interpolate the original `timeseries` object with a new time vector.

## Examples

This example shows how to resample a `timeseries` object.

Create a `timeseries` object.

```
ts1 = timeseries([1.1; 2.9; 3.7; 4.0; 3.0],1:5,'Name','speed');
```

View the time, data, and interpolation method.

```
ts1.time
ts1.data
ts1.getinterpmethod
```

Resample `ts1` using its default interpolation method.

```
res_ts=resample(ts1,[1 1.5 3.5 4.5 4.9]);
```

View the time, data, and interpolation method for the resampled object.

```
res_ts.time
res_ts.data
res_ts.getinterpmethod
```

## See Also

`timeseries` | `getinterpmethod` | `setinterpmethod` | `synchronize`

# timeseries.set

---

**Purpose** Set properties of `timeseries` object

**Syntax**

```
set(ts, PropertyName, Value)
set(ts, PropertyName)
set(ts)
```

**Description** `set(ts, PropertyName, Value)` sets the named property, `Name`, of the `timeseries` object, `ts`, to the value, `Value`. The following syntax is equivalent:

```
ts.Property = Value
```

`set(ts, PropertyName)` displays the value of the named property for the `timeseries` object, `ts`.

`set(ts)` displays all properties and values of the `timeseries` object `ts`.

## Input Arguments

**ts**  
A `timeseries` object.

### PropertyName

A string specifying the name of a `timeseries` property. For a list of `timeseries` properties, see `timeseries`.

### Value

The value to which you want to set the named property.

## Examples

Create a `timeseries`, set its name to `mytimeseries`, and then view the `timeseries` properties:

```
ts1 = timeseries(rand(5,1),[1 2 3 4 5]);
set(ts1, 'Name', 'mytimeseries')
set(ts1)
```

## See Also

`timeseries` | `get`

<b>Purpose</b>	Set times of timeseries object as date strings
<b>Syntax</b>	<pre>ts1=setabstime(ts, times) ts1=setabstime(ts, times, format)</pre>
<b>Description</b>	<p><code>ts1=setabstime(ts, times)</code> sets the times in <code>ts</code> to the date strings specified in <code>times</code>.</p> <p><code>ts1=setabstime(ts, times, format)</code> explicitly specifies the date-string format, <code>format</code>, used in <code>times</code>.</p>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The timeseries object for which you want to set times as date strings.</p> <p><b>times</b></p> <p>A cell array of strings or a char array containing valid date or time values in the same date format.</p> <p><b>format</b></p> <p>The date-string format used for the time values.</p>
<b>Output Arguments</b>	<p><b>ts1</b></p> <p>The timeseries object that results from setting times as date strings on the original timeseries object.</p>
<b>Examples</b>	<p>Create a timeseries object, and then set the absolute time vector:</p> <pre>ts = timeseries(rand(3,1)) ts1 = setabstime(ts,{'12-DEC-2005 12:34:56',... <b>See Also</b>	<code>datestr</code>   <code>getabstime</code>   <code>timeseries</code>

# timeseries.setinterpmethod

---

**Purpose** Set default interpolation method for timeseries object

**Syntax**

```
ts = setinterpmethod(ts, method)
ts = setinterpmethod(ts, fhandle)
ts = setinterpmethod(ts, interpobj)
```

**Description**

`ts = setinterpmethod(ts, method)` sets the default interpolation method, `method`, for timeseries object, `ts`, and outputs it to `ts1`.

`ts = setinterpmethod(ts, fhandle)` sets the default interpolation method for timeseries object `ts`, where `fhandle` is a function handle to the interpolation method.

`ts = setinterpmethod(ts, interpobj)` sets the default interpolation method for timeseries object `ts`, where `interpobj` is a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

**Tips**

- This method is case sensitive.

## Input Arguments

**ts**

The timeseries object for which you want to set the default interpolation method.

### method

A string specifying the interpolation method. Valid values are `linear` and `zero-order hold, zoh`.

**Default:** `linear`

### fhandle

A function handle to the interpolation method. The order of input arguments defining the function handle must be `new_time`, `time`, and `data`. The single output argument must be the interpolated data only.

### interpobj

A `tsdata.interpolation` object a `tsdata.interpolation` object that directly replaces the interpolation object stored in `ts`.

## Output Arguments

**ts1**

The `timeseries` object that results when you set the interpolation method for the original `timeseries` object.

## Examples

Set the default interpolation method for `timeseries` object `ts` to zero order hold:

```
ts = timeseries(rand(100,1),1:100);
ts = setinterpmethod(ts,'zoh');
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts`, where `fhandle` is a function handle to the interpolation method defined by function handle `myFuncHandle`:

```
ts = timeseries(rand(100,1),1:100);
myFuncHandle = @(new_time, time, data)...
 interp1(time, data, new_time,...
 'linear','extrap');
ts = setinterpmethod(ts, myFuncHandle);
ts = resample(ts, [-5:0.1:10]);
plot(ts);
```

Set the default interpolation method for `timeseries` object `ts` to a `tsdata.interpolation` object:

```
ts = timeseries(rand(100,1),1:100);
myFuncHandle = @(new_time, time, data)...
 interp1(time, data, new_time,...
 'linear','extrap');
myInterpObj = tsdata.interpolation(myFuncHandle);
ts = setinterpmethod(ts,myInterpObj);
plot(ts);
```

# timeseries.setinterpmethod

---

## See Also

`timeseries | getinterpmethod`

## Purpose

Modify uniform time vector of timeseries object

## Syntax

```
ts2 = setuniformtime(ts1,'StartTime',StartTime)
ts2 = setuniformtime(ts1,'Interval',Interval)
ts2 = setuniformtime(ts1,'EndTime',EndTime)
ts2 =
setuniformtime(ts1,'StartTime',StartTime,'Interval',Interval)
ts2 =
setuniformtime(ts1,'StartTime',StartTime,'EndTime',EndTime)
ts2 =
setuniformtime(ts1,'Interval',Interval,'EndTime',EndTime)
```

## Description

`ts2 = setuniformtime(ts1,'StartTime',StartTime)` returns the time series with a modified uniform time vector, determined from the `StartTime` and `Interval`. `EndTime = StartTime + (length(ts1) - 1)`. The unit of time is unchanged.

`ts2 = setuniformtime(ts1,'Interval',Interval)` sets the `StartTime` to 0, and uses `EndTime = (length(ts1) - 1)*Interval`.

`ts2 = setuniformtime(ts1,'EndTime',EndTime)` sets the `StartTime` to 0, and uses `Interval = EndTime/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'Interval',Interval)` uses `EndTime = StartTime + (length(ts1) - 1) * Interval`.

`ts2 = setuniformtime(ts1,'StartTime',StartTime,'EndTime',EndTime)` uses `Interval = (EndTime - StartTime)/(length(ts1) - 1)`.

`ts2 = setuniformtime(ts1,'Interval',Interval,'EndTime',EndTime)` uses `StartTime = EndTime - (length(ts1) - 1) * Interval`.

## Input Arguments

### ts1

timeseries object to which you want to assign a uniform time vector.

# timeseries.setuniformtime

---

## StartTime

Start time of uniform time vector, specified as a numeric value.

## Interval

Time interval of uniform time vector, specified as a numeric scalar value.

## EndTime

End time of uniform time vector specified as a numeric scalar value.

## Output Arguments

### ts2

Time series with uniform time vector, returned as a `timeseries` object.

## Examples

### Specify New Start Time

Modify the uniform time vector of time series data by specifying a new start time.

- 1 Load the sample data.

```
load count.dat;
```

- 2 Create a `timeseries` object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
```

- 3 Modify uniform time vector of `count_ts`.

```
count_ts = setuniformtime(count_ts,'StartTime',10);
```

The start time of the time vector is 10 seconds. `setuniformtime` uses a default time interval of 1 and computes the end time using:  $EndTime = StartTime + (length(count\_ts) - 1) * Interval$ .

## Specify New Start and End Times

Modify the uniform time vector of time series data by specifying a new start time and end time.

- 1 Load sample data.

```
load count.dat;
```

- 2 Create timeseries object.

```
count_ts = timeseries(count,1:length(count),'Name','CountPerSecond');
```

- 3 Assign a uniform time vector to count\_ts.

```
count_ts2 = setuniformtime(count_ts,'StartTime',10,'EndTime',20);
```

The start time of the time vector is now 10 seconds, and the end time is now 20 seconds. MATLAB computes the time interval using:  
$$\text{Interval} = (\text{EndTime} - \text{StartTime}) / (\text{length}(\text{count\_ts}) - 1)$$

## See Also

timeseries

# timeseries.synchronize

---

**Purpose** Synchronize and resample two `timeseries` objects using common time vector

**Syntax** `[ts1 ts2] = synchronize(ts1,ts2, synchronizemethod)`  
`[ts1 ts2] = synchronize(ts1,ts2, Name,Value)`

**Description** `[ts1 ts2] = synchronize(ts1,ts2, synchronizemethod)` creates two new `timeseries` objects by synchronizing `ts1` and `ts2` using a common time vector and the specified method.

`[ts1 ts2] = synchronize(ts1,ts2, Name,Value)` creates the two new `timeseries` objects with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ts1**

One of the `timeseries` objects that you want to synchronize and resample.

### **ts2**

The other `timeseries` object that you want to synchronize and resample.

### **synchronizemethod**

A string that defines the method for synchronizing the `timeseries` object. It can be any one of the following:

- **Union** — Resample `timeseries` objects using a time vector that is a union of the time vectors of `ts1` and `ts2` on the time range where the two time vectors overlap.
- **Intersection** — Resample `timeseries` objects on a time vector that is the intersection of the time vectors of `ts1` and `ts2`.
- **Uniform** — Requires an additional argument as follows:

```
[ts1 ts2] = synchronize(ts1,ts2,'Uniform','Interval',value)
```

This method resamples time series on a uniform time vector, where `value` specifies the time interval between two consecutive samples. The uniform time vector is the overlap of the time vectors of `ts1` and `ts2`. The interval units are the smaller units of `ts1` and `ts2`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **'InterpMethod'**

Forces the specified interpolation method (over the default method) for this synchronize operation. Can be either a string, `linear` or `zoh`, or a `tsdata.interpolation` object that contains a user-defined interpolation method.

**Default:** `linear`

### **'QualityCode'**

Integer (between -128 and 127) used as the quality code for both time series after the synchronization.

### **'KeepOriginalTimes'**

Logical value (`true` or `false`) indicating whether the new time series should keep the original time values.

