<code>[^c<sub>1</sub>c<sub>2</sub>c<sub>3</sub>]</code>	Any character not contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in 'ain', except 'rain' and 'pain' and '*ain'. For example, it matches 'gain', 'lain', or 'vain'.
<code>[c<sub>1</sub>-c<sub>2</sub>]</code>	Any character in the range of c <sub>1</sub> through c <sub>2</sub>	' <code>[A-G]</code> ' matches a single character in the range of A through G.
<code>\w</code>	Any alphabetic, numeric, or underscore character. For English character sets, <code>\w</code> is equivalent to <code>[a-zA-Z_0-9]</code>	' <code>\w*</code> ' identifies a word.
<code>\W</code>	Any character that is not alphabetic, numeric, or underscore. For English character sets, <code>\W</code> is equivalent to <code>[^a-zA-Z_0-9]</code>	' <code>\W*</code> ' identifies a substring that is not a word.
<code>\s</code>	Any white-space character; equivalent to <code>[\f\n\r\t\v]</code>	' <code>\w*n\s</code> ' matches words that end with the letter n, followed by a white-space character.
<code>\S</code>	Any non-white-space character; equivalent to <code>[^\f\n\r\t\v]</code>	' <code>\d\S</code> ' matches a numeric digit followed by any non-white-space character.
<code>\d</code>	Any numeric digit; equivalent to <code>[0-9]</code>	' <code>\d*</code> ' matches any number of consecutive digits.
<code>\D</code>	Any nondigit character; equivalent to <code>[^0-9]</code>	' <code>\w*\D\&gt;</code> ' matches words that do not end with a numeric digit.

# regexp

Metacharacter	Description	Example
<code>\oN</code> or <code>\o{N}</code>	Character of octal value N	' <code>\o{40}</code> ' matches the space character, defined by octal 40.
<code>\xN</code> or <code>\x{N}</code>	Character of hexadecimal value N	' <code>\x2C</code> ' matches the comma character, defined by hex 2C.

## Character Representation

Operator	Description
<code>\a</code>	Alarm (beep)
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

## Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
<code>expr*</code>	0 or more times consecutively.	' <code>\w*</code> ' matches a word of any length.
<code>expr?</code>	0 times or 1 time.	' <code>\w*(\.\m)?</code> ' matches words that optionally end with the extension <code>.m</code> .

Quantifier	Matches the expression when it occurs...	Example
<code>expr+</code>	1 or more times consecutively.	' <code>&lt;img src="\w+\.gif"&gt;</code> ' matches an <code>&lt;img&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least <code>m</code> times, but no more than <code>n</code> times consecutively. <code>{0,1}</code> is equivalent to <code>?</code> .	' <code>\S{4,8}</code> ' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <code>m</code> times consecutively. <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	' <code>&lt;a href="\w{1,}\.html"&gt;</code> ' matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <code>n</code> times consecutively. Equivalent to <code>{n,n}</code> .	' <code>\d{4}</code> ' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. `q` represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> '
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*?&gt;</code> ' ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):

# regexp

Mode	Description	Example
		'<tr>' ' <td>' '</td>'
exprq+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

## Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.

Grouping Operator	Description	Example
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.*)Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1 expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

### Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr\$	End of the input string.	'\w*m\$' matches words ending with m at the end of the string.
\<expr	Beginning of a word.	'\<n\w*' matches any words starting with n.
expr\>	End of a word.	'\w*e\>' matches any words ending with e.

### Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

# regexp

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?=test)</code>	Look ahead for characters that match <code>test</code> .	<code>'\w*(?=ing)'</code> matches strings that are followed by <code>ing</code> , such as <code>'Fly'</code> and <code>'fall'</code> in the input string <code>'Flying, not falling.'</code>
<code>expr(?!test)</code>	Look ahead for characters that do not match <code>test</code> .	<code>'i(?!ng)'</code> matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .
<code>(?&lt;=test)expr</code>	Look behind for characters that match <code>test</code> .	<code>'(?&lt;=re)\w*'</code> matches strings that follow <code>'re'</code> , such as <code>'new'</code> , <code>'use'</code> , and <code>'cycle'</code> in the input string <code>'renew, reuse, recycle'</code>
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match <code>test</code> .	<code>'(?&lt;!\d)(\d)(?!\d)'</code> matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both <code>test</code> and <code>expr</code> .	<code>'(?=[a-z])[^aeiou]'</code> matches consonants.
<code>(?!test)expr</code>	Match <code>expr</code> and do not match <code>test</code> .	<code>'(?![aeiou])[a-z]'</code> matches consonants.

## Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any,

to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookahead operators, or dynamic expressions of the form (?@cmd). Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
expr1 expr2	Match expression expr1 or expression expr2. If there is a match with expr1, then expr2 is ignored.	'(let tel)\w+' matches words in a string that start with let or tel.
(?(cond)expr)	If condition cond is true, then match expr.	'(?:(?@ispc)[A-Z]:\\)' matches a drive name, such as C:\, when run on a Windows system.
(?(cond)expr1 expr2)	If condition cond is true, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

### Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

# regexp

Ordinal Token Operator	Description	Example
(expr)	Capture in a token the characters that match the enclosed expression.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag)\w+).*>.*</\ktag>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex)s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

**Note** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

### Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)(??\w{\$1})' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by cmd, and include the string returned by the command in the match expression.	'(.{2,}).?(??@fliplr(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by cmd, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(\\w)(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

# regexp

---

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
<code>&amp;</code> or <code>\$0</code>	Portion of the input string that is currently a match
<code>\$`</code>	Portion of the input string that precedes the current match
<code>\$'</code>	Portion of the input string that follows the current match (use <code>\$'</code> to represent the string <code>\$'</code> )
<code>\$N</code>	Nth token
<code>\$&lt;name&gt;</code>	Named token
<code>\${cmd}</code>	String returned when MATLAB executes the command, <code>cmd</code>

## Comments

Characters	Description	Example
<code>(?#comment)</code>	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	<code>'(?# Initial digit)\&lt;\d\w+'</code> includes a comment, and matches words that begin with a number.

## Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
<code>(?-i)</code>	Match letter case (default for <code>regexp</code> and <code>regexprep</code> ).
<code>(?i)</code>	Do not match letter case (default for <code>regexpi</code> ).

Flag	Description
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

`(?i)\w*`

or inside the parentheses and separated from the flag with a colon (:), such as

`(?i:\w*)`

The latter syntax allows you to change the behavior for part of a larger expression.

**Data Types**

char | cell

**outkey - Keyword that indicates which outputs to return**

'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names' | 'split'

Keyword that indicates which outputs to return, specified as one of the following strings.

# regexp

---

Output Keyword	Returns
'start'	Starting indices of all matches, <code>startIndex</code>
'end'	Ending indices of all matches, <code>endIndex</code>
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in <code>expression</code>
'tokens'	Text of each captured token in <code>str</code>
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of <code>str</code>

## Data Types

char

## option - Search option

'once' | 'warnings' | 'ignorecase' | 'emptymatch' |  
'dotexceptnewline' | 'lineanchors' | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'matchcase'	'ignorecase'	Match letter case (default), or ignore case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.

Default	Override	Description
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With freespacing, use '\ ' and '\#' to match space and # characters.

**Data Types**

char

**Output Arguments**

**startIndex - Starting index of each match**

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

**endindex - Ending index of each match**

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).

- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

## **out** - Information about matches

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

<b>Output Keyword</b>	<b>Output Description</b>	<b>Output Type and Dimensions</b>
'start'	Starting indices of matches	For both 'start' and 'end': <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a row vector (or, if there are no matches, an empty array).</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul>
'end'	Ending indices of matches	

Output Keyword	Output Description	Output Type and Dimensions
'tokenExtents'	Starting and ending indices of all tokens	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array, where n is the number of matches. Each cell contains an m-by-2 numeric array of indices, where m is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array, where each inner cell contains an m-by-2 numeric array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either an m-by-2 numeric array or a cell array with the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index N, but is not found, then MATLAB returns extents for that token of [N,N-1].</p>

# regex

Output Keyword	Output Description	Output Type and Dimensions
'match'	Text of each substring that matches the pattern in <code>expression</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array of strings, where <code>n</code> is the number of matches.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array of strings.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the 'once' option to return only one match, the output is either a string or a cell array of strings with the same dimensions as <code>str</code> and <code>expression</code>.</p>
'tokens'	Text of each captured token in <code>str</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array, where <code>n</code> is the number of matches. Each cell contains a 1-by-<code>m</code> cell array of strings, where <code>m</code> is the number of tokens in the match.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array, where each inner cell contains a 1-by-<code>m</code> cell array of strings.</li></ul>

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"> <li>If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is a 1-by-m cell array of strings or a cell array that has the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, ''.</p>
'names'	Name and text of each named token	<p>For all matches:</p> <ul style="list-style-type: none"> <li>If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n structure array, where n is the number of matches. The structure field names correspond to the token names.</li> <li>If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n structure array.</li> <li>If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>
'split'	Text of nonmatching substrings of <code>str</code>	<p>For all matches:</p> <ul style="list-style-type: none"> <li>If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array of strings, where n is the number of nonmatching strings.</li> </ul>

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul>

## Examples

### Find Patterns in Single Strings

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car coat court CUT ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexp(str,expression)
```

```
startIndex =
```

```
5 17
```

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.

- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression. The matching word `cat` starts at index 5, and `coat` starts at index 17. The words `CUT` and `CAT` do not match because they are uppercase.

### Find Patterns in Multiple Strings

Find the location of capital letters and spaces within strings in a cell array.

```
str = {'Madrid, Spain', 'Romeo and Juliet', 'MATLAB is great'};
capExpr = '[A-Z]';
spaceExpr = '\s';
```

```
capStartIndex = regexp(str, capExpr);
spaceStartIndex = regexp(str, spaceExpr);
```

`capStartIndex` and `spaceStartIndex` are cell arrays because the input `str` is a cell array.

View the indices for the capital letters.

```
celldisp(capStartIndex)
```

```
capStartIndex{1} =
```

```
1 9
```

```
capStartIndex{2} =
```

```
1 11
```

```
capStartIndex{3} =
 1 2 3 4 5 6
```

View the indices for the spaces.

```
celldisp(spaceStartIndex)
```

```
spaceStartIndex{1} =
 8
```

```
spaceStartIndex{2} =
 6 10
```

```
spaceStartIndex{3} =
 7 10
```

## **Return Substrings Using match Keyword**

Capture words within a string that contain the letter x.

```
str = 'EXTRA! The regexp function helps you relax.';
expression = '\w*x\w*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
 'regexp' 'relax'
```

The regular expression '`\w*x\w*`' specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Contains the lowercase letter `x`.
- Ends with any number of alphanumeric or underscore characters after the `x`, including none, as indicated by `\w*`.

### Split String at Delimiter Using `split` Keyword

Split a string into several substrings, where each substring is delimited by a `^` character.

```
str = ['Split ^this string into ^several pieces'];
expression = '\^';
splitStr = regexp(str,expression,'split')
```

```
splitStr =
 'Split ' 'this string into ' 'several pieces'
```

Because the carat symbol has special meaning in regular expressions, precede it with the escape character, a backslash (`\`). To split a string at other delimiters, such as a semicolon, you do not need to include the backslash.

## Return Both Matching and Nonmatching Substrings

Capture parts of a string that match a regular expression using the 'match' keyword, and the remaining parts that do not match using the 'split' keyword.

```
str = 'She sells sea shells by the seashore.';
expression = '[Ss]h.';
[match,noMatch] = regexp(str,expression,'match','split')
```

```
match =
```

```
 'She' 'she' 'sho'
```

```
noMatch =
```

```
 '' ' sells sea ' 'lls by the sea' 're.'
```

The regular expression '[Ss]h.' specifies that:

- S or s is the first character.
- h is the second character.
- The third character can be anything, including a space, as indicated by the dot (.).

When the first (or last) character in a string matches a regular expression, the first (or last) return value from the 'split' keyword is an empty string.

Optionally, reassemble the original string from the substrings.

```
combinedStr = strjoin(noMatch,match)
```

```
combinedStr =
```

She sells sea shells by the seashore.

### Capture Substrings of Matches Using Ordinal Tokens

Find the names of HTML tags by defining a token within a regular expression. Tokens are indicated with parentheses, ().

```
str = '<title>My Title</title><p>Here is some text.</p>';
expression = '<(\w+).*>.*</\1>';
[tokens,matches] = regexp(str,expression,'tokens','match');
```

The regular expression `<(\w+).*>.*</\1>` specifies this pattern:

- `<(\w+)` finds an opening angle bracket followed by one or more alphanumeric or underscore characters. Enclosing `\w+` in parentheses captures the name of the HTML tag in a token.
- `.*>` finds any number of additional characters, such as HTML attributes, and a closing angle bracket.
- `</\1>` finds the end tag corresponding to the first token (indicated by `\1`). The end tag has the form `<tagname>`.

View the tokens and matching substrings.

```
celldisp(tokens)
```

```
tokens{1}{1} =
 title
```

```
tokens{2}{1} =
 p
```

```
celldisp(matches)
```

```
matches{1} =
 <title>My Title</title>
```

```
matches{2} =
 <p>Here is some text.</p>
```

## Capture Substrings of Matches Using Named Tokens

Parse dates that can appear with either the day or the month first, in these forms: mm/dd/yyyy or dd-mm-yyyy. Use named tokens to identify each part of the date.

```
str = '01/11/2000 20-02-2020 03/30/2000 16-04-2020';
expression = ['(?<month>\d+)/(?<day>\d+)/(?<year>\d+)' | ...
 '(?<day>\d+) - (?<month>\d+) - (?<year>\d+)'];
tokenNames = regexp(str,expression,'names');
```

The regular expression specifies this pattern:

- `(?<name>\d+)` finds one or more numeric digits and assigns the result to the token indicated by name.
- `|` is the logical or operator, which indicates that there are two possible patterns for dates. In the first pattern, slashes (/) separate the tokens. In the second pattern, hyphens (-) separate the tokens.

View the named tokens.

```
for k = 1:length(tokenNames)
 disp(tokenNames(k))
end
```

```
month: '01'
day: '11'
year: '2000'
```

```
month: '02'
day: '20'
year: '2020'
```

```
month: '03'
day: '30'
year: '2000'
```

```
month: '04'
 day: '16'
 year: '2020'
```

### Perform Case-Insensitive Matches

Find both uppercase and lowercase instances of a word.

By default, `regexp` performs case-sensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexp(str,expression,'match')
```

```
matchStr =

 'lowercase'
```

The regular expression specifies that the string:

- Begins with any number of alphanumeric or underscore characters, `\w*`.
- Ends with the literal text `case`.

The `regexpi` function uses the same syntax as `regexp`, but performs case-insensitive matching.

```
matchWithRegexpi = regexpi(str,expression,'match')
```

```
matchWithRegexpi =

 'UPPERCASE' 'lowercase'
```

# regexp

---

Alternatively, disable case-sensitive matching for regexp using the 'ignorecase' option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =
 'UPPERCASE' 'lowercase'
```

For multiple expressions, disable case-sensitive matching for selected expressions using the (?i) search flag.

```
expression = {'(?-i)\w*case';...
 '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
```

```
lowercase
```

```
matchStr{2}{1} =
```

```
UPPERCASE
```

```
matchStr{2}{2} =
```

```
lowercase
```

## Parse Strings with Newline Characters

Create a string that contains a newline, \n, and parse the string using a regular expression.

```
str = sprintf('abc\n de');
expression = '.*';
matchStr = regexp(str,expression,'match')
```

```
matchStr =
 [1x7 char]
```

By default, the dot (.) matches every character, including the newline, and returns a single match that is equivalent to the original string.

Exclude newline characters from the match using the 'dotexceptnewline' option. This returns separate matches for each line of text.

```
matchStrNoNewline = regexp(str,expression,'match','dotexceptnewline')
```

```
matchStrNoNewline =
 'abc' ' de'
```

Find the first or last character of each line using the ^ or \$ metacharacters and the 'lineanchors' option.

```
expression = '.$';
lastInLine = regexp(str,expression,'match','lineanchors')
```

```
lastInLine =
```

```
'c' 'e'
```

## Definitions

### Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form dd-mmm-yyyy, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';

mydate = regexp(str,expression,'tokens');
mydate{:}

ans =
 '01' 'April' '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';

mydate = regexp(str,expression,'names')

mydate =
 day: '01'
 month: 'Apr'
 year: '2020'
```

For more information, see “Tokens in Regular Expressions”.

## Algorithms

MATLAB parses each input string from left to right, attempting to match the text in the string with the first element of the regular

expression. During this process, MATLAB skips over any text that does not match.

When MATLAB finds the first match, it continues parsing the string to match the second piece of the expression, and so on.

**Tips**

- Use `strfind` to find an exact character match within a string. Use `regex` to look for a pattern of characters.

`regexp` | `regprep` | `regxprtranslate` | `strfind` | `strjoin` | `strsplit` | `strep`

**Concepts**

- “Regular Expressions”
- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

# regexpi

---

**Purpose** Match regular expression (case insensitive)

**Syntax** `startIndex = regexpi(str,expression)`  
`[startIndex,endIndex] = regexpi(str,expression)`

`out = regexpi(str,expression,outkey)`  
`[out1,...,outN] =`  
`regexpi(str,expression,outkey1,...,outkeyN)`

`___ = regexpi( ___,option1,...,optionM)`

**Description** `startIndex = regexpi(str,expression)` returns the starting index of each substring of `str` that matches the character patterns specified by the regular expression, without regard to letter case. If there are no matches, `startIndex` is an empty array.

`[startIndex,endIndex] = regexpi(str,expression)` returns the starting and ending indices of all matches.

`out = regexpi(str,expression,outkey)` returns the output specified by `outkey`. For example, if `outkey` is 'match', then `regexpi` returns the substrings that match the expression rather than their starting indices.

`[out1,...,outN] =`  
`regexpi(str,expression,outkey1,...,outkeyN)` returns the outputs specified by multiple output keywords, in the specified order. For example, if you specify 'match','tokens', then `regexpi` returns substrings that match the entire expression and tokens that match parts of the expression.

`___ = regexpi( ___,option1,...,optionM)` modifies the search using the specified option flags. For example, specify 'matchcase' to perform a case-sensitive match. You can include any of the inputs and request any of the outputs from previous syntaxes.

## Input Arguments

### str - Input text

string | cell array of strings

Input text, specified as a string or a cell array of strings. Each string can be of any length and contain any characters.

If `str` and `expression` are both cell arrays, they must have the same dimensions.

### Data Types

char | cell

### expression - Regular expression

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

### Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
.	Any single character, including white space	'..ain' matches sequences of five consecutive characters that end with 'ain'.
[c <sub>1</sub> c <sub>2</sub> c <sub>3</sub> ]	Any character contained within the brackets. The following characters are treated literally: \$   . * + ? and - when not used to indicate a range.	'[rp.]ain' matches 'rain' or 'pain' or '.ain'.

# regexpi

Metacharacter	Description	Example
<code>[^c<sub>1</sub>c<sub>2</sub>c<sub>3</sub>]</code>	Any character not contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in 'ain', except 'rain' and 'pain' and <code>`*ain</code> '. For example, it matches 'gain', 'lain', or 'vain'.
<code>[c<sub>1</sub>-c<sub>2</sub>]</code>	Any character in the range of c <sub>1</sub> through c <sub>2</sub>	' <code>[A-G]</code> ' matches a single character in the range of A through G.
<code>\w</code>	Any alphabetic, numeric, or underscore character. For English character sets, <code>\w</code> is equivalent to <code>[a-zA-Z_0-9]</code>	' <code>\w*</code> ' identifies a word.
<code>\W</code>	Any character that is not alphabetic, numeric, or underscore. For English character sets, <code>\W</code> is equivalent to <code>[^a-zA-Z_0-9]</code>	' <code>\W*</code> ' identifies a substring that is not a word.
<code>\s</code>	Any white-space character; equivalent to <code>[\f\n\r\t\v]</code>	' <code>\w*n\s</code> ' matches words that end with the letter n, followed by a white-space character.
<code>\S</code>	Any non-white-space character; equivalent to <code>[^\f\n\r\t\v]</code>	' <code>\d\S</code> ' matches a numeric digit followed by any non-white-space character.
<code>\d</code>	Any numeric digit; equivalent to <code>[0-9]</code>	' <code>\d*</code> ' matches any number of consecutive digits.
<code>\D</code>	Any nondigit character; equivalent to <code>[^0-9]</code>	' <code>\w*\D&gt;</code> ' matches words that do not end with a numeric digit.

Metacharacter	Description	Example
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

### Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
\char	Any character with special meaning in regular expressions that you want to match literally (for example, use \\ to match a single backslash)

### Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
expr*	0 or more times consecutively.	'\w*' matches a word of any length.
expr?	0 times or 1 time.	'\w*(\.\m)?' matches words that optionally end with the extension .m.

# regexpi

Quantifier	Matches the expression when it occurs...	Example
<code>expr+</code>	1 or more times consecutively.	'' matches an <img> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least m times, but no more than n times consecutively. {0,1} is equivalent to ?.	'\S{4,8}' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least m times consecutively. {0,} and {1,} are equivalent to * and +, respectively.	'<a href="\w{1,}\.html">' matches an <a> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly n times consecutively. Equivalent to {n,n}.	'\d{4}' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. *q* represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*>' matches all characters between <tr and /td>:  '<tr><td><p>text</p></td>'
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*?>' ends each match at the first occurrence of the closing bracket (>):

Mode	Description	Example
		'<tr>'   '<td>'   '</td>'
exprq+	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string '<tr><td><p>text</p></td>', the expression '</?t.*+>' does not return any matches, because the closing bracket is captured using .*, and is not rescanned.

### Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.

# regexpi

Grouping Operator	Description	Example
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1 expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

## Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
^expr	Beginning of the input string.	'^M\w*' matches a word starting with M at the beginning of the string.
expr\$	End of the input string.	'\w*m\$' matches words ending with m at the end of the string.
\<expr	Beginning of a word.	'\<n\w*' matches any words starting with n.
expr\>	End of a word.	'\w*e\>' matches any words ending with e.

## Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(?=test)</code>	Look ahead for characters that match <code>test</code> .	<code>'\w*(?=ing)'</code> matches strings that are followed by <code>ing</code> , such as <code>'Fly'</code> and <code>'fall'</code> in the input string <code>'Flying, not falling.'</code>
<code>expr(?!test)</code>	Look ahead for characters that do not match <code>test</code> .	<code>'i(?!ng)'</code> matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .
<code>(?&lt;=test)expr</code>	Look behind for characters that match <code>test</code> .	<code>'(?&lt;=re)\w*'</code> matches strings that follow <code>'re'</code> , such as <code>'new'</code> , <code>'use'</code> , and <code>'cycle'</code> in the input string <code>'renew, reuse, recycle'</code>
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match <code>test</code> .	<code>'(?&lt;!\d)(\d)(?!\d)'</code> matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both <code>test</code> and <code>expr</code> .	<code>'(?=[a-z])[^aeiou]'</code> matches consonants.
<code>(?!test)expr</code>	Match <code>expr</code> and do not match <code>test</code> .	<code>'(?![aeiou])[a-z]'</code> matches consonants.

### Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any,

# regexp

to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> . If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	<code>'(let tel)\w+'</code> matches words in a string that start with <code>let</code> or <code>tel</code> .
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	<code>'(?:[A-Z]:\\)'</code> matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	<code>'Mr(s?)\.*(?:her his)\w*'</code> matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

## Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
(expr)	Capture in a token the characters that match the enclosed expression.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
\N	Match the Nth token.	'<(\w+).*>.*</\1>' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag)\w+).*>.*</\k<tag>>'' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex>s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

---

**Note** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

---

## Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)((?!\w{\$1}))' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by cmd, and include the string returned by the command in the match expression.	'(.{2,}).?(?@flip1r(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by cmd, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
\$& or \$0	Portion of the input string that is currently a match
\$`	Portion of the input string that precedes the current match
\$'	Portion of the input string that follows the current match (use \$' ' to represent the string \$')
\$N	Nth token
\$<name>	Named token
\${cmd}	String returned when MATLAB executes the command, cmd

### Comments

Characters	Description	Example
(?#comment)	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	'(?# Initial digit)\<d\w+' includes a comment, and matches words that begin with a number.

### Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
(?-i)	Match letter case (default for regexp and regexprep).
(?i)	Do not match letter case (default for regexpi).

# regexpi

---

Flag	Description
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

## Data Types

char | cell

## outkey - Keyword that indicates which outputs to return

```
'start' | 'end' | 'tokenExtents' | 'match' | 'tokens' | 'names'
| 'split'
```

Keyword that indicates which outputs to return, specified as one of the following strings.

Output Keyword	Returns
'start'	Starting indices of all matches, <code>startIndex</code>
'end'	Ending indices of all matches, <code>endIndex</code>
'tokenExtents'	Starting and ending indices of all tokens
'match'	Text of each substring that matches the pattern in <code>expression</code>
'tokens'	Text of each captured token in <code>str</code>
'names'	Name and text of each named token
'split'	Text of nonmatching substrings of <code>str</code>

**Data Types**

char

**option - Search option**

'once' | 'warnings' | 'matchcase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...

Search option, specified as a string. Options come in pairs: one option that corresponds to the default behavior, and one option that allows you to override the default. Specify only one option from a pair. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match the expression as many times as possible (default), or only once.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'ignorecase'	'matchcase'	Ignore letter case (default), or match case.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.

# regexpi

Default	Override	Description
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With freespacing, use '\ ' and '\#' to match space and # characters.

## Data Types

char

## Output Arguments

### **startIndex** - Starting index of each match

row vector | cell array of row vectors

Starting indices of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).
- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

### **endIndex** - Ending index of each match

row vector | cell array of row vectors

Ending index of each match, returned as a row vector or cell array, as follows:

- If `str` and `expression` are both strings, the output is a row vector (or, if there are no matches, an empty array).

- If `str` or `expression` is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.
- If `str` and `expression` are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.

**out - Information about matches**

numeric array | cell array | structure array

Information about matches, returned as a numeric, cell, or structure array. The information in the output depends upon the value you specify for `outkey`, as follows.

Output Keyword	Output Description	Output Type and Dimensions
'start'	Starting indices of matches	For both 'start' and 'end': <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a row vector (or, if there are no matches, an empty array).</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array of row vectors. The output cell array has the same dimensions as the input cell array.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>
'end'	Ending indices of matches	

# regexpi

Output Keyword	Output Description	Output Type and Dimensions
'tokenExtents'	Starting and ending indices of all tokens	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array, where <code>n</code> is the number of matches. Each cell contains an m-by-2 numeric array of indices, where <code>m</code> is the number of tokens in the match.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array, where each inner cell contains an m-by-2 numeric array.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the 'once' option to return only one match, the output is either an m-by-2 numeric array or a cell array with the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index <code>N</code>, but is not found, then MATLAB returns extents for that token of <code>[N,N-1]</code>.</p>

Output Keyword	Output Description	Output Type and Dimensions
'match'	Text of each substring that matches the pattern in <code>expression</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array of strings, where <code>n</code> is the number of matches.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul> <p>When you specify the 'once' option to return only one match, the output is either a string or a cell array of strings with the same dimensions as <code>str</code> and <code>expression</code>.</p>
'tokens'	Text of each captured token in <code>str</code>	<p>By default, when returning all matches:</p> <ul style="list-style-type: none"> <li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-<code>n</code>-cell array, where <code>n</code> is the number of matches. Each cell contains a 1-by-<code>m</code> cell array of strings, where <code>m</code> is the number of tokens in the match.</li> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-<code>n</code> cell array, where each inner cell contains a 1-by-<code>m</code> cell array of strings.</li> </ul>

# regexpi

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul> <p>When you specify the 'once' option to return only one match, the output is a 1-by-m cell array of strings or a cell array that has the same dimensions as <code>str</code> and/or <code>expression</code>.</p> <p>If a token is expected at a particular index, but is not found, then MATLAB returns an empty string for the token, ''.</p>
'names'	Name and text of each named token	<p>For all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n structure array, where n is the number of matches. The structure field names correspond to the token names.</li><li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n structure array.</li><li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li></ul>
'split'	Text of nonmatching substrings of <code>str</code>	<p>For all matches:</p> <ul style="list-style-type: none"><li>• If <code>str</code> and <code>expression</code> are both strings, the output is a 1-by-n-cell array of strings, where n is the number of nonmatching strings.</li></ul>

Output Keyword	Output Description	Output Type and Dimensions
		<ul style="list-style-type: none"> <li>• If <code>str</code> or <code>expression</code> is a cell array of strings, the output is a cell array with the same dimensions as the input cell array. Each cell contains a 1-by-n cell array of strings.</li> <li>• If <code>str</code> and <code>expression</code> are both cell arrays, they must have the same dimensions. The output is a cell array with the same dimensions.</li> </ul>

## Examples

### Pattern Matching

Find words that start with `c`, end with `t`, and contain one or more vowels between them.

```
str = 'bat cat can car COAT court cut ct CAT-scan';
expression = 'c[aeiou]+t';
startIndex = regexpi(str,expression)
```

```
startIndex =
 5 17 28 35
```

Values in `startIndex` indicate the index of the first character of each word that matches the regular expression.

The regular expression `'c[aeiou]+t'` specifies this pattern:

- `c` must be the first character.
- `c` must be followed by one of the characters inside the brackets, `[aeiou]`.
- The bracketed pattern must occur one or more times, as indicated by the `+` operator.

- `t` must be the last character, with no characters between the bracketed pattern and the `t`.

## Case-Sensitive Match

Match letter case in all or part of an expression.

By default, `regexpi` performs case-insensitive matching.

```
str = 'A string with UPPERCASE and lowercase text.';
expression = '\w*case';
matchStr = regexpi(str,expression,'match')
```

```
matchStr =
 'UPPERCASE' 'lowercase'
```

Use the `regexp` function with the same syntax as `regexpi` to perform case-sensitive matching.

```
matchWithRegexp = regexp(str,expression,'match')
```

```
matchWithRegexp =
 'lowercase'
```

To disable case-sensitive matching for `regexp`, use the `'ignorecase'` option.

```
matchWithIgnorecase = regexp(str,expression,'match','ignorecase')
```

```
matchWithIgnorecase =
 'UPPERCASE' 'lowercase'
```

For multiple expressions, enable and disable case-insensitive matching for selected expressions using the `(?i)` and `(?-i)` search flags.

```
expression = {'(?-i)\w*case';...
 '(?i)\w*case'};
matchStr = regexp(str,expression,'match');
celldisp(matchStr)
```

```
matchStr{1}{1} =
 lowercase
```

```
matchStr{2}{1} =
 UPPERCASE
```

```
matchStr{2}{2} =
 lowercase
```

## Definitions

### Tokens

Tokens are portions of the matched text that correspond to portions of the regular expression. To create tokens, enclose part of the regular expression in parentheses.

For example, this expression finds a date of the form dd-mmm-yyyy, including tokens for the day, month, and year.

```
str = 'Here is a date: 01-Apr-2020';
expression = '(\d+)-(\w+)-(\d+)';
```

```
mydate = regexp(str,expression,'tokens');
mydate{:}
```

```
ans =
 '01' 'April' '2020'
```

You can associate names with tokens so that they are more easily identifiable:

```
str = 'Here is a date: 01-Apr-2020';
expression = '(?<day>\d+)-(?<month>\w+)-(?<year>\d+)';
```

```
mydate = regexp(str,expression,'names')
```

```
mydate =
 day: '01'
 month: 'Apr'
 year: '2020'
```

# regexpi

## **Concepts**

- “Lookahead Assertions in Regular Expressions”
- “Dynamic Regular Expressions”

## Purpose

Replace string using regular expression

## Syntax

```
newStr = regexprep(str,expression,replace)
newStr =
regexprep(str,expression,replace,option1,...optionM)
```

## Description

`newStr = regexprep(str,expression,replace)` replaces the text in `str` that matches `expression` with the text described by `replace`. The `regexprep` function returns the updated text in `newStr`.

- If `str` is a string, then `newStr` is also a string, even when `expression` or `replace` is a cell array of strings. When `expression` is a cell array, `regexprep` applies the first expression to the string, and then applies each subsequent expression to the preceding result.
- If `str` is a cell array, then `newStr` is a cell array with the same dimensions as `str`. For each element of `str`, the `regexprep` function applies each expression in sequence.
- If there are no matches to `expression`, then `newStr` is equivalent to `str`.

`newStr = regexprep(str,expression,replace,option1,...optionM)` modifies the search using the specified options. For example, specify `'ignorecase'` to perform a case-insensitive match.

## Input Arguments

### **str - Text to update**

string | cell array of strings

Text to update, specified as a string or a cell array of strings.

### **Data Types**

char | cell

### **expression - Regular expression**

string | cell array of strings

Regular expression, specified as a string or a cell array of strings. Each expression can contain characters, metacharacters, operators, tokens, and flags that specify patterns to match in `str`.

The following tables describe the elements of regular expressions.

## Metacharacters

Metacharacters represent letters, letter ranges, digits, and space characters. Use them to construct a generalized pattern of characters.

Metacharacter	Description	Example
<code>.</code>	Any single character, including white space	' <code>..ain</code> ' matches sequences of five consecutive characters that end with ' <code>ain</code> '.
<code>[c<sub>1</sub>c<sub>2</sub>c<sub>3</sub>]</code>	Any character contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[rp.]ain</code> ' matches ' <code>rain</code> ' or ' <code>pain</code> ' or ' <code>.ain</code> '.
<code>[^c<sub>1</sub>c<sub>2</sub>c<sub>3</sub>]</code>	Any character not contained within the brackets. The following characters are treated literally: <code>\$   . * + ?</code> and <code>-</code> when not used to indicate a range.	' <code>[^*rp]ain</code> ' matches all four-letter sequences that end in ' <code>ain</code> ', except ' <code>rain</code> ' and ' <code>pain</code> ' and ' <code>*ain</code> '. For example, it matches ' <code>gain</code> ', ' <code>lain</code> ', or ' <code>vain</code> '.
<code>[c<sub>1</sub>-c<sub>2</sub>]</code>	Any character in the range of <code>c<sub>1</sub></code> through <code>c<sub>2</sub></code>	' <code>[A-G]</code> ' matches a single character in the range of A through G.
<code>\w</code>	Any alphabetic, numeric, or underscore character. For English character sets, <code>\w</code> is equivalent to <code>[a-zA-Z_0-9]</code>	' <code>\w*</code> ' identifies a word.

Metacharacter	Description	Example
\W	Any character that is not alphabetic, numeric, or underscore. For English character sets, \W is equivalent to [^a-zA-Z_0-9]	'\W*' identifies a substring that is not a word.
\s	Any white-space character; equivalent to [ \f\n\r\t\v]	'\w*n\s' matches words that end with the letter n, followed by a white-space character.
\S	Any non-white-space character; equivalent to [^\f\n\r\t\v]	'\d\S' matches a numeric digit followed by any non-white-space character.
\d	Any numeric digit; equivalent to [0-9]	'\d*' matches any number of consecutive digits.
\D	Any nondigit character; equivalent to [^0-9]	'\w*\D\>' matches words that do not end with a numeric digit.
\oN or \o{N}	Character of octal value N	'\o{40}' matches the space character, defined by octal 40.
\xN or \x{N}	Character of hexadecimal value N	'\x2C' matches the comma character, defined by hex 2C.

### Character Representation

Operator	Description
\a	Alarm (beep)
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab

Operator	Description
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

## Quantifiers

Quantifiers specify the number of times a string pattern must occur in the matching string.

Quantifier	Matches the expression when it occurs...	Example
<code>expr*</code>	0 or more times consecutively.	' <code>\w*</code> ' matches a word of any length.
<code>expr?</code>	0 times or 1 time.	' <code>\w*(\.\m)?</code> ' matches words that optionally end with the extension <code>.m</code> .
<code>expr+</code>	1 or more times consecutively.	' <code>&lt;img src="\w+\.\gif"&gt;</code> ' matches an <code>&lt;img&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{m,n}</code>	At least <code>m</code> times, but no more than <code>n</code> times consecutively. <code>{0,1}</code> is equivalent to <code>?</code> .	' <code>\S{4,8}</code> ' matches between four and eight non-white-space characters.
<code>expr{m,}</code>	At least <code>m</code> times consecutively. <code>{0,}</code> and <code>{1,}</code> are equivalent to <code>*</code> and <code>+</code> , respectively.	' <code>&lt;a href="\w{1,}\.html"&gt;</code> ' matches an <code>&lt;a&gt;</code> HTML tag when the file name contains one or more characters.
<code>expr{n}</code>	Exactly <code>n</code> times consecutively. Equivalent to <code>{n,n}</code> .	' <code>\d{4}</code> ' matches four consecutive digits.

Quantifiers can appear in three modes, described in the following table. `q` represents any of the quantifiers in the previous table.

Mode	Description	Example
<code>exprq</code>	Greedy expression: match as many characters as possible.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*&gt;</code> ' matches all characters between <code>&lt;tr</code> and <code>/td&gt;</code> :  ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> '
<code>exprq?</code>	Lazy expression: match as few characters as necessary.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*?&gt;</code> ' ends each match at the first occurrence of the closing bracket ( <code>&gt;</code> ):  ' <code>&lt;tr&gt;</code> '    ' <code>&lt;td&gt;</code> '    ' <code>&lt;/td&gt;</code> '
<code>exprq+</code>	Possessive expression: match as much as possible, but do not rescan any portions of the string.	Given the string ' <code>&lt;tr&gt;&lt;td&gt;&lt;p&gt;text&lt;/p&gt;&lt;/td&gt;</code> ', the expression ' <code>&lt;/?t.*+&gt;</code> ' does not return any matches, because the closing bracket is captured using <code>.*</code> , and is not rescanned.

### Grouping Operators

Grouping operators allow you to capture tokens, apply one operator to multiple elements, or disable backtracking in a specific group.

# regexprep

Grouping Operator	Description	Example
(expr)	Group elements of the expression and capture tokens.	'Joh?n\s(\w*)' captures a token that contains the last name of any person with the first name John or Jon.
(?:expr)	Group, but do not capture tokens.	'(?:[aeiou][^aeiou]){2}' matches two consecutive patterns of a vowel followed by a nonvowel, such as 'anon'.  Without grouping, '[aeiou][^aeiou]{2}' matches a vowel followed by two nonvowels.
(?>expr)	Group atomically. Do not backtrack within the group to complete the match, and do not capture tokens.	'A(?>.* )Z' does not match 'AtoZ', although 'A(?:.* )Z' does. Using the atomic group, Z is captured using .* and is not rescanned.
(expr1 expr2)	Match expression expr1 or expression expr2.  If there is a match with expr1, then expr2 is ignored.  You can include ?: or ?> after the opening parenthesis to suppress tokens or group atomically.	'(let tel)\w+' matches words in a string that start with let or tel.

## Anchors

Anchors in the expression match the beginning or end of the string or word.

Anchor	Matches the...	Example
<code>^expr</code>	Beginning of the input string.	' <code>^M\w*</code> ' matches a word starting with <code>M</code> at the beginning of the string.
<code>expr\$</code>	End of the input string.	' <code>\w*m\$</code> ' matches words ending with <code>m</code> at the end of the string.
<code>\&lt;expr</code>	Beginning of a word.	' <code>\&lt;n\w*</code> ' matches any words starting with <code>n</code> .
<code>expr\&gt;</code>	End of a word.	' <code>\w*e\&gt;</code> ' matches any words ending with <code>e</code> .

### Lookaround Assertions

Lookaround assertions look for string patterns that immediately precede or follow the intended match, but are not part of the match.

The pointer remains at the current location, and characters that correspond to the `test` expression are not captured or discarded. Therefore, lookahead assertions can match overlapping character groups.

Lookaround Assertion	Description	Example
<code>expr(=?test)</code>	Look ahead for characters that match <code>test</code> .	' <code>\w*(?=ing)</code> ' matches strings that are followed by <code>ing</code> , such as 'Fly' and 'fall' in the input string 'Flying, not falling.'
<code>expr(?!test)</code>	Look ahead for characters that do not match <code>test</code> .	' <code>i(?!ng)</code> ' matches instances of the letter <code>i</code> that are not followed by <code>ng</code> .

Lookaround Assertion	Description	Example
<code>(?&lt;=test)expr</code>	Look behind for characters that match test..	'(?<=re)\w*' matches strings that follow 're', such as 'new', 'use', and 'cycle' in the input string 'renew, reuse, recycle'
<code>(?&lt;!test)expr</code>	Look behind for characters that do not match test.	'(?<!\d)(\d)(?!\d)' matches single-digit numbers (digits that do not precede or follow other digits).

If you specify a lookahead assertion *before* an expression, the operation is equivalent to a logical AND.

Operation	Description	Example
<code>(?=test)expr</code>	Match both test and expr.	'(?=[a-z])[^aeiou]' matches consonants.
<code>(?!test)expr</code>	Match expr and do not match test.	'(?![aeiou])[a-z]' matches consonants.

## Logical and Conditional Operators

Logical and conditional operators allow you to test the state of a given condition, and then use the outcome to determine which string, if any, to match next. These operators support logical OR, and if or if/else conditions.

Conditions can be tokens, lookaround operators, or dynamic expressions of the form `(?@cmd)`. Dynamic expressions must return a logical or numeric value.

Conditional Operator	Description	Example
<code>expr1 expr2</code>	Match expression <code>expr1</code> or expression <code>expr2</code> . If there is a match with <code>expr1</code> , then <code>expr2</code> is ignored.	' <code>(let tel)\w+</code> ' matches words in a string that start with <code>let</code> or <code>tel</code> .
<code>(?(cond)expr)</code>	If condition <code>cond</code> is true, then match <code>expr</code> .	' <code>(?(?@ispc)[A-Z]:\\)</code> ' matches a drive name, such as <code>C:\</code> , when run on a Windows system.
<code>(?(cond)expr1 expr2)</code>	If condition <code>cond</code> is true, then match <code>expr1</code> . Otherwise, match <code>expr2</code> .	' <code>Mr(s?)\..*?(?(1)her his)\w*</code> ' matches strings that include <code>her</code> when the string begins with <code>Mrs</code> , or that include <code>his</code> when the string begins with <code>Mr</code> .

### Token Operators

Tokens are portions of the matched text that you define by enclosing part of the regular expression in parentheses. You can refer to a token by its sequence in the string (an ordinal token), or assign names to tokens for easier code maintenance and readable output.