### **'tolerance'**

Real number used as the tolerance for differentiating two time values when comparing the `ts1` and `ts2` time vectors. The default tolerance is `1e-10`. For example, when the sixth time value in `ts1` is `5+(1e-12)` and the sixth time value in `ts2` is `5-(1e-13)`, both values are treated as `5` by default. To differentiate those

# timeseries.synchronize

---

two times, you can set 'tolerance' to a smaller value such as 1e-15, for example.

## Output Arguments

**ts1**

One of the `timeseries` objects that you synchronized and resampled.

**ts2**

The other `timeseries` object that you synchronized and resampled.

## Examples

This example illustrates how the `KeepOriginalTime` property affects synchronization.

```
% Create two timeseries, such that ts1.timeinfo.StartDate
% is one day after ts2.timeinfo.StartDate:
```

```
ts1 = timeseries([1 2],[datestr(now); datestr(now+1)]);
ts2 = timeseries([1 2],[datestr(now-1); datestr(now)]);
```

```
% If you use this code, then ts1.timeinfo.StartDate
% is changed to match ts2.TimeInfo.StartDate
% and ts1.Time changes to 1:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union');
```

```
% But if you use this code, then ts1.timeinfo.StartDate
% is unchanged and ts1.Time is still 0:
```

```
[ts1 ts2] = synchronize(ts1,ts2,'union','KeepOriginalTimes',true);
```

## See Also

[set](#) | [timeseries](#)

**Purpose** Transpose timeseries object

**Syntax** `ts1 = transpose(ts)`

**Description** `ts1 = transpose(ts)` returns a new `timeseries` object, `ts1`, with `IsTimeFirst` value set to the opposite of what it is for `ts`. For example, if `ts` has the first data dimension aligned with the time vector, `ts1` has the last data dimension aligned with the time vector.

- Tips**
- The `transpose` function that is overloaded for `timeseries` objects does not transpose the data. Instead, this function changes whether the first or the last dimension of the data aligns with the time vector. To transpose the data, transpose the `Data` property of the time series. For example, you can use the syntax `transpose(ts.Data)` or `(ts.Data).'`. The value of the `Data` property must be a 2-D array.
  - Consider a time series with 10 samples with the property `IsTimeFirst = True`. When you transpose this time series, the data size changes from 10-by-1 to 1-by-1-by-10. Note that the first dimension of the `Data` property is shown explicitly.

The following table summarizes how the size for `timeseries` data (up to three dimensions) display before and after transposing.

### Data Size Before and After Transposing

Size of Original Data	Size of Transposed Data
N-by-1	1-by-1-by-N
N-by-M	M-by-1-by-N
N-by-M-by-L	M-by-L-by-N

### Input Arguments

**ts** The `timeseries` object that you want to transpose.

# timeseries.transpose

---

## Output Arguments

**ts1**

The `timeseries` object that is the result of transposing the original `timeseries` object.

## Examples

Suppose that a `timeseries` object, `ts`, has `ts.Data` size 10-by-3-by-2 and its time vector has a length of 10. The `IsTimeFirst` property of `ts` is `true`, which means that the first dimension of the data aligns with the time vector. `transpose(ts)` modifies the `timeseries` object, such that the last dimension of the data now aligns with the time vector. This permutes the data, such that the size of `ts.Data` becomes 3-by-2-by-10.

## See Also

`timeseries` | `transpose`

---

<b>Purpose</b>	Standard deviation of timeseries data
<b>Syntax</b>	<pre>ts_std = std(ts) ts_std = std(ts,Name,Value)</pre>
<b>Description</b>	<p><code>ts_std = std(ts)</code> returns the standard deviation of the timeseries data.</p> <p><code>ts_std = std(ts,Name,Value)</code> specifies additional options specified with one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The timeseries object for which you want the standard deviation of the data.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>'MissingData'</b></p> <p>A string specifying one of two possible values, <code>remove</code> or <code>interpolate</code>, indicating how to treat missing data during the calculation.</p> <p><b>Default:</b> <code>remove</code></p> <p><b>'Quality'</b></p> <p>A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).</p> <p><b>'Weighting'</b></p>

# timeseries.std

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_std`

The standard deviation of `ts.Data` values as follows:

- When `ts.Data` is a vector, `ts_std` is the standard deviation of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_std` is the standard deviation of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `std` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example finds the standard deviation for a `timeseries` object. MATLAB calculates the standard deviation for each data column in the `timeseries` object.

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the standard deviation of each data column for this
% timeseries object:
```

```
std(count_ts)
```

```
MATLAB returns:
```

```
25.3703 41.4057 68.0281
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

## See Also

# timeseries.sum

---

**Purpose** Sum of timeseries data

**Syntax**  
`ts_sm = sum(ts)`  
`ts_sm = sum(ts,Name,Value)`

**Description** `ts_sm = sum(ts)` returns the sum of the timeseries data.  
`ts_sm = sum(ts,Name,Value)` specifies additional options with one or more `Name,Value` pair arguments.

**Input Arguments**

**ts**  
The timeseries object for which you want the sum of the data.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'MissingData'**

A string specifying one of two possible values, `remove` or `interpolate`, indicating how to treat missing data during the calculation.

**Default:** `remove`

**'Quality'**

A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).

**'Weighting'**

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_sm`

The sum of the `timeseries` data, as follows:

- When `ts.Data` is a vector, `ts_sm` is the sum of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_sm` is a row vector containing the sum of each column of `ts.Data`.

When `ts.Data` is a N-dimensional array, `sum` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

Calculate the sum of each data column for a `timeseries` object:

```
% Load a 24-by-3 data array:
```

```
load count.dat
```

```
% Create a timeseries object with 24 time values:
```

```
count_ts = timeseries(count,1:24,'Name','CountPerSecond');
```

```
% Calculate the sum of each data column for this timeseries object:
```

```
sum(count_ts)
```

```
MATLAB returns:
```

```
768 1117 1574
```

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

---

<b>Purpose</b>	Variance of timeseries data
<b>Syntax</b>	<pre>ts_var = var(ts) ts_var = var(ts,Name,Value)</pre>
<b>Description</b>	<p><code>ts_var = var(ts)</code> returns the variance of <code>ts.data</code>.</p> <p><code>ts_var = var(ts,Name,Value)</code> uses additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>ts</b></p> <p>The timeseries object for which you want the variance of the data.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code>.</p> <p><b>'MissingData'</b></p> <p>A string specifying one of two possible values, <code>remove</code> or <code>interpolate</code>, indicating how to treat missing data during the calculation.</p> <p><b>Default:</b> <code>remove</code></p> <p><b>'Quality'</b></p> <p>A vector of integers, indicating which quality codes represent missing samples (for vector data) or missing observations (for data arrays with two or more dimensions).</p> <p><b>'Weighting'</b></p>

# timeseries.var

---

A string specifying one of two possible values, `none` or `time`.  
When you specify `time`, larger time values correspond to larger weights.

## Output Arguments

### `ts_var`

The variance of `ts.data`, as follows:

- When `ts.Data` is a vector, then `ts_var` is the variance of `ts.Data` values.
- When `ts.Data` is a matrix, and `IsTimeFirst` is `true`, and the first dimension of `ts` is aligned with time, then `ts_var` is a row vector containing the variance of each column of `ts.Data`.

When `ts.Data` is an N-dimensional array, `var` always operates along the first nonsingleton dimension of `ts.Data`.

## Examples

The following example calculates the variance values of a multivariate `timeseries` object. MATLAB calculates the variance independently for each data column in the `timeseries` object.

Load a 24-by-3 data array. Then create a `timeseries` object with 24 time values.

```
load count.dat
count_ts = timeseries(count,[1:24], 'Name', 'CountPerSecond');
```

Calculate the variance of each data column.

```
var(count_ts)
```

MATLAB returns:

```
1.0e+03 *

## Algorithms

MATLAB determines weighting by:

- 1 Attaching a weighting to each time value, depending on its order, as follows:
  - First time point — The duration of the first time interval ( $t(2) - t(1)$ ).
  - Time point that is neither the first nor last time point — The duration between the midpoint of the previous time interval to the midpoint of the subsequent time interval ( $(t(k + 1) - t(k))/2 + (t(k) - t(k - 1))/2$ ).
  - Last time point — The duration of the last time interval ( $(t(\text{end}) - t(\text{end} - 1))$ ).
- 2 Normalizing the weighting for each time by dividing each weighting by the mean of all weightings.

---

**Note** If the `timeseries` object is uniformly sampled, then the normalized weighting for each time is 1.0. Therefore, time weighting has no effect.

---

- 3 Multiplying the data for each time by its normalized weighting.

# triangulation

---

**Purpose** Triangulation in 2-D or 3-D

**Description** Use `triangulation` to create an in-memory representation of any 2-D or 3-D triangulation data that is in matrix format, such as the matrix output from the `delaunay` function or other software tools. When your data is represented using `triangulation`, you can perform topological and geometric queries, which you can use to develop geometric algorithms. For example, you can find the triangles or tetrahedra attached to a vertex, those that share an edge, their circumcenters, and other features.

**Construction** `TR = triangulation(T,P)` creates a 2-D or 3-D triangulation representation using the triangulation connectivity list, `T`, and the points in matrix `P`.

`TR = triangulation(T,x,y)` creates a 2-D triangulation representation with the point coordinates specified as column vectors, `x` and `y`.

`TR = triangulation(T,x,y,z)` creates a 3-D triangulation representation with the point coordinates specified as column vectors, `x`, `y`, and `z`.

## Input Arguments

**T**

Triangulation connectivity list, specified as an  $m$ -by- $n$  matrix, where  $m$  is the number of triangles or tetrahedra, and  $n$  is the number of vertices per triangle or tetrahedron. Each element in `T` is a “Vertex ID” on page 1-5784. Each row of `T` contains the vertex IDs that define a triangle or tetrahedron.

**P**

Points, specified as a matrix whose columns are the `x`, `y`, (and possibly `z`) coordinates of the triangulation points. The row numbers of `P` are the vertex IDs in the triangulation.

**x**

*x*-coordinates vector, specified as a column vector containing the *x*-coordinates of the triangulation points.

## **y**

*y*-coordinates vector, specified as a column vector containing the *y*-coordinates of the triangulation points.

## **z**

*z*-coordinates vector, specified as a column vector containing the *z*-coordinates of the triangulation points.

## **Properties**

### **Points**

Points in the triangulation, represented as a matrix containing the following information:

- Each row in `TR.Points` contains the coordinates of a vertex.
- Each row number of `TR.Points` is a vertex ID.

### **ConnectivityList**

Triangulation connectivity list, represented as a matrix. This matrix contains the following information:

- Each element in `TR.ConnectivityList` is a vertex ID.
- Each row represents a triangle or tetrahedron in the triangulation.
- Each row number of `TR.ConnectivityList` is a “Triangle or Tetrahedron ID” on page 1-5784.

## **Methods**

<code>barycentricToCartesian</code>	Converts point coordinates from barycentric to Cartesian
<code>cartesianToBarycentric</code>	Converts point coordinates from Cartesian to barycentric

# triangulation

---

circumcenter	Circumcenter of triangle or tetrahedron
edgeAttachments	Triangles or tetrahedra attached to specified edge
edges	Triangulation edges
faceNormal	Triangulation face normal
featureEdges	Triangulation sharp edges
freeBoundary	Triangulation facets referenced by only one triangle or tetrahedron
incenter	Incenter of triangle or tetrahedron
isConnected	Test if two vertices are connected by edge
neighbors	Neighbors to specified triangle or tetrahedron
size	Size of triangulation connectivity list
vertexAttachments	Triangles or tetrahedra attached to specified vertex
vertexNormal	Triangulation vertex normal

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### 2-D Triangulation

Define the points in the triangulation.

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

Define the triangles. This is the triangulation connectivity list.

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

Create the triangulation representation.