Ordinal Token Operator	Description	Example
<code>(expr)</code>	Capture in a token the characters that match the enclosed expression.	' <code>Joh?n\s(\w*)</code> ' captures a token that contains the last name of any person with the first name <code>John</code> or <code>Jon</code> .
<code>\N</code>	Match the Nth token.	' <code>&lt;(\w+).*&gt;.*&lt;/\1&gt;</code> ' captures tokens for HTML tags, such

# regexprep

Ordinal Token Operator	Description	Example
		as 'title' from the string '<title>Some text</title>'.
(?(N)expr1 expr2)	If the Nth token is found, then match expr1. Otherwise, match expr2.	'Mr(s?)\..*?(?(1)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

Named Token Operator	Description	Example
(?<name>expr)	Capture in a named token the characters that match the enclosed expression.	'(?<month>\d+)-(?<day>\d+)-(?<yr>\d+)' creates named tokens for the month, day, and year in an input date string of the form mm-dd-yy.
\k<name>	Match the token referred to by name.	'<(?(tag>\w+).*>.*</\k<tag>>'' captures tokens for HTML tags, such as 'title' from the string '<title>Some text</title>'.
(?(name)expr1 expr2)	If the named token is found, then match expr1. Otherwise, match expr2.	'Mr(?(sex>s?)\..*?(?(sex)her his)\w*' matches strings that include her when the string begins with Mrs, or that include his when the string begins with Mr.

**Note** If an expression has nested parentheses, MATLAB captures tokens that correspond to the outermost set of parentheses. For example, given the search pattern '(and(y|rew))', MATLAB creates a token for 'andrew' but not for 'y' or 'rew'.

### Dynamic Regular Expressions

Dynamic expressions allow you to execute a MATLAB command or a regular expression to determine the text to match.

The parentheses that enclose dynamic expressions do *not* create a capturing group.

Operator	Description	Example
(??expr)	Parse expr and include the resulting string in the match expression.  When parsed, expr must correspond to a complete, valid regular expression. Dynamic expressions that use the backslash escape character (\) require two backslashes: one for the initial parsing of expr, and one for the complete match.	'^(\d+)(??\w{\$1})' determines how many characters to match by reading a digit at the beginning of the string. The dynamic expression is enclosed in a second set of parentheses so that the resulting match is captured in a token. For instance, matching '5XXXXX' captures tokens for '5' and 'XXXXX'.
(??@cmd)	Execute the MATLAB command represented by cmd, and include the string returned by the command in the match expression.	'(.{2,}).?(??@fliplr(\$1))' finds palindromes that are at least four characters long, such as 'abba'.
(?@cmd)	Execute the MATLAB command represented by cmd, but discard any output the command returns. (Helpful for diagnosing regular expressions.)	'\w*?(\w)(?@disp(\$1))\1\w*' matches words that include double letters (such as pp), and displays intermediate results.

# regexprep

---

Within dynamic expressions, use the following operators to define replacement strings.

Replacement String Operator	Description
<code>&amp;</code> or <code>\$0</code>	Portion of the input string that is currently a match
<code>\$`</code>	Portion of the input string that precedes the current match
<code>\$'</code>	Portion of the input string that follows the current match (use <code>\$''</code> to represent the string <code>\$'</code> )
<code>\$N</code>	Nth token
<code>\$&lt;name&gt;</code>	Named token
<code>\${cmd}</code>	String returned when MATLAB executes the command, <code>cmd</code>

## Comments

Characters	Description	Example
<code>(?#comment)</code>	Insert a comment in the regular expression. The comment text is ignored when matching the input string.	<code>'(?# Initial digit)\&lt;\d\w+'</code> includes a comment, and matches words that begin with a number.

## Search Flags

Search flags modify the behavior for matching expressions. An alternative to using a search flag within an expression is to pass an option input argument.

Flag	Description
<code>(?-i)</code>	Match letter case (default for <code>regexp</code> and <code>regexprep</code> ).
<code>(?i)</code>	Do not match letter case (default for <code>regexp</code> ).

Flag	Description
(?s)	Match dot (.) in the pattern string with any character (default).
(?-s)	Match dot in the pattern with any character that is not a newline character.
(?-m)	Match the ^ and \$ metacharacters at the beginning and end of a string (default).
(?m)	Match the ^ and \$ metacharacters at the beginning and end of a line.
(?-x)	Include space characters and comments when matching (default).
(?x)	Ignore space characters and comments when matching. Use '\ ' and '\#' to match space and # characters.

The expression that the flag modifies can appear either after the parentheses, such as

```
(?i)\w*
```

or inside the parentheses and separated from the flag with a colon (:), such as

```
(?i:\w*)
```

The latter syntax allows you to change the behavior for part of a larger expression.

### Data Types

char | cell

### replace - Replacement text

string | cell array of strings

Replacement text, specified as a string or a cell array of strings, as follows:

- If `replace` is a single string and `expression` is a cell array of strings, then `regexprep` uses the same replacement text for each expression.

# regexprep

- If `replace` is a cell array of  $N$  strings and `expression` is a single string, then `regexprep` attempts  $N$  matches and replacements.
- If both `replace` and `expression` are cell arrays of strings, then they must contain the same number of elements. `regexprep` pairs each `replace` element with its matching element in `expression`.

The replacement text can include regular characters, special characters (such as tabs or new lines), or string operators, as shown in the following tables.

Replacement String Operator	Description
<code>\$&amp;</code> or <code>\$0</code>	Portion of the input string that is currently a match
<code>\$`</code>	Portion of the input string that precedes the current match
<code>\$'</code>	Portion of the input string that follows the current match (use <code>\$''</code> to represent the string <code>\$'</code> )
<code>\$N</code>	$N$ th token
<code>\$(name)</code>	Named token
<code>\$(cmd)</code>	String returned when MATLAB executes the command, <code>cmd</code>

Operator	Description
<code>\a</code>	Alarm (beep)
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab

Operator	Description
<code>\v</code>	Vertical tab
<code>\char</code>	Any character with special meaning in regular expressions that you want to match literally (for example, use <code>\\</code> to match a single backslash)

**Data Types**

char | cell

**option - Search or replacement option**

'once' | N | 'warnings' | 'ignorecase' | 'preservecase' | 'emptymatch' | 'dotexceptnewline' | 'lineanchors' | ...

Search or replacement option, specified as a string or an integer value, as shown in the following table.

Options come in sets: one option that corresponds to the default behavior, and one or two options that allow you to override the default. Specify only one option from a set. Options can appear in any order.

Default	Override	Description
'all'	'once'	Match and replace the expression as many times as possible (default), or only once.
	N	Replace only the Nth occurrence of the match, where N is an integer value.
'nowarnings'	'warnings'	Suppress warnings (default), or display them.
'matchcase'	'ignorecase'	Match letter case (default), or ignore case while matching and replacing.
	'preservecase'	Ignore case while matching, but preserve the case of corresponding characters in the original string while replacing.
'noemptymatch'	'emptymatch'	Ignore zero length matches (default), or include them.

# regexprep

---

Default	Override	Description
'dotall'	'dotexceptnewline'	Match dot with any character (default), or all except newline (\n).
'stringanchors'	'lineanchors'	Apply ^ and \$ metacharacters to the beginning and end of a string (default), or to the beginning and end of a line.
'literalspacing'	'freespacing'	Include space characters and comments when matching (default), or ignore them. With freespacing, use '\ ' and '\#' to match space and # characters.

## Data Types

char

## Output Arguments

### newStr - Updated text

string | cell array of strings

Updated text, returned as a string or a cell array of strings. The data type of newStr is the same as the data type of str.

## Examples

### Update a Single String

Replace words that begin with M, end with y, and have at least one character between them.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
replace = 'April';
```

```
newStr = regexprep(str,expression,replace)
```

```
newStr =
```

```
My flowers may bloom in April
```

### Include Tokens in Replacement Text

Replace variations of the phrase 'walk up' by capturing the letters that follow 'walk' in a token.

```
str = 'I walk up, they walked up, we are walking up.';
expression = 'walk(\w*) up';
replace = 'ascend$1';
```

```
newStr = regexprep(str,expression,replace)
```

```
newStr =
```

```
I ascend, they ascended, we are ascending.
```

### Include Dynamic Expression in Replacement Text

Replace lowercase letters at the beginning of sentences with their uppercase equivalents using the upper function.

```
str = 'here are two sentences. neither is capitalized.';
expression = '^(|\.)\s*.';
replace = '${upper($0)}';
```

```
newStr = regexprep(str,expression,replace)
```

```
newStr =
```

```
Here are two sentences. Neither is capitalized.
```

The regular expression matches single characters (.) that follow the beginning of the string (^) or a period (\.) and any whitespace (\s\*). The replace expression calls the upper function for the currently matching character (\$0).

### Update Multiple Strings

Replace each occurrence of a double letter in a set of strings with the symbols '--'.

```
str = {
 'Whose woods these are I think I know.' ; ...
 'His house is in the village though;' ; ...
 'He will not see me stopping here' ; ...
 'To watch his woods fill up with snow.'};

expression = '(.)\1';
replace = '--';
newStr = regexprep(str,expression,replace)

newStr =

 'Whose w--ds these are I think I know.'
 'His house is in the vi--age though;'
 'He wi-- not s-- me sto--ing here'
 'To watch his w--ds fi-- up with snow.'
```

## Preserve Case in Original String

Ignore letter case in the regular expression when finding matches, but mimic the letter case of the original string when updating.

```
str = 'My flowers may bloom in May';
expression = 'M(\w+)y';
replace = 'April';

newStr = regexprep(str,expression,replace,'preserveCase')

newStr =

My flowers april bloom in April
```

## Replace Zero-Length Matches

Insert text at the beginning of a string using the '^' operator, which returns a zero-length match, and the 'emptyMatch' keyword.

```
str = 'abc';
expression = '^';
```

```
replace = '__';
newStr = regexprep(str,expression,replace,'emptymatch')

newStr =

__abc
```

- “Tokens in Regular Expressions”
- “Dynamic Regular Expressions”

# regexptranslate

---

**Purpose** Translate string into regular expression

**Syntax** `s2 = regexptranslate(type, s1)`

**Description** `s2 = regexptranslate(type, s1)` translates string `s1` into a regular expression string `s2` that you can then use as input into one of the MATLAB regular expression functions such as `regexp`. The `type` input can be either one of the following strings that define the type of translation to be performed. See “Regular Expressions” in the MATLAB Programming Fundamentals documentation for more information.

Type	Description
'escape'	Translate all special characters (e.g., '\$', '.', '?', '[') in string <code>s1</code> so that they are treated as literal characters when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation inserts an escape character ('\') before each special character in <code>s1</code> . Return the new string in <code>s2</code> .
'wildcard'	Translate all wildcard and '.' characters in string <code>s1</code> so that they are treated as literal wildcards and periods when used in the <code>regexp</code> and <code>regexprep</code> functions. The translation replaces all instances of '*' with '.', all instances of '?' with '.', and all instances of '.' with '\.'. Return the new string in <code>s2</code> .

## Examples

### Example 1 – Using the 'escape' Option

Because `regexp` interprets the sequence `\n` as a newline character, it cannot locate the two consecutive characters `\` and `n` in this string:

```
str = 'The sequence \n generates a new line';
pat = '\n';

regexp(str, pat)
ans =
 []
```

To have `regexp` interpret the expression `expr` as the characters ``\`` and ``n``, first translate the expression using `regexptranslate`:

```
pat2 = regexptranslate('escape', pat)
pat2 =
 \\n

regexp(str, pat2)
ans =
 14
```

## Example 2 – Using 'escape' In a Replacement String

Replace the word 'walk' with 'ascend' in this string, treating the characters '\$1' as a token designator:

```
str = 'I walk up, they walked up, we are walking up.';
pat = 'walk(\w*) up';

regexprprep(str, pat, 'ascend$1')
ans =
 I ascend, they ascended, we are ascending.
```

Make another replacement on the same string, this time treating the '\$1' as literal characters:

```
regexprprep(str, pat, regexptranslate('escape', 'ascend$1'))
ans =
 I ascend$1, they ascend$1, we are ascend$1.
```

## Example 3 – Using the 'wildcard' Option

Given the following string of filenames, pick out just the MAT-files. Use `regexptranslate` to interpret the '\*' wildcard as '\w+' instead of as a regular expression quantifier:

```
files = ['test1.mat, myfile.mat, newfile.txt, ' ...
 'jan30.mat, table3.xls'];
regexp(files, regexptranslate('wildcard', '*.mat'), 'match')
```

# regextranslate

---

```
ans =
 'test1.mat, myfile.mat, newfile.txt, jan30.mat'
```

To see the translation, you can type

```
regextranslate('wildcard', '*.mat')
ans =
 \w+\.mat
```

## See Also

[regexp](#) | [regexpi](#) | [regexprep](#)

## How To

- “Regular Expressions”

**Purpose** Associate event handler for COM object event at run time

**Syntax** `h.registerevent(eventhandler)`  
`registerevent(h, eventhandler)`

**Description** `h.registerevent(eventhandler)` registers event handler routines with their corresponding events. The `eventhandler` argument can be either a string that specifies the name of the event handler function, or a function handle that maps to that function. Strings used in the `eventhandler` argument are not case sensitive.

`registerevent(h, eventhandler)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Show events in the MATLAB sample control:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.events
```

```
Click = void Click()
DbClick = void DbClick()
MouseDown = void MouseDown(int16 Button, int16 Shift,
 Variant x, Variant y)
Event_Args = void Event_Args(int16 typeshort,
 int32 typelong, double typedouble, string typestring,
 bool typebool)
```

MATLAB displays all events associated with the instance of the control.

Register all events with the same event handler routine, `sampev`:

```
h.registerevent('sampev');
h.eventlisteners
```

```
ans =
 'Click' 'sampev'
```

# registerevent

---

```
'Db1Click' 'sampev'
'MouseDown' 'sampev'
'Event_Args' 'sampev'
```

---

Register individual events:

```
%Unregister existing events
h.unregisterallevents;
%Register specific events
h.registerevent({'click' 'myclick'; ...
 'dblclick' 'my2click'});
h.eventlisteners
```

```
ans =
 'click' 'myclick'
 'dblclick' 'my2click'
```

---

Register events using a function handle (@sampev) instead of the function name:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200]);
registerevent(h, @sampev);
```

## See Also

events (COM) | eventlisteners | unregisterevent |  
unregisterallevents | isevent

## How To

- “Writing Event Handlers”

**Purpose** Refresh function and file system path caches

**Syntax**

```
rehash
rehash path
rehash toolbox
rehash pathreset
rehash toolboxreset
rehash toolboxcache
```

**Description** rehash with no arguments updates the MATLAB list of known files and classes for directories on the search path that are not in *matlabroot*/toolbox. It compares the timestamps for loaded functions against their timestamps on disk. It clears loaded functions if the files on disk are newer. All of this normally happens each time MATLAB displays the Command Window prompt. Use rehash with no arguments only when you run a program file that updates another program file, and the calling file needs to reuse the updated version of the second file before the calling file has finished running.

rehash **path** performs the same updates as rehash, but uses a different technique for detecting the files and directories that require updates. Run rehash path only if you receive a warning during MATLAB startup notifying you that MATLAB could not tell if a directory has changed, and you encounter problems with MATLAB not using the most current versions of your program files.

rehash **toolbox** performs the same updates as rehash path, except it updates the list of known files and classes for *all* directories on the search path, including those in *matlabroot*/toolbox. Run rehash toolbox when you change, add, or remove files in *matlabroot*/toolbox during a session. Typically, you should not make changes to files and directories in *matlabroot*/toolbox.

rehash **pathreset** performs the same updates as rehash **path**, and also ensures the known files and classes list follows precedence rules for shadowed functions.

# rehash

---

`rehash toolboxreset` performs the same updates as `rehash toolbox`, and also ensures the known files and classes list follows precedence rules for shadowed functions.

`rehash toolboxcache` performs the same updates as `rehash toolbox`, and also updates the cache file. This is the equivalent of clicking the **Update Toolbox Path Cache** button in the General Preferences dialog box.

## How To

- “Toolbox Path Caching in MATLAB”
- “What Is the MATLAB Search Path?”

**Purpose** Release COM interface

**Syntax** `h.release`  
`release(h)`

**Description** `h.release` releases the interface and all resources used by the interface. You must release the handle when you are done with the interface. A released interface is no longer valid. MATLAB generates an error if you try to use an object that represents that interface.

`release(h)` is an alternate syntax.

Releasing the interface does not delete the control itself (see the `delete` function), since other interfaces on that object might still be active.

COM functions are available on Microsoft Windows systems only.

**See Also** `delete (COM)` | `actxcontrol` | `actxserver`

**How To**

- Releasing Interfaces

# Relational Operators (handle)

---

**Purpose** Equality and sorting of handle objects

**Syntax**

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

**Description**

```
TF = eq(H1,H2)
TF = ne(H1,H2)
TF = lt(H1,H2)
TF = le(H1,H2)
TF = gt(H1,H2)
TF = ge(H1,H2)
```

For each pair of input arrays (H1 and H2), a logical array of the same size is returned in which each element is an element-wise equality or comparison test result. These methods perform scalar expansion in the same way as the MATLAB built-in functions. See [relationaloperators](#) for more information.

You can make the following assumptions about the result of a handle comparison:

- The same two handles always compare as equal and the repeated comparison of any two handles always yields the same result in the same MATLAB session.
- Different handles are always not-equal.
- The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.
- If the input arrays belong to different classes (including the case where one input array belongs to a non-handle class such as `double`) then the comparison is always false.

- If a comparison is made between a handle object and an object of a dominant class, the method of the dominant class is invoked. You should generally test only like objects because a dominant class might not define one of these methods.
- An error occurs if the input arrays are not the same size and neither is scalar.

Use `isequal` when you want to determine if handle objects with different handles have the same data in all object properties.

## See Also

`handle` | `meta.class`

# rem

---

**Purpose**            Remainder after division

**Syntax**            `R = rem(X,Y)`

**Description**        `R = rem(X,Y)` returns the remainder after division of `X` by `Y`. In general, if `Y` does not equal 0, `R = rem(X,Y)` returns `X - n.*Y`, where `n = fix(X./Y)`. If `Y` is not an integer and the quotient `X./Y` is within roundoff error of an integer, then `n` is that integer. Inputs `X` and `Y` must have the same dimensions unless one of them is a scalar double. If one of the inputs has an integer data type, then the other input must be of the same integer data type or be a scalar double.

The following are true by convention:

- `rem(X,0)` is NaN.
- `rem(X,X)` for `X~=0` is 0.
- `rem(X,Y)` for `X~=Y` and `Y~=0` has the same sign as `X`.

## **Input Arguments**

### **X - Dividend**

scalar | vector | matrix | multidimensional array

Dividend, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

### **Y - Divisor**

scalar | vector | matrix | multidimensional array

Divisor, specified as a scalar, vector, matrix, or multidimensional array. Must be a real-valued number of any numerical type.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char

**Examples****Remainder of Two Scalars**

Compute the remainder after dividing 5 into 23.

```
X = 23;
Y = 5;
R = rem(X,Y)
```

R =

3

**Remainder of a Vector**

Create a vector, then use `rem` to find the remainder after dividing a scalar into each element of the vector.

```
X = 1:5;
Y = 3;
R = rem(X,Y)
```

R =

1 2 0 1 2

When you specify one or more of the inputs as an array, the `rem` function acts on each array element independently.

**Remainder of Two Arrays**

Create two 3-by-3 matrices, then use `rem` to find the remainder after dividing Y into X.

```
X = [1 2 3;4 5 6;7 8 9];
Y = [9 8 7;6 5 4;3 2 1];
R = rem(X,Y)
```

R =

1 2 3

```
4 0 2
1 0 0
```

Inputs  $X$  and  $Y$  must have the same dimensions unless one is a scalar double.

## Forced Rounding in rem

If  $Y$  is not an integer and  $X./Y$  is within roundoff error of an integer, then `rem` rounds to that integer for its calculation. The size of the roundoff error is very small.

```
X = 2;
Y = 2 - eps(2)
```

```
Y =
```

```
2.0000
```

It looks like  $Y$  is trivially equal to 2, but in fact there is an infinitesimal difference.

```
2 - Y
```

```
ans =
```

```
4.4409e-16
```

This difference is forced to zero by `rem` if it is small enough.

```
R = rem(X,Y)
```

```
R =
```

```
0
```

Make the difference a little larger and the forced rounding disappears.

```
Y = 2 - eps(4);
```

```
R = rem(X,Y)
```

```
R =
```

```
8.8818e-16
```

### **Difference Between rem and mod**

Define X and Y with different signs.

```
X = 5;
```

```
Y = -2;
```

Compute the remainder after division with `rem`, then compute the modulus after division with `mod`.

```
R = rem(X,Y)
```

```
R =
```

```
1
```

```
M = mod(X,Y)
```

```
M =
```

```
-1
```

`rem(X,Y)` and `mod(X,Y)` are equal if X and Y have the same sign, but differ by Y if X and Y have different signs. Notice that `rem` retains the sign of X, while `mod` retains the sign of Y.

### **See Also**

`mod`

# containers.Map.remove

---

**Purpose** Remove key-value pairs from containers.Map object

**Syntax** remove(mapObj, keySet)

**Description** remove(mapObj, keySet) erases all specified keys, and the values associated with them, from mapObj. Input keySet can be a scalar key or a cell array of keys.

**Input Arguments**

**mapObj**  
Object of class containers.Map.

**keySet**  
Scalar value, string, or cell array that specifies keys in mapObj to delete.

## Examples Remove Key-Value Pairs from a Map

Create a map and view the keys and the Count property:

```
myKeys = {'a', 'b', 'c', 'd'};
myValues = [1,2,3,4];
mapObj = containers.Map(myKeys, myValues);
```

```
mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The initial map contains four key-value pairs:

```
mapKeys =
 'a' 'b' 'c' 'd'
```

```
mapCount =
 4
```

Remove the pairs corresponding to keys b and d:

```
keySet = {'b', 'd'};
```

```
remove(mapObj, keySet)

mapKeys = keys(mapObj)
mapCount = mapObj.Count
```

The modified map contains two key-value pairs:

```
mapKeys =
 'a' 'c'

mapCount =
 2
```

### See Also

[containers.Map](#) | [keys](#) | [values](#) | [isKey](#)

# removecats

---

**Purpose** Remove categories from categorical array

**Syntax**  
B = removecats(A)  
B = removecats(A,oldcats)

**Description** B = removecats(A) removes unused categories from the categorical array, A. The output categorical array, B, has the same size and values as A. However, B possibly has fewer categories.

B = removecats(A,oldcats) removes the categories specified by oldcats. The function removecats removes categories, but does not remove any elements of the array. Therefore, elements of B, whose values correspond to oldcats, are undefined.

## Input Arguments

**A - Categorical array**  
vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **oldcats - Categories to remove**

string | cell array of strings

Categories to remove, specified as a string or cell array of strings. The default is all the unused categories from A.

## Examples

### **Remove All Unused Categories**

Create a categorical array representing political parties of four people.

```
A = categorical({'republican' 'democrat' 'democrat' 'republican'},...
 {'democrat' 'republican' 'independent'})
```

```
A =
```

```
 republican democrat democrat republican
```

A is a 1-by-4 categorical array.

Summarize the categorical array, A.

```
summary(A)
```

```

 democrat republican independent
 2 2 0

```

A has three categories. `democrat` appears twice in the array, `republican` appears twice in the array, and `independent` is unused.

Remove the unused category, `independent`.

```
B = removecats(A)
```

```
B =
```

```

 republican democrat democrat republican

```

B has the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```

 'democrat'
 'republican'

```

B has fewer categories than A.

### **Remove Categories with Corresponding Values Used in A**

Create a categorical array, A, containing modes of transportation.

```
A = categorical({'plane' 'car'; 'train' 'car'; 'plane' 'car'})
```

```
A =
```

```

 plane car

```

## removecats

---

```
 train car
 plane car
```

A is a 3-by-2 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
 'car'
 'plane'
 'train'
```

A has three categories, car, plane, and train.

Remove the category, train.

```
B = removecats(A, 'train')
```

```
B =
```

```
 plane car
 <undefined> car
 plane car
```

The element that was from the category train is now undefined.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
 'car'
 'plane'
```

B has one fewer category than A.

## Tips

- `~ismember(categories(A),unique(A))` returns logical true (1) for any unused category of A.

## See Also

`renamecats` | `reordercats`

# removets

---

**Purpose** Remove timeseries objects from tscollection object

**Syntax** `tsc = removets(tsc,Name)`

**Description** `tsc = removets(tsc,Name)` removes one or more timeseries objects with the name specified in Name from the tscollection object tsc. Name can either be a string or a cell array of strings.

**Examples** The following example shows how to remove a time series from a tscollection.

**1** Create two timeseries objects, ts1 and ts2.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

**2** Create a tscollection object tsc, which includes ts1 and ts2.

```
tsc=tscollection({ts1 ts2});
```

**3** To view the members of tsc, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time 1 seconds
End time 5 seconds
```

```
Member Time Series Objects:
```

```
acceleration
speed
```

The members of `tsc` are listed by name at the bottom: `acceleration` and `speed`. These are the `Name` properties of `ts1` and `ts2`, respectively.

- 4 Remove `ts2` from `tsc`.

```
tsc=removets(tsc,'speed');
```

- 5 To view the current members of `tsc`, type the following at the MATLAB prompt:

```
tsc
```

The response is

```
Time Series Collection Object: unnamed
```

```
Time vector characteristics
```

```
Start time 1 seconds
End time 5 seconds
```

```
Member Time Series Objects:
acceleration
```

The remaining member of `tsc` is `acceleration`. The timeseries `speed` has been removed.

## See Also

`addts` | `tscollection`

# renamecats

---

## Purpose

Rename categories in categorical array

## Syntax

```
B = renamecats(A,newnames)
B = renamecats(A,oldnames,newnames)
```

## Description

`B = renamecats(A,newnames)` renames all the categories in the categorical array, `A`. Elements of `B` use the new category names.

`B = renamecats(A,oldnames,newnames)` renames only the categories specified by `oldnames`.

## Input Arguments

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

### **newnames - New category names for B**

string | cell array of strings

New category names for `B`, specified as a string or a cell array of strings. The new category names must be unique, and must not duplicate any existing names.

### **oldnames - Old category names from A**

string | cell array of strings

Old category names from `A`, specified as a string or a cell array of strings.

## Examples

### **Rename All Categories**

Create a categorical array containing states from New England.

```
A = categorical({'MA'; 'ME'; 'CT'; 'VT'; 'ME'; 'NH'; 'VT'; 'MA'; 'NH'; 'CT'; 'RI'})
```

```
A =
```

```
 MA
```

```
ME
CT
VT
ME
NH
VT
MA
NH
CT
RI
```

A is an 11-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'CT'
'MA'
'ME'
'NH'
'RI'
'VT'
```

A has six categories.

Rename the categories to use the full state name instead of the abbreviation.

```
B = renamecats(A,{'Connecticut','Massachusetts',...
 'Maine','New Hampshire','Rhode Island','Vermont'})
```

```
B =
```

```
Massachusetts
Maine
```

# renamecats

---

```
Connecticut
Vermont
Maine
New Hampshire
Vermont
Massachusetts
New Hampshire
Connecticut
Rhode Island
```

Elements of **B** use the new category names.

Display the categories of **B**.

```
categories(B)
```

```
ans =
```

```
'Connecticut'
'Massachusetts'
'Maine'
'New Hampshire'
'Rhode Island'
'Vermont'
```

## **Rename One Category**

Create a categorical array containing colors.

```
A = categorical({'red' 'blue'; 'purple' 'white'; 'green' 'red'})
```

```
A =
```

```
red blue
purple white
green red
```

A is a 3-by-2 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =
```

```
'blue'
'green'
'purple'
'red'
'white'
```

A has five categories that are listed in alphabetical order.

Change the category name from purple to violet.

```
B = renamecats(A, 'purple', 'violet')
```

```
B =
```

```
 red blue
violet white
green red
```

The element B(2,1) is violet instead of purple.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'blue'
'green'
'violet'
'red'
'white'
```

## renamecats

---

violet replaces purple and the categories are no longer in alphabetical order. Note that the category has not changed its position.

### Tips

- Renaming categories does not change their position in `categories(B)`. Use `reordercats` to change the category ordering. For example, you can use `B = reordercats(B, sort(categories(B)))` to put the categories in alphabetical order.

### See Also

`categories` | `addcats` | `removecats` | `iscategory` | `mergecats` | `reordercats`

<b>Purpose</b>	Reorder categories in categorical array
<b>Syntax</b>	<pre>B = reordercats(A) B = reordercats(A,neworder)</pre>
<b>Description</b>	<p><code>B = reordercats(A)</code> reorders the categories in the categorical array, <code>A</code>, to be in alphanumeric order.</p> <p>The order of the categories is used by functions such as <code>summary</code> and <code>hist</code>. Furthermore, if the categorical array is ordinal, the order of the categories defines their mathematical ordering. The first category specified is the smallest and the last category is the largest.</p> <p><code>B = reordercats(A,neworder)</code> puts the categories in the order specified by <code>neworder</code>.</p>
<b>Input Arguments</b>	<p><b>A - Categorical array</b> vector   matrix   multidimensional array</p> <p>Categorical array, specified as a vector, matrix, or multidimensional array. If <code>A</code> is an ordinal categorical array, a reordering of the categories changes the mathematical meaning. Consequently, the relational operators, such as greater than and less than, might return different results.</p> <p><b>neworder - New category order for B</b> cell array of strings</p> <p>New category order for <code>B</code>, specified as a cell array of strings. <code>neworder</code> must be a permutation of <code>categories(A)</code>.</p>
<b>Examples</b>	<p><b>Alphabetize Categories of Nonordinal Categorical Array</b></p> <p>Create two categorical arrays, <code>X</code> and <code>Y</code>.</p> <pre>X = categorical({'frog';'cat';'cat';'ant';'frog'}) Y = categorical({'deer';'bear';'eagle';'deer'})</pre>

# reordercats

---

X =

```
frog
cat
cat
ant
frog
```

Y =

```
deer
bear
eagle
deer
```

X is a 5-by-1 categorical array. The categories of X are the sorted unique values from the array: {'ant'; 'cat'; 'frog'}.

Y is a 4-by-1 categorical array. The categories of Y are the sorted unique values from the array: {'bear'; 'deer'; 'eagle'}.

Concatenate X and Y into a single categorical array, A.

A = [X;Y]

A =

```
frog
cat
cat
ant
frog
deer
bear
eagle
deer
```

`vertcat` appends the values from `Y` to the values from `X`.

List the categories of the categorical array, `A`.

```
acats = categories(A)
```

```
acats =

 'ant'
 'cat'
 'frog'
 'bear'
 'deer'
 'eagle'
```

`vertcat` appends the categories of `Y` to the categories from `X`. The categories of `A` are *not* in alphabetical order.

Reorder the categories of `A` into alphabetical order.

```
B = reordercats(A)
```

```
B =

 frog
 cat
 cat
 ant
 frog
 deer
 bear
 eagle
 deer
```

The output categorical array, `B`, has the same contents as the input categorical array, `A`.

List the categories of the categorical array, `B`.

# reordercats

---

```
bcats = categories(B)

bcats =

 'ant'
 'bear'
 'cat'
 'deer'
 'eagle'
 'frog'
```

The categories of B are in alphabetical order.

## Reorder Categories in Nonordinal Categorical Array

Create a categorical array containing the color of various items.

```
A = categorical({'red'; 'green'; 'blue'; 'red'; 'green'; 'red'; 'blue'; 'blue'})
```

```
A =

 red
 green
 blue
 red
 green
 red
 blue
 blue
```

A is an 8-by-1 categorical array.

Display the categories of A.

```
categories(A)
```

```
ans =

 'blue'
```

```
'green'
'red'
```

The categories of A are in alphabetical order and have no mathematical meaning.

Reorder the categories to match the order commonly used for colors.

```
B = reordercats(A,{'red','green','blue'})
```

```
B =
```

```
red
green
blue
red
green
red
blue
blue
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
```

```
'red'
'green'
'blue'
```

B is not ordinal and the order of the categories has no mathematical meaning. Although the categories appear in the order of the color spectrum, relational operations, such as greater than and less than, have no meaning.

## Reorder Categories in Ordinal Categorical Array

Create an ordinal categorical array, `A`, containing modes of transportation. Order the categories based on the average price of travel.

```
A = categorical({'plane'; 'car'; 'train'; 'car'; 'plane'; 'car'}, ...
 {'car', 'train', 'plane'}, 'Ordinal', true)
```

```
A =
```

```
 plane
 car
 train
 car
 plane
 car
```

`A` is a 6-by-1 ordinal categorical array.

Display the categories of `A`.

```
categories(A)
```

```
ans =
```

```
 'car'
 'train'
 'plane'
```

Since `A` is ordinal, `car < train < plane`.

Reorder the categories to reflect a decrease in the cost of train travel.

```
B = reordercats(A, {'train', 'car', 'plane'})
```

```
B =
```

```
 plane
```

```
car
train
car
plane
car
```

B contains the same values as A.

Display the categories of B.

```
categories(B)
```

```
ans =
 'train'
 'car'
 'plane'
```

The mathematical ordering of the categories is now `train < car < plane`. The results from relational operations, `min`, and `max` reflect the new category ordering.

## Tips

- To convert the categorical array, B, to an ordinal categorical array, use `B = categorical(B, 'Ordinal', true)`. Furthermore, you can specify the order of the categories with `B = categorical(B, valueset, 'Ordinal', true)` where the order of the values in `valueset` defines the category order.

# FTP.rename

---

<b>Purpose</b>	Rename file on FTP server
<b>Syntax</b>	<code>rename(ftpobj,oldname,newname)</code>
<b>Description</b>	<code>rename(ftpobj,oldname,newname)</code> changes the name of the file <code>oldname</code> to <code>newname</code> in the current folder on an FTP server.
<b>Input Arguments</b>	<p><b>ftpobj</b> FTP object created by <code>ftp</code>.</p> <p><b>oldname</b> String enclosed in single quotation marks that specifies the original name of the file.</p> <p><b>newname</b> String enclosed in single quotation marks that specifies a new name for the file.</p>
<b>Examples</b>	<p>Suppose that hypothetical FTP server <code>ftp.testsite.com</code> contains a file named <code>testfile.m</code>. Rename the file to <code>final.m</code>:</p> <pre>test = ftp('ftp.testsite.com'); rename(test, 'testfile.m', 'final.m'); close(test);</pre>
<b>See Also</b>	<code>delete</code>   <code>dir</code>   <code>ftp</code>   <code>mget</code>   <code>mput</code>

<b>Purpose</b>	Replicate and tile array
<b>Syntax</b>	<pre>B = repmat(A,n) B = repmat(A,sz1,sz2,...,szN) B = repmat(A,sz)</pre>
<b>Description</b>	<p><code>B = repmat(A,n)</code> returns an n-by-n tiling of A. The size of B is <code>size(A) * n</code></p> <p><code>B = repmat(A,sz1,sz2,...,szN)</code> specifies a list of scalars, <code>sz1,sz2,...,szN</code>, to describe an N-D tiling of A. The size of B is <code>[size(A,1)*sz1, size(A,2)*sz2,...,size(A,n)*szN]</code>. For example, <code>repmat([1 2; 3 4],2,3)</code> returns a 4-by-6 matrix.</p> <p><code>B = repmat(A,sz)</code> specifies a row vector, <code>sz</code>, instead of a list of scalars, to describe the tiling of A. This syntax returns the same output as the previous syntax. For example, <code>repmat([1 2; 3 4],[2 3])</code> returns the same result as <code>repmat([1 2; 3 4],2,3)</code>.</p>
<b>Input Arguments</b>	<p><b>A - Input array</b> scalar   vector   array   cell array   table   structure   object</p> <p>Input array, specified as a scalar, vector, array, cell array, table, structure, or object.</p> <p><b>Example: 1</b></p> <p><b>Example:</b> <code>[1 2 3]</code></p> <p><b>Example:</b> <code>[1 2; 3 4]</code></p> <p><b>Example:</b> <code>{'foo',[20 30 40]}</code></p> <p><b>Example:</b> <code>table(rand(5,1),rand(5,1))</code></p> <p><b>Example:</b> <code>struct('Age',25,'Weight',110)</code></p> <p><b>n - Uniform tiling factor</b> scalar</p>

# repmat

Uniform tiling factor, specified as a scalar value. The `n` argument creates an `n`-by-`n` tiling of `A`. If `n` is 0 or negative, the result is an empty array.

**Example:** 3

## **sz1, sz2, ..., szN - Tiling factors for each dimension of A**

two or more scalars

Tiling factors for each dimension of `A`, specified as two or more scalar values. If any tiling factor is 0 or negative, the result is an empty array.

**Example:** 2, 3

**Example:** 2, 3, 4, 2

## **sz - Tiling vector**

row vector

Tiling vector, specified as a row vector. If any value in `sz` is 0 or negative, the result is an empty array.

**Example:** [2 3]

**Example:** [2 3 4 2]

## Tips

- You can use `bsxfun` to tile arrays and perform a binary operation in a single pass. In some cases, `bsxfun` provides a simpler and more memory efficient solution. For example, to add the vectors, `x=1:5` and `y=(1:10)'` to produce a 10-by-5 array, use `bsxfun(@plus,x,y)` instead of `repmat(x,10,1) + repmat(y,1,5)`.
- You can use other functions to get the same result as `repmat` when `A` is a scalar of a certain type.

repmat Syntax	Equivalent Alternative
<code>repmat(NaN,m,n)</code>	<code>NaN(m,n)</code>
<code>repmat(single(inf),m,n)</code>	<code>inf(m,n,'single')</code>
<code>repmat(int8(0),m,n)</code>	<code>zeros(m,n,'int8')</code>

repmat Syntax	Equivalent Alternative
<code>repmat(uint32(1),m,n)</code>	<code>ones(m,n,'uint32')</code>
<code>repmat(eps,m,n)</code>	<code>eps(ones(m,n))</code>

## Examples

### Replicate and Tile a Matrix

Create a diagonal matrix.

```
A = diag([100 200 300])
```

A =

```

100 0 0
 0 200 0
 0 0 300
```

Create a 2-by-2 tiling of A.

```
B = repmat(A,2)
```

B =

```

100 0 0 100 0 0
 0 200 0 0 200 0
 0 0 300 0 0 300
100 0 0 100 0 0
 0 200 0 0 200 0
 0 0 300 0 0 300
```

### Replicate and Tile an N-D Array

Create a 2-by-2-by-2 array.

```
A = zeros(2,2,2);
A(:,:,1) = diag([10 20]);
A(:,:,2) = diag([55 99]);
A
```

# repmat

---

$A(:,:,1) =$

10	0
0	20

$A(:,:,2) =$

55	0
0	99

Create a 3-by-3 tiling of A.

$B = \text{repmat}(A,3)$

$B(:,:,1) =$

10	0	10	0	10	0
0	20	0	20	0	20
10	0	10	0	10	0
0	20	0	20	0	20
10	0	10	0	10	0
0	20	0	20	0	20

$B(:,:,2) =$

55	0	55	0	55	0
0	99	0	99	0	99
55	0	55	0	55	0
0	99	0	99	0	99
55	0	55	0	55	0
0	99	0	99	0	99

## Vertical Stack of Row Vectors

Create a row vector.

```
A = 1:4
```

```
A =
```

```
 1 2 3 4
```

Create a vertical stack of four copies of A.

```
B = repmat(A,4,1)
```

```
B =
```

```
 1 2 3 4
 1 2 3 4
 1 2 3 4
 1 2 3 4
```

B contains 4 copies of A in the first dimension and 1 copy in the second dimension. This result is equivalent to `B = repmat(A,[4 1])`.

### Horizontal Stack of Column Vectors

Create a column vector.

```
A = (1:3)'
```

```
A =
```

```
 1
 2
 3
```

Create a horizontal stack of four copies of A.

```
B = repmat(A,1,4)
```

```
B =
```

```
 1 1 1 1
```

# repmat

---

```
 2 2 2 2
 3 3 3 3
```

B contains 1 copy of A in the first dimension and 4 copies in the second dimension. This result is equivalent to `B = repmat(A,[1 4])`.

## Replicate and Tile a Complex Scalar Value

Define a complex scalar value.

```
A = 5+1i;
```

Create a 3-by-2 tiling of A.

```
B = repmat(A,[3 2])
```

```
B =
```

```
 5.0000 + 1.0000i 5.0000 + 1.0000i
 5.0000 + 1.0000i 5.0000 + 1.0000i
 5.0000 + 1.0000i 5.0000 + 1.0000i
```

B contains 3 copies of A in the first dimension and 2 copies in the second dimension. This result is equivalent to `B = repmat(A,3,2)`.

## Replicate and Tile a Cell Array

Create a cell array containing a string and numeric values.

```
A = {'Values'; 10; 105}
```

```
A =
```

```
 'Values'
 [10]
 [105]
```

Create a 3-by-2 tiling of A.

```
B = repmat(A,[3 2])
```

B =

```
'Values' 'Values'
[10] [10]
[105] [105]
'Values' 'Values'
[10] [10]
[105] [105]
'Values' 'Values'
[10] [10]
[105] [105]
```

B contains 3 copies of A in the first dimension and 2 copies in the second dimension. This result is equivalent to `B = repmat(A,3,2)`.

# resample (tscollection)

---

**Purpose** Select or interpolate data in `tscollection` using new time vector

**Syntax**

```
tsc = resample(tsc,Time)
tsc = resample(tsc,Time,interp_method)
tsc = resample(tsc,Time,interp_method,code)
```

**Description** `tsc = resample(tsc,Time)` resamples the `tscollection` object `tsc` on the new `Time` vector. When `tsc` uses date strings and `Time` is numeric, `Time` is treated as numerical specified relative to the `tsc.TimeInfo.StartDate` property and in the same units that `tsc` uses. The `resample` method uses the default interpolation method for each time series member.

`tsc = resample(tsc,Time,interp_method)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. Valid interpolation methods include 'linear' and 'zoh' (zero-order hold).

`tsc = resample(tsc,Time,interp_method,code)` resamples the `tscollection` object `tsc` using the interpolation method given by the string `interp_method`. The integer `code` is a user-defined quality code for resampling, applied to all samples.

**Examples** The following example shows how to resample a `tscollection` that consists of two `timeseries` members.

**1** Create two `timeseries` objects.

```
ts1=timeseries([1.1 2.9 3.7 4.0 3.0],1:5,'name','acceleration');
ts2=timeseries([3.2 4.2 6.2 8.5 1.1],1:5,'name','speed');
```

**2** Create a `tscollection` `tsc`.

```
tsc=tscollection({ts1 ts2});
```

The time vector of the collection `tsc` is `[1:5]`, which is the same as for `ts1` and `ts2` (individually).

- 3** Get the interpolation method for acceleration by typing

```
tsc.acceleration
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length 5
Start time 1 seconds
End time 5 seconds
```

```
Data characteristics
```

```
Interpolation method linear
Size [1 1 5]
Data type double
```

- 4** Set the interpolation method for speed to zero-order hold by typing

```
setinterpmethod(tsc.speed, 'zoh')
```

MATLAB responds with

```
Time Series Object: acceleration
```

```
Time vector characteristics
```

```
Length 5
Start time 1 seconds
End time 5 seconds
```

# resample (tscollection)

---

Data characteristics

Interpolation method	zoh
Size	[1 1 5]
Data type	double

- 5 Resample the time-series collection `tsc` by individually resampling each time-series member of the collection and using its interpolation method.

```
res_tsc=resample(tsc,[1 1.5 3.5 4.5 4.9])
```

## See Also

`getinterpmethod` | `setinterpmethod` | `tscollection`

**Purpose** Reset graphics object properties to their defaults

**Syntax** `reset(h)`

**Description** `reset(h)` resets all properties on the object identified by `h` to their default values. Properties that do not have default values are not affected.

To obtain the default value of a property defined on the root level, use this statement.

```
get(0, 'DefaultFigureColor')
```

If `h` is a figure, the MATLAB software does not reset `Position`, `Units`, `WindowStyle`, or `PaperUnits`. If `h` is an axes, MATLAB does not reset `Position` and `Units`.

**Examples** `reset(gca)` resets the properties of the current axes.

`reset(gcf)` resets the properties of the current figure.

**See Also** `cla` | `clf` | `gca` | `gcf` | `hold`

# reset (RandStream)

---

**Purpose** Reset random number stream

**Class** RandStream

**Syntax**  
`reset(s)`  
`reset(s,seed)`

**Description** `reset(s)` resets the generator for the random stream, `s`, to the internal state corresponding to its seed. This is similar to clearing `s` and recreating it using `RandStream(Type,...)`, except that `reset` does not set the stream's `NormalTransform`, `Antithetic`, and `FullPrecision` properties to their original values.

`reset(s,seed)` resets the generator for the random stream, `s`, to the internal state corresponding to `seed` (the seed value), and it updates the `seed` property of `s`. The value of `seed` must be an integer between 0 and  $2^{32} - 1$ . Resetting a stream's seed can invalidate independence with other streams.

---

**Note** Resetting a stream should be used primarily for reproducing results.

---

## Examples

### Example 1

Reset a random number stream to its initial state. This does not create a random number stream, it simply resets the stream:

```
stream = RandStream('twister','Seed',0)
```

```
stream =
```

```
mt19937ar random stream
 Seed: 0
 NormalTransform: Ziggurat
```

```
reset(stream);
stream.Seed
```

```
ans =
```

```
0
```

## Example 2

Reset a random number stream using a specific seed:

```
stream = RandStream('twister','Seed',0)
```

```
stream =
```

```
mt19937ar random stream
 Seed: 0
 NormalTransform: Ziggurat
```

```
reset(stream,1);
stream.Seed
```

```
ans =
```

```
1
```

## See Also

[RandStream](#) | [RandStream.getGlobalStream](#)

# reshape

---

**Purpose** Reshape array

**Syntax**

```
B = reshape(A,m,n)
B = reshape(A,[m n])
B = reshape(A,m,n,p,...)
B = reshape(A,[m n p ...])
B = reshape(A,...,[],...)
```

**Description** `B = reshape(A,m,n)` or `B = reshape(A,[m n])` returns the m-by-n matrix B whose elements are taken column-wise from A. An error results if A does not have m\*n elements.

`B = reshape(A,m,n,p,...)` or `B = reshape(A,[m n p ...])` returns an n-dimensional array with the same elements as A but reshaped to have the size m-by-n-by-p-by-.... The product of the specified dimensions, m\*n\*p\*..., must be the same as `numel(A)`.

`B = reshape(A,...,[],...)` calculates the length of the dimension represented by the placeholder [], such that the product of the dimensions equals `numel(A)`. The value of `numel(A)` must be evenly divisible by the product of the specified dimensions. You can use only one occurrence of [].

**Examples** Reshape a 3-by-4 matrix into a 2-by-6 matrix.

```
A =
 1 4 7 10
 2 5 8 11
 3 6 9 12

B = reshape(A,2,6)

B =
 1 3 5 7 9 11
 2 4 6 8 10 12

B = reshape(A,2,[])

B =
```

```
1 3 5 7 9 11
2 4 6 8 10 12
```

## See Also

`shiftdim` | `squeeze` | `circshift` | `permute` | `repmat` | `colon` (:)

# residue

---

**Purpose** Convert between partial fraction expansion and polynomial coefficients

**Syntax**  
[r,p,k] = residue(b,a)  
[b,a] = residue(r,p,k)

**Description** The residue function converts a quotient of polynomials to pole-residue representation, and back again.

[r,p,k] = residue(b,a) finds the residues, poles, and direct term of a partial fraction expansion of the ratio of two polynomials,  $b(s)$  and  $a(s)$ , of the form

$$\frac{b(s)}{a(s)} = \frac{b_1s^m + b_2s^{m-1} + b_3s^{m-2} + \dots + b_{m+1}}{a_1s^n + a_2s^{n-1} + a_3s^{n-2} + \dots + a_{n+1}}$$

where  $b_j$  and  $a_j$  are the  $j$ th elements of the input vectors  $b$  and  $a$ .

[b,a] = residue(r,p,k) converts the partial fraction expansion back to the polynomials with coefficients in  $b$  and  $a$ .

**Definitions** If there are no multiple roots, then

$$\frac{b(s)}{a(s)} = \frac{r_1}{s-p_1} + \frac{r_2}{s-p_2} + \dots + \frac{r_n}{s-p_n} + k(s)$$

The number of poles  $n$  is

$$n = \text{length}(a) - 1 = \text{length}(r) = \text{length}(p)$$

The direct term coefficient vector is empty if  $\text{length}(b) < \text{length}(a)$ ; otherwise

$$\text{length}(k) = \text{length}(b) - \text{length}(a) + 1$$

If  $p(j) = \dots = p(j+m-1)$  is a pole of multiplicity  $m$ , then the expansion includes terms of the form

$$\frac{r_j}{s-p_j} + \frac{r_{j+1}}{(s-p_j)^2} + \dots + \frac{r_{j+m-1}}{(s-p_j)^m}$$

## Arguments

b, a	Vectors that specify the coefficients of the polynomials in descending powers of $s$
r	Column vector of residues
p	Column vector of poles
k	Row vector of direct terms

## Algorithms

It first obtains the poles with `roots`. Next, if the fraction is nonproper, the direct term `k` is found using `deconv`, which performs polynomial long division. Finally, the residues are determined by evaluating the polynomial with individual roots removed. For repeated roots, `resid2` computes the residues at the repeated root locations.

## Limitations

Numerically, the partial fraction expansion of a ratio of polynomials represents an ill-posed problem. If the denominator polynomial,  $a(s)$ , is near a polynomial with multiple roots, then small changes in the data, including roundoff errors, can make arbitrarily large changes in the resulting poles and residues. Problem formulations making use of state-space or zero-pole representations are preferable.

## Examples

If the ratio of two polynomials is expressed as

$$\frac{b(s)}{a(s)} = \frac{5s^3 + 3s^2 - 2s + 7}{-4s^3 + 8s + 3}$$

then

$$\begin{aligned} \mathbf{b} &= [ 5 \ 3 \ -2 \ 7 ] \\ \mathbf{a} &= [ -4 \ 0 \ 8 \ 3 ] \end{aligned}$$

and you can calculate the partial fraction expansion as

# residue

---

```
[r, p, k] = residue(b,a)
```

```
r =
 -1.4167
 -0.6653
 1.3320
```

```
p =
 1.5737
 -1.1644
 -0.4093
```

```
k =
 -1.2500
```

Now, convert the partial fraction expansion back to polynomial coefficients.

```
[b,a] = residue(r,p,k)
```

```
b =
 -1.2500 -0.7500 0.5000 -1.7500
```

```
a =
 1.0000 -0.0000 -2.0000 -0.7500
```

The result can be expressed as

$$\frac{b(s)}{a(s)} = \frac{-1.25s^3 - 0.75s^2 + 0.50s - 1.75}{s^3 - 2.00s - 0.75}.$$

Note that the result is normalized for the leading coefficient in the denominator.

**Purpose** Reissue error

---

**Note** As of version 7.5, MATLAB supports error handling that is based on the `MException` class. Calling `rethrow` with a structure argument, as described on this page, is now replaced by calling `rethrow` with an `MException` object, as described on the reference page for `rethrow(MException)`. `rethrow` called with a structure input will be removed in a future version.

---

**Syntax** `rethrow(errorStruct)`

**Description** `rethrow(errorStruct)` reissues the error specified by `errorStruct`. The currently running function terminates and control returns to the keyboard (or to any enclosing catch block). The `errorStruct` argument must be a MATLAB structure containing at least the message and identifier fields:

Fieldname	Description
<code>message</code>	Text of the error message
<code>identifier</code>	Message identifier of the error message
<code>stack</code>	Information about the error from the program stack

See "Message Identifiers" in the MATLAB documentation for more information on the syntax and usage of message identifiers.

**Tips** The `errorStruct` input can contain the field `stack`, identical in format to the output of the `dbstack` command. If the `stack` field is present, the stack of the rethrown error will be set to that value. Otherwise, the stack will be set to the line at which the `rethrow` occurs.

# rethrow

---

## Examples

rethrow is usually used in conjunction with `try`, `catch` statements to reissue an error from a `catch` block after performing catch-related operations. For example,

```
try
 do_something
catch
 do_cleanup
 rethrow(previous_error)
end
```

## See Also

```
rethrow(MException) | throw(MException) |
throwAsCaller(MException) | assert | error | MException |
try, catch
```

**Purpose** Reissue existing exception

**Syntax** `rethrow(exception)`

**Description** `rethrow(exception)` forces an exception (i.e., error report) to be reissued by MATLAB after the error reporting process has been temporarily suspended to diagnose or remedy the problem. MATLAB typically responds to errors by terminating the currently running program. Errors occurring within a try block, however, bypass this mechanism and transfer control of the program to error handling code in the catch block instead. This enables you to write your own error handling procedures for parts of your program that require them.

The *exception* input is a scalar object of the MException class that contains information about the cause and location of the error.

The code segment below shows the format of a typical try/catch statement.

try	try block
program-code	
program-code	
:	V
catch exception	catch block
error-handling code	
:	
rethrow(exception)	V
end	

An error detected within the try block causes MATLAB to enter the corresponding catch block. The error record constructed by MATLAB in the process of reporting this error passes to the try, catch command in the statement

```
catch exception
```

Error handling code within the catch block uses the information in the error record to address the problem in some predefined manner. The

## rethrow (MException)

---

catch block shown here ends with a `rethrow` statement which throws the exception returned in the catch statement, and then terminates the function:

```
rethrow(exception)
```

The most significant difference between `rethrow` and other MATLAB functions that throw exceptions is in how `rethrow` handles a piece of the exception record called the *stack*. The stack keeps a record of where the error occurred and what functions were called in the process. It is a struct array composed of the following fields, where each element of the array represents an exception:

Fields of the Exception Stack	Description
<code>line</code>	Line number from which the exception was thrown.
<code>name</code>	Name of the function being executed at the time.
<code>file</code>	Name of the file containing that function.

Functions such as `error`, `assert`, or `throw`, create the stack with the location from which they were executed. Calling `rethrow`, however, preserves information from the original exception. In doing so, `rethrow` enables you to retrace the path taken to the source of the error.

### Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining techniques to throw an existing exception.

- Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.

- Reissue the original exception by throwing the initial error record unmodified. Use the `MException rethrow` method to do this.
- Collect additional information on the cause of the error, store it in a new or modified error record, and issue a new exception based on that record. Use the `MException addCause` and `throw` methods to do this.
- Make it appear that the error originated in the caller of the currently running function. Use the `MException throwAsCaller` method to do this.

`rethrow` can only issue a previously caught exception. Calling `rethrow` on an exception that was not previously thrown is an error.

## Examples

This example shows the difference between using `throw` and `rethrow` at the end of a catch block. The `combineArrays` function vertically concatenates arrays A and B. When the two arrays have rows of unequal length, the function throws an error.

The first time you run the function, comment out the `rethrow` command at the end of the catch block so that the function calls `throw` instead:

```
function C = combineArrays(A, B)
try
 catAlongDim1(A, B); % Line 3
catch exception
 throw(exception) % Line 5
 % rethrow(exception) % Line 6
end

function catAlongDim1(V1, V2)
 C = cat(1, V1, V2); % Line 10
```

When MATLAB throws the exception, it reports an error on line 5 which is the line that calls `throw`. In some cases, that might be what you want but, in this case, it does not show the true source of the error.

```
A = 4:3:19; B = 3:4:19;
combineArrays(A, B)
```

## rethrow (MException)

---

```
Error using combineArrays (line 5)
CAT arguments dimensions are not consistent.
```

Make the following changes to `combineArrays.m` so that you use `rethrow` instead:

```
% throw(exception) % Line 5
rethrow(exception) % Line 6
```

Run the function again. This time, line 10 is the first line reported which is where the MATLAB concatenation function `cat` was called and the exception originated. The next error reported is on line 3 which is where the call to `catAlongDim1` was called:

```
combineArrays(A, B)
```

```
Error using cat
CAT arguments dimensions are not consistent.
```

```
Error in combineArrays>catAlongDim1 (line 10)
 C = cat(1, V1, V2); % Line 10
```

```
Error in combineArrays (line 3)
 catAlongDim1(A, B); % Line 3
```

### See Also

addCause(MException) | assert | error | MException |
try, catch
```

**Purpose** Return to invoking function

**Syntax** return

**Description** return causes a normal return to the invoking function or to the keyboard. It also terminates keyboard mode.

**Examples** This determinant function uses return to handle the special case of an empty matrix:

```
function d = det(A)
%DET det(A) is the determinant of A.
if isempty(A)
 d = 1;
 return
else
 ...
end
```

**See Also** while | keyboard | for | error | end | disp | continue | break  
| if | switch

# Tiff.rewriteDirectory

---

**Purpose** Write modified metadata to existing IFD

**Syntax** `tiffobj.rewriteDirectory()`

**Description** `tiffobj.rewriteDirectory()` writes modified metadata (tag) data to an existing directory. Use this tag when you want to change the value of a tag in an existing image file directory.

## **Examples** **Modify Value of Tag**

Write a sample TIFF file, `mytif.tif`. Create a TIFF object associated with this file.

```
imdata = peaks(256);
imwrite(imdata, 'mytif.tif');
t = Tiff('mytif.tif', 'r+');
```

Modify the value of a tag.

```
t.setTag('Software', 'MATLAB');
t.rewriteDirectory();
t.close();
```

## **References**

This method corresponds to the `TIFFRewriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.writeDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Convert RGB colormap to HSV colormap

**Syntax**

```
cmap = rgb2hsv(M)
hsv_image = rgb2hsv(rgb_image)
```

**Description** `cmap = rgb2hsv(M)` converts an RGB colormap `M` to an HSV colormap `cmap`. Both colormaps are  $m$ -by-3 matrices. The elements of both colormaps are in the range 0 to 1.

The columns of the input matrix `M` represent intensities of red, green, and blue, respectively. The columns of the output matrix `cmap` represent hue, saturation, and value, respectively.

`hsv_image = rgb2hsv(rgb_image)` converts the RGB image to the equivalent HSV image. RGB is an  $m$ -by- $n$ -by-3 image array whose three planes contain the red, green, and blue components for the image. HSV is returned as an  $m$ -by- $n$ -by-3 image array whose three planes contain the hue, saturation, and value components for the image.

**See Also** [brighten](#) | [colormap](#) | [hsv2rgb](#) | [rgbplot](#)

# rgb2ind

---

**Purpose** Convert RGB image to indexed image

**Syntax**

```
[X,map] = rgb2ind(RGB,n)
X = rgb2ind(RGB, map)
[X,map] = rgb2ind(RGB, tol)
[___] = rgb2ind(___,dither_option)
```

**Description**

`[X,map] = rgb2ind(RGB,n)` converts the RGB image to an indexed image `X` using minimum variance quantization and dithering. `map` contains at most `n` colors. `n` must be less than or equal to 65,536.

`X = rgb2ind(RGB, map)` converts the RGB image to an indexed image `X` with colormap `map` using the inverse colormap algorithm and dithering. `size(map,1)` must be less than or equal to 65,536.

`[X,map] = rgb2ind(RGB, tol)` converts the RGB image to an indexed image `X` using uniform quantization and dithering. `map` contains at most  $(\text{floor}(1/\text{tol})+1)^3$  colors. `tol` must be between 0.0 and 1.0.

`[ ___ ] = rgb2ind( ___,dither_option)` enables or disables dithering. `dither_option` is a string that can have one of these values.

'dither' (default)	Dithers, if necessary, to achieve better color resolution at the expense of spatial resolution
'nodither'	Maps each color in the original image to the closest color in the new map. No dithering is performed.

---

**Note** The values in the resultant image `X` are indexes into the colormap `map` and should not be used in mathematical processing, such as filtering operations.

---

**Class Support**

The input image can be of class `uint8`, `uint16`, `single`, or `double`. If the length of `map` is less than or equal to 256, the output image is of class `uint8`. Otherwise, the output image is of class `uint16`.

The value 0 in the output array  $X$  corresponds to the first color in the colormap.

## Tips

- If you specify `tol`, `rgb2ind` uses uniform quantization to convert the image. This method involves cutting the RGB color cube into smaller cubes of length `tol`.
- If you specify `n`, `rgb2ind` uses minimum variance quantization. This method involves cutting the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number you specify, the output colormap is also smaller.
- If you specify `map`, `rgb2ind` uses colormap mapping, which involves finding the colors in `map` that best match the colors in the RGB image.

## Algorithms

- **Uniform Quantization** — Uniform quantization cuts the RGB color cube into smaller cubes of length `tol`. For example, if you specify a `tol` of 0.1, the edges of the cubes are one-tenth the length of the RGB cube. The total number of small cubes is:

$$n = (\text{floor}(1/\text{tol})+1)^3$$

Each cube represents a single color in the output image. Therefore, the maximum length of the colormap is `n`. `rgb2ind` removes any colors that don't appear in the input image, so the actual colormap can be much smaller than `n`.

- **Minimum Variance Quantization** — Minimum variance quantization cuts the RGB color cube into smaller boxes (not necessarily cubes) of different sizes, depending on how the colors are distributed in the image. If the input image actually uses fewer colors than the number specified, the output colormap is also smaller.
- **Inverse Colormap** — The inverse colormap algorithm quantizes the specified colormap into 32 distinct levels per color component. Then, for each pixel in the input image, the closest color in the quantized colormap is found.

# rgb2ind

---

## Examples

Read and display a truecolor uint8 JPEG image of a nebula.

```
RGB = imread('ngc6543a.jpg');
figure('Name','RGB Image')
imagesc(RGB)
axis image
zoom(4)
```

Convert RGB to an indexed image with 32 colors

```
[IND,map] = rgb2ind(IMG,32);
figure('Name','Indexed image with 32 Colors')
imagesc(IND)
colormap(map)
axis image
zoom(4)
```

## Purpose

Plot colormap

## Syntax

`rgbplot(cmap)`

## Description

`rgbplot(cmap)` plots the three columns of `cmap`, where `cmap` is an  $m$ -by-3 colormap matrix. `rgbplot` draws the first column in red, the second in green, and the third in blue.

## Examples

### Copper Colormap

Plot the RGB values of the copper colormap.

```
rgbplot(copper)
```

# rgbplot

---

## Summer Colormap

Plot the RGB values of the summer colormap.

```
rgbplot(summer)
```

**See Also** `colormap`

# ribbon

---

## Purpose

Ribbon plot

## Syntax

```
ribbon(Y)
ribbon(X,Y)
ribbon(X,Y,width)
ribbon(axes_handle,...)
h = ribbon(...)
```

## Description

`ribbon(Y)` plots the columns of `Y` as three-dimensional ribbons of uniform width using `X = 1:size(Y,1)`. Ribbons advance along the  $x$ -axis centered on tick marks at unit intervals, three-quarters of a unit in width. Ribbon maps values in `X` to colors in `colormap` linearly. To change ribbon colors in the graph, change the `colormap`.

`ribbon(X,Y)` plots three dimensional ribbons for data in `Y`, centered at locations specified in `X`. `X` and `Y` are vectors or matrices of the same size. Additionally, `X` can be a row or a column vector, and `Y` a matrix with `length(X)` rows. When `Y` is a matrix, `ribbon` plots each column in `Y` as a ribbon at the corresponding `X` location.

`ribbon(X,Y,width)` specifies the width of the ribbons. The default is 0.75. If `width = 1`, the ribbons touch, leaving no space between them when viewed down the  $z$ -axis. If `width > 1`, ribbons overlap and can intersect.

`ribbon(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = ribbon(...)` returns a vector of handles to surface graphics objects. `ribbon` returns one handle per strip.

## Examples

Create a ribbon plot of the peaks function.

```
[x,y] = meshgrid(-3:.5:3,-3:.1:3);
z = peaks(x,y);
```

```
ribbon(y,z)
xlabel('X')
ylabel('Y')
zlabel('Z')
colormap hsv
```

**See Also**

# rmappdata

---

**Purpose** Remove application-defined data

**Syntax** `rmappdata(h,name)`

**Description** `rmappdata(h,name)` removes the application-defined data name from the object specified by handle `h`.

**Tips** Application data is data that is meaningful to or defined by your application which you attach to a figure or any GUI component (other than ActiveX controls) through its `AppData` property. Only Handle Graphics MATLAB objects use this property.

**See Also** `getappdata` | `isappdata` | `setappdata`

**Purpose**

Remove folder

**Syntax**

```
rmdir(folderName)
rmdir(folderName,'s')
[status, message, messageid] = rmdir(folderName,'s')
```

**Description**

`rmdir(folderName)` removes the folder `folderName` from the current folder if `folderName` is empty. If `folderName` is not in the current folder, then specify the relative path or the full path for `folderName`.

`rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder. With the 's' option, `rmdir` attempts to remove all subfolders and files in `folderName` regardless of their write permissions.

`[status, message, messageid] = rmdir(folderName,'s')` removes the folder `folderName` and its contents from the current folder, returning the status, a message, and the MATLAB message ID.

**Tips**

- If you specify the 's' flag or include a wildcard in the folder name, MATLAB produces an error if it is unable to remove all folders. The error message lists the folder and files that MATLAB could not remove.

**Input Arguments****folderName**

String specifying the absolute or relative path name of the folder you want to remove.

**Default:** None

**'s'**

Literal string that directs `rmdir` to remove all subfolders and files in the specified folder, regardless of their write permissions. The result for read-only files follows the practices of the operating system.

# rmdir

---

**Default:** `rmdir` does not remove subfolders and files in the specified folder.

## Output Arguments

### **status**

Logical scalar indicating the outcome of the `rmdir` operation. The status value is 1 if the operation was successful and 0 if it returned an error.

### **message**

String containing the warning or error message text if the operation is unsuccessful. An empty string, if the operation is successful.

### **messageid**

String containing the warning or error message ID, if the operation is unsuccessful. MATLAB returns an empty string if the operation is successful.

## Examples

These examples remove an empty folder, `myfiles`, assuming it is in the current folder:

```
% Remove myfiles from the current folder:
```

```
rmdir('myfiles')
```

```
% Use the relative path to remove myfiles. Assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project, type this:
```

```
rmdir('project/myfiles')
```

```
% Use the full path to remove myfiles, assuming
% the current folder is matlab/work and myfiles is in
% d:/matlab/work/project:
```

```
rmdir('d:/matlab/work/project/myfiles')
```

---

This example removes the `myfiles` folder and its contents, assuming `myfiles` is in the current folder:

```
rmdir('myfiles','s')
```

---

This example unsuccessfully attempts to remove the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess, id]=rmdir('myfiles')
```

MATLAB returns:

```
stat =
 0
```

```
mess =
```

```
No directories were removed.
```

```
id =
```

```
MATLAB:RMDIR:NoDirectoriesRemoved
```

---

This example successfully removes the `myfiles` folder and its contents. It directs MATLAB to display the results.

```
[stat, mess]=rmdir('myfiles','s')
```

MATLAB returns:

```
stat =
 1
```

```
mess =
```

# rmdir

---

..

## **Alternatives**

Open the Current Folder browser by running `filebrowser`. Then, in the Current Folder browser, right-click the folder name and select **Delete** from the context menu.

# rmfield

---

**Purpose** Remove fields from structure

**Syntax** `s = rmfield(s,field)`

**Description** `s = rmfield(s,field)` removes the specified field or fields from structure array `s`. Specify multiple fields using a cell array of strings. The dimensions of `s` remain the same.

## Input Arguments

### **s** - Input structure

structure array

Input structure, specified as a structure array.

### **Data Types**

struct

### **field** - Field name or names

character array | cell array of strings

Field name or names, specified as a character array or a cell array of strings.

**Example:** `'f1'`

**Example:** `{'f1';'f2'}`

### **Data Types**

char | cell

## Examples

### **Remove Single Field**

Define a scalar structure with fields named `a`, `b`, and `c`.

```
s.a = 1;
s.b = 2;
s.c = 3;
```

Remove field `b`.

```
field = 'b';
```

```
s = rmfield(s,field)
```

```
s =
 a: 1
 c: 3
```

### Remove Multiple Fields

Define a scalar structure with fields `first`, `second`, `third`, and `fourth`.

```
S.first = 1;
S.second = 2;
S.third = 3;
S.fourth = 4;
```

Remove fields `first` and `fourth`.

```
fields = {'first','fourth'};
S = rmfield(S,fields)
```

```
S =
 second: 2
 third: 3
```

# rmpath

---

<b>Purpose</b>	Remove folders from search path
<b>Syntax</b>	<code>rmpath(folderName)</code>
<b>Description</b>	<code>rmpath(folderName)</code> removes the specified folder from the search path.
<b>Input Arguments</b>	<p><b>folderName - Name of folder</b> string</p> <p>Name of folder to remove from the search path, specified as a string. Use the full path name for <code>folderName</code>.</p> <p><b>Example:</b> <code>'c:\matlab\work'</code></p> <p><b>Example:</b> <code>'/home/user/matlab'</code></p>
<b>Examples</b>	<p><b>Remove Folder from Search Path</b></p> <p>Remove <code>/usr/local/matlab/mytools</code> from the search path.</p> <pre>rmpath('/usr/local/matlab/mytools')</pre>
<b>See Also</b>	<code>addpath</code>   <code>savepath</code>   <code>path</code>
<b>Concepts</b>	<ul style="list-style-type: none"><li>• “What Is the MATLAB Search Path?”</li></ul>

**Purpose**

Remove preference

**Syntax**

```
rmpref('group','pref')
rmpref('group',{'pref1','pref2',... 'prefn'})
rmpref('group')
```

**Description**

`rmpref('group','pref')` removes the preference specified by `group` and `pref`. It is an error to remove a preference that does not exist.

`rmpref('group',{'pref1','pref2',... 'prefn'})` removes each preference specified in the cell array of preference names. It is an error if any of the preferences do not exist.

`rmpref('group')` removes all the preferences for the specified group. It is an error to remove a group that does not exist.

**Examples**

```
addpref('mytoolbox','version','1.0')
rmpref('mytoolbox')
```

**See Also**

`addpref` | `getpref` | `ispref` | `setpref` | `uigetpref` | `uisetpref`

# rng

---

**Purpose** Control random number generation

**Syntax**

```
rng(sd)
rng('shuffle')
rng(sd, generator)
rng('shuffle', generator)
rng('default')
scurr = rng
rng(s)
sprex = rng(...)
```

## Description

---

**Note** To use the `rng` function instead of `rand` or `randn` with the 'seed', 'state', or 'twister' inputs, see the documentation on “Replace Discouraged Syntaxes of `rand` and `randn`”

---

`rng(sd)` seeds the random number generator using the nonnegative integer `sd` so that `rand`, `randi`, and `randn` produce a predictable sequence of numbers.

`rng('shuffle')` seeds the random number generator based on the current time so that `rand`, `randi`, and `randn` produce a different sequence of numbers after each time you call `rng`.

`rng(sd, generator)` and `rng('shuffle', generator)` additionally specify the type of the random number generator used by `rand`, `randi`, and `randn`. The generator input is one of:

Generator	Description
'twister'	Mersenne Twister
'combRecursive'	Combined Multiple Recursive
'multFibonacci'	Multiplicative Lagged Fibonacci
'v5uniform'	Legacy MATLAB 5.0 uniform generator

Generator	Description
'v5normal'	Legacy MATLAB 5.0 normal generator
'v4'	Legacy MATLAB 4.0 generator

`rng('default')` puts the settings of the random number generator used by `rand`, `randi`, and `randn` to their default values so that they produce the same random numbers as if you restarted MATLAB. In this release, the default settings are the Mersenne Twister with seed 0.

`scurr = rng` returns the current settings of the random number generator used by `rand`, `randi`, and `randn`. The settings are returned in a structure `scurr` with fields `'Type'`, `'Seed'`, and `'State'`.

`rng(s)` restores the settings of the random number generator used by `rand`, `randi`, and `randn` back to the values captured previously with a command such as `s = rng`.

`sprev = rng(...)` returns the previous settings of the random number generator used by `rand`, `randi`, and `randn` before changing the settings.

## Examples

### Example 1 – Retrieve and Restore Generator Settings

Save the current generator settings in `s`:

```
s = rng;
```

Call `rand` to generate a vector of random values:

```
x = rand(1,5)
```

```
x =
```

```
 0.8147 0.9058 0.1270 0.9134 0.6324
```

Restore the original generator settings by calling `rng`. Generate a new set of random values and verify that `x` and `y` are equal:

```
rng(s);
y = rand(1,5)
```

```
y =
 0.8147 0.9058 0.1270 0.9134 0.6324
```

## Example 2 – Restore Settings for Legacy Generator

Use the legacy generator.

```
sprev = rng(0, 'v5uniform')
```

```
sprev =
 Type: 'twister'
 Seed: 0
 State: [625x1 uint32]
```

```
x = rand
```

```
x =
 0.9501
```

Restore the previous settings by calling `rng`:

```
rng(sprev)
```

- “Generate Random Numbers That Are Different”

### Concepts

- “Why Do Random Numbers Repeat After Startup?”

**Purpose** Root

**Description** The root is a graphics object that corresponds to the computer screen. There is only one root object and it has no parent. The children of the root object are figures.

The root object exists when you start MATLAB; you never have to create it and you cannot destroy it. Use `set` and `get` to access the root properties.

**Object Hierarchy**

**See Also** [diary](#) | [echo](#) | [figure](#) | [format](#) | [gcf](#) | [get](#) | [set](#) | [Root Properties](#)

# Root Properties

---

**Purpose** Root properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The set and get commands enable you to set and query the values of properties.

To change the default values of properties, see “Setting Default Property Values”.

## Root Properties

This section provides a description of properties. Curly braces { } enclose default values.

BusyAction

cancel | {queue}

Not used by the root object.

ButtonDownFcn

string

Not used by the root object.

CallbackObject

handle (read-only)

*Handle of current callback's object.* Contains the handle of the object whose callback routine is currently executing. If no callback routines are executing, this property contains an empty double array [ ]. See also the `gco` command.

Children

vector of handles

*Handles of child objects.* A vector containing the handles of all nonhidden figure objects (see `HandleVisibility` for more

information). You can change the order of the handles and thereby change the sorting order of the figures on the display.

## Clipping

{on} | off

*Clipping mode.* This property has no effect on the root object.

## CommandWindowSize

[columns rows]

---

**Note** The `CommandWindowSize` root property will be removed in a future release. To determine the number of columns and rows that display in the Command Window, given its current size, call `matlab.desktop.commandwindow.size`.

---

*Current size of command window.* Size of the MATLAB command window, in a two-element vector. The first element is the number of columns wide and the second element is the number of rows tall.

For example, a value of `[50,25]` means that 50 characters can display across the Command Window, and 25 lines can display without scrolling.

Enabling the Command Window Display preference **Set matrix display width to eighty columns** forces the returned value for number of columns wide to be 80 regardless of the window width.

## CreateFcn

The root object does not use this property.

## CurrentFigure

figure handle

*Handle of the current figure,* which is the one most recently created, clicked in, or made current with the statement:

# Root Properties

---

```
figure(h) % h is a figure handle
```

which re-sorts the figure to the top of the figures displayed on the screen, or:

```
set(0, 'CurrentFigure', h)
```

which does not re-sort the figures. In these statements, `h` is the handle of an existing figure. If there are no figure objects:

```
get(0, 'CurrentFigure')
```

returns an empty double array. Note, however, that `gcf` always returns a figure handle. Calling `gcf` creates a new figure if there are no existing figure objects that can become the current figure (for example, figures with hidden handles cannot become the current figure).

DeleteFcn  
string

This property is not used because you cannot delete the root object.

Diary  
on | {off}

*Diary file mode.* When this property is on, MATLAB maintains a file (whose name is specified by the `DiaryFile` property) that saves a copy of all keyboard input and most of the resulting output. See also the `diary` command.

DiaryFile  
string

*Diary file name.* The default name is `diary`. Set this property to the name of the file MATLAB uses write the command-line diary when the `Diary` property is set to on.

Echo  
on | {off}

*Script echoing mode.* When Echo is on, MATLAB displays each line of a script file as it executes. See also the `echo` command.

ErrorMessage  
string

*Text of last error message.* Contains the last error message issued by MATLAB.

FixedWidthFontName  
font name

*Fixed-width font to use for axes, text, and uicontrols whose FontName is set to FixedWidth.* MATLAB uses the font name specified for this property as the value for axes, text, and uicontrol FontName properties when their FontName property is FixedWidth.

Specifying the font name with this property eliminates the need to hardcode font names in MATLAB applications and thereby enables these applications to run without modification in locales where non-ASCII character sets are required. In these cases, MATLAB attempts to set the value of FixedWidthFontName to the correct value for a given locale.

MATLAB application developers should not change this property, but should create axes, text, and uicontrols with FontName properties set to FixedWidth when they want to use a fixed-width font for these objects.

MATLAB end users can set this property if they do not want to use the preselected value. Courier is the default in locales that use Latin-based characters.

Format  
short | {shortE} | long | longE | bank |  
hex | + | rat

# Root Properties

---

*Output format mode.* Format used to display numbers. See also the `format` command.

- `short` — Fixed-point format with 5 digits
- `shortE` — Floating-point format with 5 digits
- `shortG` — Fixed- or floating-point format displaying as many significant figures as possible with 5 digits
- `long` — Scaled fixed-point format with 15 digits
- `longE` — Floating-point format with 15 digits
- `longG` — Fixed- or floating-point format displaying as many significant figures as possible with 15 digits
- `bank` — Fixed-format of dollars and cents
- `hex` — Hexadecimal format
- `+` — Displays + and - symbols
- `rat` — Approximation by ratio of small integers

`FormatSpacing`  
`compact` | `{loose}`

*Output format spacing* (see also `format` command).

- `compact` — Suppress extra line feeds for more compact display.
- `loose` — Display extra line feeds for a more readable display.

`HandleVisibility`  
`{on}` | `callback` | `off`

This property is not useful on the root object because the handle is always 0.

`HitTest`  
`{on}` | `off`

This property is not useful on the root object.

Interruptible  
{on} | off

This property is not useful on the root object.

Language  
string

System environment setting.

MonitorPositions

*Width and height of monitors, in pixels.* Contains information about the size and relative location of monitors connected to your computer. The information returned by the `MonitorPosition` property depends on which computer system you are using.

## Windows Systems

Windows systems define one monitor as device 1, which becomes the reference by which MATLAB determines other monitor positions. The position data is of the form:

```
[xmin2,ymin2,xmax2,ymax2;
 xmin1,ymin1,xmax1,ymax1]
```

The values for minimum and maximum are relative to the origin.

The following picture show the values returned when querying the `MonitorPositions` property on a Windows system having two monitors arranged as shown.

# Root Properties

Windows System with Two Monitors

```
get(0, 'MonitorPosition')
```

```
-1279 1 0 1024
 1 1 1920 1200
```

The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the n<sup>th</sup> monitor and the last row corresponds to device 1.

The monitor labeled as device 1 in the Windows control panel remains the reference monitor that defines the position of the origin however you reposition the monitors.

## Linux Systems

On Linux systems, the upper-left corner of a rectangle enclosing the system monitors forms the origin. The position data is of the form:

```
[xp yp widthp heightp;
 xs ys widths heights]
```

Where the values represent the offset from the left (x), the offset from the top (y), and the width and height of the monitor. The `MonitorPositions` property contains an n-by-4 array, with each row representing a monitor position. The first row is the position of the primary monitor.

The following picture show the values returned when querying the `MonitorPositions` property on a Linux system that has two monitors arranged as shown.

```
get(0, 'MonitorPosition')
```

```
1281 0 1920 1200
 1 503 1280 1024
```

# Root Properties

---

MATLAB on Linux reads control panel settings only at startup. MATLAB does not recognize changes made to the arrangement of monitors during a MATLAB session.

## Macintosh Systems

MATLAB on Macintosh systems recognize only the main monitor. The position data is of the form:

[x,y,width,height-menuHeight]

Where the values are  $x = 0$ ,  $y = 0$ , monitor width, and monitor height minus the height of the menubar.

The main monitor is determined by which display has the menu bar. The **System Preferences Displays** control panel provides a way to arrange representations of multiple displays, and set one as the main monitor. To make another display the main monitor, drag the representation of the menu bar in the panel from the default display to the other display.

Parent  
handle

*Handle of parent object.* This property always contains an empty double array, because the root object has no parent.

PointerLocation  
[x,y]

*Current location of pointer.* A vector containing the  $x$ - and  $y$ -coordinates of the pointer position, measured from the lower left corner of the screen. Move the pointer by changing the values of this property. The Units property determines the units of this measurement.

PointerLocation always contains the current pointer location, even if the pointer is not in a MATLAB window. A callback

routine querying the `PointerLocation` property can get a value that is different from the location of the pointer when the callback was triggered. This difference results from delays in callback execution caused by competition for system resources.

On Apple Macintosh platforms, you cannot change the pointer location using the `set` command.

## `PointerWindow`

handle (read-only)

*Handle of window containing the pointer.* MATLAB sets this property to the handle of the figure containing the pointer. If the pointer is not in a MATLAB window, the value of this property is 0. A callback routine querying the `PointerWindow` can get the wrong window handle if you move the pointer to another window before the callback executes. This error results from delays in callback execution caused by competition for system resources.

## `RecursionLimit`

integer

*Number of nested MATLAB file calls.* The limit of the number of nested calls to MATLAB files that MATLAB makes before stopping (or potentially running out of memory). By default the value is set to a large value. Setting this property to a smaller value (something like 150, for example) should prevent MATLAB from running out of memory and instead causes MATLAB to issue an error when it reaches the limit.

## `ScreenDepth`

bits per pixel

*Screen depth.* The depth of the display bitmap (the number of bits per pixel). The maximum number of simultaneously displayed colors on the current graphics device is 2 raised to this power.

# Root Properties

---

`ScreenDepth` supersedes the `BlackAndWhite` property. To override automatic hardware checking, set this property to 1. Then MATLAB assumes the display is monochrome. Setting `ScreenDepth` to 1 is useful if MATLAB is running on color hardware but is being displayed on a monochrome terminal. Such a situation can cause MATLAB to determine erroneously that the display is color.

`ScreenPixelsPerInch`  
Display resolution

*DPI setting for your display.* Contains the setting of your display resolution specified in your system preferences.

`ScreenSize`  
four-element rectangle vector (read-only)

*Screen size.* A four-element vector:

[left,bottom,width,height]

that defines the display size. `left` and `bottom` are 0 for all Units except pixels, in which case `left` and `bottom` are both 1. `width` and `height` are the screen dimensions in units specified by the `Units` property.

## Determining Screen Size

Note that the screen size in absolute units (for example, inches) is determined by dividing the number of pixels in width and height by the screen DPI (see the `ScreenPixelPerInch` property). This value is approximate and might not represent the actual size of the screen.

Note that the `ScreenSize` property is static. Its values are read-only at MATLAB startup and not updated if system display settings change. Also, the values returned might not represent

the usable screen size for application developers due to the presence of other GUIs, such as the Microsoft Windows task bar.

**Selected**  
on | off

This property has no effect on the root object.

**SelectionHighlight**  
{on} | off

This property has no effect on the root object.

**ShowHiddenHandles**  
on | {off}

*Show or hide handles marked as hidden.* When set to on, this property disables handle hiding and exposes all object handles regardless of the setting of an object's `HandleVisibility` property. When set to off, all objects so marked remain hidden within the graphics hierarchy.

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. While it is not necessary to identify the root object with a tag (since its handle is always 0), you can use this property to store any string value, which you can later retrieve using `get`.

**Type**  
string (read-only)

*Class of graphics object.* For the root object, `Type` is always the string `root`.

**UIContextMenu**  
handle

# Root Properties

---

This property is not used by the root object.

## Units

{pixels} | normalized | inches | centimeters | points  
| characters

*Unit of measurement.* Specifies the units MATLAB uses to interpret size and location data contained in the `PointerLocation` and `ScreenSize` properties. All units are measured from the lower left corner of the screen.

- `normalized` — Map the lower left corner of the screen to (0,0) and the upper right corner to (1.0,1.0).
- `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $1/72$  inch.
- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter x, and the height of one `characters` unit is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your operation, so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Data you want to associate with the root object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Object visibility.* This property has no effect on the root object.

## See Also

root object

**Purpose**

Polynomial roots

**Syntax**

`r = roots(c)`

**Description**

`r = roots(c)` returns a column vector whose elements are the roots of the polynomial `c`.

Row vector `c` contains the coefficients of a polynomial, ordered in descending powers. If `c` has  $n+1$  components, the polynomial it represents is  $c_1s^n + \dots + c_n s + c_{n+1}$ .

**Tips**

Note the relationship of this function to `p = poly(r)`, which returns a row vector whose elements are the coefficients of the polynomial. For vectors, `roots` and `poly` are inverse functions of each other, up to ordering, scaling, and roundoff error.

**Examples**

The polynomial  $s^3 - 6s^2 - 72s - 27$  is represented in MATLAB software as

```
p = [1 -6 -72 -27]
```

The roots of this polynomial are returned in a column vector by

```
r = roots(p)
```

```
r =
 12.1229
 -5.7345
 -0.3884
```

**Algorithms**

The algorithm simply involves computing the eigenvalues of the companion matrix:

```
A = diag(ones(n-1,1),-1);
A(1,:) = -c(2:n+1)./c(1);
eig(A)
```

# roots

---

It is possible to prove that the results produced are the exact eigenvalues of a matrix within roundoff error of the companion matrix  $A$ , but this does not mean that they are the exact roots of a polynomial with coefficients within roundoff error of those in  $c$ .

## See Also

`fzero` | `poly` | `residue`

**Purpose**

Angle histogram plot

**Syntax**

```
rose(theta)
rose(theta,x)
rose(theta,nbins)
rose(axes_handle,...)
h = rose(...)
[tout,rout] = rose(...)
```

**Description**

`rose(theta)` creates an angle histogram, which is a polar plot showing the distribution of values grouped according to their numeric range, showing the distribution of `theta` in 20 angle bins or less. The vector `theta`, expressed in radians, determines the angle of each bin from the origin. The length of each bin reflects the number of elements in `theta` that fall within a group, which ranges from 0 to the greatest number of elements deposited in any one bin.

`rose(theta,x)` uses the vector `x` to specify the number and the locations of bins. `length(x)` is the number of bins and the values of `x` specify the center angle of each bin. For example, if `x` is a five-element vector, `rose` distributes the elements of `theta` in five bins centered at the specified `x` values.

`rose(theta,nbins)` plots `nbins` equally spaced bins in the range `[0, 2*pi]`. The default is 20.

`rose(axes_handle,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = rose(...)` returns the handle of the line object used to create the graph.

`[tout,rout] = rose(...)` returns the vectors `tout` and `rout` so `polar(tout,rout)` generates the histogram for the data. This syntax does not generate a plot.

## Examples

### Create Rose Histogram

Load the `sunspot.dat` data set which contains the 2-column matrix `sunspot`. Store the second column of the data set as `theta`.