```
TR = triangulation(T,P)
```

```
TR =
```

```
triangulation with properties:
```

```
 Points: [6x2 double]
ConnectivityList: [4x3 double]
```

Examine the coordinates of the vertices of the first triangle.

```
TR.Points(TR.ConnectivityList(1,:),:)
```

```
ans =
```

```
 1.0000 6.5000
```

# triangulation

<b>Purpose</b>	Converts point coordinates from barycentric to Cartesian
<b>Syntax</b>	<code>PC = barycentricToCartesian(TR,ti,B)</code>
<b>Description</b>	<code>PC = barycentricToCartesian(TR,ti,B)</code> returns the Cartesian coordinates of the points in <code>B</code> . Each row, <code>B(j,:)</code> , contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, <code>ti(j)</code> . The point, <code>PC(j,:)</code> , is the <code>j</code> th point represented in Cartesian coordinates.
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> . <b>ti</b> Triangle or tetrahedron IDs, specified as a column vector. <b>B</b> Barycentric coordinates, specified as a matrix. Each row, <code>B(j,:)</code> , contains the barycentric coordinates of a point with respect to the triangle or tetrahedron, <code>ti(j)</code> .
<b>Output Arguments</b>	<b>PC</b> Cartesian coordinates, returned as a matrix. The point, <code>PC(j,:)</code> , is the <code>j</code> th point represented in Cartesian coordinates.
<b>Definitions</b>	<b>Triangle or Tetrahedron ID</b> A row number of the matrix, <code>TR.ConnectivityList</code> . Use this ID to refer a specific triangle or tetrahedron.
<b>Examples</b>	<b>Barycentric Coordinates Converted to Cartesian Coordinates</b> Create a triangulation from a set of points, <code>P</code> , and triangulation connectivity list, <code>T</code> .

# triangulation.barycentricToCartesian

---

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

```
TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Specify the barycentric coordinates of the second point in the triangle.

```
B = [0 1 0];
```

Convert the point to Cartesian coordinates.

```
PC = barycentricToCartesian(TR,ti,B)
```

```
PC =
```

```
2.5000 5.0000
```

## Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
```

```
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2), '*r');
hold off;
axis equal;
```

# triangulation.barycentricToCartesian

---

Create a new triangulation which is a deformed version of DT .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of DT, and use them to compute the Cartesian coordinates of the analogous points in TR.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
```

```
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```

# triangulation.barycentricToCartesian

---

```

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

```
TR = triangulation(T,P);
```

Specify the first triangle.

```
ti = 1;
```

Get the coordinates of the third vertex in the first triangle.

```
PC = TR.Points(TR.ConnectivityList(1,3),:)
```

```
PC =
```

```
2.5000 8.0000
```

Convert the point to barycentric coordinates.

```
B = cartesianToBarycentric(TR,ti,PC)
```

```
B =
```

```
0 0 1
```

## Mapped Incenters of Deformed Triangulation

Create a Delaunay triangulation from a set of points.

```
x = [0 4 8 12 0 4 8 12]';
y = [0 0 0 0 8 8 8 8]';
DT = delaunayTriangulation(x,y);
```

Calculate the Cartesian coordinates of the incenters.

```
cc = incenter(DT);
```

Plot the original triangulation and reference points.

```
figure
subplot(1,2,1);
triplot(DT);
hold on;
plot(cc(:,1),cc(:,2),'*r');
hold off;
axis equal;
```

# triangulation.cartesianToBarycentric

---

Create a new triangulation which is a deformed version of DT .

```
ti = DT.ConnectivityList;
y = [0 0 0 0 16 16 16 16]';
TR = triangulation(ti,x,y);
```

Compute the barycentric coordinates for the incenters of DT, and use them to compute the Cartesian coordinates of the analogous points in TR.

```
b = cartesianToBarycentric(DT,[1:length(ti)]',cc);
```

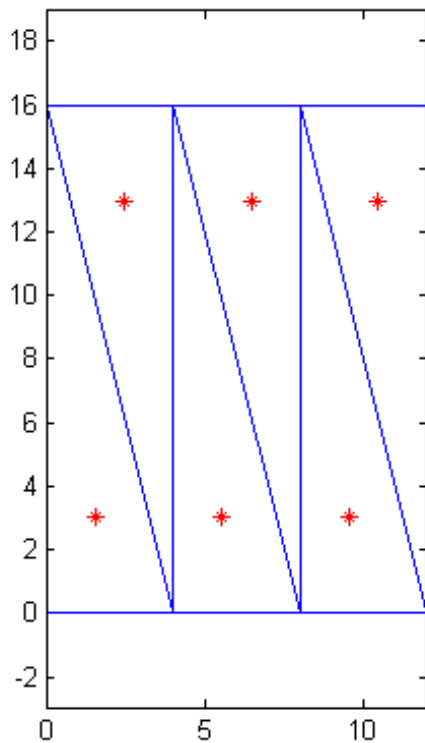

```
xc = barycentricToCartesian(TR,[1:length(ti)]',b);
```

Plot the deformed triangulation and mapped locations of the reference points.

```
subplot(1,2,2);
triplot(TR);
hold on;
plot(xc(:,1),xc(:,2),'*r');
hold off;
axis equal;
```

# triangulation.cartesianToBarycentric

---

**See Also**

[barycentricToCartesian](#) | [delaunayTriangulation](#)

**Purpose** Circumcenter of triangle or tetrahedron

**Syntax**

```
CC = circumcenter(TR,ti)
[CC,r] = circumcenter(TR,ti)
CC = circumcenter(TR)
[CC,r] = circumcenter(TR)
```

**Description**

`CC = circumcenter(TR,ti)` returns the coordinates of the circumcenter of each triangle or tetrahedron specified in `ti`.

`[CC,r] = circumcenter(TR,ti)` also returns the corresponding radii of the circumscribed circles or spheres.

`CC = circumcenter(TR)` returns the circumcenters of all triangles or tetrahedra in the triangulation.

`[CC,r] = circumcenter(TR)` also returns the corresponding radii of the circumscribed circles or spheres for the entire triangulation.

**Input Arguments**

**TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**

Triangle or tetrahedron IDs, specified as a column vector.

**Output Arguments**

**CC**

Circumcenters, returned as a matrix. Each row, `CC(j,:)`, contains the coordinates of the circumcenter of `ti(j)`.

**r**

Radii of the circumscribed circles or spheres, returned as a vector. The radius at `r(j)` corresponds to the circle or sphere circumscribing `ti(j)`.

# triangulation.circumcenter

---

## Definitions

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Circumcenters in 2-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Compute the circumcenters.

```
CC = circumcenter(TR);
triplot(TR)
axis([-50 350 -50 350]);
axis equal;
hold on;
plot(CC(:,1),CC(:,2),'*r');
hold off;
```

The circumcenters represent points on the medial axis of the polygon.

## **Circumcenters in 3-D Delaunay Triangulation**

Create the Delaunay triangulation using a random set of points, P.

```
P = gallery('uniformdata',10,3,0);
DT = delaunayTriangulation(P);
```

Calculate the circumcenters of the first five tetrahedra in DT.

# triangulation.circumcenter

---

```
CC = circumcenter(DT,[1:5]')
```

```
CC =
```

```
 0.9626 0.3892 0.0928
 6.3458 0.2377 3.1814
 0.4820 0.9064 0.5176
 -1.2993 1.8384 -1.2185
 -0.1595 1.0852 -0.2536
```

**See Also**      [incenter](#) | [delaunayTriangulation](#)

**Purpose**

Triangles or tetrahedra attached to specified edge

**Syntax**

```
ti = edgeAttachments(TR,vstart,vend)
ti = edgeAttachments(TR,E)
```

**Description**

`ti = edgeAttachments(TR,vstart,vend)` returns the triangles or tetrahedra attached to the specified edges. To specify the edges, use the vectors, `vstart` and `vend`. These vectors contain the “Vertex ID” on page 1-5804 at the start and end of each edge.

`ti = edgeAttachments(TR,E)` specifies the starting and ending vertices of each edge in a 2-column matrix, `E`.

**Input Arguments****TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**vstart**

IDs of starting vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the start of an edge.

**vend**

IDs of ending vertices, specified as a column vector of vertex IDs. Each ID refers to a vertex at the end of an edge.

**E**

IDs of the edge vertices, specified as a 2-column matrix of vertex IDs. Each row of `E` corresponds to an edge and contains two IDs:

- $E(j,1)$  is the ID of the vertex at the start of an edge.
- $E(j,2)$  is the ID of the vertex at end of the edge.