```
load sunspot.dat
theta = sunspot(:,2);
```

Create a rose histogram of `theta` using 12 bins.

```
figure
rose(theta,12)
```

# rosser

---

**Purpose** Classic symmetric eigenvalue test problem

**Syntax** A = rosser  
A = rosser(classname)

**Description** A = rosser returns the Rosser matrix in double precision.

A = rosser(classname) returns the Rosser matrix with a class specified by `classname`. Specify `classname` as 'single' to return the Rosser matrix in single precision.

**Input Arguments** **classname - Input class**  
'double' (default) | 'single'

Input class, specified as 'double' (default) or 'single'. `rosser(C)` produces a matrix of the specified class.

**Examples** **Generate the Rosser matrix**

`rosser` returns the Rosser matrix.

```
rosser
```

```
ans =
 611 196 -192 407 -8 -52 -49 29
 196 899 113 -192 -71 -43 -8 -44
 -192 113 899 196 61 49 8 52
 407 -192 196 611 8 44 59 -23
 -8 -71 61 8 411 -599 208 208
 -52 -43 49 44 -599 411 208 208
 -49 -8 8 59 208 208 99 -911
 29 -44 52 -23 208 208 -911 99
```

**Generate matrix of class 'single'**

Specify `classname` as `single` to return a Rosser matrix of that class.

```
Y = rosser('single')
```

```
whos('Y')
```

```
Y =
```

```

 611 196 -192 407 -8 -52 -49 29
 196 899 113 -192 -71 -43 -8 -44
 -192 113 899 196 61 49 8 52
 407 -192 196 611 8 44 59 -23
 -8 -71 61 8 411 -599 208 208
 -52 -43 49 44 -599 411 208 208
 -49 -8 8 59 208 208 99 -911
 29 -44 52 -23 208 208 -911 99

```

```

Name Size Bytes Class Attributes
Y 8x8 256 single

```

## Definitions

### Rosser Matrix

The Rosser matrix is a well known matrix used, for example, to evaluate eigenvalue algorithms. The matrix is 8-by-8 with integer elements. It has:

- A double eigenvalue
- Three nearly equal eigenvalues
- Dominant eigenvalues of the opposite sign
- A zero eigenvalue
- A small, nonzero eigenvalue

## See Also

eig

# rot90

---

**Purpose** Rotate array 90 degrees

**Syntax**  
 $B = \text{rot90}(A)$   
 $B = \text{rot90}(A, k)$

**Description**  $B = \text{rot90}(A)$  rotates array  $A$  counterclockwise by 90 degrees. For multidimensional arrays,  $\text{rot90}$  rotates in the plane formed by the first and second dimensions.

$B = \text{rot90}(A, k)$  rotates array  $A$  counterclockwise by  $k \cdot 90$  degrees, where  $k$  is an integer.

**Input Arguments**

**A - Input array**

vector | matrix | array | cell array | categorical array | table

Input array, specified as a vector, matrix, array, cell array, categorical array, or table of data type.

**Complex Number Support:** Yes

**k - Rotation constant**

integer

Rotation constant, specified as an integer. Specify  $k$  to rotate by  $k \cdot 90$  degrees rather than nesting calls to  $\text{rot90}$ .

**Example:**  $\text{rot90}(A, -2)$  rotates  $A$  by -180 degrees and is equivalent to  $\text{rot90}(A, 2)$ , which rotates by 180 degrees.

**Examples**

**Rotate Column Vector**

Create a column vector of sequential elements.

$A = (1:5)'$

$A =$

1  
2

```

3
4
5

```

Rotate A counterclockwise by 90 degrees using rot90.

```
B = rot90(A)
```

```
B =
```

```

1 2 3 4 5

```

The result, B, has the same elements as A but a different orientation.

### Rotate Multidimensional Array

Create a 3-by-3-by-2 cell array of strings.

```
A = cat(3,{'a' 'b' 'c';'d' 'e' 'f';'g' 'h' 'i'},{'j' 'k' 'l';'m' 'n'
```

```
A(:,:,1) =
```

```

'a' 'b' 'c'
'd' 'e' 'f'
'g' 'h' 'i'

```

```
A(:,:,2) =
```

```

'j' 'k' 'l'
'm' 'n' 'o'
'p' 'q' 'r'

```

Rotate the cell array by 270 degrees.

```
B = rot90(A,3)
```

```
B(:,:,1) =
```

# rot90

---

```
'g' 'd' 'a'
'h' 'e' 'b'
'i' 'f' 'c'
```

```
B(:,:,2) =
```

```
'p' 'm' 'j'
'q' 'n' 'k'
'r' 'o' 'l'
```

The function rotates each page of the array independently. Since a full 360 degree rotation ( $k = 4$ ) leaves the array unchanged, `rot90(A,3)` is equivalent to `rot90(A,-1)`.

## Tips

- Use the `flip` function to flip arrays in any dimension.

## See Also

`flip` | `flipud` | `fliplr`

---

<b>Purpose</b>	Rotate object about specified origin and direction
<b>Syntax</b>	<code>rotate(h,direction,alpha)</code> <code>rotate(...,origin)</code>
<b>Description</b>	<p>The <code>rotate</code> function rotates a graphics object in three-dimensional space.</p> <p><code>rotate(h,direction,alpha)</code> rotates the graphics object <code>h</code> by <code>alpha</code> degrees. <code>direction</code> is a two- or three-element vector that describes the axis of rotation in conjunction with the origin of the axis of rotation. The default origin of the axis of rotation is the center of the plot box. This point is not necessarily the origin of the axes.</p> <p>Positive <code>alpha</code> is defined as the righthand-rule angle about the direction vector as it extends from the origin of rotation.</p> <p>If <code>h</code> is an array of handles, all objects must be children of the same axes.</p> <p><code>rotate(...,origin)</code> specifies the origin of the axis of rotation as a three-element vector <code>[x<sub>0</sub>,y<sub>0</sub>,z<sub>0</sub>]</code>.</p>
<b>Tips</b>	<p>The rotation transformation modifies the object's data. This technique is different from that used by <code>view</code> and <code>rotate3d</code>, which modify only the viewpoint.</p> <p>The axis of rotation is defined by an origin of rotation and a point <code>P</code>. Specify <code>P</code> as the spherical coordinates <code>[theta phi]</code> or as the Cartesian coordinates <code>[x<sub>p</sub>,y<sub>p</sub>,z<sub>p</sub>]</code>.</p>

# rotate

---

In the two-element form for direction,  $\theta$  is the angle in the  $x$ - $y$  plane counterclockwise from the positive  $x$ -axis.  $\phi$  is the elevation of the direction vector from the  $x$ - $y$  plane.

The three-element form for direction specifies the axis direction using Cartesian coordinates. The direction vector is the vector from the origin of rotation to P.

## Examples **Rotate Plot Around x-Axis**

Create a surface plot of the peaks function and return the surface handle.

```
hSurface = surf(peaks(20));
```

Rotate the surface plot 25 degrees around its x-axis.

```
direction = [1 0 0];
```

# rotate

---

```
rotate(hSurface,direction,25)
```

## Rotate Plot Around y-Axis

Create a surface plot of the peaks function and return the surface handle.

```
hSurface = surf(peaks(20));
```

Rotate the surface plot 25 degrees around its y-axis.

```
direction = [0 1 0];
rotate(hSurface,direction,25)
```

# rotate

---

## Rotate Plot Around x-Axis and y-Axis

Create a surface plot of the peaks function and return the surface handle.

```
hSurface = surf(peaks(20));
```

Rotate the surface plot 25 degrees around its  $x$ -axis and  $y$ -axis.

```
direction = [1 1 0];
rotate(hSurface,direction,25)
```

# rotate

---

## Tips

rotate changes the values of the Xdata, Ydata, and Zdata properties to rotate graphics objects.

## See Also

rotate3d | sph2cart | view | CameraPosition | CameraTarget | CameraUpVector | CameraViewAngle

**Purpose** Rotate 3-D view using mouse

**Syntax**

```
rotate3d on
rotate3d off
rotate3d
rotate3d(figure_handle,...)
rotate3d(axes_handle,...)
h = rotate3d(figure_handle)
```

**Description**

`rotate3d on` enables mouse-base rotation on all axes within the current figure.

`rotate3d off` disables interactive axes rotation in the current figure.

`rotate3d` toggles interactive axes rotation in the current figure.

`rotate3d(figure_handle,...)` enables rotation within the specified figure instead of the current figure.

`rotate3d(axes_handle,...)` enables rotation only in the specified axes.

`h = rotate3d(figure_handle)` returns a `rotate3d mode object` for figure `figure_handle` for you to customize the mode's behavior.

### Using Rotate Mode Objects

You access the following properties of rotate mode objects via `get` and modify some of them using `set`.

- `FigureHandle <handle>` — The associated figure handle, a read-only property that cannot be set
- `Enable 'on' | 'off'` — Specifies whether this figure mode is currently enabled on the figure
- `RotateStyle 'orbit' | 'box'` — Sets the method of rotation
  - 'orbit' rotates the entire axes; 'box' rotates a plot-box outline of the axes.

## Rotate3D Mode Callbacks

You can program the following callbacks for rotate3d mode operations.

- **ButtonDownFilter** <function\_handle> — Function to intercept ButtonDown events

The application can inhibit the rotate operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to handle callbacks):

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object that has been clicked on
% event_obj handle to event data object (empty in this release)
% res [output] logical flag to determine whether the rotate
 operation should take place or the 'ButtonDownFcn'
 property of the object should take precedence
```

- **ActionPreCallback** <function\_handle> — Function to execute before rotating

Set this callback to listen to when a rotate operation will start. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data
```

The event data has the following field:

Axes	The handle of the axes that is being panned
------	---------------------------------------------

- **ActionPostCallback** <function\_handle> — Function to execute after rotating

Set this callback to listen to when a rotate operation has finished. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks):

```
function myfunction(obj,event_obj)
% obj handle to the figure that has been clicked on
% event_obj object containing struct of event data (same as the
% event data of the 'ActionPreCallback' callback)
```

### Rotate3D Mode Utility Functions

The following functions in pan mode query and set certain of its properties.

- `flags = isAllowAxesRotate(h,axes)` — Function querying permission to rotate axes

Calling the function `isAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, as input will return a logical array of the same dimension as the axes handle vector which indicate whether a rotate operation is permitted on the axes objects.

- `setAllowAxesRotate(h,axes,flag)` — Function to set permission to pan axes

Calling the function `setAllowAxesRotate` on the `rotate3d` object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, will either allow or disallow a rotate operation on the axes objects.

## Examples

### Example 1

Rotate the plot using the mouse:

```
surf(peaks);
rotate3d on;
```

### Example 2

Rotate the plot using the "Plot Box" rotate style:

```
surf(peaks);
h = rotate3d;
set(h,'RotateStyle','box','Enable','on');
```

### Example 3

Create two axes as subplots and then prevent one from rotating:

```
ax1 = subplot(1,2,1);
surf(peaks);
h = rotate3d;
set(h,'Enable','on')
ax2 = subplot(1,2,2);
surf(membrane);
setAllowAxesRotate(h,ax2,false); % disable rotating for second plot
```

### Example 4

Create a `ButtonDown` callback for rotate mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd
% Allow a line to have its own 'ButtonDownFcn' callback
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = rotate3d;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse-click on the line
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end
```

## Example 5

Create callbacks for pre- and post-buttonDown events for rotate3D mode objects to trigger. Copy the following code to a new file, execute it, and observe rotation behavior:

```
function demo_mbd2
% Listen to rotate events
surf(peaks);
h = rotate3d;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');

function myprecallback(obj,evd)
disp('A rotation is about to occur.');
```

```
function mypostcallback(obj,evd)
newView = round(get(evd.Axes,'View'));
msgbox(sprintf('The new view is [%d %d].',newView));
```

## Tips

When enabled, rotate3d provides continuous rotation of axes and the objects it contains through mouse movement. A numeric readout appears in the lower left corner of the figure during rotation, showing the current azimuth and elevation of the axes. Releasing the mouse button removes the animated box and the readout. This differs from the camorbit function in that while the rotate3d tool modifies the View property of the axes, the camorbit function fixes the aspect ratio and modifies the CameraTarget, CameraPosition and CameraUpVector properties of the axes. See [Axes Properties](#) for more information.

You can also enable 3-D rotation from the figure **Tools** menu or the figure toolbar.

You can create a rotate3d mode object once and use it to customize the behavior of different axes, as example 3 illustrates. You can also change its callback functions on the fly.

---

**Note** Do not change figure callbacks within an interactive mode. While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should some keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different 3-D rotation behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse will carry over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the Rotate3D tool  on the figure toolbar to enable and disable `rotate3D` mode on a plot, or select **Rotate 3D** from the figure's **Tools** menu. For details, see “Rotate in 3-D”.

## See Also

`camorbit` | `pan` | `rotate` | `view` | `zoom` | `Axes Properties`

**Purpose** Round to nearest integer

**Syntax**  $Y = \text{round}(X)$

**Description**  $Y = \text{round}(X)$  rounds the elements of  $X$  to the nearest integers. Positive elements with a fractional part of 0.5 round up to the nearest positive integer. Negative elements with a fractional part of -0.5 round down to the nearest negative integer. For complex  $X$ , the imaginary and real parts are rounded independently.

**Examples**  $a = [-1.9, -0.2, 3.4, 5.6, 7.0, 2.4+3.6i]$

```
a =
Columns 1 through 4
-1.9000 -0.2000 3.4000 5.6000
Columns 5 through 6
7.0000 2.4000 + 3.6000i
```

```
round(a)
```

```
ans =
Columns 1 through 4
-2.0000 0 3.0000 6.0000
Columns 5 through 6
7.0000 2.0000 + 4.0000i
```

**See Also** `ceil` | `fix` | `floor`

# rowfun

---

## Purpose

Apply function to table rows

## Syntax

```
B = rowfun(func,A)
B = rowfun(func,A,Name,Value)
```

## Description

`B = rowfun(func,A)` applies the function `func` to each row of the table `A` and returns the results in the table `B`.

`func` accepts `size(A,2)` inputs.

`B = rowfun(func,A,Name,Value)` applies the function `func` to each row of the table `A` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables to pass to the function `func` and how to call `func`.

## Input Arguments

### **func** - Function

function handle

Function, specified as a function handle. You can define the function in a file or as an anonymous function. If `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

`func` can accept no more than `size(A,2)` inputs. By default, `rowfun` returns the first output of `func`. To return more than one output from `func`, use the `'NumOutputs'` or `'OutputVariableNames'` name-value pair arguments.

**Example:** `func = @(x,y) x.^2+y.^2;` takes two inputs and finds the sum of the squares.

### **A** - Input table

table

Input table, specified as a table.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'InputVariables', 2` uses only the second variable in `A` as an input to `func`.

### 'InputVariables' - Variables of A to pass to func

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `rowfun` only passes the variables in `A` where the specified function returns 1 (`true`).

### 'GroupingVariables' - One or more variables in A that define groups of rows

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in `A` that have the same grouping variable values belong to the same group. `rowfun` applies `func` to each group of rows, rather than separately to each row of `A`. The output, `B`, contains one row for each group.

## **'SeparateInputs' - Indicator for calling func with separate inputs**

true (default) | false | 1 | 0

Indicator for calling func with separate inputs, specified as the comma-separated pair consisting of 'SeparateInputs' and either true, false, 1, or 0.

true                    func expects separate inputs. rowfun calls func with size(A,2) inputs, one argument for each data variable.

This is the default behavior.

false                    func expects one vector containing all inputs. rowfun creates the input vector to func by concatenating the values in each row of A.

## **'ExtractCellContents' - Indicator to pass values from cell variables to func**

false (default) | true | 0 | 1

Indicator to pass values from cell variables to func, specified as the comma-separated pair consisting of 'ExtractCellContents' and either false, true, 0, or 1.

true                    rowfun extracts the contents of a variable in A whose data type is cell and passes the values, rather than the cells, to func

For grouped computation, the values within each group in a cell variable must allow vertical concatenation.

false                    rowfun passes the cells of a variable in A whose data type is cell to func.

This is the default behavior.

## **'OutputVariableNames' - Variable names for outputs of func**

string | cell array of nonempty, distinct strings

Variable names for outputs of `func`, specified as the comma-separated pair consisting of `'OutputVariableNames'` and a string or a cell array of nonempty, distinct strings. The number of strings must equal the number of outputs desired from `func`.

Furthermore, the strings must be valid MATLAB identifiers. If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of  $N$  strings of the form `{'Var1' ... 'VarN'}` where  $N$  is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

### **'NumOutputs' - Number of outputs from func**

0 | positive integer

Number of outputs from `func`, specified as the comma-separated pair consisting of `'NumOutputs'` and 0 or a positive integer. The integer must be less than or equal to the possible number of outputs from `func`.

**Example:** `'NumOutputs',2` causes `rowfun` to call `func` with two outputs.

### **'OutputFormat' - Format of B**

`'table'` (default) | `'uniform'` | `'cell'`

Format of `B`, specified as the comma-separated pair consisting of `'OutputFormat'` and either the string `'table'`, `'uniform'`, or `'cell'`.

`'table'` `rowfun` returns a table with one variable for each output of `func`. For grouped computation, `B`, also contains the grouping variables.

`'table'` allows you to use a function that returns values of different sizes or data types. However, for ungrouped computation, all of the outputs from `func` must have one row each time it is called. For grouped computation, all of the outputs from `func` must have the same number of rows.

This is the default output format.

- 'uniform' rowfun concatenates the values returned by func into a vector. All of the outputs from func must be scalars with the same data type.
- 'cell' rowfun returns B as a cell array. 'cell' allows you to use a function that returns values of different sizes or data types.

### **'ErrorHandler' - Function to call if func fails**

function handle

Function to call if func fails, specified as the comma-separated pair consisting of 'ErrorHandler' and a function handle. Define this function so that it rethrows the error or returns valid outputs for function func.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

identifier	Error identifier.
message	Error message text.
index	Row or group index at which the error occurred.
- The set of input arguments to function func at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message);
A = NaN; B = NaN;
```

## Output Arguments

### B - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Apply Function with Single Output to Rows

Apply the function `hypot` to each row of the 5-by-2 table `A` to find the shortest distance between the variables `x` and `y`.

Create a table, `A`, with two variables of numeric data.

```
x = gallery('integerdata',10,[5,1],2);
y = gallery('integerdata',10,[5,1],8);
```

```
A = table(x,y)
```

```
A =
```

```
 x y
 — —
 9 1
 4 5
 3 2
 7 3
 1 10
```

Apply the function, `hypot` to each row of `A`. The function `hypot` takes two inputs and returns one output.

```
B = rowfun(@hypot,A,'OutputVariableNames','z')
```

```
B =
```

```
 z
 —
```

```
9.0554
6.4031
3.6056
7.6158
10.05
```

B is a table.

Append the function output, B, to the input table, A.

```
[A B]
```

```
ans =
```

```
 x y z
 -- -- --
 9 1 9.0554
 4 5 6.4031
 3 2 3.6056
 7 3 7.6158
 1 10 10.05
```

## Apply Function with Multiple Outputs to Rows

Define and apply a geometric Brownian motion model to a range of parameters.

Create a function in a file named `gbmSim.m` that contains the following code.

```
function [m,mtrue,s,strue] = gbmSim(mu,sigma)
% Discrete approximation to geometric Brownian motion
%
% [m,mtrue,s,strue] = gbmSim(mu,sigma) computes the
% simulated mean, true mean, simulated standard deviation,
% and true standard deviation based on the parameters mu and sigma.
```

```

numReplicates = 1000; numSteps = 100;
y0 = 1;
t1 = 1;
dt = t1 / numSteps;
y1 = y0*prod(1 + mu*dt + sigma*sqrt(dt)*randn(numSteps,numReplicates));
m = mean(y1); s = std(y1);
% Theoretical values
mtrue = y0 * exp(mu*t1); strue = mtrue * sqrt(exp(sigma^2*t1) - 1);

```

gbmSim accepts two inputs, mu and sigma, and returns four outputs, m, mtrue, s, and strue.

Define the table, params, containing the parameters to input to the Brownian Motion Model.

```

mu = [-.5; -.25; 0; .25; .5];
sigma = [.1; .2; .3; .2; .1];

```

```

params = table(mu,sigma)

```

```

params =

```

mu	sigma
-0.5	0.1
-0.25	0.2
0	0.3
0.25	0.2
0.5	0.1

Apply the function, gbmSim to the rows of the table, params.

```

stats = rowfun(@gbmSim,params,...
 'OutputVariableNames',...
 {'simulatedMean' 'trueMean' 'simulatedStd' 'trueStd'})

```

```

stats =

```

simulatedMean	trueMean	simulatedStd	trueStd
0.60501	0.60653	0.05808	0.060805
0.77916	0.7788	0.161	0.15733
1.0024	1	0.3048	0.30688
1.2795	1.284	0.25851	0.25939
1.6498	1.6487	0.16285	0.16529

The 4 strings specified by the 'OutputVariableNames' name-value pair argument indicate that rowfun should obtain 4 outputs from gbmSim. You can specify fewer output variable names to return fewer outputs from gbmSim.

Append the function output, stats, to the input, params.

```
[params stats]
```

```
ans =
```

mu	sigma	simulatedMean	trueMean	simulatedStd	trueStd
-0.5	0.1	0.60501	0.60653	0.05808	0.060805
-0.25	0.2	0.77916	0.7788	0.161	0.15733
0	0.3	1.0024	1	0.3048	0.30688
0.25	0.2	1.2795	1.284	0.25851	0.25939
0.5	0.1	1.6498	1.6487	0.16285	0.16529

## Apply Function to Groups of Rows

Create a table, A, where g is a grouping variable.

```
g = gallery('integerdata',3,[15,1],1);
x = gallery('uniformdata',[15,1],9);
y = gallery('uniformdata',[15,1],2);
```

```
A = table(g,x,y)
```

A =

g	x	y
3	0.24756	0.87516
3	0.4358	0.3179
3	0.97755	0.27323
2	0.85995	0.6765
3	0.30063	0.071171
2	0.26589	0.19659
3	0.13338	0.52908
2	0.7425	0.17176
1	0.85692	0.86996
2	0.24286	0.24369
3	0.19492	0.84291
2	0.39076	0.55766
1	0.29683	0.35681
1	0.39031	0.2324
2	0.18726	0.6476

Define the anonymous function, `func`, to compute the average difference between `x` and `y`.

```
func = @(x,y) mean(x-y);
```

Find the average difference between variables in groups 1, 2, and 3 defined by the grouping variable, `g`.

```
B = rowfun(func,A,...
 'GroupingVariable','g',...
 'OutputVariableName','MeanDiff')
```

B =

g	GroupCount	MeanDiff
—	—————	—————

# rowfun

---

1	1	3	0.028298
2	2	6	0.032569
3	3	6	-0.10327

The variable `GroupCount` indicates the number of rows in `A` for each group.

## See Also

`varfun` | `cellfun` | `structfun` | `arrayfun` | `isvarname`

## Concepts

- “Anonymous Functions”

**Purpose** Reduced row echelon form

**Syntax**

```
R = rref(A)
[R, jb] = rref(A)
[R, jb] = rref(A, tol)
```

**Description** `R = rref(A)` produces the reduced row echelon form of `A` using Gauss Jordan elimination with partial pivoting. A default tolerance of  $(\max(\text{size}(A)) * \text{eps} * \text{norm}(A, \text{inf}))$  tests for negligible column elements.

`[R, jb] = rref(A)` also returns a vector `jb` such that:

- `r = length(jb)` is this algorithm's idea of the rank of `A`.
- `x(jb)` are the pivot variables in a linear system  $Ax = b$ .
- `A(:, jb)` is a basis for the range of `A`.
- `R(1:r, jb)` is the `r`-by-`r` identity matrix.

`[R, jb] = rref(A, tol)` uses the given tolerance in the rank tests.

Roundoff errors may cause this algorithm to compute a different value for the rank than `rank`, `orth` and `null`. Additionally, use `mldivide` to solve linear systems when high precision is required.

**Examples** Use `rref` on a rank-deficient magic square:

```
A = magic(4), R = rref(A)
```

```
A =
 16 2 3 13
 5 11 10 8
 9 7 6 12
 4 14 15 1
```

```
R =
 1 0 0 1
 0 1 0 3
```

# rref

---

$$\begin{array}{cccc} 0 & 0 & 1 & -3 \\ 0 & 0 & 0 & 0 \end{array}$$

[inv](#) | [lu](#) | [rank](#)

**Purpose** Convert real Schur form to complex Schur form

**Syntax** `[U,T] = rsf2csf(U,T)`

**Description** The *complex Schur form* of a matrix is upper triangular with the eigenvalues of the matrix on the diagonal. The *real Schur form* has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal.

`[U,T] = rsf2csf(U,T)` converts the real Schur form to the complex form.

Arguments `U` and `T` represent the unitary and Schur forms of a matrix `A`, respectively, that satisfy the relationships:  $A = U^*T^*U'$  and  $U' * U = \text{eye}(\text{size}(A))$ . See `schur` for details.

## Examples

Given matrix `A`,

```

1 1 1 3
1 2 1 1
1 1 3 1
-2 1 1 4

```

with the eigenvalues

```

4.8121 1.9202 + 1.4742i 1.9202 + 1.4742i 1.3474

```

Generating the Schur form of `A` and converting to the complex Schur form

```

[u,t] = schur(A);
[U,T] = rsf2csf(u,t)

```

yields a triangular matrix `T` whose diagonal (underlined here for readability) consists of the eigenvalues of `A`.

`U =`

-0.4916	-0.2756 - 0.4411i	0.2133 + 0.5699i	-0.3428
-0.4980	-0.1012 + 0.2163i	-0.1046 + 0.2093i	0.8001
-0.6751	0.1842 + 0.3860i	-0.1867 - 0.3808i	-0.4260
-0.2337	0.2635 - 0.6481i	0.3134 - 0.5448i	0.2466

T =

<b>Purpose</b>	Run MATLAB script
<b>Syntax</b>	<code>run(scriptname)</code>
<b>Description</b>	<code>run(scriptname)</code> runs the MATLAB script specified by <code>scriptname</code> .
<b>Input Arguments</b>	<b>scriptname - Full or relative script path</b> <i>string</i> Full or relative script path to a MATLAB script, specified as a string. <code>scriptname</code> can specify any file type that MATLAB can execute, such as MATLAB script files, Simulink models, or MEX-files.
<b>Tips</b>	<ul style="list-style-type: none"><li>• <code>run</code> executes scripts not currently on the MATLAB path. However, you should use <code>cd</code> or <code>addpath</code> to navigate to or to add the appropriate folder, making a script executable by entering its name alone.</li><li>• <code>scriptname</code> can access any variables in the current workspace.</li><li>• <code>run</code> changes to the folder that contains the script, executes it, and resets back to the original folder. If the script itself changes folders, then <code>run</code> does not revert to the original folder, unless <code>scriptname</code> changes to the folder in which this script resides.</li><li>• If <code>scriptname</code> corresponds to both a <code>.m</code> file and a P-file residing in the same folder, then <code>run</code> executes the P-file. This occurs even if you specify <code>scriptname</code> with a <code>.m</code> extension.</li><li>• If a script is not on the MATLAB path, executing the <code>run</code> command caches the script. In the same session and after calling <code>run</code>, you can edit the script using an external editor. Call <code>clear scriptname</code> before calling <code>run</code> again to use the changed version of the script rather than the cached version. If you edit the script with the MATLAB editor, <code>run</code> executes the changed version and there is no need to call <code>clear scriptname</code>.</li></ul>
<b>Examples</b>	<b>Run Script Not on Current Path</b> Create a temporary folder and copy an example MATLAB script to it.

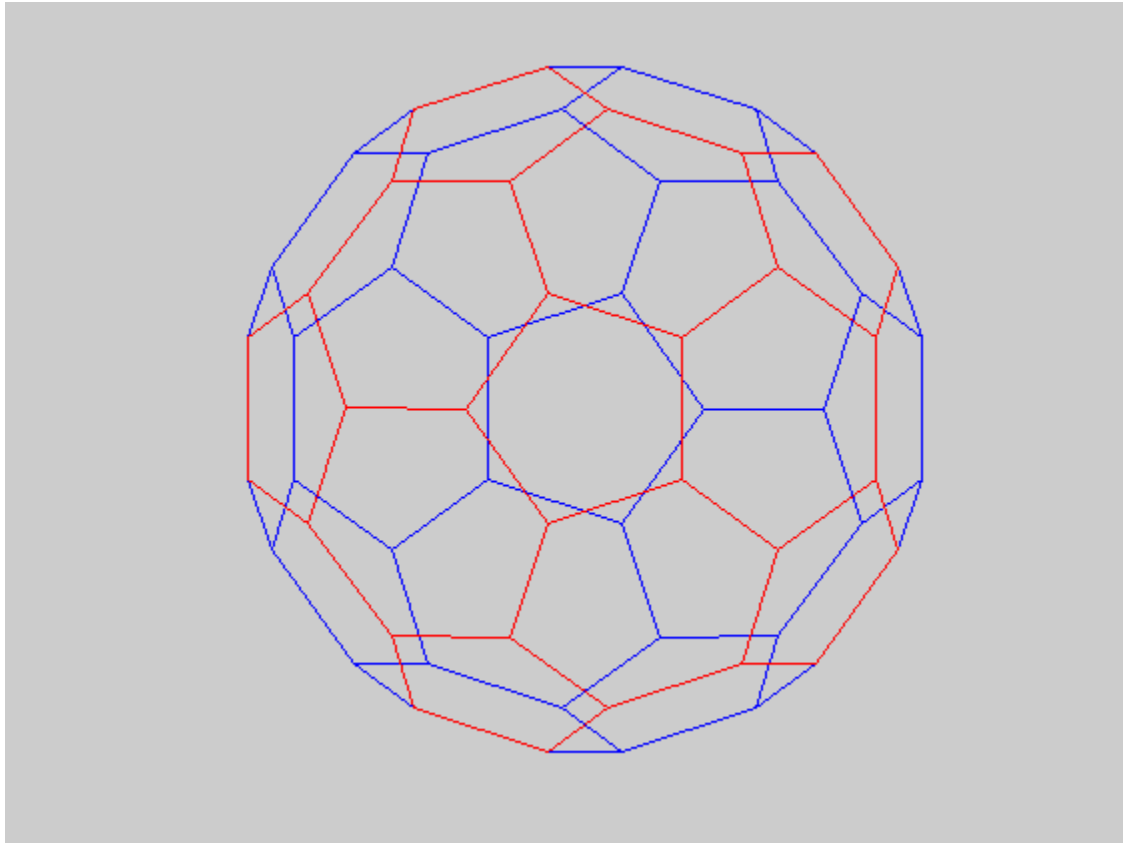

# run

---

```
tmp = tempname;
mkdir(tmp);
runtmp = fullfile(tmp,'buckyball.m');
demodir = fullfile(matlabroot,'toolbox','matlab',...
 'demos','buckydem.m');
copyfile(demodir,runtmp);
```

Run the new script.

```
run(runtmp)
```

# runtests

---

## Purpose

Run set of tests

## Syntax

```
results = runtests(tests)
results = runtests(tests,Name,Value)
```

## Description

`results = runtests(tests)` runs a set of tests, and returns the results as a `TestResult` object.

`results = runtests(tests,Name,Value)` runs a set of tests with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### tests - Array of tests

string | cell array of strings

Suite of tests specified as a string or cell array of strings. Each string in the cell array can contain the name of a test class, a test file, a package that containing your test classes, or a folder containing your test files.

**Example:** `'mypackage.MyTestClass'`

**Example:** `'ATestFile.m'`

**Example:** `pwd`

**Example:**

```
{'mypackage.MyTestClass','ATestFile.m',pwd,'mypackage.subpackage'}
```

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:**

**'Recursively' - Indicator to run tests in subfolders and subpackages**

false (default) | true | 0 | 1

Indicator to run tests in subfolders and subpackages, specified as `false` or `true` (0 or 1). By default `runtests` runs tests in the specified folder or package and not in their subfolders or subpackages.

### **Data Types**

logical

### **'Name' - Name of suite element**

string

String indicating the name of the suite element. For the testing framework to run a test, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty' - Name of parameterization property**

string

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName' - Name of parameter**

string

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder' - Name of base folder**

string

String indicating the name of the folder that contains the file defining the test class or function. For the testing framework to run a test, the test element must be contained in the specified base folder. Use the

wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

## Examples

### Run Tests Using File Name

Create the test file shown below, and save it as `runtestsExampleTest.m` on your MATLAB path.

```
function tests = runtestsExampleTest
tests = functiontests(localfunctions);
```

```
function testFunctionOne(testCase)
```

Run the tests.

```
results = runtests('runtestsExampleTest.m');
```

```
Running runtestsExampleTest
.
Done runtestsExampleTest
```

---

### Run Tests in Subdirectory

If it doesn't already exist, create the test file, `runtestsExampleTest.m`, in the example above.

Create a subdirectory, `tmpTest`, and, in that directory, create the following `runtestsExampleSubFolderTest.m` file.

```
function tests = runtestsExampleSubFolderTest
tests = functiontests(localfunctions);
```

```
function testFunctionTwo(testCase)
```

Run the tests from the directory above `tmpTest` by setting 'Recursively' to true.

```
results = runtests(pwd, 'Recursively', true);
```

```
Running runtestsExampleTest
```

```
.
Done runtestsExampleTest
```

```
Running runtestsExampleSubFolderTest
```

```
.
Done runtestsExampleSubFolderTest
```

`runtests` ran the tests in both the current directory and the subdirectory.

If you do not specify the `'Recursively'` property for the `runtests` function, it does not run the test in the subdirectory.

```
results = runtests(pwd);
```

```
Running runtestsExampleTest
```

```
.
Done runtestsExampleTest
```

## Run Select Parameterized Tests

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
```

## runtests

---

```
function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
end

function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
end

function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
end
function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
end

function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
end
end
end
```

The full test suite has 11 test elements: 6 from the `testClass` method, 2 from the `testSize` method, and 1 each from the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

At the command prompt, run the test elements that use the `outSize` parameter property.

```
runtests('testZeros','ParameterProperty','outSize')
```

```
Running testZeros
.....
Done testZeros
```

```

ans =
```

1x8 TestResult array with properties:

Name  
Passed  
Failed  
Incomplete  
Duration

Totals:

8 Passed, 0 Failed, 0 Incomplete.  
0.013499 seconds testing time.

**runtests** executed eight tests that use the **outSize** parameter property:  
six from the **testClass** method and two from the **testSize** method.

At the command prompt, run the test elements that use the **singe**  
parameter name.

```
runtests('testZeros', 'ParameterName', 'single')
```

```
Running testZeros
```

```
..
```

```
Done testZeros
```

---

```
c =
```

1x2 TestResult array with properties:

Name  
Passed  
Failed  
Incomplete  
Duration

Totals:

2 Passed, 0 Failed, 0 Incomplete.

# runtests

---

```
0.0034442 seconds testing time.
```

`runtests` executed the two tests from the `testClass` method that use the `outSize` parameter name.

**Purpose**

Save workspace variables to file

**Syntax**

```
save(filename)
save(filename,variables)
save(filename,variables,fmt)
save(filename,variables,version)
save(filename,variables,'-append')
```

```
save filename
```

**Description**

`save(filename)` saves all variables from the current workspace in a MATLAB formatted binary file (MAT-file) called `filename`. If `filename` already exists, `save` overwrites the file.

`save(filename,variables)` saves only the variables or fields of a structure array specified by `variables`.

`save(filename,variables,fmt)` saves in the file format specified by `fmt`. The `variables` argument is optional. If you do not specify `variables`, the `save` function saves all variables in the workspace.

`save(filename,variables,version)` saves to the MAT-file version specified by `version`. The `variables` argument is optional, as described above.

`save(filename,variables,'-append')` adds new variables to an existing file, and does not overwrite it. The `variables` argument is optional, as described above.

To append to a Version 6 MAT-file, you must also include `'-v6'` as an input argument.

`save filename` is the command form of the syntax. Command form requires fewer special characters. You do not need to type parentheses

or enclose input strings in single quotes. Separate inputs with spaces instead of commas.

For example, to save a file named `test.mat`, these statements are equivalent:

```
save test.mat % command form
save('test.mat') % function form
```

You can include any of the inputs described in previous syntaxes. For example, to save the variable named `X`:

```
save test.mat X % command form
save('test.mat','X') % function form
```

Do not use command form when any of the inputs, such as `filename`, are variables.

## Input Arguments

### **filename** - Name of file

`'matlab.mat'` (default) | string

Name of file, specified as a string. If you do not specify `filename`, the `save` function saves to a file named `matlab.mat`.

If `filename` has no extension (that is, no text after a period), and the value of `format` is `-mat` (the default), then MATLAB appends `.mat`. If `filename` does not include a full path, MATLAB saves to the current folder. You must have permission to write to the file.

When using the command form of `save`, it is unnecessary to enclose input strings in single quotes. However, if `filename` contains a space, you must enclose the argument in single quotes. For example, save `'filename withspace.mat'`.

**Example:** `'myFile.mat'`

### **Data Types**

char

### **variables** - Names of variables to save

string

Names of variables to save, specified as one or more strings. When using the command form of `save`, you do not need to enclose input strings in single quotes. `variables` can be in one of the following forms.

Form of variables Input	Variables to Save
<code>var1, ..., varN</code>	Save the listed variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>save('filename.mat', 'A*')</code> saves all variables in the file that start with A.
<code>'-regex', expr1, ..., exprN</code>	Save only the variables whose names match the regular expressions, specified as strings. For example, <code>save('filename.mat', '-regex', '^Mon', '^Tue')</code> saves only the variables in the file whose names begin with Mon or Tues.
<code>'-struct', structName</code>	Store the fields of the scalar structure specified by <code>structName</code> as individual variables in the file. For example, <code>save('filename.mat', '-struct', 'S')</code> saves the scalar structure, S.
<code>'-struct', structName, field1, field2, ...</code>	Store the specified fields of the specified scalar structure as individual variables in the file. For example, <code>save('filename.mat', '-struct', 'S', 'a', 'b')</code> saves the fields S.a and S.b.
<code>'-struct', structName, '-regex', regex</code>	Store only the fields whose names match the regular expressions, specified as strings.

## Data Types

char

### fmt - File format

```
'-mat' (default) | '-ascii' | '-ascii','-tabs' |
'-ascii','-double' | '-ascii','-double','-tabs'
```

File format, specified as one of the following strings. When using the command form of `save`, you do not need to enclose input strings in single quotes, for example, `save myFile.txt -ascii -tabs`.

Value of <code>fmt</code>	File Format
'-mat'	Binary MAT-file format.
'-ascii'	Text format with 8 digits of precision.
'-ascii','-tabs'	Tab-delimited text format with 8 digits of precision.
'-ascii','-double'	Text format with 16 digits of precision.
'-ascii','-double','-tabs'	Tab-delimited text format with 16 digits of precision.

For MAT-files, data saved on one machine and loaded on another machine retains as much accuracy and range as the different machine floating-point formats allow.

Use one of the text formats to save MATLAB numeric values to text files. In this case:

- Each variable must be a two-dimensional double array.
- The output includes only the real component of complex numbers.
- MATLAB writes data from each variable sequentially to the file. If you plan to use the `load` function to read the file, all variables must have the same number of columns. The `load` function creates a single variable from the file.

If you specify a text format and any variable is a two-dimensional character array, then MATLAB translates characters to their corresponding internal ASCII codes. For example, 'abc' appears in a text file as:

```
9.7000000e+001 9.8000000e+001 9.9000000e+001
```

### version - MAT-file version

```
'-v7.3' | '-v7' | '-v6' | '-v4'
```

MAT-file version, specified as one of the following strings. When using the command form of save, you do not need to enclose input strings in single quotes.

Value of version	Can Load in MATLAB Versions	Supported Features
'-v7.3'	7.3 (R2006b) or later	Version 7.0 features, plus support for data items greater than or equal to 2 GB on 64-bit systems.
'-v7'	7.0 (R14) or later	Version 6 features, plus data compression and Unicode character encoding. Unicode encoding enables file sharing between systems that use different default character encoding schemes.
'-v6'	5 (R8) or later	Version 4 features, plus <i>N</i> -dimensional arrays, cell arrays and structures, and variable names greater than 19 characters.
'-v4'	all	Two-dimensional double, character, and sparse arrays.

If any data items require features that the specified version does not support, MATLAB does not save those items and issues a warning. You

cannot specify a version later than your current version of MATLAB software.

To view or set the default version for MAT-files, select a **MAT-file save format** option in the General Preferences.

## Examples

### Save All Workspace Variables to MAT-File

Save all variables from the workspace in a binary MAT-file, `test.mat`. If `filename` is a variable, you must use function syntax.

```
filename = 'test.mat';
save(filename)
```

Otherwise, you also can use command syntax.

```
save test.mat
```

Remove the variables from the workspace, and then retrieve the data with the `load` function.

```
clear
load('test.mat')
```

### Save Specific Variables to MAT-File

Create and save two variables, `p` and `q`, to a file called `pqfile.mat`.

```
p = rand(1,10);
q = ones(10);
save('pqfile.mat','p','q')
```

MATLAB saves the variables to the file, `pqfile.mat`, in the current folder.

You also can use command syntax to save the variables, `p` and `q`.

```
save pqfile.mat p q
```

## Save Data to ASCII File

Create two variables, save them to an ASCII file, and then view the contents of the file.

```
p = rand(1,10);
q = ones(10);
save('pqfile.txt','p','q','-ascii')
type('pqfile.txt')
```

The type function displays the contents of the file.

Alternatively, use command syntax for the save operation.

```
save pqfile.txt p q -ascii
```

## Save Structure Fields as Individual Variables

Create a structure, `s1`, that contains three fields, `a`, `b`, and `c`.

```
s1.a = 12.7;
s1.b = {'abc',[4 5; 6 7]};
s1.c = 'Hello!';
```

Save the fields of structure `s1` as individual variables in a file called `newstruct.mat`.

```
save('newstruct.mat','-struct','s1');
```

Check the contents of the file using the `whos` function.

```
disp('Contents of newstruct.mat:')
whos('-file','newstruct.mat')
```

```
Contents of newstruct.mat:
 Name Size Bytes Class Attributes
 a 1x1 8 double
 b 1x2 262 cell
```

```
c 1x6 12 char
```

## Save Variables to Version 7.3 MAT-File

Create two variables and save them to a version 7.3 MAT-file called `example.mat`.

```
A = rand(5);
B = magic(10);
save('example.mat', 'A', 'B', '-v7.3')
```

You also can use command syntax for the save operation.

```
save example.mat A B -v7.3
```

## Append Variable to MAT-File

Save two variables to a MAT-file. Then, append a third variable to the same file.

```
p = rand(1,10);
q = ones(10);
save('test.mat', 'p', 'q')
```

View the contents of the MAT-file.

```
whos('-file', 'test.mat')
```

Name	Size	Bytes	Class	Attributes
p	1x10	80	double	
q	10x10	800	double	

Create a new variable, `a`, and append it to the MAT-file.

```
a = 50;
save('test.mat', 'a', '-append')
```

View the contents of the MAT-file.

```
whos('-file', 'test.mat')
```

---

Name	Size	Bytes	Class	Attributes
a	1x1	8	double	
p	1x10	80	double	
q	10x10	800	double	

The variable, `a`, is appended to `test.mat`, without overwriting the previous variables, `p` and `q`.

---

**Note** To append to a Version 6 MAT-file, specify both `'-v6'` and `'-append'`. For example, to save variable `a` to the file, `test.mat`, call:

```
save('test.mat','a','-v6','-append')
```

---

## Tips

- For more flexibility in creating ASCII files, use `dlmwrite` or `fprintf`.

- “Regular Expressions”

# save (COM)

---

**Purpose** Serialize control object to file

**Syntax** `h.save('filename')`  
`save(h, 'filename')`

**Description** `h.save('filename')` saves the COM control object, `h`, to the file specified in the string, `filename`.  
`save(h, 'filename')` is an alternate syntax for the same operation.

---

**Note** The COM save function is only supported for controls at this time.

---

**Tips** COM functions are available on Microsoft Windows systems only.

**Examples** Create an `mwsamp` control and save its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';
h.Radius = 50;
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');
h.get
```

MATLAB displays the original values:

```
ans =
 Label: 'Label'
 Radius: 20
```

**See Also**

load (COM) | actxcontrol | actxserver | release | delete (COM)

# save (serial)

---

**Purpose** Save serial port objects and variables to file

**Syntax** `save filename`  
`save filename obj1 obj2...`

**Description** `save filename` saves all MATLAB variables to the file `filename`. If an extension is not specified for `filename`, then the `.mat` extension is used.

`save filename obj1 obj2...` saves the serial port objects `obj1 obj2...` to the file `filename`.

**Tips** You can use `save` in the functional form as well as the command form shown above. When using the functional form, you must specify the filename and serial port objects as strings. For example, to save the serial port object `s` to the file `MySerial.mat` on a Windows platform

```
s = serial('COM1');
save('MySerial','s')
```

Any data that is associated with the serial port object is not automatically stored in the file. For example, suppose there is data in the input buffer for `obj`. To save that data to a file, you must bring it into the MATLAB workspace using one of the synchronous read functions, and then save to the file using a separate variable name. You can also save data to a text file with the `record` function.

You return objects and variables to the MATLAB workspace with the `load` command. Values for read-only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. To determine if a property is read-only, examine its reference pages.

**Examples** This example illustrates how to use the command and functional form of `save` on a Windows platform.

```
s = serial('COM1');
set(s,'BaudRate',2400,'StopBits',1)
save MySerial1 s
```

```
set(s, 'BytesAvailableFcn', @mycallback)
save('MySerial2', 's')
```

### See Also

[load](#) | [record](#) | [Status](#)

**Purpose** Save figure or Simulink block diagram using specified format

**Alternatives** Use **File > Save As** on the figure window menu to access the Save As dialog, in which you can select a graphics format. For details, see “Exporting in a Specific Graphics Format” in the MATLAB Graphics documentation. Sizes of files written to image formats by this GUI and by `saveas` can differ due to disparate resolution settings.

**Syntax**

```
saveas(h, 'filename.ext')
saveas(h, 'filename', 'format')
```

**Description** `saveas(h, 'filename.ext')` saves the figure or Simulink block diagram with the handle `h` to the file `filename.ext`. The format of the file is determined by the extension, `ext`. Allowable values for `ext` are listed in this table.

You can pass the handle of any Handle Graphics object to `saveas`, which then saves the parent figure to the object you specified should `h` not be a figure handle. This means that `saveas` cannot save a subplot without also saving all subplots in its parent figure.

Text Value	Format
ai	Adobe Illustrator '88 Support for this format will be removed in a future release.
bmp	Windows bitmap
emf	Enhanced metafile
eps	EPS Level 1
fig	MATLAB figure (invalid for Simulink block diagrams)
jpg	JPEG image (invalid for Simulink block diagrams)
m	MATLAB file (invalid for Simulink block diagrams)

Text Value	Format
pbm	Portable bitmap
pcx	Paintbrush 24-bit
pdf	Portable Document Format
pgm	Portable Graymap
png	Portable Network Graphics
ppm	Portable Pixmap
tif	TIFF image, compressed

`saveas(h, 'filename', 'format')` saves the figure or Simulink block diagram with the handle `h` to the file called `filename` using the specified `format`. The filename can have an extension, but the extension is not used to define the file format. If no extension is specified, the standard extension corresponding to the specified format is automatically appended to the filename.

Allowable values for `format` are the extensions in the table above and the device drivers and graphic formats supported by `print`. The drivers and graphic formats supported by `print` include additional file formats not listed in the table above. When using a `print` device type to specify format for `saveas`, do not prefix it with `-d`.

## Tips

You can use `open` to open files saved using `saveas` with an `m` or `fig` extension. Other `saveas` and `print` formats are not supported by `open`. Both the **Save As** and **Export Setup** dialog boxes that you access from a figure's **File** menu use `saveas` with the `format` argument, and support all device and file types listed above.

---

**Note** Whenever you specify a format for saving a figure with the **Save As** menu item, that file format is used again the next time you save that figure or a new one. If you do not want to save in the previously-used format, use **Save As** and be sure to set the **Save as type** drop-down menu to the kind of file you want to write. However, saving a figure with the `saveas` function and a format does not change the **Save as type** setting in the GUI.

---

If you want to control the size or resolution of figures saved in image (bit-mapped) formats, such as BMP or JPG, use the `print` command and specify dots-per-inch resolution with the `r` switch.

### Examples

#### Example 1: Specify File Extension

Save the current figure that you annotated using the Plot Editor to a file named `pred_pre` using the MATLAB `fig` format. This allows you to open the file `pred_pre.fig` at a later time and continue editing it with the Plot Editor.

```
saveas(gcf, 'pred_pre.fig')
```

#### Example 2: Specify File Format but No Extension

Save the current figure, using a Portable Document format, to the file `logo`. Use the `pdf` extension from the above table to specify the format. The file created is `logo.pdf`.

```
saveas(gcf, 'logo', 'pdf')
```

The file created is `logo.pdf`. MATLAB automatically appends the `pdf` extension because no extension was specified.

#### Example 3: Specify File Format and Extension

Save the current figure to the file `star.eps` using the Level 2 Color PostScript format. If you use `doc print` or `help print`, you can see from

the table for print device types that the device type for this format is `-dpsc2`. The file created is `star.eps`.

```
saveas(gcf, 'star.eps', 'psc2')
```

In another example, save the current Simulink block diagram to the file `trans.tiff` using the TIFF format with no compression. From the table for print device types, you can see that the device type for this format is `-dtiffn`. The file created is `trans.tiff`.

```
saveas(gcf, 'trans.tiff', 'tiffn')
```

#### **Example 4: Saving a Simulink Diagram**

Save a Simulink diagram from command line. The file is saved as `counters.bmp`

```
sldemo_tank
saveas(get_param('sldemo_tank', 'Handle'), 'topmodel.bmp');
```

Using `get_param`, get the handle of the model and save using the `saveas` command. The file can be saved in any desired standard image formats.

#### **See Also**

`hgsave` | `open` | `print` | `save_system`

# savefig

---

**Purpose** Save figure to FIG-file

**Syntax** `savefig(filename)`  
`savefig(h,filename)`

**Description** `savefig(filename)` saves the current figure to a FIG-file named `filename`.

`savefig(h,filename)` saves one or more figures referred to by `h`, where `h` can be a single figure handle or an array of figure handles.

## Input Arguments

**h - Handle to one or more figures**  
single figure handle | array of figure handles

Handle to one or more figures, specified as a single figure handle or an array of figure handles.

**filename - file name**  
'Untitled.fig' (default) | string

File name, specified as a string. If you do not specify a file name, then MATLAB saves the file as `Untitled.fig`, which is the default.

If the specified string does not include a `.fig` file extension, then MATLAB appends the extension. `savefig` does not accept other file extensions.

**Example:** 'ExampleFile.fig'

## Examples Save Current Figure to FIG-File

Create a surface plot of the peaks function. Save the figure to the file `PeaksFile.fig`. Close the figure after saving it.

```
figure;
surf(peaks);
savefig('PeaksFile.fig');
close(gcf)
```

To open the figure, use the command `openfig('PeaksFile.fig')`.

### Save Multiple Figures to FIG-File

Create two plots and store the figure handles in array `h`. Save the figures to the file `TwoFiguresFile.fig`. Close the figures after saving them.

```
h(1) = figure;
z = peaks;
surf(z)

h(2) = figure;
plot(z)

savefig(h, 'TwoFiguresFile.fig');
close(h)
```

To open the two figures, use the command `openfig('TwoFiguresFile.fig')`.

### Tips

- You must use MATLAB to open files saved using `savefig`. To open the file, pass the file name to the function `openfig`, `hgload`, or `open`. For example,

```
openfig('ExampleFile.fig')
```

opens the file, `ExampleFile.fig`, in MATLAB.

- `savefig` saves the full MATLAB figure. To save only part of a figure, such as an axes, or to save handles in addition to the data, use the `save` function to create a MAT-file.

### See Also

`openfig` | `save` | `open` | `load`

# saveobj

---

**Purpose** Modify save process for object

**Syntax** `b = saveobj(a)`

**Description** `b = saveobj(a)` is called by the `save` function if the class of `a` defines a `saveobj` method. `save` writes the returned value, `b`, to the MAT-file.

Define a `loadobj` method to take the appropriate action when loading the object.

If `A` is an array of objects, MATLAB invokes `saveobj` separately for each object saved.

**Examples** Call the superclass `saveobj` method from the subclass implementation of `saveobj` with the following syntax:

```
classdef mySub < super
 methods
 function subj = saveobj(obj)
 % Call superclass saveobj method
 subj = saveobj@super(obj);
 % Perform subclass save operations
 ...
 end
 ...
 end
 ...
end
```

See “Saving and Loading Objects from Class Hierarchies”.

---

Update object when saved:

```
function b = saveobj(a)
 % If the object does not have an account number,
 % Add account number to AccountNumber property
 if isempty(a.AccountNumber)
 a.AccountNumber = getAccountNumber(a);
 end
end
```

```
 end
 b = a;
end
```

See “Maintaining Class Compatibility”.

# savepath

---

<b>Purpose</b>	Save current search path
<b>Alternatives</b>	As an alternative to the <code>savepath</code> function, use the Set Path dialog box.
<b>Syntax</b>	<pre>savepath savepath folderName/pathdef.m status = savepath...</pre>
<b>Description</b>	<p><code>savepath</code> updates the MATLAB search path for all users on the system so that the path can be reused in a future session. <code>savepath</code> saves the search path to the <code>pathdef.m</code> file that MATLAB located at startup, or to the current folder if a <code>pathdef.m</code> file exists there. To save the search path programmatically each time you exit MATLAB, use <code>savepath</code> in a <code>finish.m</code> file.. On a Windows system with User Account Control (UAC) enabled, UAC might prompt you to allow the update operation because it requires administrator-level permission.</p> <p><code>savepath folderName/pathdef.m</code> saves the current search path to <code>pathdef.m</code> located in <code>folderName</code>. Use this form of the syntax if you do not have write access to the current <code>pathdef.m</code>. If you do not specify <code>folderName</code>, MATLAB saves <code>pathdef.m</code> in the current folder. <code>folderName</code> can be a relative or absolute path. To use the saved search path automatically in a future session, make <code>folderName</code> be the startup folder for MATLAB.</p> <p><code>status = savepath...</code> returns 0 when <code>savepath</code> was successful and 1 when <code>savepath</code> failed.</p>
<b>Examples</b>	<p>Save the current search path to <code>pathdef.m</code>, located in <code>I:/my_matlab_files</code>:</p> <pre>savepath I:/my_matlab_files/pathdef.m</pre>
<b>See Also</b>	<pre>addpath   cd   dir   finish   genpath   matlabroot   pathsep   pathtool   rehash   restoredefaultpath   rmpath   startup   userpath   what</pre>

**How To**

- “Running a Script When Exiting”
- “What Is the MATLAB Search Path?”

# scatter

---

**Purpose** Scatter plot

**Syntax**

```
scatter(X,Y)
scatter(X,Y,S)
scatter(X,Y,S,C)
scatter(__ , 'fill')
scatter(__ , markertype)
scatter(__ , Name, Value)

scatter(axes_handle, __)

h = scatter(__)
```

**Description** `scatter(X,Y)` displays circles at the locations specified by the vectors `X` and `Y`. This type of graph is also known as a bubble plot.

`scatter(X,Y,S)` draws each circle with the size specified by `S`. To plot each circle with equal size, specify `S` as a scalar. To plot each circle with a specific size, specify `S` as a vector with length equal to the length of `X` and `Y`.

`scatter(X,Y,S,C)` draws each circle with the color specified by `C`.

- If `C` is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If `C` is a three column matrix with the number of rows in `C` equal to the length of `X` and `Y`, then each row of `C` specifies an RGB color value for the corresponding circle.
- If `C` is a vector with length equal to the length of `X` and `Y`, then the values in `C` are linearly mapped to the colors in the current colormap.

`scatter( __ , 'fill' )` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter( ___, markertype )` specifies the marker type.

`scatter( ___, Name, Value )` specifies scattergroup property settings using one or more Name, Value pair arguments.

`scatter( axes_handle, ___ )` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The `axes_handle` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter( ___ )` returns the scattergroup object handle, `h`.

## Input Arguments

### **X - Value of data to display on x-axis**

vector

Value of data to display on the *x*-axis, specified as a vector. *X* and *Y* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Y - Value of data to display on y-axis**

vector

Value of data to display on the *y*-axis, specified as a vector. *X* and *Y* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **S - Marker area**

36 (default) | scalar | row or column vector | []

Marker area, specified as a scalar, a row or column vector, or []. The values in *S* must be positive. The units for area are points squared.

# scatter

---

- If **S** is a scalar, then `scatter` plots all markers with the specified area.
- If **S** is a row or column vector, then each entry in **S** specifies the area for the corresponding marker. The length of **S** must equal the length of **X** and **Y**, and corresponding entries in **X**, **Y**, and **S** determine the location and area of each marker.
- If **S** is empty, then the default size of 36 points squared is used.

**Example:** 50

**Example:** [36,25,25,17,46]

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

## C - Marker color

[0 0 1] (blue) (default) | color string | RGB row vector | three-column matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify **C** as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'

RGB Vector	Short Name	Long Name
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'k'

**Example:** [1,2,3,4]

**Example:** reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

### markertype - Marker type

'o' (default) | string

Marker type, specified as a string. This table lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle

Specifier	Marker Type
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'p'

## Data Types

char

## axes\_handle - Axes handle

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'MarkerFaceColor','red'` sets the marker face color to red.

For more information on these settings see `scattergroup`.

## 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of `'LineWidth'` and a scalar in points. The scalar sets the width size of the marker edge.

Example: 'LineWidth',0.75

### 'MarkerEdgeColor' - Marker edge color

'none' | 'auto' | 'flat' (default) | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'flat'	Sets the color using the CData property.
'auto'	Sets the color to the axes Color property. If the axes Color property is none, then sets the color to the figure Color property.
'none'	Specifies no color, which makes nonfilled markers invisible.

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'

RGB Vector	Short Name	Long Name
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** `'MarkerEdgeColor',[1 .8 .1]`

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | 'flat' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'flat'	Sets the fill color using the CData property.
'auto'	Sets the fill color to the axes Color property. If the axes Color property is none, then sets the fill color to the figure Color property.
'none'	Makes the interior of the marker transparent, allowing the background to show through.

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

## Output Arguments

### **h - Scattergroup object handle**

scalar

Scattergroup object handle, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the scattergroup object.

## Examples

### **Create Scatter Plot**

Define  $x$  to contain 200 equally spaced values between 0 and  $3\pi$ . Initialize the random-number generator to make the output of `rand` repeatable, and define  $y$  to contain cosine values with random noise.

```
x = linspace(0,3*pi,200);
rng(0,'twister');
y = cos(x)+ rand(1,200);
```

Create a scatter plot using the two vector inputs.

```
figure
scatter(x,y)
```

## scatter

---

scatter plots entries in  $x$  against corresponding entries in  $y$ .

### **Vary Circle Size**

Load the sample data from `seamount` to get vectors  $x$  and  $y$ . Define  $s$  as a vector of linearly spaced values between 1 and 50 that is the same length as  $x$ . Create a scatter plot and vary the circle size. Use `zoom` to zoom in on the scatter plot.

figure

```
load seamount
s = linspace(1,50,length(x));
scatter(x,y,s)
zoom(2)
```

Corresponding entries in  $x$ ,  $y$ , and  $s$  determine the location and size of each marker.

## Vary Circle Color

Load the sample data from `seamount` to get vectors `x` and `y`. Define `c` as a vector of linearly spaced values between 1 and 10 that is the same length as `x`. Create a scatter plot and vary the circle color. Use `zoom` to zoom in on the scatter plot.

```
figure
load seamount
s = 10;
c = linspace(1,10,length(x));
scatter(x,y,s,c)
zoom(2)
```

Corresponding entries in `x`, `y`, and `c` determine the location and color of each marker. Since `s` is a scalar value, all markers are the same size.

### Vary Circle Size and Color

Load sample data from `seamount` to get vectors `x`, `y`, and `z`. Create a scatter plot and vary the circle size and color. Fill in the circles and use `zoom` to zoom in on the scatter plot.

`figure`

# scatter

```
load seamount
s = sqrt(-z/2);
c = z;
scatter(x,y,s,c,'fill')
zoom(2)
```

scatter plots each circle with a specific size and color determined by the vectors  $s$  and  $c$ , respectively.

### **Specify Marker Symbol**

Initialize the random-number generator to make the output of rand repeatable. Set up vectors x and y as sine and cosine values with random noise.

```
rng(0, 'twister');
theta = linspace(0, 2*pi, 150);
x = sin(theta) + 0.75*rand(1, 150);
y = cos(theta) + 0.75*rand(1, 150);
```

Create a scatter plot and set the marker type to diamonds with an area of 140 points squared.

```
figure
s = 140;
scatter(x, y, s, 'd')
```

## scatter

---

To fill in the diamonds, use the 'fill' option.

### **Specify Marker Properties**

Initialize the random-number generator to make the output of rand repeatable. Define vectors x and y as sine and cosine values with random noise.

```
rng(0,'twister');
theta = linspace(0,2*pi,300);
```

```
x = sin(theta) + 0.75*rand(1,300);
y = cos(theta) + 0.75*rand(1,300);
```

Create a scatter plot and set the marker size, edge color, face color, and line width using Name,Value pair arguments.

```
figure
s = 40;
scatter(x,y,s,'MarkerEdgeColor','b',...
 'MarkerFaceColor','c',...
 'LineWidth',1.5)
```

## scatter

---

### Specify Scatter Plot Axes

Load the sample data from `seamount` to get vectors `x`, `y`, and `z`.

```
load seamount
```

Create a figure with two subplots and return the handles to the two subplot axes in array `hs`. Create a scatter plot in the upper subplot using the axes handle, `hs(1)`. In the lower subplot, create another scatter plot from the same data sample and use filled, diamond markers.

```
figure
hs(1) = subplot(1,2,1);
hs(2) = subplot(1,2,2);
s = 30;
c = z;
scatter(hs(1),x,y,s,c)
scatter(hs(2),x,y,s,c,'fill','d')
```

## Set Marker Properties Using the Handle

Use `|sphere|` to define vectors `|x|`, `|y|`, and `|z|`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vectors `s` and `c` to specify the size and color for each marker.

```
S = repmat([70,50,20],numel(X),1);
C = repmat([1,2,3],numel(X),1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and return the scattergroup handle, `h`.

```
figure
h = scatter3(x,y,z,s,c);
```

Use the handle to set the marker face color for the scatter plot.

```
set(h, 'MarkerFaceColor', [0 .5 .5])
```

## scatter

---

### See Also

[scatter3](#) | [plot3](#) | [scattergroup](#) | [ColorSpec](#) | [LineStyle](#)

**Purpose**

3-D scatter plot

**Syntax**

```
scatter3(X,Y,Z)
scatter3(X,Y,Z,S)
scatter3(X,Y,Z,S,C)
scatter3(__ , 'fill')
scatter3(__ , markertype)
scatter3(__ , Name, Value)

scatter3(axes_handle, __)

h = scatter3(__)
```

**Description**

`scatter3(X,Y,Z)` displays circles at the locations specified by the vectors *X*, *Y*, and *Z*.

`scatter3(X,Y,Z,S)` draws each circle with the size specified by *S*. To plot each circle with equal size, specify *S* as a scalar. To plot each circle with a specific size, specify *S* as a vector.

`scatter3(X,Y,Z,S,C)` draws each circle with the color specified by *C*.

- If *C* is a color string or an RGB row vector, then all circles are plotted with the specified color.
- If *C* is a three column matrix with the number of rows in *C* equal to the length of *X*, *Y*, and *Z*, then each row of *C* specifies an RGB color value for the corresponding circle.
- If *C* is a vector with length equal to the length of *X*, *Y*, and *Z*, then the values in *C* are linearly mapped to the colors in the current colormap.

`scatter3( __ , 'fill' )` fills in the circles, using any of the input argument combinations in the previous syntaxes.

`scatter3( __ , markertype)` specifies the marker type.

# scatter3

---

`scatter3( ___, Name, Value)` specifies scattergroup property settings using one or more `Name, Value` pair arguments.

`scatter3(axes_handle, ___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The `axes_handle` option can precede any of the input argument combinations in the previous syntaxes.

`h = scatter3( ___)` returns the scattergroup object handle, `h`.

## Input Arguments

### **X - Value of data to display on x-axis**

vector

Value of data to display on the *x*-axis, specified as a vector. *X*, *Y*, and *Z* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Y - Value of data to display on y-axis**

(default) | vector

Value of data to display on the *y*-axis, specified as a vector. *X*, *Y*, and *Z* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

### **Z - Value of data to display on z-axis**

(default) | vector

Value of data to display on the *z*-axis, specified as a vector. *X*, *Y*, and *Z* must be vectors of equal length.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical

**S - Marker area**

36 (default) | scalar | vector | []

Marker area, specified as a scalar, a vector, or []. The values in S must be positive. The units for area are points squared.

- If S is a scalar, then scatter3 plots all markers with the specified area.
- If S is a row or column vector, then each entry in S specifies the area for the corresponding marker. The length of S must equal the length of X, Y and Z. Corresponding entries in X, Y, Z and S determine the location and area of each marker.
- If S is empty, then the default size of 36 points squared is used.

**Example:** 50

**Example:** [36,25,25,17,46]

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**C - Marker color**

[0 0 1] (blue) (default) | color string | RGB row vector | three-column  
matrix of RGB values | vector

Marker color, specified as a color string, an RGB row vector, a three-column matrix of RGB values, or a vector. For an RGB row vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. If you have three points in the scatter plot and want the colors to be indices into the colormap, specify C as a three-element column vector.

This table lists the predefined colors and their RGB equivalents.

# scatter3

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'y'

**Example:** [1,2,3,4]

**Example:** reshape([0,1,0,0,0,1,0.5,1,0.2],3,3)

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

## markertype - Marker type

'o' (default) | string

Marker type, specified as a string. The table below lists the supported marker types.

Specifier	Marker Type
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross

Specifier	Marker Type
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

### **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'MarkerFaceColor', 'red'` sets the marker face color to red.

For more information on these properties see `scattergroup`.

### **'LineWidth' - Line width**

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the marker edge.

**Example:** 'LineWidth',0.75

### 'MarkerEdgeColor' - Marker edge color

'none' | 'auto' | 'flat' (default) | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'flat'	Sets the color using the CData property.
'auto'	Sets the color to the axes Color property. If the axes Color property is none, then sets the color to the figure Color property.
'none'	Specifies no color, which makes nonfilled markers invisible.

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'

RGB Vector	Short Name	Long Name
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | 'flat' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'flat'	Sets the fill color using the CData property.
'auto'	Sets the fill color to the axes Color property. If the axes Color property is none, then sets the fill color to the figure Color property.
'none'	Makes the interior of the marker transparent, allowing the background to show through.

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

# scatter3

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

## Output Arguments

### **h** - Scattergroup object handle

scalar

Scattergroup object handle, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the scattergroup.

## Examples

### **Create 3-D Scatter Plot**

Create a 3-D scatter plot. Use sphere to define vectors x, y, and z.

```
figure
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
scatter3(x,y,z)
```

### Vary Marker Size

Use `sphere` to define vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vector `s` to specify the marker sizes.

## scatter3

---

```
S = repmat([100,50,5],numel(X),1);
s = S(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s)
view(40,35)
```

Corresponding entries in `x`, `y`, `z`, and `s` determine the location and size of each marker.

### Vary Marker Color

Use `sphere` to define vectors `x`, `y`, and `z`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vectors `s` and `c` to specify the size and color of each marker.

```
S = repmat([50,25,10], numel(X), 1);
C = repmat([1,2,3], numel(X), 1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,s,c)
view(40,35)
```

## scatter3

---

Corresponding entries in  $x$ ,  $y$ ,  $z$ , and  $c$  determine the location and color of each marker.

### Fill in Markers

Initialize the random-number generator to make the output of `rand` repeatable. Define vectors  $x$  and  $y$  as cosine and sine values with random noise.

```
rng(0, 'twister');
```

```
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and fill in the markers. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,'fill')
view(-30,10)
```

## scatter3

---

### Set Marker Type

Initialize the random-number generator to make the output of `rand` repeatable. Define vectors `x` and `y` as cosine and sine values with random noise.

```
rng(0,'twister');
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker type. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z, '*')
view(-30,10)
```

## Set Marker Properties

Initialize the random-number generator to make the output of `rand` repeatable. Define vectors `x` and `y` as cosine and sine values with random noise.

```
rng(0, 'twister');
z = linspace(0,4*pi,250);
x = 2*cos(z) + rand(1,250);
y = 2*sin(z) + rand(1,250);
```

Create a 3-D scatter plot and set the marker edge color and the marker face color. Use `view` to change the angle of the axes in the figure.

```
figure
scatter3(x,y,z,...
 'MarkerEdgeColor','k',...
 'MarkerFaceColor',[0 .75 .75])
view(-30,10)
```

### Specify Axes for 3-D Scatter Plot

Load the seamount data set to get vectors  $x$ ,  $y$ , and  $z$ .

```
load seamount
```

Create a figure with two subplots and return the handles to the two axes in array  $hs$ . In each subplot, create a 3-D scatter plot. Specify the marker properties for each scatter plot.

# scatter3

```
figure
hs(1) = subplot(2,1,1);
hs(2) = subplot(2,1,2);
scatter3(hs(1),x,y,z,'MarkerFaceColor',[0 .75 .75])
scatter3(hs(2),x,y,z,'*')
```

## Set Marker Properties Using the Handle

Use `|sphere|` to define vectors `|x|`, `|y|`, and `|z|`.

```
[X,Y,Z] = sphere(16);
x = [0.5*X(:); 0.75*X(:); X(:)];
y = [0.5*Y(:); 0.75*Y(:); Y(:)];
z = [0.5*Z(:); 0.75*Z(:); Z(:)];
```

Define vectors **s** and **c** to specify the size and color for each marker.

```
S = repmat([70,50,20], numel(X), 1);
C = repmat([1,2,3], numel(X), 1);
s = S(:);
c = C(:);
```

Create a 3-D scatter plot and return the scattergroup handle, **h**.

```
figure
h = scatter3(x,y,z,s,c);
```

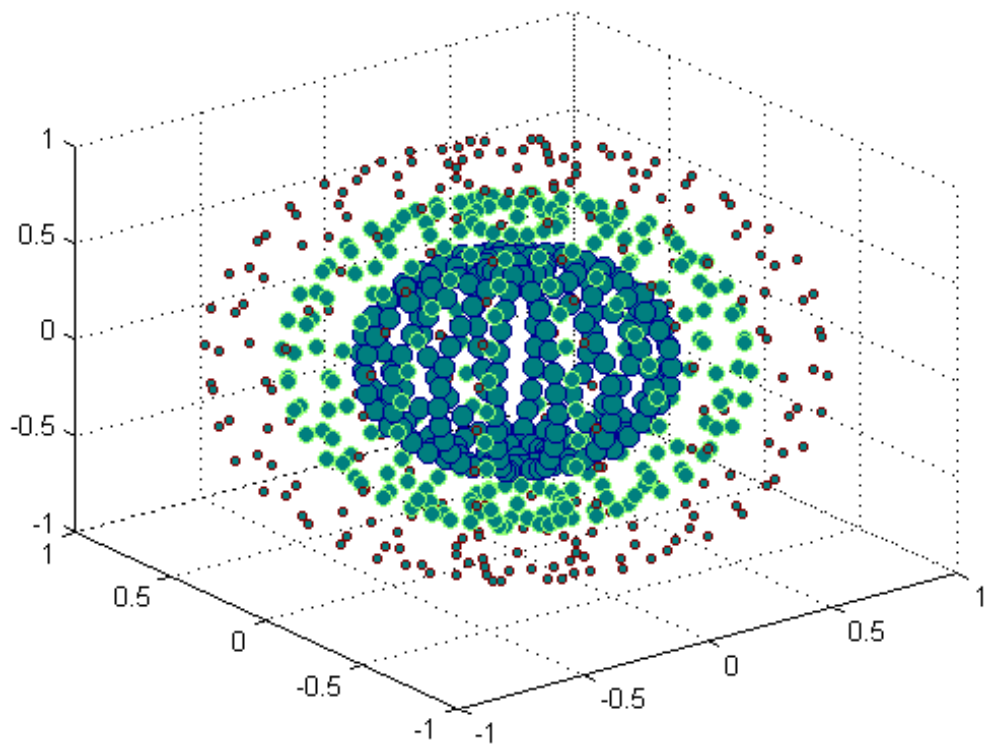

## scatter3

---

Use the handle to set the marker face color for the scatter plot.

```
set(h,'MarkerFaceColor',[0 .5 .5])
```

**See Also**[scatter](#) | [plot3](#) | [scattergroup](#) | [ColorSpec](#) | [LineStyle](#)

# Scattergroup Properties

---

**Purpose** Define scattergroup properties

**Modifying Properties** You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for scattergroup objects.

See Plot Objects for information on scattergroup objects.

**Scattergroup Property Descriptions** This section provides a description of properties. Curly braces { } enclose default values.

Annotation

`hg.Annotation` object (read-only)

*Control the display of scattergroup objects in legends.* Specifies whether this scattergroup object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the scattergroup object is displayed in a figure legend.

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
<code>on</code>	Include the scattergroup object in a legend as one entry, but not its children objects
<code>off</code>	Do not include the scattergroup or its children in a legend (default)
<code>children</code>	Include only the children of the scattergroup as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

# Scattergroup Properties

---

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## CData

vector | m-by-3 matrix | ColorSpec

*Color of markers.* When CData is a vector the same length as XData and YData, the values in CData are linearly mapped to the colors in the current colormap. When CData is a length(XData)-by-3 matrix, it specifies the colors of the markers as RGB values.

## CDataSource

string (MATLAB variable)

*Link CData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the CData.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change CData.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## Children

array of graphics object handles

# Scattergroup Properties

---

*Children of the scattergroup object.* An array containing the handle of a patch object parented to the scattergroup object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the scattergroup object in the legend. The default is an empty string.

# Scattergroup Properties

---

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background Color, or the figure background Color if the axes Color property is none. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes Color property. Set the figure background color with the figure Color property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

# Scattergroup Properties

---

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the markers that compose the scatter plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

on | {off}

*Select the object by clicking markers or area of extent.* Select plot objects by:

- Clicking scatter markers (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the scatter markers to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the scatter markers).

# Scattergroup Properties

---

Interruptible  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineWidth

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.

## Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square

# Scattergroup Properties

---

Specifier	Marker Type
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' 'H'	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | auto | {flat}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the axes Color property. If the axes Color property is none, then sets the color to the figure Color property.
- flat — Uses the CData property to set the color.

## MarkerFaceColor

ColorSpec | {none} | auto | flat

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.

- `none` — Specifies no color, which makes the interior of the marker transparent and allows the background to show through..
- `auto` — Uses same color as the axes `Color` property. If the axes `Color` property is `none`, then sets the color to the figure `Color` property.
- `flat` — Uses the `CData` property to set the color.

## Parent

handle of parent axes, `hgggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hgggroup`, or `hgtransform` object that contains the object.

## Selected

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

## SelectionHighlight

`{on}` | `off`

*Object highlighted when selected.*

- `on` — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- `off` — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

## SizeData

square points

# Scattergroup Properties

---

*Size of markers in square points.* Area of the marker in the scatter graph in units of points. Since there are 72 points to one inch, to specify a marker that has an area of one square inch you would use a value of  $72^2$ .

**SizeDataSource**  
string (MATLAB variable)

*Link SizeData to MATLAB variable.* Set this property to a MATLAB variable that, by default, is evaluated in the base workspace to generate the **SizeData**.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change **SizeData**.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Tag**  
string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the **Tag** property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an areaseries object and set the Tag property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For `stemseries` objects, `Type` is `'hggroup'`. The following statement finds all the `hggroup` objects in the current axes.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

# Scattergroup Properties

---

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-coordinates of scatter markers.* The `scatter` function draws individual markers at each *x*-axis location in the `XData` array. The input argument `X` in the `scatter` function calling syntax assigns values to `XData`.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

*Y-coordinates of scatter markers.* The `scatter` function draws individual markers at each *y*-axis location in the YData array.

The input argument *Y* in the `scatter` function calling syntax assigns values to YData.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

# Scattergroup Properties

---

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector

*Z-coordinates.* A vector defining the *z*-coordinates for the graph. XData and YData must be the same length and have the same number of rows.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the ZData. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's ZDataSource does not change the object's ZData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose**

Schur decomposition

**Syntax**

```
T = schur(A)
T = schur(A, flag)
[U, T] = schur(A, ...)
```

**Description**

The `schur` command computes the Schur form of a matrix.

`T = schur(A)` returns the Schur matrix `T`.

`T = schur(A, flag)` for real matrix `A`, returns a Schur matrix `T` in one of two forms depending on the value of `flag`:

'complex'	<code>T</code> is triangular and is complex if <code>A</code> is real and has complex eigenvalues.
'real'	<code>T</code> has the real eigenvalues on the diagonal and the complex eigenvalues in 2-by-2 blocks on the diagonal. 'real' is the default when <code>A</code> is real.

If `A` is complex, `schur` returns the complex Schur form in matrix `T` and `flag` is ignored. The complex Schur form is upper triangular with the eigenvalues of `A` on the diagonal.

The function `rsf2csf` converts the real Schur form to the complex Schur form.

`[U, T] = schur(A, ...)` also returns a unitary matrix `U` so that  $A = U^*T^*U'$  and  $U' * U = \text{eye}(\text{size}(A))$ .

**Examples**

`H` is a 3-by-3 eigenvalue test matrix:

```
H = [-149 -50 -154
 537 180 546
 -27 -9 -25]
```

Its Schur form is

```
schur(H)
```

```
ans =
 1.0000 -7.1119 -815.8706
 0 2.0000 -55.0236
 0 0 3.0000
```

The eigenvalues, which in this case are 1, 2, and 3, are on the diagonal. The fact that the off-diagonal elements are so large indicates that this matrix has poorly conditioned eigenvalues; small changes in the matrix elements produce relatively large changes in its eigenvalues.

**Purpose** Sequence of MATLAB statements in file

**Description** A script file is an external file that contains a sequence of MATLAB statements. By typing the filename, you can obtain subsequent MATLAB input from the file. Script files have a filename extension of `.m`.

Scripts are the simplest kind of MATLAB program. They are useful for automating blocks of MATLAB commands, such as computations you have to perform repeatedly from the command line. Scripts can operate on existing data in the workspace, or they can create new data on which to operate. Although scripts do not return output arguments, any variables that they create remain in the workspace, so you can use them in further computations. In addition, scripts can produce graphical output using commands like `plot`.

Scripts can contain any series of MATLAB statements. They require no declarations or begin/end delimiters.

Like any MATLAB program, scripts can contain comments. Any text following a percent sign (`%`) on a given line is comment text. Comments can appear on lines by themselves, or you can append them to the end of any executable line.

# scatteredInterpolant

---

**Purpose** Scattered data interpolation

**Description** Use `scatteredInterpolant` to perform interpolation on a 2-D or 3-D “Scattered Data” on page 1-6207 set. For example, you can pass a set of  $(x, y)$  points and values,  $v$ , to `scatteredInterpolant`, and it returns a surface of the form  $v = F(x, y)$ . This surface always passes through the sample values at the point locations. You can evaluate this surface at any query point,  $(xq, yq)$ , to produce an interpolated value,  $vq$ .

Use `scatteredInterpolant` to create the “Interpolant” on page 1-6207,  $F$ . Then, you can evaluate  $F$  at specific points using any of the following syntaxes:

- $Vq = F(Pq)$  specifies the query points in the matrix  $Pq$ . Each row in  $Pq$  contains the coordinates of a query point.
- $Vq = F(Xq, Yq)$  and  $Vq = F(Xq, Yq, Zq)$  specify the query points as two or three matrices of equal size.
- $Vq = F(\{xq, yq\})$  and  $Vq = F(\{xq, yq, zq\})$  specify the query points as “Grid Vectors” on page 1-6207. The interpolated values are returned in  $Vq$ . Use this syntax to conserve memory when you want to query a large grid of points.

**Construction**  $F = \text{scatteredInterpolant}(x, y, v)$  creates an interpolant that fits a surface of the form  $v = F(x, y)$ . Vectors  $x$  and  $y$  specify the  $(x, y)$  coordinates of the sample points.  $v$  is a vector that contains the sample values associated with the points,  $(x, y)$ .

$F = \text{scatteredInterpolant}(x, y, z, v)$  creates a 3-D interpolant of the form  $v = F(x, y, z)$ .

$F = \text{scatteredInterpolant}(P, v)$  specifies the coordinates of the sample points as an array. The rows of  $P$  contain the  $(x, y)$  or  $(x, y, z)$  coordinates for the values in  $v$ .

$F = \text{scatteredInterpolant}(\_, \text{Method})$  specifies a string that describes an interpolation method: 'nearest', 'linear', or 'natural'. Specify `Method` as the last input argument in any of the first three syntaxes.

`F = scatteredInterpolant( ___, Method, ExtrapolationMethod)` specifies both the interpolation and extrapolation methods as strings. `Method` can be one of three strings: 'nearest', 'linear', or 'natural'. Specify `ExtrapolationMethod` as one of the following strings: 'nearest', 'linear', or 'none'. Pass `Method` and `ExtrapolationMethod` together as the last two input arguments in any of the first three syntaxes.

`F = scatteredInterpolant()` creates an empty scattered data interpolant. Use `F.Points = P` to initialize `F` with the points in matrix `P`. Use `F.Values = v` to initialize `F` with the values in `v`.

## Input Arguments

### **x**

Sample points *x*-coordinates, specified as a vector of the same size as `v`.

### **y**

Sample points *y*-coordinates, specified as a vector of the same size as `v`.

### **z**

Sample points *z*-coordinates, specified as a vector of the same size as `v`.