**Output Arguments****ti**

IDs of the triangles or tetrahedra attached to the edges, returned as an  $m$ -by-1 cell array. Each cell in `ti` contains the IDs of the

# triangulation.edgeAttachments

---

attached triangles or tetrahedra. The attachments to the edge located between the vertices, `vstart(j)` and `vend(j)`, or `E(j, :)`, are returned in `ti{j}`. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each edge can vary.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

### Triangle or Tetrahedron ID

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

## Examples

### Edge Attachments in 3-D Triangulation

Load 2-D triangulation data and create a triangulation representation.

```
load tetmesh
TR = triangulation(tet,X);
```

Define the starting and ending vertices of the edges.

```
vstart = [15; 21];
vend = [936; 716];
```

Find the edge attachments.

```
ti = edgeAttachments(TR,vstart,vend);
```

Examine the attachments to the first edge.

```
ti{1}
```

```
ans =
```

```
 927 2060 3438 3423 2583 4690
```

## Edge Attachments in 2-D Delaunay Triangulation

Create a Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to edge (1,5).

```
ti = edgeAttachments(DT,1,5);
ti{:}
```

```
ans =
```

```
 4 1
```

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Feature Edges Shown on a Surface

Use `featureEdges` to find the feature edges of a surface and display them on a plot.

Create a surface triangulation.

```
x = [0 0 0 0 0 3 3 3 3 3 3 6 6 6 6 6 9 9 9 9 9 9]';
y = [0 2 4 6 8 0 1 3 5 7 8 0 2 4 6 8 0 1 3 5 7 8]';
DT = delaunayTriangulation(x,y);
T = DT(:,:);
```

Elevate the 2-D mesh to create a surface.

```
z = [0 0 0 0 0 2 2 2 2 2 2 0 0 0 0 0 0 0 0 0 0 0]';
subplot(1,2,1);
trisurf(T,x,y,z,'FaceColor','cyan');
axis equal;
```

# triangulation.featureEdges

---

Compute the feature edges using a filter angle of  $\pi/6$ .

```
TR = triangulation(T,x,y,z);
fe = featureEdges(TR,pi/6)';
subplot(1,2,2);
trisurf(TR,'FaceColor','cyan','EdgeColor',...
'none','FaceAlpha',0.8);
axis equal;
```

```
% Add the feature edges to the plot.
```

```
hold on;
plot3(x(fe), y(fe), z(fe), 'k', 'LineWidth',1.5);
hold off;
```

**See Also** [edges](#) | [delaunayTriangulation](#)

# triangulation.freeBoundary

---

**Purpose** Triangulation facets referenced by only one triangle or tetrahedron

**Syntax** `FBtri = freeBoundary(TR)`  
`[FBtri,FBpoints] = freeBoundary(TR)`

**Description** `FBtri = freeBoundary(TR)` returns the free boundary facets of `TR.ConnectivityList`. A facet in `TR` is on the free boundary if it is referenced by only one triangle or tetrahedron.

`[FBtri,FBpoints] = freeBoundary(TR)` also returns a matrix containing the vertices of the free boundary facets.

## Input Arguments

**TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

## Output Arguments

**FBtri**  
Triangulation connectivity list, returned as a matrix that contains the following information:

- Each row in `FBtri` represents a facet on the free boundary.
- Each element is a “Vertex ID” on page 1-5817.

The vertex IDs in `FBtri` reference a specific matrix, depending on the syntax you choose:

- If you call `freeBoundary` with one output argument, then the elements of `FBtri` are row numbers of `TR.Points`.
- If you call `freeBoundary` with two output arguments, then the elements of `FBtri` are row numbers of `FBpoints`.

**FBpoints**

Free boundary points, returned as a matrix containing the coordinates of the vertices of the free boundary facets. Each row of `FBpoints` contains coordinates of a vertex.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points` or `FBpoints`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Surface of 3-D Triangulation

Use `freeBoundary` to extract the facets of a 3-D triangulation that cover the surface of an object.

Load a 3-D triangulation.

```
load tetmesh;
TR = triangulation(tet,X);
```

Compute the boundary triangulation.

```
[FBtri,FBpoints] = freeBoundary(TR);
```

Plot the boundary triangulation.

```
trisurf(FBtri,FBpoints(:,1),FBpoints(:,2),FBpoints(:,3), ...
 'FaceColor','cyan','FaceAlpha', 0.8);
```

# triangulation.freeBoundary

---

## Free Boundary of 2-D Delaunay Triangulation

Use `freeBoundary` when you want to highlight the outer edges of a 2-D Delaunay triangulation.

Create a triangulation from a random set of points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the free boundary edges.

```
fe = freeBoundary(DT)';
```

Plot the mesh and highlight the free boundary edges in red.

```
triplot(DT);
hold on;
plot(x(fe),y(fe),'-r','LineWidth',2) ;
hold off;
```

# triangulation.freeBoundary

---

<b>Purpose</b>	Incenter of triangle or tetrahedron
<b>Syntax</b>	<code>IC = incenter(TR,ti)</code> <code>[IC,r] = incenter(TR,ti)</code>
<b>Description</b>	<code>IC = incenter(TR,ti)</code> returns the coordinates of the incenter of each triangle or tetrahedron specified by <code>ti</code> . <code>[IC,r] = incenter(TR,ti)</code> also returns the radii of the inscribed circles or spheres.
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> . <b>ti</b> Triangle or tetrahedron IDs, specified as a column vector.
<b>Output Arguments</b>	<b>IC</b> Incenters, returned as a matrix. Each row of <code>IC</code> contains the coordinates of an incenter. For example, <code>IC(j,:)</code> is the incenter of <code>ti(j)</code> . <b>r</b> Radii of the inscribed circles or spheres, returned as a vector. <code>r(j)</code> is the radius of the inscribed circle or sphere whose center is <code>IC(j,:)</code> .
<b>Definitions</b>	<b>Triangle or Tetrahedron ID</b> A row number of the matrix, <code>TR.ConnectivityList</code> . Use this ID to refer a specific triangle or tetrahedron.
<b>Examples</b>	<b>Find Incenters in 3-D Triangulation</b> Load a 3-D triangulation.

# triangulation.incenter

---

```
load tetmesh
```

Calculate the incenters of the first five tetrahedra.

```
TR = triangulation(tet,X);
IC = incenter(TR,[1:5]')
```

```
IC =
```

```
-6.1083 -31.0234 8.1439
-2.1439 -31.0283 5.8742

-4.3019 -30.8460 10.5169
-3.1596 -29.3642 6.1851
```

## Find Incenters in 2-D Delaunay Triangulation

Create the Delaunay triangulation.

```
x = [0 1 1 0 0.5]';
y = [0 0 1 1 0.5]';
DT = delaunayTriangulation(x,y);
```

Calculate incenters of the triangles

```
IC = incenter(DT)
```

```
IC =
```

```
0.2071 0.5000
0.5000 0.7929
0.7929 0.5000
0.5000 0.2071
```

Plot the triangles and incenters.

```
triplot(DT);
axis equal;
axis([-0.2 1.2 -0.2 1.2]);
hold on;
plot(IC(:,1),IC(:,2),'*r');
hold off;
```

# triangulation.incenter

---

## See Also

`circumcenter` | `deLaunayTriangulation`

**Purpose**

Test if two vertices are connected by edge

**Syntax**

```
tf = isConnected(TR,vstart,vend)
tf = isConnected(TR,E)
```

**Description**

`tf = isConnected(TR,vstart,vend)` returns a logical array of true or false values that indicate whether the specified pairs of vertices are connected by an edge. Element `tf(j)` is true when the vertices, `vstart(j)` and `vend(j)`, are connected by an edge.

`tf = isConnected(TR,E)` specifies the edge start and end indices in matrix `E`. Element `tf(j)` is true when the vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

**Input Arguments****TR**

Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**vstart**

IDs of start vertices, specified as a column vector. Each vertex ID refers to a vertex at the start of an edge.

**vend**

IDs of end vertices, specified as a column vector. Each vertex ID refers to a vertex at the end of an edge.

**E**

IDs of the edge vertices, specified as a two-column matrix. Each row of `E` corresponds to a candidate edge and contains two IDs:

- `E(j,1)` is the ID of the vertex at the start of a candidate edge.
- `E(j,2)` is the ID of the vertex at end of the edge.

# triangulation.isConnected

---

## Output Arguments

**tf**

Logical values, returned as a column vector. Element `tf(j)` is true when either of the following are true:

- The vertices, `vstart(j)` and `vend(j)`, are connected by an edge.
- The vertices, `E(j,1)` and `E(j,2)`, are connected by an edge.

Otherwise, `tf(j)` is false.

## Definitions

### Vertex ID

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Determine Whether Vertices are connected by an Edge in 2-D

Load a 2-D triangulation.

```
load trimesh2d
TR = triangulation(tri,x,y);
```

Determine whether vertices 3 and 117 are connected by an edge.

```
isConnected(TR,3,117)
```

```
ans =
```

```
1
```

The vertices are connected by an edge.

Determine whether vertices 3 and 164 are connected by an edge.

```
isConnected(TR,3,164)
```

```
ans =
```

0

The vertices are not connected by an edge.

## Determine Whether Vertices are connected by an Edge in 3-D

```
X = gallery('uniformdata',[10,3],0);
DT = delaunayTriangulation(X);
```

Determine whether vertices 2 and 7 are connected by an edge.

```
E = [2 7];
isConnected(DT,E)
```

```
ans =
```

1

The vertices are connected by an edge.

# triangulation.neighbors

---

**Purpose** Neighbors to specified triangle or tetrahedron

**Syntax** `N = neighbors(TR,ti)`  
`N = neighbors(TR)`

**Description** `N = neighbors(TR,ti)` returns the neighbors of the triangles or tetrahedra specified in `ti`.  
`N = neighbors(TR)` returns the neighbors of all the triangles or tetrahedra.

**Input Arguments** **TR**  
Triangulation representation, see `triangulation` or `delaunayTriangulation`.

**ti**  
Triangle or tetrahedron IDs, specified as a column vector.

**Output Arguments** **TN**  
IDs of the neighboring triangles or tetrahedra, returned as a matrix. The elements in `TN(i,:)` are the neighbors associated with `ti(i)`.  
By convention, `TN(i,j)` is the neighbor opposite the `j`th vertex of `ti(i)`. If a triangle or tetrahedron has one or more boundary facets, the nonexistent neighbors are represented as NaN values in `TN`.

**Definitions** **Triangle or Tetrahedron ID**

A row number of the matrix, `TR.ConnectivityList`. Use this ID to refer a specific triangle or tetrahedron.

**Vertex ID**

A row number of the matrix, `TR.Points`. Use this ID to refer a specific vertex in the triangulation.

## Examples

### Query Neighbors in 2-D Delaunay Triangulation

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[10,1],0);
y = gallery('uniformdata',[10,1],1);
DT = delaunayTriangulation(x,y);
```

Find the neighbors of the first triangle.

```
TN = neighbors(DT,1)
```

```
TN =
```

```
NaN 4 5
```

The first triangle has a boundary edge and two neighbors.

Examine the vertex IDs of the first neighbor, TN(2).

```
DT.ConnectivityList(TN(2),:)
```

```
ans =
```

```
2 4 7
```

### Query Neighbors in 3-D Triangulation

Create the Delaunay triangulation.

```
load tetmesh
TR = triangulation(tet,X);
```

Find the neighbors to each triangle in the triangulation.

```
TN = neighbors(TR);
```

Find the neighbors of the fifth tetrahedron.

```
TN(5,:)
```

# triangulation.neighbors

---

```
ans =
 2360 1539 2 1851
```

Examine the vertex IDs of the first neighbor, `TN(1)`.

```
TR.ConnectivityList(TN(1),:)
```

```
ans =
 1093 891 893 858
```

## See Also

[edgeAttachments](#) | [delaunayTriangulation](#)

<b>Purpose</b>	Size of triangulation connectivity list
<b>Syntax</b>	<code>sz = size(TR)</code>
<b>Description</b>	<code>sz = size(TR)</code> returns the size the triangulation connectivity list.
<b>Input Arguments</b>	<b>TR</b> Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code> .
<b>Output Arguments</b>	<b>sz</b> Size of connectivity list, returned as a two-element row vector. The first element, <code>sz(1)</code> is the number of triangles or tetrahedra in the triangulation, and <code>sz(2)</code> is the number of vertices per triangle or tetrahedron.

## Examples **Size of 2-D Triangulation**

Create a triangulation.

```
P = [2.5 8.0
 6.5 8.0
 2.5 5.0
 6.5 5.0
 1.0 6.5
 8.0 6.5];
```

```
T = [5 3 1;
 3 2 1;
 3 4 2;
 4 6 2];
```

```
TR = triangulation(T,P);
```

Get the size of the connectivity list.

# triangulation.size

---

```
size(TR)
```

```
ans =
```

```
 4 3
```

The triangulation has 4 triangles, and each triangle has 3 vertices.

## See Also

[size](#) | [delaunayTriangulation](#)

<b>Purpose</b>	Triangles or tetrahedra attached to specified vertex
<b>Syntax</b>	<pre>ti = vertexAttachments(TR,vi) ti = vertexAttachments(TR)</pre>
<b>Description</b>	<p><code>ti = vertexAttachments(TR,vi)</code> returns the triangles or tetrahedra attached to the specified vertices, <code>vi</code>.</p> <p><code>ti = vertexAttachments(TR)</code> returns the triangles or tetrahedra attached to every vertex in the triangulation.</p>
<b>Input Arguments</b>	<p><b>TR</b></p> <p>Triangulation representation, see <code>triangulation</code> or <code>delaunayTriangulation</code>.</p> <p><b>vi</b></p> <p>Query vertices, specified as a column vector of vertex IDs.</p>
<b>Output Arguments</b>	<p><b>ti</b></p> <p>IDs of the triangles or tetrahedra attached to the vertices, returned as an <code>m</code>-by-1 cell array. Each cell in <code>ti</code> contains the IDs of the attached triangles or tetrahedra. <code>ti{j}</code> contains the attachments to the vertex, <code>vi(j)</code>. The attachments are returned in a cell array because the number of triangles or tetrahedra associated with each vertex can vary.</p>
<b>Definitions</b>	<p><b>Triangle or Tetrahedron ID</b></p> <p>A row number of the matrix, <code>TR.ConnectivityList</code>. Use this ID to refer a specific triangle or tetrahedron.</p> <p><b>Vertex ID</b></p> <p>A row number of the matrix, <code>TR.Points</code>. Use this ID to refer a specific vertex in the triangulation.</p>

# triangulation.vertexAttachments

---

## Examples

### Attachments to Specific Vertex in 2-D Delaunay Triangulation

Locate and plot the attachments to a specific vertex.

Create a Delaunay triangulation from a set of random points.

```
x = gallery('uniformdata',[20,1],0);
y = gallery('uniformdata',[20,1],1);
DT = delaunayTriangulation(x,y);
```

Find the triangles attached to the fifth vertex.

```
ti = vertexAttachments(DT,5);
ti{:}
```

```
ans =
```

```
 18 23 21 22
```

Plot the triangulation.

```
triplot(DT);
hold on;

% Plot the triangles attached to vertex 5 (in red).
triplot(DT(ti{:},:),x,y,'Color','r');
hold off;
```

**See Also** [edgeAttachments](#) | [delaunayTriangulation](#)

# triangulation.vertexNormal

---

**Purpose** Triangulation vertex normal

**Syntax** VN = vertexNormal(TR,vi)  
VN = vertexNormal(TR)

**Description** VN = vertexNormal(TR,vi) returns the unit normal vector to each of the specified vertices in vi.  
VN = vertexNormal(TR) returns the normal information for all vertices in the triangulation.

**Input Arguments** **TR**  
Triangulation representation, see triangulation or delaunayTriangulation.

**vi**  
IDs of vertices to query, specified as a column vector. Each element in vi is a “Vertex ID” on page 1-5836.

**Output Arguments** **VN**  
Vertex normals, returned a matrix. Each row, VN(j,:), is the unit normal vector at the vertex vi(j). The vector at VN(j,:) is the average unit normal of the faces attached to vertex vi(j).  
If you do not specify vi, then vertexNormal returns the unit normal information for all vertices in the triangulation. In this case, the normal associated with TR.Points(j,:) is VN(j,:).

**Definitions** **Vertex ID**  
A row number of the matrix, TR.Points. Use this ID to refer a specific vertex in the triangulation.

**Examples** **Unit Normal Vectors to the Surface of a Cube**

Create a 3-D triangulation representing the volume of a cube.

```
[X,Y,Z] = meshgrid(1:4);
X = X(:);
Y = Y(:);
Z = Z(:);
dt = delaunayTriangulation(X,Y,Z);
```

Find the surfaces of the cube and isolate them in a 2-D triangulation.

```
[Tfb,Xfb] = freeBoundary(dt);
TR = triangulation(Tfb,Xfb);
```

Find the unit normal vectors to the triangles on the surface of the cube.

```
vn = vertexNormal(TR);
```

Plot the results.

```
trisurf(TR,'FaceColor',[0.8 0.8 1.0]);
axis equal
hold on
quiver3(Xfb(:,1),Xfb(:,2),Xfb(:,3),...
 vn(:,1),vn(:,2),vn(:,3),0.5,'color','b');
hold off
```

# triangulation.vertexNormal

---

## See Also

`freeBoundary` | `deLaunayTriangulation`

**Purpose**

Create table from file

**Syntax**

```
T = readtable(filename)
T = readtable(filename,Name,Value)
```

**Description**

`T = readtable(filename)` creates a table by reading column oriented data from a file.

`readtable` determines the file format from the file name's extension:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, `.xlsx`, `.xltm`, `.xltx`, or `.ods` for spreadsheet files

`readtable` creates one variable in `T` for each column in the file and reads variable names from the first row of the file. By default, the variables created are `double` if the entire column is numeric, or cell arrays of strings if any element in a column is not numeric.

`T = readtable(filename,Name,Value)` creates a table from a file with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify not to read the first row of the file as variable names.

**Input Arguments****filename - Name of file to read**

string

Name of the file to read, specified as a string. If `filename` includes the file extension, then `readtable` determines the file format from the extension. Otherwise, you must specify the 'FileType' name-value pair arguments to indicate the type of file.

On Windows systems with Microsoft Excel software, `readtable` reads any Excel spreadsheet file format recognized by your version of Excel. If your system does not have Excel for Windows, `readtable` operates

# readtable

---

in `basic` import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

For a delimited text file, `readtable` converts empty fields in the file to either NaN (for a numeric variable) or the empty string (for a string-valued variable). All lines in the text file must have the same number of delimiters. `readtable` ignores insignificant white space in the file.

**Example:** `'myFile.xlsx'`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'ReadVariableNames'`, `false` indicates that the first row of the file does not correspond to variable names.

## **'FileType' - Type of file**

`'text' | 'spreadsheet'`

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

You must specify the `'FileType'` name-value pair argument if the filename input argument does not include the file extension or if the extension is other than one of the following.

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xism`, `.xlsx`, `.xlsm`, `.xltx`, or `.ods` for spreadsheet files

**Example:** `'FileType', 'text'`

## **'ReadVariableNames' - Indicator for reading first row as variable names**

`true (default) | false | 1 | 0`

Indicator for reading the first row as variable names, specified as the comma-separated pair consisting of 'ReadVariableNames' and either true, false, 1, or 0.

**true**            The first row of the region to read contains the variable names for the table. This is the default behavior.

If both the 'ReadVariableNames' and 'ReadRowNames' logical indicators are true, then readtable saves the name in the first column of the first row of the region to read as the first dimension name in the property, T.Properties.DimensionNames.

**false**            The first row of the region to read contains the first row of data in the table.

readtable creates default variable names of the form 'Var1', ..., 'VarN', where N is the number of variables.

## **'ReadRowNames' - Indicator for reading the first column as row names**

false (default) | true | 0 | 1

Indicator for reading first column as row names, specified as the comma-separated pair consisting of 'ReadRowNames' and either false, true, 0, or 1.

# readtable

---

false	The first column of the region to read contains the first variable in the table. It does not contain the row names for the table. This is the default behavior.
true	The first column of the region to read contains the row names for the table.  If both the 'ReadVariableNames' and 'ReadRowNames' logical indicators are true, then readtable saves the name in the first column of the first row of the region to read as the first dimension name in the property, T.Properties.DimensionNames.

## 'TreatAsEmpty' - Strings to treat as empty value

string | cell array of strings

Strings to treat as empty value, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a string or a cell array of strings. Table elements corresponding to these are set to NaN.

'TreatAsEmpty' only applies to numeric columns in the file, and readtable does not accept numeric literals, such as '-99'.

**Example:** 'TreatAsEmpty', 'N/A' sets N/A within numeric columns to NaN.

**Example:** 'TreatAsEmpty', {'.', 'NA', 'N/A'} sets ., NA and N/A within numeric columns to NaN.

## 'Delimiter' - Field delimiter character

string

Field delimiter character, specified as the comma-separated pair consisting of 'Delimiter' and one of the following strings:

<code>' , '</code>	Comma. This is the default behavior.
<code>' comma '</code>	
<code>' ' '</code>	Space
<code>' space '</code>	
<code>' \t '</code>	Tab
<code>' tab '</code>	
<code>' ; '</code>	Semicolon
<code>' semi '</code>	
<code>'   '</code>	Vertical bar
<code>' bar '</code>	

You can use the `'Delimiter'` name-value pair only with delimited text files.

**Example:** `'Delimiter','space'`

### **'HeaderLines' - Number of lines to skip at beginning of file**

0 (default) | positive integer

Number of lines to skip at beginning of file, specified as the comma-separated pair consisting of `'HeaderLines'` and a positive integer.

You can use the `'HeaderLines'` name-value pair only with delimited text files.

### **Data Types**

single | double

### **'Format' - Format of columns in file**

string of one or more conversion specifiers

Format of the columns in the file, specified as the comma-separated pair consisting of `'Format'` and a string of one or more conversion specifiers.

By default, the variables created are either `double`, if the entire column is numeric, or cell arrays of strings, if any element in a column is not numeric.

The conversion specifiers are the same as those accepted by the `textscan` function. If you specify the 'Format' name-value pair argument, you can specify any of the name-value pair arguments accepted by the `textscan` function.

Specifying the format can significantly improve speed for some large files.

You can use the 'Format' name-value pair only with delimited text files.

## 'Sheet' - Worksheet to read

1 (default) | positive integer indicating worksheet index | string containing worksheet name

Worksheet to read, specified as the comma-separated pair consisting of 'Sheet' and a positive integer indicating the worksheet index or a string containing the worksheet name. The worksheet name string cannot contain a colon (:). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsfinfo(filename)`.

You can use the 'Sheet' name-value pair only with spreadsheet files.

**Example:** 'Sheet',2

## 'Range' - Rectangular portion of worksheet to read

string

Rectangular portion of the worksheet to read, specified as the comma-separated pair consisting of 'Range' and a string.

Specify the range using the syntax '*Corner1:Corner2*', where *Corner1* and *Corner2* are two opposing corners that define the region to read. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The 'Range' name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).

If the spreadsheet contains figures or other nontabular information, use the 'Range' name-value pair argument to read only the tabular data. By default, `readtable` reads data from a spreadsheet contiguously out to the right-most column that contains data, including any empty columns that precede it.

You can use the 'Range' name-value pair only with spreadsheet files.

**Example:** 'Range', 'D2:H4'

### 'Basic' - Indicator for reading in basic mode

true | false | 1 | 0

Indicator for reading in basic mode, specified as the comma-separated pair consisting of 'Basic' and either true, false, 1, or 0.

basic mode is the default for systems without Excel for Windows. In basic mode, `readtable`:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support the 'Range' name-value pair argument when reading XLS files.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

You can use the 'Basic' name-value pair only with spreadsheet files.

## Output Arguments

### T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Create Table from Text File

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

# readtable

---

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file.