### **P**

Sample points array, specified as an *m*-by-*n* matrix, where *m* is the number of points and *n* is the dimension of the space where the points reside. Each row of `P` contains the (*x*, *y*) or (*x*, *y*, *z*) coordinates of a sample point.

### **v**

Sample values vector, specified as a vector of that defines the values at the sample points.

## Method

# scatteredInterpolant

---

Interpolation method, specified as one of these strings.

Method String	Description
'linear' (default)	Linear interpolation.
'nearest'	Nearest neighbor interpolation.
'natural'	Natural neighbor interpolation.

## ExtrapolationMethod

Extrapolation method, specified as one of these strings.

ExtrapolationMethod String	Description
'linear'	Linear extrapolation based on boundary gradients. Default when Method is
'nearest'	Nearest neighbor extrapolation. This method evaluates to the value of the nearest neighbor on the boundary. Default when Method = 'nearest'.
'none'	No extrapolation. Any queries outside the convex hull of F.Points return NaN.

## Properties

### Points

Array of sample points (locations) for the values in F.Values. Each row of F.Points contains the (x, y) or (x, y, z) coordinates of a sample point.

### Values

Vector of values associated with each point in F.Points.

### Method

A string specifying the method used to interpolate the data: 'nearest', 'linear', or 'natural'.

## ExtrapolationMethod

A string specifying the method used to extrapolate the data: 'nearest', 'linear', or 'none'. A value of 'none' indicates that extrapolation is disabled.

## Definitions

### Interpolant

Interpolating function that you can evaluate at query locations.

### Scattered Data

A set of points that have no structure among their relative locations.

### Full Grid

A grid represented as a set of arrays. For example, you can create a full grid using `ndgrid`.

### Grid Vectors

A set of vectors that serve as a compact representation of a grid in `ndgrid` format. For example, `[X,Y] = ndgrid(xg,yg)` returns a full grid in the matrices X and Y. You can represent the same grid using the grid vectors, `xg` and `yg`.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Indexing

`scatteredInterpolant` supports index-based editing of the properties of `F`. You can add or remove points in `F.Points` and update the corresponding values in `F.Values`. For example, `F.Points(5,:) = []` removes the fifth point, and `F.Values(5) = []` removes the corresponding value.

## Examples

### 2-D Interpolation

Define 200 random points.

```
xy = -2.5 + 5*gallery('uniformdata',[200 2],0);
x = xy(:,1);
```

# scatteredInterpolant

---

```
y = xy(:,2);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v);
```

Evaluate the interpolant at query locations ( $xq$ ,  $yq$ ).

```
ti = -2:.25:2;
[xq,yq] = meshgrid(ti,ti);
vq = F(xq,yq);
```

Plot the result.

```
figure
mesh(xq,yq,vq);
hold on;
plot3(x,y,v,'o');
hold off;
```

## 2-D Extrapolation

Query the interpolant at a single point outside the convex hull using nearest neighbor extrapolation.

Define a matrix of 200 random points.

```
P = -2.5 + 5*gallery('uniformdata',[200 2],0);
```

# scatteredInterpolant

---

Sample an exponential function. These are the sample values for the interpolant.

```
x = P(:,1);
y = P(:,2);
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant, specifying linear interpolation and nearest neighbor extrapolation.

```
F = scatteredInterpolant(P,v,'linear','nearest')
```

```
F =
```

```
scatteredInterpolant with properties:
```

```
Points: [200x2 double]
```

```
Values: [200x1 double]
```

```
Method: 'linear'
```

```
ExtrapolationMethod: 'nearest'
```

Evaluate the interpolant outside the convex hull.

```
vq = F(3.0,-1.5)
```

```
vq =
```

```
0.0031
```

Disable extrapolation and evaluate F at the same point.

```
F.ExtrapolationMethod = 'none';
```

```
vq = F(3.0,-1.5)
```

```
vq =

 NaN
```

## Replacement of Sample Values

Replace the elements in the `Values` property when you want to change the values at the sample points. You get immediate results when you evaluate the new interpolant because the original triangulation has not changed.

Create 50 random points.

```
x = -2.5 + 5*gallery('uniformdata',[50 1],0);
y = -2.5 + 5*gallery('uniformdata',[50 1],1);
```

Sample an exponential function. These are the sample values for the interpolant.

```
v = x.*exp(-x.^2-y.^2);
```

Create the interpolant.

```
F = scatteredInterpolant(x,y,v)
```

```
F =
```

```
scatteredInterpolant with properties:
```

```
 Points: [50x2 double]
 Values: [50x1 double]
 Method: 'linear'
 ExtrapolationMethod: 'linear'
```

# scatteredInterpolant

---

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =
```

```
0.0029
```

Change the interpolant sample values.

```
vnew = x.^2 + y.^2;
```

```
F.Values = vnew;
```

Evaluate the interpolant at (1.40,1.90).

```
F(1.40,1.90)
```

```
ans =
```

```
6.1109
```

## How To

- Class Attributes
- Property Attributes
- “Interpolating Gridded Data”

<b>Purpose</b>	Secant of angle in radians
<b>Syntax</b>	$Y = \sec(X)$
<b>Description</b>	$Y = \sec(X)$ returns the secant of the elements of $X$ . The <code>sec</code> function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of $X$ in the interval $[-\text{Inf}, \text{Inf}]$ , <code>sec</code> returns real values in the interval $[-\text{Inf}, -1]$ and $[1, \text{Inf}]$ . For complex values of $X$ , <code>sec</code> returns complex values. All angles are in radians.
<b>Input Arguments</b>	<b>X - Input angle in radians</b> scalar value   vector   matrix   N-D array  Input angle in radians, specified as a real-valued or complex-valued scalar value, vector, matrix or N-D array. The <code>sec</code> operation is element-wise when $X$ is non-scalar.  <b>Data Types</b> single   double <b>Complex Number Support:</b> Yes
<b>Output Arguments</b>	<b>Y - Secant of input angle</b> scalar value   vector   matrix   N-D array  Secant of input angle, returned as real-valued or complex-valued scalar value, vector, matrix or N-D array.
<b>Examples</b>	<b>Plot Secant Function</b>  Plot the secant over the domain $-\pi/2 < x < \pi/2$ and $\pi/2 < x < 3\pi/2$ .  <pre>x1 = -pi/2+0.01:0.01:pi/2-0.01; x2 = pi/2+0.01:0.01:(3*pi/2)-0.01; plot(x1,sec(x1),x2,sec(x2)), grid on</pre>

### **Secant of Vector of Complex Angles**

Calculate the secant of the complex angles in vector x.

```
x = [-i pi+i*pi/2 -1+i*4];
y = sec(x)
```

y =

$$0.6481 + 0.0000i \quad -0.3985 + 0.0000i \quad 0.0198 - 0.0308i$$

## Definitions

### Secant Function

The secant of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\secant(\alpha) = \frac{1}{\cosine(\alpha)} = \frac{\text{hypotenuse}}{\text{adjacent side}} = \frac{h}{b}.$$

The secant of a complex angle,  $\alpha$ , is

$$\secant(\alpha) = \frac{2}{e^{i\alpha} + e^{-i\alpha}}.$$

**See Also**

secd | sech | asec | asecd | asech

<b>Purpose</b>	Secant of argument in degrees
<b>Syntax</b>	$Y = \text{secd}(X)$
<b>Description</b>	$Y = \text{secd}(X)$ returns the secant of the elements of $X$ , which are expressed in degrees.
<b>Input Arguments</b>	<p><b>X - Angle in degrees</b> scalar value   vector   matrix   N-D array</p> <p>Angle in degrees, specified as a real-valued or complex-valued scalar, vector, matrix, or N-D array. The <code>secd</code> operation is element-wise when <math>X</math> is nonscalar.</p> <p><b>Example:</b></p> <p><b>Data Types</b> single   double</p> <p><b>Complex Number Support:</b> Yes</p>
<b>Output Arguments</b>	<p><b>Y - Secant of angle</b> scalar value   vector   matrix   N-D array</p> <p>Secant of angle, returned as a real-valued or complex-valued scalar, vector, matrix, or N-D array of the same size as <math>X</math>.</p>
<b>Examples</b>	<p><b>Secant of 90 degrees compared to secant of <math>\pi/2</math> radians</b></p> <pre>secd(90)  ans =       Inf  sec(pi/2)  ans =   1.6331e+16</pre>

# secd

---

$\text{secd}(90)$  is infinite, whereas  $\text{sec}(\pi/2)$  is large but finite.

## **Secant of vector of complex angles, specified in degrees**

```
z = [35+i 15+2i 10+3i];
y = secd(z)
```

```
y =
```

```
1.2204 + 0.0149i 1.0346 + 0.0097i 1.0140 + 0.0094i
```

## **See Also**

[sec](#) | [asec](#) | [asecd](#)

**Purpose** Hyperbolic secant

**Syntax**  $Y = \operatorname{sech}(X)$

**Description** The sech function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  $Y = \operatorname{sech}(X)$  returns an array the same size as  $X$  containing the hyperbolic secant of the elements of  $X$ .

**Examples** **Graph of Hyperbolic Secant Function**

Graph the hyperbolic secant over the domain  $-2\pi \leq x \leq 2\pi$ .

```
x = -2*pi:0.01:2*pi;
plot(x,sech(x)), grid on
```

# sech

---

## Definitions **Hyperbolic Secant**

The hyperbolic secant of  $z$  is

$$\text{sech}(z) = \frac{1}{\cosh(z)}.$$

**See Also**    [asech](#) | [sec](#) | [sinh](#) | [cosh](#)

**Purpose** Select, move, resize, or copy axes and uicontrol graphics objects

**Syntax** `A = selectmoveresize`  
`set(gca, 'ButtonDownFcn', 'selectmoveresize')`

**Description** `selectmoveresize` is useful as the callback routine for axes and uicontrol button down functions. When executed, it selects the object and allows you to move, resize, and copy it.

`A = selectmoveresize` returns a structure array containing

- `A.Type`: a string containing the action type, which can be `Select`, `Move`, `Resize`, or `Copy`
- `A.Handles`: a list of the selected handles, or, for a `Copy`, an `m-by-2` matrix containing the original handles in the first column and the new handles in the second column

`set(gca, 'ButtonDownFcn', 'selectmoveresize')` sets the `ButtonDownFcn` property of the current axes to `selectmoveresize`:

**See Also** `axes` | `uicontrol`

# matlab.unittest.selectors

---

**Purpose** Summary of classes in MATLAB Selectors Interface

**Description** Use selectors to filter or select elements of a test suite based on their attributes. The matlab.unittest.selectors package consists of the following selectors.

matlab.unittest.selectors.HasBaseFolder Selector for TestSuite elements determined by folder

matlab.unittest.selectors.HasName Selector for TestSuite elements determined by name

matlab.unittest.selectors.HasParameters Selector for TestSuite elements determined by parameterization

matlab.unittest.selectors.HasSharedTestFixture Selector for TestSuite elements that use shared test fixture

**See Also** matlab.unittest.TestSuite.selectIf

- Purpose** Selector for TestSuite elements determined by parameterization
- Description** The HasParameter selector filters TestSuite array elements determined by parameterization.
- Construction** matlab.unittest.selectors.HasParameter constructs a selector for TestSuite elements determined by their parameterization. When you instantiate HasParameter without input arguments, the resulting TestSuite array only contains elements that have parameterized test methods.

matlab.unittest.selectors.HasParameter(Name, Value) constructs a selector with additional options specified by one or more Name, Value pair arguments. The selector filters based on the name of the property that defines a parameter, the name of the parameter, and the value of the parameter. For an element to be selected for the TestSuite array, it must have at least one parameter that satisfies all the conditions.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### Property

Name of the property that defines the parameter specified as a string or as an instance of the matlab.unittest.constraints.Constraint class. If the specified property name is a string, the testing framework creates an IsEqualTo constraint with the input string, Property, as the expected value.

### Name

Name of the parameter specified as a string or as an instance of the matlab.unittest.constraints.Constraint class. If the specified

# matlab.unittest.selectors.HasParameter

---

name is a string, the testing framework creates an `IsEqualTo` constraint with the input string, `Name`, as the expected value.

## Value

Value of the parameter specified as any MATLAB data type or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified property name is not a constraint, the testing framework creates an `IsEqualTo` constraint with the input data, `Value`, as the expected value.

## Properties

### PropertyConstraint

Condition that the test element's parameter property name must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Property` input argument.

### NameConstraint

Condition that the test element's parameter name must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Name` input argument.

### ValueConstraint

Condition that the test element's parameter property value must satisfy to be included in the test suite, specified as an instance of the `Constraint` in the `Value` input argument.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects](#) in the MATLAB documentation.

## Examples

### Filter Test Suite by Parameterization

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
```

# matlab.unittest.selectors.HasParameter

---

```
 outSize = struct('s2d',3, 's3d',[2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end

 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
 end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the file.

```
s = matlab.unittest.TestSuite.fromFile('testZeros.m');
{s.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
```

# matlab.unittest.selectors.HasParameter

---

```
'testZeros/testClass(type=double,outSize=s3d) '
'testZeros/testClass(type=uint16,outSize=s2d) '
'testZeros/testClass(type=uint16,outSize=s3d) '
'testZeros/testSize(outSize=s2d) '
'testZeros/testSize(outSize=s3d) '
'testZeros/testDefaultClass '
'testZeros/testDefaultSize '
'testZeros/testDefaultValue '
```

The suite contains 11 test elements: 6 from the parameterized `testClass` method, 2 from the parameterized `testSize` method, and 1 from each of the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

Select all of the test elements from parameterized test methods.

```
import matlab.unittest.selectors.HasParameter;
```

```
s1 = s.selectIf(HasParameter);
{s1.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d) '
'testZeros/testClass(type=single,outSize=s3d) '
'testZeros/testClass(type=double,outSize=s2d) '
'testZeros/testClass(type=double,outSize=s3d) '
'testZeros/testClass(type=uint16,outSize=s2d) '
'testZeros/testClass(type=uint16,outSize=s3d) '
'testZeros/testSize(outSize=s2d) '
'testZeros/testSize(outSize=s3d) '
```

The suite contains the eight test elements from the two parameterized test methods.

Select all of the test elements from nonparameterized test methods.

```
s2 = s.selectIf(~HasParameter);
```

```
{s2.Name}'

ans =

 'testZeros/testDefaultClass'
 'testZeros/testDefaultSize'
 'testZeros/testDefaultValue'
```

Select all test elements that are parameterized and have a property named 'type' with a parameter name 'double'.

```
s3 = s.selectIf(HasParameter('Property','type','Name','double'));
{s3.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

The resulting suite contains two elements. The `testClass` method is the only method in `testZeros` that uses the 'type' property. Selecting only 'double' from the parameters results in two test elements — one for each value of 'outSize'.

Select all test elements that have a parameter defined by a property starting with 't'.

```
import matlab.unittest.constraints.StartsWithSubstring;

s4 = s.selectIf(HasParameter('Property',StartsWithSubstring('t')));
{s4.Name}'

ans =

 'testZeros/testClass(type=single,outSize=s2d)'
 'testZeros/testClass(type=single,outSize=s3d)'
 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

# matlab.unittest.selectors.HasParameter

---

```
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
```

The resulting suite contains the six parameterized test elements from the `testClass` method. The `testSize` method is parameterized, but the elements from the method are not included in the suite because the method does not use a property that starts with 't'.

Select all test elements that are parameterized and test the zeros function with a 2-D array. A parameter value representing a 2-D array has a length of 1 (for example `zeros(3)`) or 2 (for example `zeros(2,3)`).

```
import matlab.unittest.constraints.HasLength;

s5 = s.selectIf(HasParameter('Property','outSize',...
 'Value', HasLength(1)|HasLength(2)));
{s5.Name}'
```

```
ans =

 'testZeros/testClass(type=single,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=uint16,outSize=s2d)'
 'testZeros/testSize(outSize=s2d)'
```

Select only the test element that tests that the output is a double data type and that it has the correct size for a 2-D array.

```
s6 = s.selectIf(HasParameter('Property','type','Name','double')...
 & HasParameter('Property','outSize','Name','s2d'))
```

```
s6 =
```

Test with properties:

```
 Name: 'testZeros/testClass(type=double,outSize=s2d)'
Parameterization: [1x2 matlab.unittest.parameters.TestParameter]
SharedTestFixtures: []
```

## Concepts

# matlab.unittest.selectors.HasSharedTestFixture

---

**Purpose** Selector for TestSuite elements that use shared test fixture

**Description** The HasSharedTestFixture selector filters TestSuite array elements based on shared test fixtures.

**Construction** `matlab.unittest.selectors.HasSharedTestFixture(f)` constructs a selector for TestSuite elements based on their required shared test fixtures. For an element to be selected for the TestSuite array, it must use a fixture that is compatible with the specified fixture, `f`.

## Input Arguments

### **f** - Shared test fixture

Fixture

Shared test fixture specified as a `matlab.unittest.fixtures.Fixture` instance. The TestSuite array element must use the shared test fixture, `f`, to be selected for the TestSuite.

**Properties** **ExpectedFixture**

The shared test fixture that a TestSuite array element must use to be selected for the TestSuite. The `ExpectedFixture` property is specified as a `matlab.unittest.fixtures.Fixture` in the input argument, `f`.

**Copy Semantics** Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

**Examples** **Filter Test Suite by Shared Test Fixtures**

Create a package folder, `+mytestpackage`, in your current working folder. This package contains two test classes.

In the `+mytestpackage` folder, create `AExampleTest.m`. This class contains two tests that use a suppressed warnings fixture.

```
classdef (SharedTestFixtures={matlab.unittest.fixtures.SuppresseWarnings
```

# matlab.unittest.selectors.HasSharedTestFixture

---

```
 'MATLAB:rmpath:DirNotFound'}})...
 AExampleTest < matlab.unittest.TestCase
 methods (Test)
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 end
end
```

In the `+mytestpackage` folder, create `BExampleTest.m`. This class contains one test that uses a shared path fixture and a suppressed warnings fixture.

```
classdef (SharedTestFixtures={...
 matlab.unittest.fixtures.PathFixture(...
 fullfile(matlabroot,'help','techdoc','matlab_oo','examples')
 matlab.unittest.fixtures.SuppressedWarningsFixture(...
 'MATLAB:rmpath:DirNotFound'}}) ...
 BExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 end
end
```

At the command prompt, define the following fixtures.

```
pf = matlab.unittest.fixtures.PathFixture(...
 fullfile(matlabroot,'help','techdoc','matlab_oo','examples'));
swf = matlab.unittest.fixtures.SuppressedWarningsFixture(...
 'MATLAB:rmpath:DirNotFound');
```

Create a test suite from the package.

# matlab.unittest.selectors.HasSharedTestFixture

---

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasSharedTestFixture;
```

```
suite = TestSuite.fromPackage('mytestpackage')
```

```
suite =
```

```
1x3 Test array with properties:
```

```
 Name
Parameterization
SharedTestFixtures
```

The test suite has three test elements.

Create a filtered suite that only contains tests that use the path fixture, `pf`.

```
s1 = suite.selectIf(HasSharedTestFixture(pf));
```

The resulting suite, `s1`, contains the test element from `BExampleTest.m`, since the test in that class uses the shared test fixture, `pf`.

Alternatively, pass the selector to the `TestSuite.fromPackage` method instead of generating a full test suite, and then using the `TestSuite.selectIf` method to filter the suite.

```
s1 = TestSuite.fromPackage('mytestpackage', HasSharedTestFixture(pf));
```

Create a filtered test suite that contains tests that use the suppressed warnings fixture, `swf`, but not the path fixture, `pf`.

```
s2 = suite.selectIf(~HasSharedTestFixture(pf) & HasSharedTestFixture(swf))
```

The test suite, `s2`, only contains the two test elements from `AExampleTest.m`. Tests in `BExampleTest.m` are excluded because, in addition to the suppressed warnings fixture, they use the path fixture.

# matlab.unittest.selectors.HasSharedTestFixture

---

Create a filtered suite that only contains tests that use the path fixture to a different location.

```
pf2 = matlab.unittest.fixtures.PathFixture(fullfile(matlabroot));
s3 = TestSuite.fromPackage('mytestpackage', HasSharedTestFixture(pf2,

s3 =
```

1x0 Test array with properties:

```
Name
Parameterization
SharedTestFixtures
```

The test suite does not contain any test elements. The tests in `BExampleTest.m` use a shared path fixture, but the selected path fixture, `pf2`, adds a different folder to the path so its tests are not included in the suite.

## Concepts

# matlab.unittest.selectors.HasBaseFolder

---

**Purpose** Selector for TestSuite elements determined by folder

**Description** The HasBaseFolder selector filters TestSuite array elements determined by the name of the folder that contains the file that defines the test class or function.

**Construction** `matlab.unittest.selectors.HasBaseFolder(f)` constructs a selector for TestSuite elements determined by the folder, `f`, which contains the file that defines the test class or function. You can specify the base folder as a string or as an instance of the `matlab.unittest.constraints.Constraint` class. If the specified base folder, `f`, is a string instead of a Constraint, the testing framework creates an `IsEqualTo` constraint with the input string, `f`, as the expected value.

For a test element to be included in the suite, the file that defines it must be contained in the specified base folder. For test classes defined in packages, the base folder is the parent of the top-level package folder. The base folder never contains any folders that start with '+' or '@'.

## Input Arguments

### **f** - Base folder

string | Constraint

Base folder specified as a string or a `matlab.unittest.constraints.Constraint` instance. The following conditions must be satisfied for the test element to be selected for the TestSuite:

- If `f` is a string, the test element's base folder must exactly match the specified folder.
- If `f` is a constraint, the test element's base folder must satisfy the specified constraint.

## Properties

### Constraint

Condition the base folder must satisfy to be included in the test suite, specified as an instance of the `matlab.unittest.constraints.Constraints` class.

## Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### Filter Test Suite by Base Folder

Create a folder, `MyTests`, in your current working folder. In this folder, create two subfolders, `Feature1` and `Feature2`.

In a new file, `Feature1_Test.m`, in the `Feature1` subfolder, create the following test class.

```
classdef Feature1_Test < matlab.unittest.TestCase
 methods (Test)
 function testA1(testCase)
 % test code
 end
 function testB1(testCase)
 % test code
 end
 end
end
```

In a new file, `Feature2_Test.m`, in the `Feature2` subfolder, create the following test class.

```
classdef Feature2_Test < matlab.unittest.TestCase
 methods (Test)
 function testA2(testCase)
 % test code
 end
 function testB2(testCase)
 % test code
 end
 end
end
```

# matlab.unittest.selectors.HasBaseFolder

---

```
 end
 end
end
```

If necessary, set your current working folder to the folder above `MyTests`. At the command prompt, create a test suite from the `MyTests` folder and examine the contents.

```
import matlab.unittest.TestSuite
import matlab.unittest.selectors.HasBaseFolder;
import matlab.unittest.constraints.ContainsSubstring;

suite = TestSuite.fromFolder('MyTests', 'IncludingSubfolders', true);
{suite.Name}

ans =

 'Feature1_Test/testA1' 'Feature1_Test/testB1' 'Feature2_Test/te
```

The suite contains the four tests from the two test files.

Select all test suite elements for classes that are defined in the `'Feature1'` folder.

```
s1 = suite.selectIf(HasBaseFolder(fullfile(pwd, 'MyTests', 'Feature1')));
{s1.Name}

ans =

 'Feature1_Test/testA1' 'Feature1_Test/testB1'
```

The filtered test suite contains only test elements from the `Feature1` folder.

Select all the test suite elements for classes that are defined in folders that do not contain the string `'Feature1'`, and then examine the contents.

```
s1 = suite.selectIf(HasBaseFolder(...
```

```
 fullfile(pwd, 'MyTests', 'Feature1')));
{s1.Name}

ans =

 'Feature2_Test/testA2' 'Feature2_Test/testB2'
```

The filtered test suite only contains test elements from the Feature2 folder.

Alternatively, to generate a filtered suite directly, pass the selector to the `TestSuite.fromFolder` method.

```
s1 = TestSuite.fromFolder('MyTests',...
 ~HasBaseFolder(ContainsSubstring('Feature1')),...
 'IncludingSubfolders',true);
```

## Concepts

# matlab.unittest.selectors.HasName

---

<b>Purpose</b>	Selector for TestSuite elements determined by name
<b>Description</b>	The HasName selector filters TestSuite array elements determined by the test element name.
<b>Construction</b>	<p><code>matlab.unittest.selectors.HasName(n)</code> constructs a selector for TestSuite elements determined by the test element name, <code>n</code>. You can specify the name as a string or as an instance of the <code>matlab.unittest.constraints.Constraint</code> class. If the specified name, <code>n</code>, is a string, the testing framework creates an <code>IsEqualTo</code> constraint with the input string, <code>n</code>, as the expected value.</p> <p>For a test element to be included in the suite, the test element must have the same name as the specified name.</p> <p><b>Input Arguments</b></p> <p><b>n - Test element name</b> <code>string</code>   <code>Constraint</code></p> <p>Test element name specified as a string or <code>matlab.unittest.constraints.Constraint</code> instance. The following conditions must be satisfied for the test element to be selected for the TestSuite:</p> <ul style="list-style-type: none"><li>• If <code>n</code> is a string, the test element's name must exactly match the specified name.</li><li>• If <code>n</code> is a constraint, the test element's name must satisfy the specified constraint.</li></ul>
<b>Properties</b>	<p><b>Constraint</b></p> <p>Condition the test element name must satisfy to be included in the test suite, specified as an instance of the <code>matlab.unittest.constraints.Constraints</code> class.</p>
<b>Copy Semantics</b>	Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Filter Test Suite by Name

Create the following test class in a file, `ExampleTest.m`, in your current working folder.

```
classdef ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 function testOne(testCase)
 % test code
 end
 function testTwo(testCase)
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the `ExampleTest.m` file and examine the contents.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasName;
import matlab.unittest.constraints.EndsWithSubstring;

suite = TestSuite.fromFile('ExampleTest.m');
{suite.Name}

ans =

 'ExampleTest/testPathAdd' 'ExampleTest/testOne' 'ExampleTest/testTwo'
```

The suite contains three tests.

Select all the test suite elements that have the name `'ExampleTest/testPathAdd'`, and examine the contents.

```
s1 = suite.selectIf(HasName('ExampleTest/testPathAdd'));
```

# matlab.unittest.selectors.HasName

---

```
{s1.Name}
```

```
ans =
```

```
 'ExampleTest/testPathAdd'
```

The filtered test suite only contains one test element.

Select all the test suite elements that end in either 'One' or 'Two', and examine the contents.

```
s1 = suite.selectIf(HasName(EndsWithSubstring('One')) | ...
 HasName(EndsWithSubstring('Two')));
{s1.Name}
```

```
ans =
```

```
 'ExampleTest/testOne' 'ExampleTest/testTwo'
```

At the time of the test suite construction, create a test suite that only contains tests with the substring 'One'.

```
import matlab.unittest.constraints.ContainsSubstring;
s2 = TestSuite.fromFile('ExampleTest.m',...
 HasName(ContainsSubstring('One')))
```

```
s2 =
```

```
Test with properties:
```

```
 Name: 'ExampleTest/testOne'
 Parameterization: []
 SharedTestFixtures: []
```

## Concepts

**Purpose**

Semilogarithmic plot

**Syntax**

```
semilogx(Y)
semilogx(X1,Y1,...)
semilogx(X1,Y1,LineStyle,...)
semilogx(...,'PropertyName',PropertyValue,...)
h = semilogx(...)
```

**Description**

semilogx plot data as logarithmic scales for the  $x$ -axis.

semilogx(Y) creates a plot using a base 10 logarithmic scale for the  $x$ -axis and a linear scale for the  $y$ -axis. It plots the columns of Y versus their index if Y contains real numbers. semilogx(Y) is equivalent to semilogx(real(Y), imag(Y)) if Y contains complex numbers. semilogx ignores the imaginary component in all other uses of this function.

semilogx(X1,Y1,...) plots all Yn versus Xn pairs. If only one of Xn or Yn is a matrix, semilogx plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

semilogx(X1,Y1,LineStyle,...) plots all lines defined by the Xn,Yn,LineStyle triples. LineSpec determines line style, marker symbol, and color of the plotted lines.

semilogx(...,'PropertyName',PropertyValue,...) sets property values for all lineseries graphics objects created by semilogx.

h = semilogx(...) return a vector of handles to lineseries graphics objects, one handle per line.

## Tips

If you do not specify a color when plotting more than one line, `semilogx` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, \textit{LineStyle}$  triples; for example,

```
semilogx(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

## Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

### Logarithmic Scale for x-Axis

Create a plot with a logarithmic scale for the x-axis and a linear scale for the y-axis.

```
x = 0:1000;
y = log(x);

figure
semilogx(x,y)
```

**See Also**

`line` | `LineSpec` | `loglog` | `plot` | `semilogy`

# semilogy

---

## Purpose

Semilogarithmic plot

## Syntax

```
semilogy(Y)
semilogy(X1,Y1,...)
semilogy(X1,Y1,LineStyle,...)
semilogy(...,'PropertyName',PropertyValue,...)
h = semilogy(...)
```

## Description

semilogy plots data with logarithmic scale for the y-axis.

semilogy(Y) creates a plot using a base 10 logarithmic scale for the y-axis and a linear scale for the x-axis. It plots the columns of Y versus their index if Y contains real numbers. semilogy(Y) is equivalent to semilogy(real(Y), imag(Y)) if Y contains complex numbers. semilogy ignores the imaginary component in all other uses of this function.

semilogy(X1,Y1,...) plots all Yn versus Xn pairs. If only one of Xn or Yn is a matrix, semilogy plots the vector argument versus the rows or columns of the matrix, along the dimension of the matrix whose length matches the length of the vector. If the matrix is square, its columns plot against the vector if their lengths match.

semilogy(X1,Y1,LineStyle,...) plots all lines defined by the Xn,Yn,LineStyle triples. LineSpec determines line style, marker symbol, and color of the plotted lines.

semilogy(...,'PropertyName',PropertyValue,...) sets property values for all lineseries graphics objects created by semilogy.

h = semilogy(...) returns a vector of handles to lineseries graphics objects, one handle per line.

## Tips

If you do not specify a color when plotting more than one line, `semilogy` automatically cycle through the colors and line styles in the order specified by the current axes `ColorOrder` and `LineStyleOrder` properties.

You can mix  $X_n, Y_n$  pairs with  $X_n, Y_n, LineSpec$  triples; for example,

```
semilogy(X1, Y1, X2, Y2, LineSpec, X3, Y3)
```

If you attempt to add a `loglog`, `semilogx`, or `semilogy` plot to a linear axis mode graph with `hold on`, the axis mode remains as it is and the new data plots as linear.

## Renderer Support

The OpenGL renderer does not support logarithmic-scale axes. MATLAB automatically selects a different renderer when using logarithmic scaling. If you set the figure `Renderer` property to `opengl`, axis scales become linear. See the figure `Renderer` property for more information on renderers.

## Examples

### Logarithmic Scale for y-Axis

Create a plot with a logarithmic scale for the y-axis and a linear scale for the x-axis.

```
x = 0:0.1:10;
y = exp(x);
```

```
figure
semilogy(x,y);
```

# semilogy

---

**See Also**      `line` | `LineSpec` | `loglog` | `plot` | `semilogx`

**Purpose** Send email message to address list

**Syntax**

```
sendmail(recipients,subject)
sendmail(recipients,subject,message)
sendmail(recipients,subject,message,attachments)
```

**Description** `sendmail(recipients,subject)` sends email to recipients with the specified subject. The recipients input is a string for a single address, or a cell array of strings for multiple addresses.

`sendmail(recipients,subject,message)` includes the specified message. If message is a string, `sendmail` automatically wraps text at 75 characters. To force a line break in the message text, use 10, as shown in the Examples. If message is a cell array of strings, each cell represents a new line of text.

`sendmail(recipients,subject,message,attachments)` attaches the files listed in the string or cell array attachments.

## Tips

- The `sendmail` function does not support HTML-formatted messages. However, you can send HTML files as attachments.
- If `sendmail` cannot determine your email address or outgoing SMTP mail server from your system registry, specify those settings using the `setpref` function. For example:

```
setpref('Internet','SMTP_Server','my_server.example.com');
setpref('Internet','E_mail','my_email@example.com');
```

To identify the SMTP server for the call to `setpref`, check the preferences for your electronic mail application, or consult your email system administrator. If you cannot easily determine the server name, try 'mail', which is a common default, such as:

```
setpref('Internet','SMTP_Server','mail');
```

- By default, the `sendmail` function does not support email servers that require authentication. To support these servers, change your

# sendmail

---

system settings and set preferences for the SMTP user name and password, with commands in the following form:

```
props = java.lang.System.getProperties();
props.setProperty('mail.smtp.auth', 'true');

setpref('Internet', 'SMTP_Username', 'myaddress@example.com');
setpref('Internet', 'SMTP_Password', 'mypassword');
```

- To override the default character encoding, set the preference for email character encoding as follows:

```
setpref('Internet', 'E_mail_Charset', encoding);
```

where *encoding* is a string specifying the character encoding, such as 'SJIS'.

## Examples

Send a message with two attachments to a hypothetical email address:

```
sendmail('user@otherdomain.com', ...
 'Test subject', 'Test message', ...
 {'folder/attach1.html', 'attach2.doc'});
```

---

Send a message with forced line breaks (using 10) to a hypothetical email address:

```
sendmail('user@otherdomain.com', 'New subject', ...
 ['Line1 of message' 10 'Line2 of message' 10 ...
 'Line3 of message' 10 'Line4 of message']);
```

The resulting message is:

```
Line1 of message
Line2 of message
Line3 of message
Line4 of message
```

Gmail™ servers require authentication and an encrypted connection (SSL) on port 465. Change your system settings to use your Gmail server and send a test message to your Gmail account:

```
% Modify these two lines to reflect
% your account and password.
myaddress = 'myaddress@gmail.com';
mypassword = 'mypassword';

setpref('Internet', 'E_mail', myaddress);
setpref('Internet', 'SMTP_Server', 'smtp.gmail.com');
setpref('Internet', 'SMTP_Username', myaddress);
setpref('Internet', 'SMTP_Password', mypassword);

props = java.lang.System.getProperties;
props.setProperty('mail.smtp.auth', 'true');
props.setProperty('mail.smtp.socketFactory.class', ...
 'javax.net.ssl.SSLSocketFactory');
props.setProperty('mail.smtp.socketFactory.port', '465');

sendmail(myaddress, 'Gmail Test', 'This is a test message.');
```

## Alternatives

On Windows systems with Microsoft Outlook®, you can send email directly through Outlook by accessing the COM server with actxserver. For an example, see Solution 1-RTY6J.

## How To

- “Specify Proxy Server Settings for Connecting to the Internet”

# serial

---

**Purpose** Create serial port object

**Syntax**  
`obj = serial('port')`  
`obj = serial('port', 'PropertyName', PropertyValue, ...)`

**Description** `obj = serial('port')` creates a serial port object associated with the serial port specified by *port*. If *port* does not exist, or if it is in use, you will not be able to connect the serial port object to the device.

*Port* object name will depend upon the platform that the serial port is on. `instrhwinfo('serial')` provides a list of available serial ports. This list is an example of serial constructors on different platforms:

Platform	Serial Port Constructor
Linux and Linux 64	<code>serial('/dev/ttyS0');</code>
Mac OS X 64	<code>serial('/dev/tty.KeySerial1');</code>
Windows 32 and Windows 64	<code>serial('com1');</code>

`obj = serial('port', 'PropertyName', PropertyValue, ...)` creates a serial port object with the specified property names and property values. If an invalid property name or property value is specified, an error is returned and the serial port object is not created.

**Tips** When you create a serial port object, these property values are automatically configured:

- The **Type** property is given by `serial`.
- The **Name** property is given by concatenating `Serial` with the port specified in the `serial` function.
- The **Port** property is given by the port specified in the `serial` function.

You can specify the property names and property values using any format supported by the `set` function. For example, you can use property name/property value cell array pairs. Additionally, you can

specify property names without regard to case, and you can make use of property name completion. For example, the following commands are all valid on a Windows platform.

```
s = serial('COM1','BaudRate',4800);
s = serial('COM1','baudrate',4800);
s = serial('COM1','BAUD',4800);
```

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can use with `serial`.

Before you can communicate with the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt a read or write operation while the object is not connected to the device. You can connect only one serial port object to a given serial port.

## Examples

This example creates the serial port object `s1` associated with the serial port COM1 on a Windows platform.

```
s1 = serial('COM1');
```

The `Type`, `Name`, and `Port` properties are automatically configured.

```
get(s1,{'Type','Name','Port'})
ans =
 'serial' 'Serial-COM1' 'COM1'
```

To specify properties during object creation

```
s2 = serial('COM2','BaudRate',1200,'DataBits',7);
```

## See Also

[fclose](#) | [fopen](#) | [Name](#) | [Port](#) | [Status](#) | [Type](#)

# serialbreak

---

**Purpose** Send break to device connected to serial port

**Syntax** `serialbreak(obj)`  
`serialbreak(obj,time)`

**Description** `serialbreak(obj)` sends a break of 10 milliseconds to the device connected to the serial port object, `obj`.  
`serialbreak(obj,time)` sends a break to the device with a duration, in milliseconds, specified by `time`. Note that the duration of the break might be inaccurate under some operating systems.

**Tips** For some devices, the break signal provides a way to clear the hardware buffer.

Before you can send a break to the device, it must be connected to `obj` with the `fopen` function. A connected serial port object has a `Status` property value of `open`. An error is returned if you attempt to send a break while `obj` is not connected to the device.

`serialbreak` is a synchronous function, and blocks the command line until execution is complete.

If you issue `serialbreak` while data is being asynchronously written, an error is returned. In this case, you must call the `stopasync` function or wait for the write operation to complete.

**See Also** `fopen` | `stopasync` | `Status`

**Purpose** Set Handle Graphics object properties

**Syntax**

```
set(H, 'PropertyName', PropertyValue, ...)
set(H, a)
set(H, pn, pv, ...)
set(H, pn, MxN_pv)
a = set(h)
pv = set(h, 'PropertyName')
```

## Description

---

**Note** Do not use the `set` function on Java objects as it will cause a memory leak. For more information, see “Accessing Private and Public Data”

---

`set(H, 'PropertyName', PropertyValue, ...)` sets the named properties to the specified values on the object(s) identified by H. H can be a vector of handles, in which case `set` sets the properties' values for all the objects. If H is empty (that is, `[]`), `set` does nothing, but does not return an error or warning.

`set(H, a)` sets the named properties to the specified values on the object(s) identified by H. `a` is a structure array whose field names are the object property names and whose field values are the values of the corresponding properties.

`set(H, pn, pv, ...)` sets the named properties specified in the cell array `pn` to the corresponding value in the cell array `pv` for all objects identified in H.

`set(H, pn, MxN_pv)` sets `n` property values on each of `m` graphics objects, where `m = length(H)` and `n` is equal to the number of property names contained in the cell array `pn`. This allows you to set a given group of properties to different values on each object.

`a = set(h)` returns the user-settable properties and possible values for the object identified by `h`. `a` is a structure array whose field names are the object's property names and whose field values are the possible values of the corresponding properties. If you do not specify an output

argument, the MATLAB software displays the information on the screen. `h` must be scalar.

`pv = set(h, 'PropertyName')` returns the possible values for the named property. If the possible values are strings, `set` returns each in a cell of the cell array `pv`. For other properties, `set` returns a statement indicating that `PropertyName` does not have a fixed set of property values. If you do not specify an output argument, MATLAB displays the information on the screen. `h` must be scalar.

---

**Note** Consult the specific object page (figure, axes, and so on) to determine what properties you can set.

---

## Tips

You can use any combination of property name/property value pairs, structure arrays, and cell arrays in one call to `set`.

### Setting Property Units

Note that if you are setting both the `FontSize` and the `FontUnits` properties in one function call, you must set the `FontUnits` property first so that the MATLAB software can correctly interpret the specified `FontSize`. The same applies to figure and axes units — always set the `Units` property before setting properties whose values you want to be interpreted in those units. For example,

```
f = figure('Units','characters',...
 'Position',[30 30 120 35]);
```

## Examples

Set the `Color` property of the current axes to blue.

```
axes;
set(gca,'Color','b')
```

Change all the lines in a plot to black.

```
plot(peaks)
set(findobj('Type','line'),'Color','k')
```

You can define a group of properties in a structure to better organize your code. For example, these statements define a structure called `active`, which contains a set of property definitions used for the `uicontrol` objects in a particular figure. When this figure becomes the current figure, MATLAB changes the colors and enables the controls.

```
active.BackgroundColor = [.7 .7 .7];
active.Enable = 'on';
active.ForegroundColor = [0 0 0];

if gcf == control_fig_handle
 set(findobj(control_fig_handle,'Type','uicontrol'),active)
end
```

You can use cell arrays to set properties to different values on each object. For example, these statements define a cell array to set three properties,

```
PropName(1) = {'BackgroundColor'};
PropName(2) = {'Enable'};
PropName(3) = {'ForegroundColor'};
```

These statements define a cell array containing three values for each of three objects (i.e., a 3-by-3 cell array).

```
PropVal(1,1) = {[.5 .5 .5]};
PropVal(1,2) = {'off'};
PropVal(1,3) = {[.9 .9 .9]};
PropVal(2,1) = {[1 0 0]};
PropVal(2,2) = {'on'};
PropVal(2,3) = {[1 1 1]};
PropVal(3,1) = {[.7 .7 .7]};
PropVal(3,2) = {'on'};
PropVal(3,3) = {[0 0 0]};
```

Now pass the arguments to `set`,

```
set(H,PropName,PropVal)
```

where `length(H) = 3` and each element is the handle to a uicontrol.