```
T = readtable('myCsvTable.dat')
```

```
T =
```

LastName	Gender	Age	Height	Weight	Smoker
'Smith'	'M'	38	71	176	1
'Johnson'	'M'	43	69	163	0
'Williams'	'F'	38	64	131	0
'Jones'	'F'	40	67	133	0
'Brown'	'F'	49	64	119	0

T contains one variable for each column in the file and `readtable` the entries in first line of the file as variable names.

## Create Table from Text File without Column Headings

Create a file, `mySpaceDelimTable.txt`, that contains the following space delimited, column oriented data.

```
M 45 45 NY true
F 41 32 CA false
M 40 34 MA false
```

Create a table from the space delimited text file that does not contain variable names as column headings.

```
T = readtable('mySpaceDelimTable.txt',...
 'Delimiter',' ','ReadVariableNames',false)
```

```
T =
```

Var1	Var2	Var3	Var4	Var5
'M'	45	45	'NY'	'true'
'F'	41	32	'CA'	'false'
'M'	40	34	'MA'	'false'

T contains default variable names.

### Create and Format Table from Text File

Create a file, `myCsvTable.dat`, that contains the following comma-separated column oriented data.

```
LastName,Gender,Age,Height,Weight,Smoker
Smith,M,38,71,176,1
Johnson,M,43,69,163,0
Williams,F,38,64,131,0
Jones,F,40,67,133,0
Brown,F,49,64,119,0
```

Create a table from the comma-separated text file. Format the first two variables as strings, the third variable as `uint32`, and the next two variables as double-precision, floating-point numbers. Format the last variable as a string.

```
T = readtable('myCsvTable.dat','Format','%s%s%u%f%f%s')
```

```
T =
```

LastName	Gender	Age	Height	Weight	Smoker
'Smith'	'M'	38	71	176	'1'
'Johnson'	'M'	43	69	163	'0'
'Williams'	'F'	38	64	131	'0'
'Jones'	'F'	40	67	133	'0'

# readtable

---

```
'Brown' 'F' 49 64 119 '0'
```

The conversion specifiers are %s for a cell array of strings, %f for double, and %u for uint32.

## Create Table from Spreadsheet Including Row Names

Create a table from a spreadsheet that contains variable names in the first row and row names in the first column.

```
T = readtable('patients.xls','ReadRowNames',true);
```

Display the first five rows and first four variables of the table.

```
T(1:5,1:4)
```

```
ans =
```

	Gender	Age	Location	Height
Smith	'Male'	38	'County General Hospital'	71
Johnson	'Male'	43	'VA Hospital'	69
Williams	'Female'	38	'St. Mary's Medical Center'	64
Jones	'Female'	40	'VA Hospital'	67
Brown	'Female'	49	'County General Hospital'	64

View the DimensionNames property of the table.

```
T.Properties.DimensionNames
```

```
ans =
```

```
'LastName' 'Variable'
```

'LastName' is the name in the first column of the first row of the spreadsheet.

## Read Specific Range of Data from Spreadsheet

Create a table from the 5-by-3 rectangular region between the two corners C2 and E6 on the spreadsheet `patients.xls`. Do not use the first row of this region as variable names.

```
T = readtable('patients.xls',...
 'Range','C2:E6',...
 'ReadVariableNames',false)
```

T =

Var1	Var2	Var3
38	'County General Hospital'	71
43	'VA Hospital'	69
38	'St. Mary's Medical Center'	64
40	'VA Hospital'	67
49	'County General Hospital'	64

# real

---

**Purpose** Real part of complex number

**Syntax** `X = real(Z)`

**Description** `X = real(Z)` returns the real part of the elements of the complex array `Z`.

**Examples** `real(2+3*i)` is 2.

**See Also** `abs` | `angle` | `conj` | `i` | `j` | `imag`

**Purpose** Natural logarithm for nonnegative real arrays

**Syntax** `Y = reallog(X)`

**Description** `Y = reallog(X)` returns the natural logarithm of each element in array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

**Examples**

```
M = magic(4)

M =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
reallog(M)
```

```
ans =
 2.7726 0.6931 1.0986 2.5649
 1.6094 2.3979 2.3026 2.0794
 2.1972 1.9459 1.7918 2.4849
 1.3863 2.6391 2.7081 0
```

# realmax

---

**Purpose** Largest positive floating-point number

**Syntax** `n = realmax`

**Description** `n = realmax` returns the largest finite floating-point number in IEEE double precision.

`realmax('double')` is the same as `realmax` with no arguments.

`realmax('single')` returns the largest finite floating-point number in IEEE single precision.

**Examples** Find the value of the constant `realmax`:

```
ndouble = realmax
nsingle = realmax('single')
```

```
ndouble =
 1.7977e+308
```

```
nsingle =
 3.4028e+38
```

# realpow

---

**Purpose** Array power for real-only output

**Syntax** `Z = realpow(X,Y)`

**Description** `Z = realpow(X,Y)` raises each element of array `X` to the power of its corresponding element in array `Y`. Arrays `X` and `Y` must be the same size. The range of `realpow` is the set of all real numbers, i.e., all elements of the output array `Z` must be real.

**Examples** `X = -2*ones(3,3)`

```
X =
 -2 -2 -2
 -2 -2 -2
 -2 -2 -2
```

```
Y = pascal(3)
```

```
ans =
 1 1 1
 1 2 3
 1 3 6
```

```
realpow(X,Y)
```

```
ans =
 -2 -2 -2
 -2 4 -8
 -2 -8 64
```

**See Also** `reallog` | `realsqrt` | `power` | `mpower`

**Purpose** Square root for nonnegative real arrays

**Syntax** `Y = realsqrt(X)`

**Description** `Y = realsqrt(X)` returns the square root of each element of array `X`. Array `X` must contain only nonnegative real numbers. The size of `Y` is the same as the size of `X`.

**Examples** `M = magic(4)`

```
M =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

 3.0000 2.6458 2.4495 3.4641
 2.0000 3.7417 3.8730 1.0000
```

**See Also** `reallog` | `realpow` | `sqrt` | `sqrtm`

# record

---

**Purpose** Record data and event information to file

**Syntax** `record(obj)`  
`record(obj, 'switch')`

**Description** `record(obj)` toggles the recording state for the serial port object, `obj`. `record(obj, 'switch')` initiates or terminates recording for `obj`. `switch` can be `on` or `off`. If `switch` is `on`, recording is initiated. If `switch` is `off`, recording is terminated.

**Tips** Before you can record information to disk, `obj` must be connected to the device with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to record information while `obj` is not connected to the device. Each serial port object must record information to a separate file. Recording is automatically terminated when `obj` is disconnected from the device with `fclose`.

The `RecordName` and `RecordMode` properties are read-only while `obj` is recording, and must be configured before using `record`.

For a detailed description of the record file format and the properties associated with recording data and event information to a file, refer to [Debugging: Recording Information to Disk](#).

**Examples** This example creates the serial port object `s` on a Windows platform. It connects `s` to the device, configures `s` to record information to a file, writes and reads text data, and then disconnects `s` from the device.

```
s = serial('COM1');
fopen(s)
s.RecordDetail = 'verbose';
s.RecordName = 'MySerialFile.txt';
record(s, 'on')
fprintf(s, '*IDN?')
out = fscanf(s);
record(s, 'off')
```

`fclose(s)`

## **See Also**

`fclose` | `fopen` | `RecordDetail` | `RecordMode` | `RecordName` | `RecordStatus` | `Status`

# audiorecorder.record

---

**Purpose** Record audio to audiorecorder object

**Syntax** `record(recorderObj)`  
`record(recorderObj, length)`

**Description** `record(recorderObj)` records audio from an input device, such as a microphone connected to your system. `recorderObj` is an audiorecorder object that defines the sample rate, bit depth, and other properties of the recording.

`record(recorderObj, length)` records for the number of seconds specified by `length`.

**Examples** Record 5 seconds of your speech with a microphone:

```
myVoice = audiorecorder;

% Define callbacks to show when
% recording starts and completes.
myVoice.StartFcn = 'disp(''Start speaking.'')';
myVoice.StopFcn = 'disp(''End of recording.'')';

record(myVoice, 5);
```

To listen to the recording, call the `play` method:

```
play(myVoice);
```

**See Also** [audiorecorder](#) | [getaudiodata](#) | [recordblocking](#)

**How To**

- “Record Audio”
- “Record or Play Audio within a Function”

<b>Purpose</b>	Record audio to audiorecorder object, holding control until recording completes
<b>Syntax</b>	<code>recordblocking(recorderObj, length)</code>
<b>Description</b>	<code>recordblocking(recorderObj, length)</code> records audio from an input device, such as a microphone connected to your system, for the number of seconds specified by <i>length</i> . The <code>recordblocking</code> method does not return control until recording completes. <i>recorderObj</i> is an audiorecorder object that defines the sample rate, bit depth, and other properties of the recording.
<b>Examples</b>	Record 5 seconds of your speech with a microphone, and play it back:  <pre>myVoice = audiorecorder;  disp('Start speaking.');</pre> <code>recordblocking(myVoice, 5);</code> <pre>disp('End of recording. Playing back ...');</pre> <pre>play(myVoice);</pre>
<b>See Also</b>	<code>audiorecorder</code>   <code>getaudiodata</code>   <code>record</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Record Audio”</li></ul>

# rectangle

---

**Purpose** Create 2-D rectangle object

**Syntax**

```
rectangle
rectangle('Position',[x,y,w,h])
rectangle('Curvature',[x,y])
rectangle('PropertyName',propertyvalue,...)
h = rectangle(...)
```

**Properties** For a list of properties, see Rectangle Properties.

**Description** `rectangle` draws a rectangle with Position `[0,0,1,1]` and Curvature `[0,0]` (i.e., no curvature).

`rectangle('Position',[x,y,w,h])` draws the rectangle from the point `x,y` and having a width of `w` and a height of `h`. Specify values in axes data units.

Note that, to display a rectangle in the specified proportions, you need to set the axes data aspect ratio so that one unit is of equal length along both the `x` and `y` axes. You can do this with the command `axis equal` or `daspect([1,1,1])`.

`rectangle('Curvature',[x,y])` specifies the curvature of the rectangle sides, enabling it to vary from a rectangle to an ellipse. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from 0 (no curvature) to 1 (maximum curvature). A value of `[0,0]` creates a rectangle with square sides. A value of `[1,1]` creates an ellipse. If you specify only one value for Curvature, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

`rectangle('PropertyName',propertyvalue,...)` draws the rectangle using the values for the property name/property value pairs specified and default values for all other properties. For a description of the properties, see Rectangle Properties.

`h = rectangle(...)` returns the handle of the rectangle object created.

## Tips

Rectangle objects are 2-D and can be drawn in an axes only if the view is `[0 90]` (i.e., `view(2)`). Rectangles are children of axes and are defined in coordinates of the axes data.

## Examples

This example sets the data aspect ratio to `[1,1,1]` so that the rectangle is displayed in the specified proportions (`daspect`). Note that the horizontal and vertical curvature can be different. Also, note the effects of using a single value for `Curvature`.

```
rectangle('Position',[0.59,0.35,3.75,1.37],...
 'Curvature',[0.8,0.4],...
 'LineWidth',2,'LineStyle','--')
daspect([1,1,1])
```

Specifying a single value of `[0.4]` for `Curvature` produces

# rectangle

---

A Curvature of [1] produces a rectangle with the shortest side completely round:

This example creates an ellipse and colors the face red.

```
rectangle('Position',[1,2,5,10],'Curvature',[1,1],...
 'FaceColor','r')
daspect([1,1,1])
xlim([0,7])
```

```
ylim([1,13])
```

## Setting Default Properties

You can set default rectangle properties on the axes, figure, and root object levels:

```
set(0, 'DefaultRectangleProperty', PropertyValue...)
set(gcf, 'DefaultRectangleProperty', PropertyValue...)
set(gca, 'DefaultRectangleProperty', PropertyValue...)
```

where *Property* is the name of the rectangle property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the surface properties.

# rectangle

---

## **See Also**

[line](#) | [patch](#) | [annotation](#) | [Rectangle Properties](#)

## Purpose

Define rectangle properties

## Creating Rectangle Objects

Use `rectangle` to create rectangle objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- “Customize Objects in Graph” is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

See “Core Graphics Objects” for general information about this type of object.

## Rectangle Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this rectangle object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the rectangle object is displayed in a figure legend:

# Rectangle Properties

---

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Represent this rectangle object in a legend (default)
off	Do not include this rectangle object in a legend
children	Same as on because rectangle objects do not have children

## Setting the IconDisplayStyle property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Control Legend Content” for more information and examples.

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

**BusyAction**  
cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the **Interruptible** property of the callback controls whether other callbacks can interrupt the *running* callback, see the **Interruptible** property description.

**ButtonDownFcn**  
function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the rectangle object.

See the figure's **SelectionType** property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

# Rectangle Properties

---

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
 sel_typ = get(gcf, 'SelectionType')
 switch sel_typ
 case 'normal'
 disp('User clicked left-mouse button')
 set(src, 'Selected', 'on')
 case 'extend'
 disp('User did a shift-click')
 set(src, 'Selected', 'on')
 case 'alt'
 disp('User did a control-click')
 set(src, 'Selected', 'on')
 set(src, 'SelectionHighlight', 'off')
 end
end
```

Suppose `h` is the handle of a rectangle object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h, 'ButtonDownFcn', @button_down)
```

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

**Children**  
vector of handles

The empty matrix; rectangle objects have no children.

**Clipping**  
{on} | off

*Clipping mode.* MATLAB clips rectangles to the axes plot box by default. If you set `Clipping` to `off`, rectangles are displayed outside the axes plot box. This can occur if you create a rectangle, set `hold` to `on`, freeze axis scaling (`axis` set to `manual`), and then create a larger rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a rectangle object. You must define this property as a default value for rectangles or in a call to the `rectangle` function to create a new rectangle object. For example, the statement:

```
set(0,'DefaultRectangleCreateFcn',@rect_create)
```

defines a default value for the rectangle `CreateFcn` property on the root level that sets the axes `DataAspectRatio` whenever you create a rectangle object. The callback function must be on your MATLAB path when you execute the above statement.

```
function rect_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
 axh = get(src,'Parent');
 set(axh,'DataAspectRatio',[1,1,1])
end
```

MATLAB executes this function after setting all rectangle properties. Setting this property on an existing rectangle object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function

# Rectangle Properties

---

and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Curvature

one- or two-element vector [x,y]

*Amount of horizontal and vertical curvature.* Specifies the curvature of the rectangle sides, which enables the shape of the rectangle to vary from rectangular to ellipsoidal. The horizontal curvature `x` is the fraction of width of the rectangle that is curved along the top and bottom edges. The vertical curvature `y` is the fraction of the height of the rectangle that is curved along the left and right edges.

The values of `x` and `y` can range from 0 (no curvature) to 1 (maximum curvature). A value of [0,0] creates a rectangle with square sides. A value of [1,1] creates an ellipse. If you specify only one value for `Curvature`, then the same length (in axes data units) is curved along both horizontal and vertical sides. The amount of curvature is determined by the shorter dimension.

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete rectangle callback function.* Executes when you delete the rectangle object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
```

```
obj_tp = get(src,'Type');
disp([obj_tp, ' object deleted'])
disp('Its user data is:')
disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the rectangle object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

# Rectangle Properties

---

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

## EdgeColor

`{ColorSpec} | none`

*Color of the rectangle edges.* Specifies the color of the rectangle edges as a color or specifies that no edges be drawn.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase rectangle objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the rectangle when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- `xor` — Draw and erase the rectangle by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath the rectangle.

However, the rectangle's color depends on the color of whatever is beneath it on the display.

- **background** — Erase the rectangle by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is none. This damages objects that are behind the erased rectangle, but rectangles are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

`FaceColor`  
`ColorSpec` | `{none}`

*Color of rectangle face.* Specifies the color of the rectangle face, which is not colored by default.

`HandleVisibility`  
`{on}` | `callback` | `off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.

# Rectangle Properties

---

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the `Root ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

`HitTest`  
{on} | off

*Selectable by mouse click.* Determines if the rectangle can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the

rectangle. If `HitTest` is off, clicking the rectangle selects the object below it (which might be the axes containing it).

## Interruptible

off | {on}

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

# Rectangle Properties

---

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of rectangle edge.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Width of the rectangle edge line.* Specify this value in points. 1 point =  $\frac{1}{72}$  inch. The default value is 0.5 points.

## Parent

handle of axes, hgroup, or hgtransform

*Parent of rectangle object.* Contains the handle of the rectangle object's parent. The parent of a rectangle object is the axes, hgroup, or hgtransform object that contains it.

## Position

four-element vector [x,y,width,height]

*Location and size of rectangle.* Specifies the location and size of the rectangle in the data units of the axes. The point defined by x, y specifies one corner of the rectangle, and width and height define the size in units along the x- and y-axes respectively.

## Selected

on | off

*Is object selected?* When this property is on MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing handles at each vertex. When SelectionHighlight is off, MATLAB does not draw the handles.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

# Rectangle Properties

---

## Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For rectangle objects, Type is always 'rectangle'.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the rectangle.* Assign this property the handle of a uicontextmenu object created in the same figure as the rectangle. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the rectangle.

## UserData

matrix

*User-specified data.* Data you want to associate with the rectangle object. The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Rectangle visibility.* By default, all rectangles are visible. When set to off, the rectangle is not visible, but still exists, and you can get and set its properties.

## See Also

rectangle

**Purpose** Rectangle intersection area

**Syntax** `area = rectint(A,B)`

**Description** `area = rectint(A,B)` returns the area of intersection of the rectangles specified by position vectors `A` and `B`.

If `A` and `B` each specify one rectangle, the output `area` is a scalar.

`A` and `B` can also be matrices, where each row is a position vector. `area` is then a matrix giving the intersection of all rectangles specified by `A` with all the rectangles specified by `B`. That is, if `A` is `n`-by-4 and `B` is `m`-by-4, then `area` is an `n`-by-`m` matrix where `area(i,j)` is the intersection area of the rectangles specified by the `i`th row of `A` and the `j`th row of `B`.

---

**Note** A position vector is a four-element vector `[x,y,width,height]`, where the point defined by `x` and `y` specifies one corner of the rectangle, and `width` and `height` define the size in units along the `x` and `y` axes respectively.

---

# recycle

---

**Purpose** Set option to move deleted files to recycle folder

**Syntax** `status = recycle`  
`oldState = recycle(state)`

**Description** `status = recycle` returns the current state for recycling files you remove using the `delete` function. When `status` is `off`, the `delete` function permanently removes the files. When `status` is `on`, deleted files move to a different location. For details, see the Tips section.

`oldState = recycle(state)` sets the recycle option for MATLAB to the specified state, either `on` or `off`. The `previousStat` value is the recycle state before running the statement.

## Input Arguments

### **state - State of recycle option**

`'on' | 'off'`

State of the recycle option, specified as `'on'` or `'off'`.

## Examples

### **View Current Recycling State**

Start from a state where file recycling is `off`. Verify the current recycle state.