## Setting Different Values for the Same Property on Multiple Objects

Suppose you want to set the value of the `Tag` property on five line objects, each to a different value. Note how the value cell array needs to be transposed to have the proper shape.

```
h = plot(rand(5));
set(h,{'Tag'},{'line1','line2','line3','line4','line5'})
```

## Setting Different Values for Multiple Properties on Multiple Objects

Suppose you want to set the values of the `Marker` and `Tag` properties on three different `stemseries` objects to different values. Each row of the value cell array corresponds to an object in `h` and contains two values, one for the `Marker` property and one for the `Tag` property.

```
x = 0:30;
y = [1.5*cos(x);4*exp(-.1*x).*cos(x);exp(.05*x).*cos(x)]';
h = stem(x,y);
set(h,{'Marker','Tag'},...
 {'o','Decaying Exponential';...
 'square','Growing Exponential';...
 '*','Steady State'})
```

## See Also

`findobj` | `gca` | `gcf` | `gco` | `gcbo` | `get`

**Purpose** Set property values for audioplayer object

**Syntax**

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

**Description** `set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

**Tips** The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

**Examples** View the list of properties that you can set for an audioplayer object:

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj)
```

---

Set the `Tag` and `UserData` properties of an audioplayer object using a structure array:

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

# audioplayer.set

---

```
load handel.mat;
handelObj = audioplayer(y, Fs);
set(handelObj, newValues)

% View the values all properties.
get(handelObj)
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the Tag property for an object called handelObj (as created in the Examples):

```
handelObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(handelObj, 'Tag', 'This is my tag.');
```

# set (hgsetget)

---

**Purpose** Assign property values to handle objects derived from hgsetget class

**Syntax**

```
set(H, 'PropertyName', value, ...)
set(H, pn, pv)
set(H, S)
S = set(h)
```

**Description**

`set(H, 'PropertyName', value, ...)` sets the named property to the specified value for the objects in the handle array `H`.

`set(H, pn, pv)` sets the named properties specified in the cell array of strings `pn` to the corresponding values in the cell array `pv` for all objects specified in `H`. The cell array `pn` must be 1-by-`n` (where `n` is the number of property names), but the cell array `pv` can be `m`-by-`n` where `m` is equal to `length(H)`. `set` updates each object with the associated set of values for the list of property names contained in.

`set(H, S)` sets the properties identified by each field name of struct `S` with the values contained in `S`. `S` is a struct whose field names are object property names.

`S = set(h)` returns the user-settable properties of scalar `h`. `S` is a struct whose field names are the object's property names and whose values are empty cell arrays.

Override the hgsetget class `setdisp` method to change how MATLAB displays this information.

**See Also** [handle](#) | [hgsetget](#) | [set](#) | [get \(hgsetget\)](#)

**How To**

- “Implementing a Set/Get Interface for Properties”

**Purpose** Set property values for video reader object

**Syntax**

```
set(obj,Name,Value)
set(obj,cellOfNames,cellOfValues)
set(obj,structOfProperties)
settableProperties = set(obj)
```

**Description** `set(obj,Name,Value)` sets the named property to the specified value for the object `obj`.

`set(obj,cellOfNames,cellOfValues)` sets the properties listed in the cell array `cellOfNames` to the corresponding values in the cell array `cellOfValues`. Each cell array must contain the same number of elements.

`set(obj,structOfProperties)` sets the properties identified by each field of the structure array `structOfProperties` to the values of the associated fields.

`settableProperties = set(obj)` returns the names of the properties that you can set in a structure array. The field names of `settableProperties` are the property names.

**Tips** The `set` function allows combinations of property name/value pairs, cell array pairs, and structure arrays in the same function call.

## **Examples** **View Settable Properties**

View the list of properties that you can set for a video reader object.

```
xyloObj = VideoReader('xylophone.mp4');
set(xyloObj)
```

```
General Settings:
 Tag
 UserData
```

## Set Object Properties

Set the `Tag` and `UserData` properties of a video reader object using a structure array.

```
newValues.Tag = 'My Tag';
newValues.UserData = {'My User Data', pi, [1 2 3 4]};
```

```
xyloObj = VideoReader('xylophone.mp4');
set(xyloObj, newValues)
```

View the values all properties.

```
get(xyloObj)
```

```
General Settings:
```

```
Duration = 4.7000
Name = xylophone.mp4
Path = matlabroot\toolbox\matlab\audiovideo
Tag = My Tag
Type = VideoReader
UserData = {'My User Data' [3.1416] [1 2 3 4]}
```

```
Video Settings:
```

```
BitsPerPixel = 24
FrameRate = 30
Height = 240
NumberOfFrames = 141
VideoFormat = RGB24
Width = 320
```

## Alternatives

To set the value of a single property, you can use dot notation. Reference each property as though it is a field of a structure array. For example, set the `Tag` property for a reader object called `xyloObj` (as created in the Examples):

```
xyloObj.Tag = 'This is my tag.';
```

This command is exactly equivalent to:

```
set(xyloObj, 'Tag', 'This is my tag.');
```

## See Also

VideoReader | get

# set (RandStream)

---

**Purpose** Set random number stream property

**Class** RandStream

**Syntax**

```
set(stream, 'PropertyName', Value)
set(stream, 'Property1', Value1, 'Property2', Value2, ...)
set(stream, A)
A = set(stream, 'Property')
set(stream, 'Property')
A = set(stream)
set(stream)
```

**Description**

`set(stream, 'PropertyName', Value)` sets the property 'PropertyName' of the random stream `stream` to the value `Value`.

`set(stream, 'Property1', Value1, 'Property2', Value2, ...)` sets multiple random stream property values with a single statement.

`set(stream, A)` where `A` is a structure whose field names are property names of the random stream `stream` sets the properties of `stream` named by each field with the values contained in those fields.

`A = set(stream, 'Property')` or `set(stream, 'Property')` displays possible values for the specified property of `stream`.

`A = set(stream)` or `set(stream)` displays or returns all writable properties of `stream` and their possible values.

**See Also** RandStream | get (RandStream) | rand | randn | randi

**Purpose** Configure or display serial port object properties

**Syntax**

```
set(obj)
props = set(obj)
set(obj, 'PropertyName')
props = set(obj, 'PropertyName')
set(obj, 'PropertyName', PropertyValue, ...)
set(obj, PN, PV)
set(obj, S)
```

**Description** `set(obj)` displays all configurable properties values for the serial port object, `obj`. If a property has a finite list of possible string values, then these values are also displayed.

`props = set(obj)` returns all configurable properties and their possible values for `obj` to `props`. `props` is a structure whose field names are the property names of `obj`, and whose values are cell arrays of possible property values. If the property does not have a finite set of possible values, then the cell array is empty.

`set(obj, 'PropertyName')` displays the valid values for *PropertyName* if it possesses a finite list of string values.

`props = set(obj, 'PropertyName')` returns the valid values for *PropertyName* to `props`. `props` is a cell array of possible string values or an empty cell array if *PropertyName* does not have a finite list of possible values.

`set(obj, 'PropertyName', PropertyValue, ...)` configures multiple property values with a single command.

`set(obj, PN, PV)` configures the properties specified in the cell array of strings `PN` to the corresponding values in the cell array `PV`. `PN` must be a vector. `PV` can be `m-by-n` where `m` is equal to the number of serial port objects in `obj` and `n` is equal to the length of `PN`.

`set(obj, S)` configures the named properties to the specified values for `obj`. `S` is a structure whose field names are serial port object properties, and whose field values are the values of the corresponding properties.

# set (serial)

---

## Tips

Refer to [Configuring Property Values](#) for a list of serial port object properties that you can configure with `set`.

You can use any combination of property name/property value pairs, structures, and cell arrays in one call to `set`. Additionally, you can specify a property name without regard to case, and you can make use of property name completion. For example, if `s` is a serial port object, then the following commands are all valid.

```
set(s, 'BaudRate')
set(s, 'baudrate')
set(s, 'BAUD')
```

## Examples

This example illustrates some of the ways you can use `set` to configure or return property values for the serial port object `s`, on a Windows platform.

```
s = serial('COM1');
set(s, 'BaudRate', 9600, 'Parity', 'even')
set(s, {'StopBits', 'RecordName'}, {2, 'sydney.txt'})
set(s, 'Parity')
[{none} | odd | even | mark | space]
```

## See Also

`get`

**Purpose**

Set properties of tscollection object

**Syntax**

```
set(tsc, 'Property', Value)
set(tsc, 'Property1', Value1, 'Property2', Value2, ...)
set(tsc, 'Property')
```

**Description**

set(tsc, 'Property', Value) sets the property 'Property' of the tscollection tsc to the value Value. The following syntax is equivalent:

```
tsc.Property = Value
```

set(tsc, 'Property1', Value1, 'Property2', Value2, ...) sets multiple property values for tsc with a single statement.

set(tsc, 'Property') displays values for the specified property in the time-series collection tsc.

set(tsc) displays all properties and values of the tscollection object tsc.

**See Also**

get (tscollection)

# setabstime (tscollection)

---

**Purpose** Set times of tscollection object as date strings

**Syntax**

```
tsc = setabstime(tsc,Times)
tsc = setabstime(tsc,Times,format)
```

**Description** `tsc = setabstime(tsc,Times)` sets the times in `tsc` using the date strings `Times`. `Times` must be either a cell array of strings, or a char array containing valid date or time values in the same date format.

`tsc = setabstime(tsc,Times,format)` specifies the date-string format used in `Times` explicitly.

**Examples** **1** Create a `tscollection` object.

```
tsc = tscollection(timeseries(rand(3,1)))
```

**2** Set the absolute time vector.

```
tsc = setabstime(tsc,{'12-DEC-2005 12:34:56',...
 '12-DEC-2005 13:34:56','12-DEC-2005 14:34:56'})
```

**See Also** `datestr` | `tscollection` | `getabstime (tscollection)`

**Purpose** Specify application-defined data

**Syntax** `setappdata(h,name,val)`

**Description** `setappdata(h,name,val)` stores values of `val` in a GUI. The first argument, `h`, is a handle to a component in the GUI. The second argument, `name`, is a string that serves as a name for the data. The values of `h` and `name` uniquely identify the location of the data so that you can retrieve the values of `val` elsewhere in your code using the `getappdata` function.

---

**Note** `h` can be a handle to any GUI component except an ActiveX component.

---

**See Also** `getappdata` | `isappdata` | `rmappdata`

**Concepts**

- “Share Data Among Callbacks”

# setdiff

---

**Purpose** Set difference of two arrays

**Syntax**

```
C = setdiff(A,B)
C = setdiff(A,B,'rows')
[C,ia] = setdiff(A,B)
[C,ia] = setdiff(A,B,'rows')

[C,ia] = setdiff(__,setOrder)
[C,ia] = setdiff(A,B,'legacy')
[C,ia] = setdiff(A,B,'rows','legacy')
```

**Description** `C = setdiff(A,B)` returns the data in A that is not in B.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `setdiff` returns the values in A that are not in B. The values of C are in sorted order.
- If A and B are tables, then `setdiff` returns the rows from A that are not in B, with repetitions removed. The rows of table C are in sorted order.

`C = setdiff(A,B,'rows')` treats each row of A and each row of B as single entities and returns the rows from A that are not in B. The rows of C are in sorted order.

The 'rows' option does not support cell arrays.

`[C,ia] = setdiff(A,B)` also returns the index vector `ia`.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `C = A(ia)`.
- If A and B are tables, then `C = A(ia,:)`.

`[C,ia] = setdiff(A,B,'rows')` also returns the index vector `ia`, such that `C = A(ia,:)`.

`[C,ia] = setdiff(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia] = setdiff(A,B,'legacy')` and `[C,ia] = setdiff(A,B,'rows','legacy')` preserve the behavior of the `setdiff` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Input Arguments

### A,B - Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

`A` and `B` must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of `C` are the sorted union of the categories from `A` and `B`.

If you specify the `'rows'` option, `A` and `B` must have the same number of columns.

If `A` and `B` are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

# setdiff

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- eq
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

## setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: <code>C = setdiff([4 1 3 2],[2 1],'sorted')</code> returns <code>C = [3 4]</code> .
'stable'	The values (or rows) in C return in the same order as in A. For example: <code>C = setdiff([4 1 3 2],[2 1],'stable')</code> returns <code>C = [4 3]</code> .

## Output Arguments

### C - Difference of A and B

vector | matrix | table

Difference of A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of C when the inputs are vectors or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified and A is a row vector, then C is a row vector.

- If the 'rows' flag is not specified and A is not a row vector, then C is a column vector.
- If the 'rows' flag is specified, then C is a matrix containing the rows of A that are not in B.
- If all the values (or rows) of A are also in B, then C is an empty matrix.

The class of C is the same as the class of A, unless:

- A is a character array and B is a cell array of strings, in which case C is a cell array of strings.
- A is a cell array of strings or single string and B is a categorical array, in which case C is a categorical array.

### **ia - Index to A**

column vector

Index to A, returned as a column vector when the 'legacy' flag is not specified. `ia` identifies the values (or rows) in A that are not in B. If there is a repeated value (or row) appearing exclusively in A, then `ia` contains the index to the first occurrence of the value (or row).

## **Examples**

### **Difference of Two Vectors**

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in A that are not in B.

```
C = setdiff(A,B)
```

```
C =
```

```
 1 3 5
```

### **Difference of Two Tables**

Define two tables with rows in common.

# setdiff

---

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

A =

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false

B =

Var1	Var2	Var3
1	A	false
3	C	false
5	E	false
7	G	false
9	I	false

Find the rows in A that are not in B.

```
C = setdiff(A,B)
```

C =

Var1	Var2	Var3
2	B	true
4	D	true

## **Difference of Two Vectors and Indices to Different Values**

Define two vectors with values in common.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
```

Find the values in A that are not in B as well as the index vector `ia`, such that `C = A(ia)`.

```
[C,ia] = setdiff(A,B)
```

```
C =
```

```
 1 3 5
```

```
ia =
```

```
 4
 1
 5
```

### Difference of Two Tables and Indices to Different Rows

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F';'M';'F'],[27;52;31;46;35],[74;68;64;61;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty' 'Bob' 'Judy'})
```

```
A =
```

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64
Bob	M	46	61
Judy	F	35	64

Define a table, B, with the same variables as A.

```
B = table(['F';'M';'F';'F'],[64;68;62;58],[31;47;35;23],...
'VariableNames',{'Gender' 'Height' 'Age'},...)
```

# setdiff

---

```
'RowNames',{ 'Meg' 'Joe' 'Beth' 'Amy' })
```

```
B =
```

	Gender	Height	Age
	-----	-----	---
Meg	F	64	31
Joe	M	68	47
Beth	F	62	35
Amy	F	58	23

Find the rows in A that are not in B, as well as the index vector ia, such that  $C = A(ia, :)$ .

```
[C,ia] = setdiff(A,B)
```

```
C =
```

	Gender	Age	Height
	-----	---	-----
Judy	F	35	64
Ted	M	27	74
Bob	M	46	61
Fred	M	52	68

```
ia =
```

```
5
1
4
2
```

The rows of C are in sorted order first by Gender and next by Age.

## **Difference of Rows in Two Matrices**

Define two matrices with rows in common.

```
A = [7 9 7; 0 0 0; 7 9 7; 5 5 5; 1 4 5];
B = [0 0 0; 5 5 5];
```

Find the rows from A that are not in B as well as the index vector `ia`, such that `C = A(ia,:)`.

```
[C,ia] = setdiff(A,B,'rows')
```

```
C =
```

```
 1 4 5
 7 9 7
```

```
ia =
```

```
 5
 1
```

### Difference of Two Vectors with Specified Output Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` or `'sorted'` when the order of the values in C are important.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C,ia] = setdiff(A,B,'stable')
```

```
C =
```

```
 3 1 5
```

```
ia =
```

```
 1
 4
 5
```

Alternatively, you can specify `'sorted'` order.

# setdiff

---

```
[C,ia] = setdiff(A,B,'sorted')

C =

 1 3 5

ia =

 4
 1
 5
```

## Difference of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN];
```

Find the set difference of A and B.

```
C = setdiff(A,B)
```

```
C =

 NaN NaN
```

setdiff treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog','cat','fish','horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ','cat','fish ','horse'};
```

Find the strings in A that are not in B.

```
[C,ia] = setdiff(A,B)
```

```
C =
```

```
 'dog' 'fish'
```

```
ia =
```

```
 1
 3
```

setdiff treats trailing white space in cell arrays of strings as distinct characters.

### **Difference of Char and Cell Array of Strings**

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings, B.

```
B={'dog', 'cat', 'fish', 'horse'};
class(B)
```

```
ans =
```

```
cell
```

Find the strings in A that are not in B.

```
C = setdiff(A,B)
```

# setdiff

---

```
C =

 'fox'
 'pig'
```

The result, `C`, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

## Preserve Legacy Behavior of setdiff

Use the `'legacy'` flag to preserve the behavior of `setdiff` from R2012b and prior releases in your code.

Find the difference of `A` and `B` with the current behavior.

```
A = [3 6 2 1 5 1 1]; B = [2 4 6];
[C1,ia1] = setdiff(A,B)
```

```
C1 =

 1 3 5
```

```
ia1 =
```

```
 4
 1
 5
```

Find the difference of `A` and `B`, and preserve the legacy behavior.

```
[C2,ia2] = setdiff(A,B,'legacy')
```

```
C2 =
```

```
 1 3 5
ia2 =
 7 1 5
```

**Tips**

- To find the set difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setdiff(A(:,vars),B(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

**See Also**

`unique` | `intersect` | `ismember` | `issorted` | `union` | `setxor` | `sort`

**Concepts**

- “Combine Categorical Arrays”

# Tiff.setDirectory

---

**Purpose** Make specified IFD current IFD

**Syntax** `tiffobj.setDirectory(dirNum)`

**Description** `tiffobj.setDirectory(dirNum)` sets the image file directory (IFD) specified by `dirNum` as the current IFD. Tiff object methods operate on the current IFD. The directory index number is one-based.

**Examples** Open a TIFF file and move to an IFD in the file by specifying its index number. The TIFF file should contain multiple images.

```
t = Tiff('example.tif', 'r');
t.setDirectory(2);
t.close();
```

**References** This method corresponds to the `TIFFSetDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.currentDirectory` | `Tiff.nextDirectory`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

<b>Purpose</b>	Override to change command window display
<b>Syntax</b>	setdisp(H)
<b>Description</b>	setdisp(H) called by set when set is called with no output arguments and a single input argument that is a handle array. Override this hgsetget class method in a subclass to change how property information is displayed in the command window.
<b>See Also</b>	hgsetget   set (hgsetget)
<b>How To</b>	<ul style="list-style-type: none"><li>• “Implementing a Set/Get Interface for Properties”</li></ul>

# setenv

---

**Purpose** Set environment variable

**Syntax** `setenv(name,value)`  
`setenv(name)`

**Description** `setenv(name,value)` sets the value of an environment variable belonging to the underlying operating system. Inputs `name` and `value` are both strings. If `name` already exists as an environment variable, then `setenv` replaces its current value with the string given in `value`. If `name` does not exist, `setenv` creates a new environment variable called `name` and assigns `value` to it.

`setenv(name)` is equivalent to `setenv(name, '')` and assigns a null value to the variable `name`. On the Microsoft Windows platform, this is equivalent to undefining the variable. On most UNIX platforms, it is possible to have an environment variable defined as empty.

The maximum number of characters in `name` is  $2^{15} - 2$  (or 32766). If `name` contains the character `=`, `setenv` throws an error. The behavior of environment variables with `=` in the name is not well-defined.

On all platforms, `setenv` passes the `name` and `value` strings to the operating system unchanged. Special characters such as `;`, `/`, `:`, `$`, `%`, etc. are left unexpanded and intact in the variable value.

Values assigned to variables using `setenv` are picked up by any process that is spawned using the MATLAB `system`, `unix`, `dos` or `!` functions. You can retrieve any value set with `setenv` by using `getenv(name)`.

**Examples** `% Set and retrieve a new value for the environment variable TEMP:`

```
setenv('TEMP', 'C:\TEMP');
getenv('TEMP')
```

`% Append the Perl\bin folder to your system PATH variable:`

```
setenv('PATH', [getenv('PATH') 'D:\Perl\bin']);
```

**See Also** `getenv` | `system` | `unix` | `dos` | `!`

**Purpose**

Assign values to structure array field

**Syntax**

```
s = setfield(s, 'field', value)
s =
setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN}, value)
```

**Description**

`s = setfield(s, 'field', value)`, where `s` is a 1-by-1 structure, sets the contents of the specified field, equivalent to `s.field = value`. If `s` does not contain the specified `field`, the `setfield` function creates the field and assigns the specified value. Pass field references as strings.

```
s =
setfield(s, {sIndx1, ..., sIndxM}, 'field', {fIndx1, ..., fIndxN}, value)
```

sets the contents of the specified field, equivalent to `s(sIndx1, ..., sIndxM).field(fIndx1, ..., fIndxN) = value`. The `setfield` function supports multiple sets of `field` and `fIndx` inputs. If structure `s` or any of the fields is a nonscalar structure, the `Indx` inputs associated with that input are required. Otherwise, the `Indx` inputs are optional. If you specify a single colon operator for an index input, enclose it in single quotation marks: `' : '`.

**Tips**

- For most cases, add data to a structure array by indexing rather than using the `setfield` function. For more information, see “Access Data in a Structure Array” and “Generate Field Names from Variables”.
- Call `setfield` to simplify references to structure arrays with nested fields, as shown in the Examples section.

**Examples**

Add values to a structure that contains nested fields:

```
grades = [];
level = 5;
semester = 'Fall';
subject = 'Math';
student = 'John_Doe';
fieldnames = {semester subject student};
newGrades_Doe = [85, 89, 76, 93, 85, 91, 68, 84, 95, 73];
```

# setfield

---

```
grades = setfield(grades, {level}, ...
 fieldnames{:}, {10, 21:30}, ...
 newGrades_Doe);

% View the new contents.
grades(level).(semester).(subject).(student)(10, 21:30)
```

---

Using the structure defined in the previous example, remove the tenth row of the specified field:

```
grades = setfield(grades, {level}, fieldnames{:}, {10,':'}, []);
```

## See Also

## How To

- “Generate Field Names from Variables”
- “Access Data in a Structure Array”

**Purpose** Set component position in pixels

**Syntax** `setpixelposition(handle,position)`  
`setpixelposition(handle,position,recursive)`

**Description** `setpixelposition(handle,position)` sets the position of the component specified by `handle`, to the specified position relative to its parent. `position` is a four-element vector that specifies the location and size of the component: [pixels from left, pixels from bottom, pixels across, pixels high].

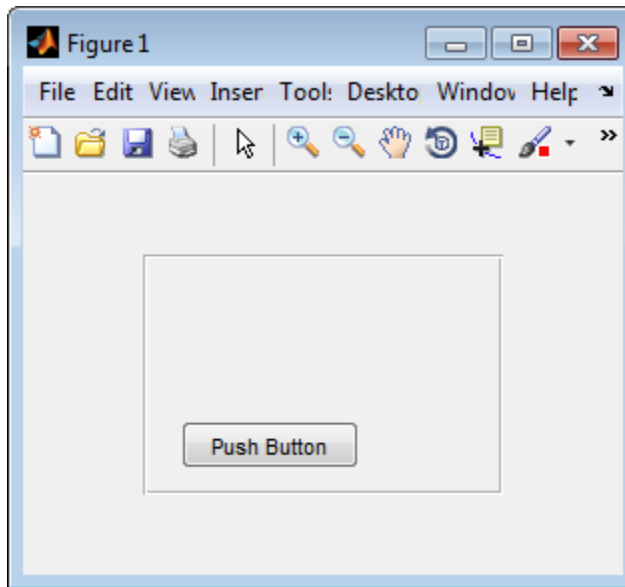

`setpixelposition(handle,position,recursive)` sets the position as above. If Boolean `recursive` is true, the position is set relative to the parent figure of `handle`.

**Examples** This example first creates a push button within a panel.

```
f = figure('Position',[300 300 300 200]);
p = uipanel('Position',[.2 .2 .6 .6]);
h1 = uicontrol(p,'Style','PushButton',...
 'Units','normalized',...
 'String','Push Button',...
 'Position',[.1 .1 .5 .2]);
```

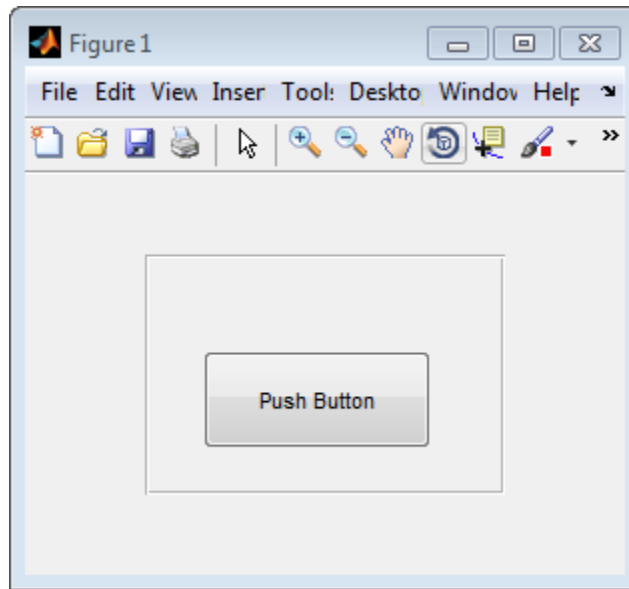

# setpixelposition

---

The example then retrieves the position of the push button and changes its position with respect to the panel.

```
pos1 = getpixelposition(h1);
setpixelposition(h1,pos1 + [10 10 25 25]);
```

**See Also** [getpixelposition](#) | [uicontrol](#) | [uipanel](#)

# setpref

---

## Purpose

Set preference

## Syntax

```
setpref('group','pref',val)
setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})
```

## Description

`setpref('group','pref',val)` sets the preference specified by `group` and `pref` to the value `val`. Individual preference values can be any MATLAB data type, including numeric types, strings, cell arrays, structures, and objects. Setting a preference that does not yet exist causes it to be created.

`group` labels a related collection of preferences. You can choose any name that is a legal variable name, and is descriptive enough to be unique, e.g., `'MathWorks_GUIDE_ApplicationPrefs'`. The input argument `pref` identifies an individual preference in that group, and must be a legal variable name.

`setpref('group',{'pref1','pref2',...,'prefn'},{val1,val2,...,valn})` sets each preference specified in the cell array of names to the corresponding value.

---

**Note** Preference values are persistent and maintain their values between MATLAB sessions. Where they are stored is system dependent.

---

## Examples

Use `addpref` to create a preference group called `mytoolbox` and a preference within it called `version`, and then modify the contents of `version` using `setpref`:

```
addpref('mytoolbox','version','1.0')
getpref('mytoolbox','version')
```

```
ans =
1.0
```

```
setpref('mytoolbox','version',{'1.0','beta'})
getpref('mytoolbox','version')
```

```
ans =
 '1.0' 'beta'
```

## See Also

addpref | getpref | ispref | rmpref | uigetpref | uisetpref

# setstr

---

**Purpose** Set string flag

---

**Note** setstr is not recommended. Use char instead.

---

**Description** This MATLAB 4 function has been renamed char in MATLAB 5.

<b>Purpose</b>	Make subIFD specified by byte offset current IFD
<b>Syntax</b>	<code>tiffobj.setSubDirectory(offset)</code>
<b>Description</b>	<code>tiffobj.setSubDirectory(offset)</code> sets the subimage file directory (subIFD) specified by <code>offset</code> the current IFD. The <code>offset</code> value is given in bytes. Use this method when you want to access subIFDs linked through the SubIFD tag.
<b>Examples</b>	<p><b>Set Subimage File Directory</b></p> <p>Open a TIFF file and read the value of the SubIFD tag in the current IFD. The SubIFD tag contains byte offsets that specify the location of subIFDs in the IFD. The TIFF file should contain subIFDs.</p> <pre>t = Tiff('example.tif', 'r');</pre> <p>Read the value of the SubIFD tag to get subdirectory offsets.</p> <pre>offsets = t.getTag('SubIFD');</pre> <p>Set one of the subdirectories (if more than one) as the current directory.</p> <pre>t.setSubDirectory(offsets(1)); t.close();</pre>
<b>References</b>	This method corresponds to the <code>TIFFSetSubDirectory</code> function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at <a href="#">LibTIFF - TIFF Library and Utilities</a> .
<b>See Also</b>	<code>Tiff.setDirectory</code>
<b>Tutorials</b>	<ul style="list-style-type: none"><li>• “Exporting Image Data and Metadata to TIFF Files”</li><li>• “Reading Image Data and Metadata from TIFF Files”</li></ul>

# Tiff.setTag

---

**Purpose** Set value of tag

**Syntax** `tiffobj.setTag(tagId,tagValue)`  
`tiffobj.setTag(tagStruct)`

**Description** `tiffobj.setTag(tagId,tagValue)` sets the value of the TIFF tag specified by `tagId` to the value specified by `tagValue`. You can specify `tagId` as a character string ('ImageWidth') or using the numeric tag identifier defined by the TIFF specification (256). To see a list of all the tags with their numeric identifiers, view the value of the Tiff object `TagID` property. Use the `TagID` property to specify the value of a tag. For example, `Tiff.TagID.ImageWidth` is equivalent to the tag's numeric identifier.

`tiffobj.setTag(tagStruct)` sets the values of all of the tags with `name/value` fields in `tagStruct`. The names of fields in `tagstruct` must be the name of TIFF tags.

---

**Note** If you are modifying a tag rather than creating it, you must use the `Tiff.rewriteDirectory` method after using the `Tiff.setTag` method.

---

## Examples **Set Tag Values**

Write TIFF tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a `Tiff` object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');
t = Tiff('myfile.tif','w');
```

Set tag values by specifying the numeric tag identifier. Use the `TagID` property to obtain the tag identifier.

```
t.setTag(Tiff.TagID.ImageLength,size(imdata,1));
```

```
t.setTag(Tiff.TagID.ImageWidth, size(imdata,2));
```

Set tag values by specifying the tag name.

```
t.setTag('Photometric', Tiff.Photometric.RGB);
t.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.Chunky);
```

Create a structure with fields named after TIFF tags and assign values to the fields. Pass this structure to the `setTag` method to set the values of these tags.

```
tagStruct.BitsPerSample = 8;
tagStruct.SamplesPerPixel = 3;
tagStruct.TileWidth = 128;
tagStruct.TileLength = 128;
tagStruct.Compression = Tiff.Compression.JPEG;
tagStruct.Software = 'MATLAB';
t.setTag(tagStruct);
```

Write the image data to the TIFF file.

```
t.write(imdata);
t.close();
```

## References

This method corresponds to the `TIFFSetField` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

# settimeseriesnames

---

**Purpose** Change name of `timeseries` object in `tscollection`

**Syntax** `tsc = settimeseriesnames(tsc,old,new)`

**Description** `tsc = settimeseriesnames(tsc,old,new)` replaces the old name of `timeseries` object with the new name in `tsc`.

**See Also** `tscollection`

**Purpose**

Set exclusive OR of two arrays

**Syntax**

```
C = setxor(A,B)
C = setxor(A,B,'rows')
[C,ia,ib] = setxor(A,B)
[C,ia,ib] = setxor(A,B,'rows')

[C,ia,ib] = setxor(__,setOrder)

[C,ia,ib] = setxor(A,B,'legacy')

[C,ia,ib] = setxor(A,B,'rows','legacy')
```

**Description**

`C = setxor(A,B)` returns the data of `A` and `B` that are not in their intersection (the symmetric difference).

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `setxor` returns the values that occur in `A` or `B`, but not both. The values of `C` are in sorted order.
- If `A` and `B` are tables, then `setxor` returns the rows that occur in one or the other of the two tables, but not both. The rows of table `C` are in sorted order.

`C = setxor(A,B,'rows')` treats each row of `A` and each row of `B` as single entities and returns the rows of matrices `A` and `B` that are not in their intersection. The rows of `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ib] = setxor(A,B)` also returns index vectors `ia` and `ib`.

- If `A` and `B` are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `C` is a sorted combination of the elements `A(ia)` and `B(ib)`.

- If A and B are tables, then C is a sorted combination of the rows of A(ia,:) and B(ib,:).

`[C,ia,ib] = setxor(A,B,'rows')` also returns index vectors `ia` and `ib`, such that C is a sorted combination of the rows of A(ia,:) and B(ib,:).

`[C,ia,ib] = setxor(___,setOrder)` returns C in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of C in sorted order. `setOrder='stable'` returns the values (or rows) of C in the same order as A and B. If no value is specified, the default is 'sorted'.

`[C,ia,ib] = setxor(A,B,'legacy')` and `[C,ia,ib] = setxor(A,B,'rows','legacy')` preserve the behavior of the `setxor` function from R2012b and prior releases.

The 'legacy' option does not support categorical arrays or tables.

## Input Arguments

### A,B - Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

A and B must belong to the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with double arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If A and B are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither A nor B are ordinal, they need not have the same sets of categories, and the comparison is

performed using the category names. In this case, the categories of C are the sorted union of the categories from A and B.

If you specify the 'rows' option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- eq
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = setxor([5 1 3],[4 1 2],'sorted') returns C = [2 3 4 5].
'stable'	The values (or rows) in C return in the same order as in A and B. For example: C = setxor([5 1 3],[4 1 2],'stable') returns C = [5 3 4 2].

## Output Arguments

### **C** - Symmetric difference array

vector | matrix | table

Symmetric difference array, returned as a vector, matrix, or table. If the inputs **A** and **B** are tables, the order of the variables in the resulting table, **C**, is the same as the order of the variables in **A**.

The following describes the shape of **C** when the inputs are vector or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the rows of **A** and **B** that are not in the intersection.
- If all the values (or rows) of **A** are also in **B**, then **C** is an empty matrix.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then **C** is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.

### **ia** - Index to A

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** identifies the values (or rows) in **A** that contribute to the symmetric difference. If there is a repeated value (or row) appearing

exclusively in A, then `ia` contains the index to the first occurrence of the value (or row).

### **ib - Index to B**

column vector

Index to B, returned as a column vector when the 'legacy' flag is not specified. `ib` identifies the values (or rows) in B that contribute to the symmetric difference. If there is a repeated value (or row) appearing exclusively in B, then `ib` contains the index to the first occurrence of the value (or row).

## **Examples**

### **Symmetric Difference of Two Vectors**

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of A and B that are not in their intersection.

```
C = setxor(A,B)
```

```
C =
```

```
 2 3 4 5
```

### **Symmetric Difference of Two Tables**

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false

# setxor

---

```
4 D true
5 E false
```

B =

```
Var1 Var2 Var3
---- ---- -----
1 A false
3 C false
5 E false
7 G false
9 I false
```

Find the rows of A and B that are not in their intersection.

```
C = setxor(A,B)
```

C =

```
Var1 Var2 Var3
---- ---- -----
2 B true
4 D true
7 G false
9 I false
```

## Symmetric Difference of Two Vectors and Indices to Different Values

Define two vectors with a value in common.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

Find the values of A and B that are not in their intersection as well as the index vectors ia and ib.

```
[C,ia,ib] = setxor(A,B)
```

```
C =
 2 3 4 5
```

```
ia =
 3
 1
```

```
ib =
 3
 1
```

C is a sorted combination of the elements A(ia) and B(ib).

### Symmetric Difference of Two Tables and Indices to Different Rows

Define a table, A, of gender, age, and height for five people.

```
A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})
```

```
A =
```

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64

Define a table, B, with the same variables as A.

```
B = table(['F';'M'],[64;68],[31;47],...
```

# setxor

---

```
'VariableNames',{ 'Gender' 'Height' 'Age'},...
'RowNames',{ 'Meg' 'Joe'})
```

B =

	Gender	Height	Age
	-----	-----	---
Meg	F	64	31
Joe	M	68	47

Find the rows of A and B that are not in their intersection, as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B)
```

C =

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Joe	M	47	68
Fred	M	52	68

ia =

```
1
2
```

ib =

```
2
```

C is a sorted combination of the elements `A(ia,:)` and `B(ib,:)`.

## Symmetric Difference of Rows in Two Matrices

Define two matrices with rows in common.

```
A = [7 8 9; 7 7 1; 7 7 1; 1 2 3; 4 5 6];
B = [1 2 3; 4 5 6; 7 7 2];
```

Find the rows of A and B that are not in their intersection as well as the index vectors `ia` and `ib`.

```
[C,ia,ib] = setxor(A,B,'rows')
```

C =

```

 7 7 1
 7 7 2
 7 8 9
```

ia =

```

 2
 1
```

ib =

```

 3
```

C is a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

## Symmetric Difference of Two Vectors in Specified Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as A and B.

```
A = [5 1 3 3 3]; B = [4 1 2];
```

# setxor

---

```
[C,ia,ib] = setxor(A,B,'stable')
```

```
C =
```

```
 5 3 4 2
```

```
ia =
```

```
 1
 3
```

```
ib =
```

```
 1
 3
```

Alternatively, you can specify 'sorted' order.

```
[C,ia,ib] = setxor(A,B,'sorted')
```

```
C =
```

```
 2 3 4 5
```

```
ia =
```

```
 3
 1
```

```
ib =
```

```
 3
 1
```

### Symmetric Difference of Vectors Containing NaNs

Define two vectors containing NaN.

```
A = [5 NaN NaN]; B = [5 NaN NaN];
```

Find the symmetric difference of vectors A and B.

```
C = setxor(A,B)
```

```
C =
```

```
NaN NaN NaN NaN
```

The `setxor` function treats NaN values as distinct.

### Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Find the strings that are not in the intersection of A and B.

```
[C,ia,ib] = setxor(A,B)
```

```
C =
```

```
'dog' 'dog ' 'fish' 'fish '
```

```
ia =
```

```
1
3
```

```
ib =
```

```
 1
 3
```

setxor treats trailing white space in cell arrays of strings as distinct characters.

## **Symmetric Difference of Vectors of Different Classes and Shapes**

Create a column vector character array.

```
A = ['A';'B';'C'], class(A)
```

```
A =
```

```
A
B
C
```

```
ans =
```

```
char
```

Create a row vector containing elements of numeric type double.

```
B = [66 67 68], class(B)
```

```
B =
```

```
 66 67 68
```

```
ans =
```

```
double
```

Find the symmetric difference of A and B.

```
C = setxor(A,B)
```

```
C =
```

```
A
```

```
D
```

The result is a column vector character array.

```
class(C)
```

```
ans =
```

```
char
```

### **Symmetric Difference of Char and Cell Array of Strings**

Create a character array, A.

```
A = ['cat'; 'dog'; 'fox'; 'pig'];
```

```
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings, B.

```
B={'dog', 'cat', 'fish', 'horse'};
```

```
class(B)
```

```
ans =
```

```
cell
```

Find the strings that are not in the intersection of A and B.

```
C = setxor(A,B)
```

```
C =
```

```
 'fish'
 'fox'
 'horse'
 'pig'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

## **Preserve Legacy Behavior of setxor**

Use the 'legacy' flag to preserve the behavior of setxor from R2012b and prior releases in your code.

Find the symmetric difference of A and B with the current behavior.

```
A = [5 1 3 3 3]; B = [4 1 2 2];
```

```
[C1,ia1,ib1] = setxor(A,B)
```

```
C1 =
```

```
 2 3 4 5
```

```
ia1 =
```

```
 3
 1
```

```
ib1 =
```

```
 3
 1
```

Find the symmetric difference and preserve the legacy behavior.

```
[C2,ia2,ib2] = setxor(A,B,'legacy')
```

```
C2 =
```

```
 2 3 4 5
```

```
ia2 =
```

```
 5 1
```

```
ib2 =
```

```
 4 1
```

## Tips

- To find the symmetric difference with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `setxor(A(:,vars),B(:,vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

## Concepts

- “Combine Categorical Arrays”

# shading

---

**Purpose** Set color shading properties

**Syntax**

```
shading flat
shading faceted
shading interp
shading(axes_handle,...)
```

**Description** The shading function controls the color shading of surface and patch graphics objects.

`shading flat` each mesh line segment and face has a constant color determined by the color value at the endpoint of the segment or the corner of the face that has the smallest index or indices.

`shading faceted` flat shading with superimposed black mesh lines. This is the default shading mode.

`shading interp` varies the color in each line segment and face by interpolating the colormap index or true color value across the line or face.

`shading(axes_handle,...)` applies the shading type to the objects in the axes specified by `axes_handle`, instead of the current axes. Use quoted strings when using a function form. For example:

```
shading(gca, 'interp')
```

## **Examples**      **Display Sphere with Different Types of Shading**

Plot the sphere function and use different types of shading.

```
figure
subplot(2,2,1)
sphere(16)
title('Faceted Shading (Default)')

subplot(2,2,2)
sphere(16)
shading flat
```

```
title('Flat Shading')

subplot(2,2,3)
sphere(16)
shading interp
title('Interpolated Shading')
```

Faceted Shading (Default)

Flat Shading

Interpolated Shading

## Algorithms

`shading` sets the `EdgeColor` and `FaceColor` properties of all surface and patch graphics objects in the current axes. `shading interp` sets the

# shading

---

appropriate values, depending on whether the surface or patch objects represent meshes or solid surfaces.

## **See Also**

`fill` | `fill3` | `hidden` | `light` | `lighting` | `mesh` | `patch` | `pcolor`  
| `surf` | `patch` | `surface`

**Purpose** Show most recent graph window

**Syntax** shg

**Description** shg makes the current figure visible and raises it above all other figures on the screen. This is identical to using the command `figure(gcf)`.

**See Also** figure | gca | gcf

# shiftdim

---

**Purpose** Shift dimensions

**Syntax** `B = shiftdim(X,n)`  
`[B,nshifts] = shiftdim(X)`

**Description** `B = shiftdim(X,n)` shifts the dimensions of `X` by `n`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(X)` returns the array `B` with the same number of elements as `X` but with any leading singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. `nshifts` is the number of dimensions that are removed.

If `X` is a scalar, `shiftdim` has no effect.

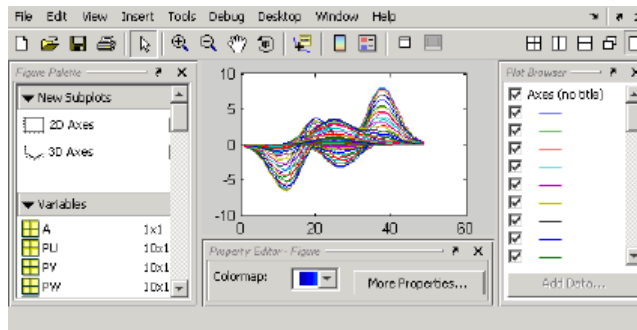

**Examples** The `shiftdim` command is handy for creating functions that, like `sum` or `diff`, work along the first nonsingleton dimension.