```
state = recycle
```

```
state =
```

```
off
```

### **Turn File Recycling On**

Turn file recycling `on`. Then, delete an existing file and move it to the recycle bin or temporary folder.

```
recycle('on');
delete('myfile.txt')
```

## Tips

- The location for storing recycled files varies by platform, as follows:
  - Microsoft Windows systems — Recycle bin.
  - Apple Macintosh systems — Trash.
  - Linux systems — Subfolder with the prefix `MATLAB_Files_` in the system temporary folder, as returned by the `tempdir` function.
- The general preference for **Deleting files** sets the state of the `recycle` function at startup. When you change the preference, it changes the state of `recycle`. However, when you change the state of `recycle`, it does not change the preference.

# reducepatch

---

**Purpose** Reduce number of patch faces

**Syntax**

```
reducepatch(p,r)
nfv = reducepatch(p,r)
nfv = reducepatch(fv,r)
nfv = reducepatch(p)
nfv = reducepatch(fv)
reducepatch(...,'fast')
reducepatch(...,'verbose')
nfv = reducepatch(f,v,r)
[nf,nv] = reducepatch(...)
```

**Description** `reducepatch(p,r)` reduces the number of faces of the patch identified by handle `p`, while attempting to preserve the overall shape of the original object. The MATLAB software interprets the reduction factor `r` in one of two ways depending on its value:

- If `r` is less than 1, `r` is interpreted as a fraction of the original number of faces. For example, if you specify `r` as 0.2, then the number of faces is reduced to 20% of the number in the original patch.
- If `r` is greater than or equal to 1, then `r` is the target number of faces. For example, if you specify `r` as 400, then the number of faces is reduced until there are 400 faces remaining.

`nfv = reducepatch(p,r)` returns the reduced set of faces and vertices but does not set the `Faces` and `Vertices` properties of patch `p`. The struct `nfv` contains the faces and vertices after reduction.

`nfv = reducepatch(fv,r)` performs the reduction on the faces and vertices in the struct `fv`.

`nfv = reducepatch(p)` and `nfv = reducepatch(fv)` uses a reduction value of 0.5.

`reducepatch(...,'fast')` assumes the vertices are unique and does not compute shared vertices.

`reducepatch(...,'verbose')` prints progress messages to the command window as the computation progresses.

`nfv = reducepatch(f,v,r)` performs the reduction on the faces in `f` and the vertices in `v`.

`[nf,nv] = reducepatch(...)` returns the faces and vertices in the arrays `nf` and `nv`.

## Tips

If the patch contains nonshared vertices, MATLAB computes shared vertices before reducing the number of faces. If the faces of the patch are not triangles, MATLAB triangulates the faces before reduction. The faces returned are always defined as triangles.

The number of output triangles may not be exactly the number specified with the reduction factor argument (`r`), particularly if the faces of the original patch are not triangles.

## Examples

This example illustrates the effect of reducing the number of faces to only 15% of the original value.

```
[x,y,z,v] = flow;
p = patch(isosurface(x,y,z,v,-3));
set(p,'facecolor','w','EdgeColor','b');
daspect([1,1,1])
view(3)
figure;
h = axes;
p2 = copyobj(p,h);
reducepatch(p2,0.15)
daspect([1,1,1])
view(3)
```

# reducepatch

---

Before Reduction

After Reduction to 15% of Original Number of Faces

# reducevolume

---

**Purpose** Reduce number of elements in volume data set

**Syntax**  
`[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])`  
`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])`  
`nv = reducevolume(...)`

**Description** `[nx,ny,nz,nv] = reducevolume(X,Y,Z,V,[Rx,Ry,Rz])` reduces the number of elements in the volume by retaining every  $R_x^{\text{th}}$  element in the  $x$  direction, every  $R_y^{\text{th}}$  element in the  $y$  direction, and every  $R_z^{\text{th}}$  element in the  $z$  direction. If a scalar  $R$  is used to indicate the amount or reduction instead of a three-element vector, the MATLAB software assumes the reduction to be `[R R R]`.

The arrays  $X$ ,  $Y$ , and  $Z$  define the coordinates for the volume  $V$ . The reduced volume is returned in  $nv$ , and the coordinates of the reduced volume are returned in  $nx$ ,  $ny$ , and  $nz$ .

`[nx,ny,nz,nv] = reducevolume(V,[Rx,Ry,Rz])` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as `[X,Y,Z] = meshgrid(1:n,1:m,1:p)`, where `[m,n,p] = size(V)`.

`nv = reducevolume(...)` returns only the reduced volume.

## Examples

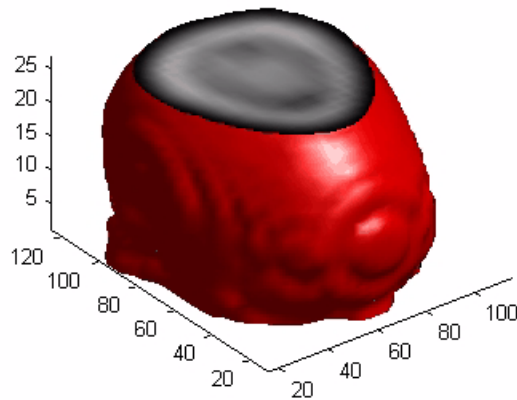

This example uses a data set that is a collection of MRI slices of a human skull. This data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then reduced (`reducevolume`) so that what remains is every fourth element in the  $x$  and  $y$  directions and every element in the  $z$  direction.
- The reduced data is smoothed (`smooth3`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with an interpolated face color draws the end caps (`FaceColor`) `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).

- A 100-element grayscale colormap provides coloring for the end caps (colormap).
- Adding a light to the right of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = reducevolume(D,[4,4,1]);
D = smooth3(D);
p1 = patch(isosurface(x,y,z,D, 5,'verbose'),...
 'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
 'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight; lighting gouraud
```

# refresh

---

**Purpose** Redraw current figure

**Syntax** refresh  
refresh(h)

**Description** refresh erases and redraws the current figure.  
refresh(h) redraws the figure identified by h.

**Purpose**

Refresh data in graph when data source is specified

**Syntax**

```
refreshdata
refreshdata(figure_handle)
refreshdata(object_handles)
refreshdata(object_handles, 'workspace')
```

**Description**

`refreshdata` evaluates any data source properties (XDataSource, YDataSource, or ZDataSource) on all objects in graphs in the current figure. If the specified data source has changed, the MATLAB software updates the graph to reflect this change.

---

**Note** The variable assigned to the data source property must be in the base workspace or you must specify the *workspace* option as '*caller*'.

---

`refreshdata(figure_handle)` refreshes the data of the objects in the specified figure.

`refreshdata(object_handles)` refreshes the data of the objects specified in *object\_handles* or the children of those objects. Therefore, *object\_handles* can contain figure, axes, or plot object handles.

`refreshdata(object_handles, 'workspace')` enables you to specify whether the data source properties are evaluated in the base workspace or the workspace of the function in which `refreshdata` was called. *workspace* is a string that can be

- `base` — Evaluate the data source properties in the base workspace.
- `caller` — Evaluate the data source properties in the workspace of the function that called `refreshdata`.

**Tips**

The Linked Plots feature (see documentation for `linkdata`) sets up data sources for graphs and synchronizes them with the workspace variables they display. When you use this feature, you do not also need to call

# refreshdata

---

refreshdata, as it is essentially automatically triggered every time a data source changes.

If you are not using the Linked Plots feature, you need to set the XDataSource, YDataSource, and/or ZDataSource properties of a graph in order to use refreshdata. You can do that programmatically, as shown in the examples below, or use the Property Editor, one of the plotting tools. In the Property Editor, select the graph (e.g., a lineseries object) and type in (or select from the drop-down choices) the name(s) of the workspace variable(s) from which you want the plot to refresh, in the fields labelled **X Data Source**, **Y Data Source**, and/or **Z Data Source**. The call to refreshdata causes the graph to update.

## Examples

### Refresh Graph with Updated Data

Plot a sine wave and return the line handle, h.

```
x = linspace(0,8);
y = sin(x);
figure
h = plot(x,y);
```

Identify the data sources for the plot by setting the `XDataSource` and `YDataSource` properties of the line to `x` and `y`, respectively. Then, modify `y`. Call `refreshdata` so that the graph updates with the changes to `y`.

```
set(h,'XDataSource','x');
set(h,'YDataSource','y');
```

```
y = sin(x.^3);
refreshdata
```

# refreshdata

---

## How To

- plot objects
- “Updating Plot Object Axis and Color Data”

**Purpose**

Match regular expression (case sensitive)

**Syntax**

```
startIndex = regexp(str,expression)
[startIndex,endIndex] = regexp(str,expression)
```

```
out = regexp(str,expression,outkey)
[out1,...,outN] =
regexp(str,expression,outkey1,...,outkeyN)
```

```
___ = regexp(___,option1,...,optionM)
```

**Description**

`startIndex = regexp(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexp(str,expression)` returns the starting and ending indices of all matches.

`out = regexp(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is 'match', then `regexp` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] = regexp(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify 'match','tokens', then `regexp` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexp( ___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify 'ignorecase' to perform a case-insensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

## Input Arguments

### **str - Input text**

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If **str** and **expression** are both cell arrays, they must have the same dimensions.

### **Data Types**

char | cell

### **expression - Regular expression**

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in **str**.

The following tables describe the elements of regular expressions.

### **Metacharacters**

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	'..ain' matches sequences of five consecutive characters that end with 'ain'.
[c <sub>1</sub> c <sub>2</sub> c <sub>3</sub> ]	Any character contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	'[rp.]ain' matches 'rain' or 'pain' or '.ain'.

Metacharacter	Description	Example