```
a = rand(1,1,3,1,2);
[b,n] = shiftdim(a); % b is 3-by-1-by-2 and n is 2.
c = shiftdim(b,-n); % c == a.
d = shiftdim(a,3); % d is 1-by-2-by-1-by-1-by-3.
```

**See Also** `circshift` | `reshape` | `squeeze` | `permute` | `ipermute`

**Purpose** Show or hide figure plot tool

**Syntax**

```
showplottool('tool')
showplottool('on','tool')
showplottool('off','tool')
showplottool('toggle','tool')
showplottool(figure_handle,...)
```

**Description** `showplottool('tool')` shows the specified plot tool on the current figure. `tool` can be one of the following strings:

- `figurepalette`
- `plotbrowser`
- `propertyeditor`

`showplottool('on','tool')` shows the specified plot tool on the current figure.

`showplottool('off','tool')` hides the specified plot tool on the current figure.

`showplottool('toggle','tool')` toggles the visibility of the specified plot tool on the current figure.

`showplottool(figure_handle,...)` operates on the specified figure instead of the current figure.

# showplottool

---

---

**Note** When you dock, undock, resize, or reposition a plotting tool and then close it, it will still be configured as you left it the next time you open it. There is no command to reset plotting tools to their original, default locations.

---

## Alternatives

Click the larger Plotting Tools icon  on the figure toolbar to collectively enable plotting tools, and the smaller icon  to collectively disable them. Individually select the **Figure Palette**, **Plot Browser**, and **Property Editor** tools from the figure's **View** menu. For details, see “Customize Graph Using Plot Tools”.

## See Also

`figurepalette` | `plotbrowser` | `plottools` | `propertyeditor`

## Purpose

Reduce size of patch faces

## Syntax

```
shrinkfaces(p,sf)
nfv = shrinkfaces(p,sf)
nfv = shrinkfaces(fv,sf)
shrinkfaces(p)
nfv = shrinkfaces(f,v,sf)
[nf,nv] = shrinkfaces(...)
```

## Description

`shrinkfaces(p,sf)` shrinks the area of the faces in patch `p` to shrink factor `sf`. A shrink factor of 0.6 shrinks each face to 60% of its original area. If the patch contains shared vertices, the MATLAB software creates nonshared vertices before performing the face-area reduction.

`nfv = shrinkfaces(p,sf)` returns the face and vertex data in the struct `nfv`, but does not set the `Faces` and `Vertices` properties of patch `p`.

`nfv = shrinkfaces(fv,sf)` uses the face and vertex data from the struct `fv`.

`shrinkfaces(p)` and `shrinkfaces(fv)` (without specifying a shrink factor) assume a shrink factor of 0.3.

`nfv = shrinkfaces(f,v,sf)` uses the face and vertex data from the arrays `f` and `v`.

`[nf,nv] = shrinkfaces(...)` returns the face and vertex data in two separate arrays instead of a struct.

## Examples

This example uses the flow data set, which represents the speed profile of a submerged jet within an infinite tank (type `help flow` for more information). Two isosurfaces provide a before and after view of the effects of shrinking the face size.

- First `reducevolume` samples the flow data at every other point and then `isosurface` generates the faces and vertices data.
- The `patch` command accepts the face/vertex struct and draws the first (`p1`) isosurface.

# shrinkfaces

---

- Use the `daspect`, `view`, and `axis` commands to set up the view and then add a title.
- The `shrinkfaces` command modifies the face/vertex data and passes it directly to `patch`.

```
[x,y,z,v] = flow;
[x,y,z,v] = reducevolume(x,y,z,v,2);
fv = isosurface(x,y,z,v,-3);
p1 = patch(fv);
set(p1,'FaceColor','red','EdgeColor',[.5,.5,.5]);
daspect([1 1 1]); view(3); axis tight
title('Original')
```

```
figure
p2 = patch(shrinkfaces(fv,.3));
set(p2,'FaceColor','red','EdgeColor',[.5,.5,.5]);
daspect([1 1 1]); view(3); axis tight
title('After Shrinking')
```

# shrinkfaces

---

## See Also

[isosurface](#) | [patch](#) | [reducevolume](#) | [daspect](#) | [view](#) | [axis](#)

**Purpose** Signum function

**Syntax** `Y = sign(X)`

**Description** `Y = sign(X)` returns an array `Y` the same size as `X`, where each element of `Y` is:

- 1 if the corresponding element of `X` is greater than zero
- 0 if the corresponding element of `X` equals zero
- -1 if the corresponding element of `X` is less than zero

For nonzero complex `X`, `sign(X) = X./abs(X)`.

**See Also** `abs` | `conj` | `imag` | `real`

# sin

---

**Purpose** Sine of argument in radians

**Syntax** `Y = sin(X)`

**Description** `Y = sin(X)` returns the sine of the elements of `X`. The `sin` function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of `X` in the interval `[-Inf, Inf]`, `sin` returns real values in the interval `[-1, 1]`. For complex values of `X`, `sin` returns complex values. All angles are in radians.

**Input Arguments** **X - Input angle in radians**  
scalar value | vector | matrix | N-D array

Input angle in radians, specified as a real-valued or complex-valued scalar, vector, matrix or N-D array. The `sin` operation is element-wise when `X` is non-scalar.

**Data Types**

single | double

**Complex Number Support:** Yes

**Output Arguments** **Y - Sine of input angle**  
scalar value | vector | matrix | N-D array

Sine of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.

**Examples** **Plot Sine Function**

Plot the sine function over the domain  $-\pi \leq x \leq \pi$ .

```
x = -pi:0.01:pi;
plot(x,sin(x)), grid on
```

### Sine of Vector of Complex Angles

Calculate the sine of the complex angles in vector x.

```
x = [-i pi+i*pi/2 -1+i*4];
y = sin(x)
```

y =

# sin

## Definitions

### Sine Function

The sine of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\text{sine}(\alpha) = \frac{\text{opposite side}}{\text{hypotenuse}} = \frac{a}{h}.$$

The sine of a complex angle,  $\alpha$ , is

$$\text{sine}(\alpha) = \frac{e^{i\alpha} - e^{-i\alpha}}{2i}.$$

# single

---

**Purpose** Convert to single precision

**Syntax** `B = single(A)`

**Description** `B = single(A)` converts the matrix `A` to single precision, returning that value in `B`. `A` can be any numeric object (such as a `double`). If `A` is already single precision, `single` has no effect. Single-precision quantities require less storage than double-precision quantities, but have less precision and a smaller range.

The `single` class is primarily meant to be used to store single-precision values. Hence most operations that manipulate arrays without changing their elements are defined. Examples are `reshape`, `size`, the relational operators, subscripted assignment, and subscripted reference.

You can define your own methods for the `single` class by placing the appropriately named method in an `@single` folder within a folder on your path.

## Examples

```
a = magic(4);
b = single(a);
```

```
whos
```

Name	Size	Bytes	Class
a	4x4	128	double array
b	4x4	64	single array

**See Also** `double`

**Purpose** Hyperbolic sine of argument in radians

**Syntax**  $Y = \sinh(X)$

**Description** The `sinh` function operates element-wise on arrays. The function's domains and ranges include complex values. All angles are in radians.  $Y = \sinh(X)$  returns the hyperbolic sine of the elements of  $X$ .

**Examples** **Graph of Hyperbolic Sine Function**

Graph the hyperbolic sine over the domain  $-5 \leq x \leq 5$ .

```
x = -5:0.01:5;
plot(x,sinh(x)), grid on
```

# sinh

---

## Definitions      Hyperbolic Sine

The hyperbolic sine of  $z$  is

$$\sinh(z) = \frac{e^z - e^{-z}}{2}.$$

## See Also      [sin](#) | [asinh](#) | [cosh](#)

**Purpose**

Array dimensions

**Syntax**

```
d = size(X)
[m,n] = size(X)
m = size(X,dim)
[d1,d2,d3,...,dn] = size(X),
```

**Description**

`d = size(X)` returns the sizes of each dimension of array `X` in a vector, `d`, with `ndims(X)` elements.

- If `X` is a scalar, then `size(X)` returns the vector `[1 1]`. Scalars are regarded as a 1-by-1 arrays in MATLAB.
- If `X` is a table, `size(X)` returns a two-element row vector consisting of the number of rows and the number of variables in the table. Variables in the table can have multiple columns, but `size` only counts the variables and rows.

`[m,n] = size(X)` returns the size of matrix `X` in separate variables `m` and `n`.

`m = size(X,dim)` returns the size of the dimension of `X` specified by scalar `dim`.

`[d1,d2,d3,...,dn] = size(X)`, for `n > 1`, returns the sizes of the dimensions of the array `X` in the variables `d1,d2,d3,...,dn`, provided the number of output arguments `n` equals `ndims(X)`. If `n` does not equal `ndims(X)`, the following exceptions hold:

- |                              |                                                                                                                                                                                                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>n &lt; ndims(X)</code> | <code>di</code> equals the size of the <code>i</code> th dimension of <code>X</code> for $0 < i < n$ , but <code>dn</code> equals the product of the sizes of the remaining dimensions of <code>X</code> , that is, dimensions <code>n</code> through <code>ndims(X)</code> . |
| <code>n &gt; ndims(X)</code> | <code>size</code> returns ones in the “extra” variables, that is, those corresponding to <code>ndims(X)+1</code> through <code>n</code> .                                                                                                                                     |

# size

---

---

**Note** For a Java array, `size` returns the length of the Java array as the number of rows. The number of columns is always 1. For a Java array of arrays, the result describes only the top level array.

---

## Examples

### Size of Dimensions in 3-D Array

Find the size of `rand(2,3,4)`.

```
d = size(rand(2,3,4))
```

```
d =
```

```
 2 3 4
```

The size is output as a single vector.

Find the size of the second dimension of `rand(2,3,4)`.

```
m = size(rand(2,3,4),2)
```

```
m =
```

```
 3
```

The size is output as a scalar.

Assign the size of each dimension to a separate variable.

```
[m,n,p] = size(rand(2,3,4))
```

```
m =
```

```
 2
```

```
n =
```

3

p =

4

**Size of Table**

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
X = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

X =

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the size of the table.

```
d = size(X)
```

d =

5 4

# size

---

`size` counts four variables, even though the variable `BloodPressure` contains two columns.

## **Specify Different Number of Outputs than `ndims(X)`**

Assign the size of each dimension to a separate variable where the number of outputs matches the number of dimensions.

```
X = ones(3,4,5);
[d1,d2,d3] = size(X)
```

```
d1 =
```

```
3
```

```
d2 =
```

```
4
```

```
d3 =
```

```
5
```

There is one output for each dimension of `X`.

Specify fewer output variables than `ndims(X)`.

```
[d1,d2] = size(X)
```

```
d1 =
```

```
3
```

```
d2 =
```

```
20
```

The “extra” dimensions are collapsed into a single product.

Specify more output variables than `ndims(X)`.

```
[d1,d2,d3,d4,d5,d6] = size(X)
```

```
d1 =
```

```
 3
```

```
d2 =
```

```
 4
```

```
d3 =
```

```
 5
```

```
d4 =
```

```
 1
```

```
d5 =
```

```
 1
```

```
d6 =
```

```
 1
```

The “extra” variables all represent singleton dimensions.

# size

---

## See Also

`exist` | `length` | `ndims` | `numel` | `whos`

## Purpose

Size of containers.Map object

## Syntax

```
dim = size(mapObj,1)
dimVector = size(mapObj)
[dim1,dim2,...,dimN] = size(mapObj)
```

## Description

`dim = size(mapObj,1)` returns a scalar numeric value that indicates the number of key-value pairs in `mapObj`. If you call `size` with a numeric second input argument other than 1, the `size` method returns the scalar numeric value 1.

`dimVector = size(mapObj)` returns a two-element vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

`[dim1,dim2,...,dimN] = size(mapObj)` returns `[k,1,...,1]`.

## Input Arguments

### mapObj

Object of class `containers.Map`.

## Output Arguments

### dim

Scalar numeric value that indicates the number of key-value pairs in `mapObj`.

### dimVector

Two-element numeric vector `[k,1]`, where `k` is the number of key-value pairs in `mapObj`.

### [dim1,dim2,...,dimN]

Numeric scalar values. Variable `dim1` equals `k`, where `k` is the number of key-value pairs in `mapObj`. All other outputs equal 1.

## Examples

### Determine the Size of a Map

Construct a map and find the number of key-value pairs:

```
myKeys = {'a','b','c'};
myValues = [1,2,3];
```

## containers.Map.size

---

```
mapObj = containers.Map(myKeys,myValues);
dim = size(mapObj,1)
```

This code returns a scalar numeric value:

```
dim =
 3
```

If you do not specify a second input argument,

```
dimVector = size(mapObj)
```

then the `size` method returns a vector:

```
dimVector =
 3 1
```

<b>Purpose</b>	Array dimensions
<b>Syntax</b>	<pre>allDims = size(matObj,variable) [dim1,...,dimN] = size(matObj,variable) selectedDim = size(matObj,variable,dim)</pre>
<b>Description</b>	<p><code>allDims = size(matObj,variable)</code> returns the size of each dimension of the specified variable in the file corresponding to <code>matObj</code>. Output <code>allDims</code> is a 1-by-<code>m</code> vector, where <code>m = ndims(variable)</code>.</p> <p><code>[dim1,...,dimN] = size(matObj,variable)</code> returns the sizes of each dimension in separate output variables <code>dim1,...,dimN</code>.</p> <p><code>selectedDim = size(matObj,variable,dim)</code> returns the size of the specified dimension.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Do not call <code>size</code> with the syntax <code>size(matObj.variable)</code>. This syntax loads the entire contents of the variable into memory. For very large variables, this load operation results in Out of Memory errors.</li></ul>
<b>Input Arguments</b>	<p><b>matObj</b> Object created by the <code>matfile</code> function.</p> <p><b>variable</b> String enclosed in single quotation marks that specifies the name of a variable in the MAT-file corresponding to <code>matObj</code>.</p> <p><b>dim</b> Nonzero positive scalar integer that specifies a dimension of the variable.</p>
<b>Output Arguments</b>	<p><b>allDims</b> 1-by-<code>m</code> vector of sizes of the dimensions of the specified variable, where <code>m = ndims(variable)</code>.</p> <p><b>dim1,...,dimN</b></p>

Scalar numeric values, where `dimK` contains the size of the `K`th dimension of variable:

- If `N < ndims(variable)`, then `dimN`, equals the product of the sizes of dimensions `N` through `ndims(variable)`.
- If `N > ndims(variable)`, the `size` method returns ones in the output variables corresponding to dimensions `ndims(variable)+1` through `N`.

## **selectedDim**

Scalar numeric value that contains the size of the selected dimension for the specified variable.

## **Examples**

Find the size of the matrix `topo` in `topography.mat` without loading any data:

```
matObj = matfile('topography.mat');
[nrows,ncols] = size(matObj,'topo');
```

---

Determine the dimensions of a variable, and process one part of the variable at a time. In this case, calculate and store the average of each column of variable `stocks` in the example file `stocks.mat`:

```
filename = 'stocks.mat';
matObj = matfile(filename);
[nrows,ncols] = size(matObj,'stocks');

avgs = zeros(1,ncols);
for idx = 1:ncols
 avgs(idx) = mean(matObj.stocks(:,idx));
end
```

---

Create a three-dimensional array, and call the `size` method with different numbers of output arguments:

```
matObj = matfile('temp.mat','Writable',true);
matObj.X = rand(2,3,4);

d = size(matObj,'X')
d2 = size(matObj,'X',2)
[m,n] = size(matObj,'X')
[m1,m2,m3,m4] = size(matObj,'X')
```

This code returns

```
d =
 2 3 4

d2 =
 3

m =
 2
n =
 12

m1 =
 2
m2 =
 3
m3 =
 4
m4 =
 1
```

## See Also

# size (serial)

---

**Purpose** Size of serial port object array

**Syntax**

```
d = size(obj)
[m,n] = size(obj)
[m1,m2,m3,...,mn] = size(obj)
m = size(obj,dim)
```

**Description**

`d = size(obj)` returns the two-element row vector `d` containing the number of rows and columns in the serial port object, `obj`.

`[m,n] = size(obj)` returns the number of rows, `m` and columns, `n` in separate output variables.

`[m1,m2,m3,...,mn] = size(obj)` returns the length of the first `n` dimensions of `obj`.

`m = size(obj,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(obj,1)` returns the number of rows.

**See Also** `length`

**Purpose** (Will be removed) Size of triangulation matrix

---

**Note** `size(TriRep)` will be removed in a future release. Use `size(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `size(TR)`

**Description** `size(TR)` provides size information for a triangulation matrix. The matrix is of size `mtri-by-nv`, where `mtri` is the number of simplices and `nv` is the number of vertices per simplex (triangle/tetrahedron, etc).

**Input Arguments**

<code>TR</code>	Triangulation matrix
-----------------	----------------------

**Definitions** A simplex is a triangle/tetrahedron or higher-dimensional equivalent.

**See Also** `size` | `deLaunayTriangulation` | `triangulation`

## size (tscollection)

---

<b>Purpose</b>	Size of tscollection object
<b>Syntax</b>	<code>size(tsc)</code>
<b>Description</b>	<code>size(tsc)</code> returns <code>[n m]</code> , where <code>n</code> is the length of the time vector and <code>m</code> is the number of tscollection members.
<b>See Also</b>	<code>length (tscollection)</code>   <code>isempty (tscollection)</code>   <code>tscollection</code>

**Purpose**

Volumetric slice plot

**Syntax**

```
slice(V, sx, sy, sz)
slice(X, Y, Z, V, sx, sy, sz)
slice(V, XI, YI, ZI)
slice(X, Y, Z, V, XI, YI, ZI)
slice(..., 'method')
slice(axes_handle, ...)
h = slice(...)
```

**Description**

`slice` displays orthogonal slice planes through volumetric data.

`slice(V, sx, sy, sz)` draws slices along the  $x$ ,  $y$ ,  $z$  directions in the volume  $V$  at the points in the vectors `sx`, `sy`, and `sz`.  $V$  is an  $m$ -by- $n$ -by- $p$  volume array containing data values at the default location  $X = 1:n$ ,  $Y = 1:m$ ,  $Z = 1:p$ . Each element in the vectors `sx`, `sy`, and `sz` defines a slice plane in the  $x$ -,  $y$ -, or  $z$ -axis direction.

`slice(X, Y, Z, V, sx, sy, sz)` draws slices of the volume  $V$ .  $X$ ,  $Y$ , and  $Z$  are three-dimensional arrays specifying the coordinates for  $V$ .  $X$ ,  $Y$ , and  $Z$  must be monotonic and orthogonally spaced (as if produced by the function `meshgrid`). The color at each point is determined by 3-D interpolation into the volume  $V$ .

`slice(V, XI, YI, ZI)` draws data in the volume  $V$  for the slices defined by  $XI$ ,  $YI$ , and  $ZI$ .  $XI$ ,  $YI$ , and  $ZI$  are matrices that define a surface, and the volume is evaluated at the surface points.  $XI$ ,  $YI$ , and  $ZI$  must all be the same size.

`slice(X, Y, Z, V, XI, YI, ZI)` draws slices through the volume  $V$  along the surface defined by the arrays  $XI$ ,  $YI$ ,  $ZI$ .

`slice(..., 'method')` specifies the interpolation method. `'method'` is `'linear'`, `'cubic'`, or `'nearest'`.

- `linear` specifies trilinear interpolation (the default).

# slice

---

- `cubic` specifies tricubic interpolation.
- `nearest` specifies nearest-neighbor interpolation.

`slice(axes_handle,...)` plots into the axes with the handle `axes_handle` instead of into the current axes object (`gca`). The axes `clim` property is set to span the finite values of `V`.

`h = slice(...)` returns a vector of handles to surface graphics objects.

## Tips

The color drawn at each point is determined by interpolation into the volume `V`.

## Examples

Visualize the function

$$v = xe^{(-x^2-y^2-z^2)}$$

over the range  $-2 \leq x \leq 2$ ,  $-2 \leq y \leq 2$ ,  $-2 \leq z \leq 2$ :

```
[x,y,z] = meshgrid(-2:.2:2,-2:.25:2,-2:.16:2);
v = x.*exp(-x.^2-y.^2-z.^2);
xslice = [-1.2,.8,2]; yslice = 2; zslice = [-2,0];
slice(x,y,z,v,xslice,yslice,zslice)
colormap hsv
```

### Slicing At Arbitrary Angles

You can also create slices that are oriented in arbitrary planes. To do this,

- Create a slice surface in the domain of the volume (`surf`, `linspace`).
- Orient this surface with respect to the axes (`rotate`).
- Get the `XData`, `YData`, and `ZData` of the surface (`get`).
- Use this data to draw the slice plane within the volume.

For example, these statements slice the volume in the first example with a rotated plane. Placing these commands within a `for` loop “passes” the plane through the volume along the  $z$ -axis.

```
for i = -2:.5:2
 hsp = surf(linspace(-2,2,20),linspace(-2,2,20),...
 zeros(20)+i);
```

# slice

---

```
rotate(hsp,[1,-1,1],30)
xd = get(hsp,'XData');
yd = get(hsp,'YData');
zd = get(hsp,'ZData');
delete(hsp)
slice(x,y,z,v,[-2,2],2,-2) % Draw some volume boundaries
hold on
slice(x,y,z,v,xd,yd,zd)
hold off
axis tight
view(-5,10)
drawnow
end
```

The following picture illustrates three positions of the same slice surface as it passes through the volume.

## Slicing with a Nonplanar Surface

You can slice the volume with any surface. This example probes the volume created in the previous example by passing a spherical slice surface through the volume.

```
[xsp,ysp,zsp] = sphere;
% Draw some volume boundaries
% Draw some volume boundaries
slice(x,y,z,v,[-2,2],2,-2)
for i = -3:.2:3
 hsp = surface(xsp+i,ysp,zsp);
 rotate(hsp,[1 0 0],90)
 xd = get(hsp,'XData');
 yd = get(hsp,'YData');
 zd = get(hsp,'ZData');
 delete(hsp)
 hold on
 hslicer = slice(x,y,z,v,xd,yd,zd);
 axis tight
 xlim([-3,3])
 view(-10,35)
 drawnow
 delete(hslicer)
 hold off
end
```

The following picture illustrates three positions of the spherical slice surface as it passes through the volume.

# slice

---

## How To

- Exploring Volumes with Slice Planes

**Purpose**

Smooth 3-D data

**Syntax****Description**

`W = smooth3(V)` smooths the input data `V` and returns the smoothed data in `W`.

`W = smooth3(V, 'filter')` *filter* determines the convolution kernel and can be the strings

- 'gaussian'
- 'box' (default)

`W = smooth3(V, 'filter', size)` sets the size of the convolution kernel (default is [3 3 3]). If `size` is scalar, then `size` is interpreted as [size, size, size].

`W = smooth3(V, 'filter', size, sd)` sets an attribute of the convolution kernel. When *filter* is gaussian, `sd` is the standard deviation (default is .65).

**Examples**

This example smooths some random 3-D data and then creates an isosurface with end caps.

```
rng(9, 'twister')
data = rand(10,10,10);
data = smooth3(data, 'box', 5);
patch(isocaps(data, .5), ...
 'FaceColor', 'interp', 'EdgeColor', 'none');
p1 = patch(isosurface(data, .5), ...
 'FaceColor', 'blue', 'EdgeColor', 'none');
isonormals(data, p1)
view(3);
axis vis3d tight
camlight left;
lighting phong
```

# smooth3

---

## How To

- [Displaying an Isosurface](#)

<b>Purpose</b>	Force snapshot of image for inclusion in published document
<b>Syntax</b>	snapnow
<b>Description</b>	The snapnow command forces a snapshot of the image or plot that the code has most recently generated for presentation in a published document. The output appears in the published document at the end of the cell that contains the snapnow command. When used outside the context of publishing a file, snapnow has the same behavior as drawnow. That is, if you run a file that contains the snapnow command, the MATLAB software interprets it as though it were a drawnow command.
<b>Examples</b>	<p>This example demonstrates the difference between publishing code that contains the snapnow command and running that code. The first image shows the results of publishing the code and the second image shows the results of running the code.</p> <p>Suppose you have a file that contains the following code:</p> <pre>%% Scale magic Data and %% Display as Image:  for i=1:3     imagesc(magic(i))     snapnow end</pre> <p>When you publish the code to HTML, the published document contains a title, a table of contents, the commented text, the code, and each of the three images produced by the for loop. (In the published document shown, the size of the images have been reduced.)</p>

## Scale magic Data and

### Contents

- [Display as Image:](#)

### Display as Image:

```
for i=1:3
 imagesc(magic(i))
 snapnow
end
```

When you run the code, a single Figure window opens and MATLAB updates the image within this window as it evaluates each iteration of the for loop. Each successive image replaces the one that preceded it, so that the Figure window appears as follows when the code evaluation completes.

**Concepts**

- “Image Snapshot”

# sort

---

**Purpose** Sort array elements

**Syntax**

```
B = sort(A)
B = sort(A,dim)
B = sort(__ ,mode)
[B,I] = sort(__)
```

**Description** `B = sort(A)` sorts the elements of `A` in ascending order along the first array dimension whose size does not equal 1. For strings, this is a sort in ASCII dictionary order. The sort is case-sensitive; uppercase letters appear in the output before lowercase.

- If `A` is a vector, then `sort(A)` sorts the vector elements.
- If `A` is a nonempty, nonvector matrix, then `sort(A)` treats the columns of `A` as vectors and sorts each column.
- If `A` is an empty 0-by-0 matrix, then `sort(A)` returns an empty 0-by-0 matrix.
- If `A` is a multidimensional array, then `sort(A)` treats as vectors all values along the first array dimension whose size does not equal 1, and then sorts each vector.

`B = sort(A,dim)` sorts the elements of `A` along dimension `dim`. For example, if `A` is a matrix, then `sort(A,2)` sorts the elements in each row.

`B = sort( __ ,mode)` sorts in the order specified by `mode` using any of the above syntaxes. The single string, 'ascend', indicates ascending order (default) and 'descend' indicates descending order.

`[B,I] = sort( __ )` also returns a collection of index vectors in an array, `I`, using any of the above syntaxes. `I` is the same size as `A` and describes the rearrangement of the elements along the sorted dimension. In general, if `B` is an array with  $N$  dimensions whose sizes do not equal 1, then  $N-1$  loops are required to use the indexing array, `I`.

This requirement is because `I` contains only location information for the single dimension being sorted. For example,

- If you sort a numeric vector or cell array of strings, then  $B = A(I)$ .
- If you sort the columns of a matrix, then the above relation holds for each column independently. That is, each column of `I` is a permutation vector of the corresponding column of `A` such that

```
for j = 1:size(A,2)
 B(:,j) = A(I(:,j),j);
end
```

## Input Arguments

### A - Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array. The data type of `A` can be numeric, `logical`, `char`, `cell`, or categorical. If `A` contains NaN values or undefined categorical elements, `sort(A)` places them on the high end of the sort (as if they are large numbers).

If `A` is complex, the `sort` function sorts the elements by magnitude. If magnitudes are equal, the `sort` function also sorts by phase angle on the interval  $[-\pi, \pi]$ .

**Complex Number Support:** Yes

### dim - Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1. You cannot use the `dim` or `mode` inputs with a cell array.

Consider a two-dimensional input array, `A`:

- `sort(A,1)` sorts the elements in the columns of `A`.
- `sort(A,2)` sorts the elements in the rows of `A`.

# sort

---

`sort` returns `A` if `dim` is greater than `ndims(A)`.

## mode - Sorting mode

'ascend' (default) | 'descend'

Sorting mode, specified as 'ascend' (default) or 'descend'. You cannot use the `dim` or `mode` options with a cell array.

**Example:** `sort(A,2,'descend')` sorts the rows of `A` in descending order.

## Data Types

char

## Output Arguments

### B - Sorted array

array

Sorted array, returned as an array of the same size and class as `A`. The ordering of the elements in `B` preserves the order of any equal elements in `A`.

### I - Sort index

collection of index vectors

Sort index, returned as a collection of index vectors. The index vectors are oriented along the same dimension that `sort` operates on. For example, if `A` is a 2-by-3 matrix, `[B,I] = sort(A,2)` sorts the elements in each row of `A` and `I` is a collection of 1-by-3 row index vectors describing the rearrangement. If you don't specify `dim`, then `[B,I] = sort(A)` sorts the columns of `A` and `I` is a collection of 2-by-1 column index vectors.

If A has repeated elements of equal value, the indices in I preserve the original ordering.

## Examples

### Sort Vector Elements

Create a row vector of random integers.

```
rng(0)
A = randi(10,1,10)
```

A =

```
 9 10 2 10 7 1 3 6 10 10
```

Sort the vector elements in ascending order.

```
B = sort(A)
```

B =

```
 1 2 3 6 7 9 10 10 10 10
```

The result, B, lists the integers from smallest to largest.

Alternatively, use the `mode` input to sort the vector in descending order.

```
C = sort(A, 'descend')
```

C =

```
 10 10 10 10 9 7 6 3 2 1
```

The result, C, lists the integers from largest to smallest.

### Sort Matrix Columns and Rows

Create a 5-by-5 matrix of random integers.

```
rng(1);
```

# sort

---

```
A = randi(100,5,5)
```

```
A =
```

```
 42 10 42 68 81
 73 19 69 42 97
 1 35 21 56 32
 31 40 88 15 70
 15 54 3 20 88
```

Sort the columns of A.

```
B = sort(A)
```

```
B =
```

```
 1 10 3 15 32
 15 19 21 20 70
 31 35 42 42 81
 42 40 69 56 88
 73 54 88 68 97
```

The result independently orders each column in ascending (smallest to largest) order.

Sort the rows of A in descending order using the `dim` and `mode` inputs.

```
B1 = sort(A,2, 'descend')
```

```
B1 =
```

```
 81 68 42 42 10
 97 73 69 42 19
 56 35 32 21 1
 88 70 40 31 15
 88 54 20 15 3
```

The result independently orders each row in descending (largest to smallest) order.

### Sort Complex Matrix Elements

Create a 4-by-2 matrix of complex numbers.

```
A = [1+1i 2-3i; -1-1i 4+3i; -1+1i 3+2i; 1-1i -2+3i]
```

A =

```

 1.0000 + 1.0000i 2.0000 - 3.0000i
 -1.0000 - 1.0000i 4.0000 + 3.0000i
 -1.0000 + 1.0000i 3.0000 + 2.0000i
 1.0000 - 1.0000i -2.0000 + 3.0000i
```

Sort the columns of A in ascending order.

```
B = sort(A)
```

B =

```

 -1.0000 - 1.0000i 2.0000 - 3.0000i
 1.0000 - 1.0000i 3.0000 + 2.0000i
 1.0000 + 1.0000i -2.0000 + 3.0000i
 -1.0000 + 1.0000i 4.0000 + 3.0000i
```

The `sort` function sorts complex elements first by absolute value (magnitude), then by phase angle.

Find the absolute values of the complex elements in A.

```
C = abs(A)
```

C =

```

 1.4142 3.6056
 1.4142 5.0000
 1.4142 3.6056
```

# sort

---

```
1.4142 3.6056
```

In this case, many of the elements in each column of A have equal magnitudes, so the value of `angle` largely determines the sorting order.

Evaluate the phase angles of each element in A.

```
P = angle(A)
```

```
P =
```

```
0.7854 -0.9828
-2.3562 0.6435
2.3562 0.5880
-0.7854 2.1588
```

The values in P determine the sort order for the column elements in A with equal magnitude in C.

## Sort Cell Array of Strings

Create a 3-by-3 cell array of strings.

```
A = {'Mud' 'Advent' 'Chair'; 'Truth' 'Jester' 'Fall'; 'Create' 'Double' 'Hyper'}
```

```
A =
```

```
'Mud' 'Advent' 'Chair'
'Truth' 'Jester' 'Fall'
'Create' 'Double' 'Hyper'
```

Sort the strings in the cell array in alphabetical order using `sort`.

```
[B,I] = sort(A)
```

```
B =
```

```
'Advent'
'Chair'
```

```
'Create'
'Double'
'Fall'
'Hyper'
'Jester'
'Mud'
'Truth'
```

```
I =
```

```
4
7
3
6
8
9
5
1
2
```

The result, **B**, is a 9-by-1 cell array with the strings in alphabetical order.

Use the index vector, **I**, to obtain **B** directly from **A**.

```
A(I)
```

```
ans =
```

```
'Advent'
'Chair'
'Create'
'Double'
'Fall'
'Hyper'
'Jester'
'Mud'
'Truth'
```

The result is the same as B because I describes the rearrangement of strings such that  $A(I) = B$ .

## Sort Multidimensional Array

Create a 2-by-2-by-3 multidimensional array of random integers.

```
rng(2);
A = randi(100,2,2,3)
```

```
A(:,:,1) =
```

```
 44 55
 3 44
```

```
A(:,:,2) =
```

```
 43 21
 34 62
```

```
A(:,:,3) =
```

```
 30 63
 27 53
```

Sort the columns on each page of the array.

```
B = sort(A)
```

```
B(:,:,1) =
```

```
 3 44
 44 55
```

```
B(:,:,2) =
```

```
34 21
43 62
```

```
B(:,:,3) =
```

```
27 53
30 63
```

The result orders the values in each column from smallest to largest.

Sort the array in the third (`dim = 3`) dimension.

```
[C,I] = sort(A,3)
```

```
C(:,:,1) =
```

```
30 21
3 44
```

```
C(:,:,2) =
```

```
43 55
27 53
```

```
C(:,:,3) =
```

```
44 63
34 62
```

```
I(:,:,1) =
```

```
3 2
1 1
```

## sort

---

```
I(:,:,2) =
```

```
 2 1
 3 3
```

```
I(:,:,3) =
```

```
 1 3
 2 2
```

The result, `C`, orders the corresponding elements on each page of `A` from smallest to largest. For example, `C(1,1,1) < C(1,1,2) < C(1,1,3)`. The corresponding elements on each page of `I` form 1-by-1-by-3 permutation vectors describing the rearrangement of the elements in `A` along the third dimension.

Verify the use of the index array with the original array, `A`.

```
for i = 1:size(A,1)
 for j = 1:size(A,2)
 D(i,j,:) = A(i,j,I(i,j,:));
 end
end
isequal(D,C)
```

```
ans =
```

```
 1
```

The result of logical `1` (`true`) confirms the validity of the index array, `I`. Since the permutation vectors are 3-D, two loops are required to use the indexing array.

**Tips**

- The `sortrows` function provides additional flexibility for subsorting over multiple columns of nonvector input arrays.
- The `sort` function and the relational operators use different orderings for complex numbers. For more information, see “Relational Operations”.

**See Also**

`issorted` | `max` | `mean` | `median` | `min` | `sortrows` | `unique`

**Concepts**

- “Shifting and Sorting Matrices”

# sortrows

---

**Purpose** Sort array rows

**Syntax**

```
B = sortrows(A)
B = sortrows(A,column)
[B,index] = sortrows(___)

tblB = sortrows(tblA)
tblB = sortrows(tblA,'RowNames')
tblB = sortrows(tblA,vars)

tblB = sortrows(tblA,mode)

tblB = sortrows(tblA,'RowNames',mode)
tblB = sortrows(tblA,vars,mode)

[tblB,index] = sortrows(tblA, ___)
```

**Description** `B = sortrows(A)` sorts the rows of `A` in ascending order. For strings, this is the familiar dictionary sort.

`B = sortrows(A, column)` sorts matrix `A` based on the columns specified in the vector, `column`. This input is used to perform multiple column sorts in succession.

`[B,index] = sortrows( ___ )` also returns an index vector using any of the previous syntaxes. The index vector satisfies `B = A(index,:)`.

`tblB = sortrows(tblA)` sorts the rows of table `tblA` in ascending order by the first variable, then by the second variable, and so on.

`tblB = sortrows(tblA,'RowNames')` sorts by the row names.

`tblB = sortrows(tblA,vars)` sorts by the variables specified by `vars`.

`tblB = sortrows(tblA,mode)` and `tblB = sortrows(tblA, 'RowNames',mode)` sorts `tblA` in the order specified by `mode`. The single string, 'ascend', indicates ascending order (default) and 'descend' indicates descending order.

`tblB = sortrows(tblA,vars,mode)` uses `mode` to specify the sort order. `mode` can be a single string or a cell array of strings containing 'ascend' for ascending order (default) or 'descend' for descending order.

- When `mode` is a single string, `sortrows` sorts in the specified direction for all variables in `vars`.
- When `mode` is a cell array of strings, `sortrows` sorts in the specified direction for each variable in `vars`.

`[tblB,index] = sortrows(tblA, ___)` also returns an index vector, `index`, such that `tblB = tblA(index,:)`.

## Input Arguments

### A - Input array

column vector | matrix

Input array, specified as a column vector or matrix of a numeric, logical, char, cell, or categorical class.

When `A` is complex, `sortrows` sorts the elements by magnitude, and, where magnitudes are equal, further sorts by phase angle on the interval  $[-\pi, \pi]$ .

**Complex Number Support:** Yes

### column - Column sorting vector

vector of integers

Column sorting vector, specified as a vector of integers. Each integer value indicates a column to sort by. The sign of the integer indicates ascending (positive) or descending (negative) sort order.

**Example:** `sortrows(A,[2 -3])` sorts the rows of `A` first in ascending order for the second column, and then it sorts by descending order for the third column.

## **tblA - Input table**

table

Input table, specified as a table. Each variable in `tblA` must be a valid input to `sort` or `sortrows`.

## **Data Types**

table

## **'RowNames' - Row sort input**

string

Row sort input, specified as the string `'RowNames'`. Specify the `'RowNames'` option to sort a table by row names rather than by variables. If `tblA.Properties.RowNames` is empty, `sortrows(tblA, 'RowNames')` returns `tblA`.

## **vars - Sorting variables**

integer | vector of integers | variable name | cell array of variable names | logical vector

Sorting variables, specified as an integer, a vector of integers, a variable name, a cell array of variable names, or a logical vector. `vars` indicates the table variables to sort by. You also can use the `mode` input to indicate ascending or descending order for each sorting variable.

If an element of `vars` is a positive integer, `sortrows` sorts the corresponding variable in `tblA` in ascending order. If an element of `vars` is a negative integer, `sortrows` sorts the corresponding variable in `tblA` in descending order. If you provide the `mode` input argument, MATLAB ignores the sign of the integers.

**Example:** `sortrows(tblA, {'Height', 'Weight'})` sorts the rows of `tblA` in ascending order, first by the variable `Height`, and then it sorts by the variable `Weight`.

**Example:** `sortrows(tblA, [1 4], {'descend' 'ascend'})` sorts the first variable of `tblA` in descending order, then it sorts the fourth variable in ascending order.

**mode - Sorting mode**

single string | cell array of strings

Sorting mode, specified as a single string or cell array of strings composed of the options 'ascend' (default), or 'descend'. If mode is a cell array of strings, the number of required entries depends on whether you are sorting by variables or by row names.

- If tblA is being sorted by variables, the cell array must have an entry for each variable.
- If tblA is being sorted by row names, the cell array must have one entry.

**Data Types**

char | cell

**Output Arguments****B - Sorted array**

array

Sorted array, returned as an array of the same size and class as A.

**tblB - Sorted table**

table

Sorted table, returned as a table with the same variables as tblA.

**index - Sort index**

index vector

Sort index, returned as an index vector. The sort index describes the rearrangement of elements or rows in the input.

**Examples****Sort Rows of Matrix**

Start with an arbitrary matrix, A.

```
A = floor(gallery('uniformdata',[6 7],0)*100);
A(1:4,1) = 95; A(5:6,1) = 76; A(2:4,2) = 7; A(3,3) = 73
```

# sortrows

---

```
A =
 95 45 92 41 13 1 84
 95 7 73 89 20 74 52
 95 7 73 5 19 44 20
 95 7 40 35 60 93 67
 76 61 93 81 27 46 83
 76 79 91 0 19 41 1
```

Sort the rows of A.

```
B = sortrows(A)
```

```
B =
 76 61 93 81 27 46 83
 76 79 91 0 19 41 1
 95 7 40 35 60 93 67
 95 7 73 5 19 44 20
 95 7 73 89 20 74 52
 95 45 92 41 13 1 84
```

When called with only a single input argument, `sortrows` bases the sort on the first column of the matrix. For any rows that have equal elements in a particular column, (e.g., `A(1:4,1)` for this matrix), sorting is based on the column immediately to the right, (`A(1:4,2)` in this case).

When called with two input arguments, `sortrows` bases the sort entirely on the column specified in the second argument.

Sort the rows of A based on the values in the second column.

```
C = sortrows(A,2)
```

```
C =
 95 7 73 89 20 74 52
 95 7 73 5 19 44 20
 95 7 40 35 60 93 67
 95 45 92 41 13 1 84
 76 61 93 81 27 46 83
 76 79 91 0 19 41 1
```

Rows that have equal elements in the specified column, (e.g., `A(2:4, :)`, if sorting matrix `A` by column 2) remain in their original order.

Specify two columns to sort by: columns 1 and 7.

```
D = sortrows(A, [1 7])
```

```
D =
 76 79 91 0 19 41 1
 76 61 93 81 27 46 83
 95 7 73 5 19 44 20
 95 7 73 89 20 74 52
 95 7 40 35 60 93 67
 95 45 92 41 13 1 84
```

`sortrows` sorts by column 1 first, and then for any rows with equal values in column 1, sorts by column 7.

Sort the rows in descending order using the values in column 4.

```
[E, index] = sortrows(A, -4)
```

```
E =
 95 7 73 89 20 74 52
 76 61 93 81 27 46 83
 95 45 92 41 13 1 84
 95 7 40 35 60 93 67
 95 7 73 5 19 44 20
 76 79 91 0 19 41 1
```

```
index =
```

```
 2
 5
 1
```

```
4
3
6
```

The index vector, `index`, describes the rearrangement of the rows, such that `E = A(index,:)`.

## Sort Rows of Cell Array

Create a 6-by-2 cell array of strings.

```
A = {'Germany' 'Lukas'; 'USA' 'William'; 'USA' 'Andrew'; ...
 'Germany' 'Andreas'; 'USA' 'Olivia'; 'Germany' 'Julia'}
```

```
A =
```

```
 'Germany' 'Lukas'
 'USA' 'William'
 'USA' 'Andrew'
 'Germany' 'Andreas'
 'USA' 'Olivia'
 'Germany' 'Julia'
```

The result is a list of countries and names.

Sort the rows of A.

```
B = sortrows(A)
```

```
B =
```

```
 'Germany' 'Andreas'
 'Germany' 'Julia'
 'Germany' 'Lukas'
 'USA' 'Andrew'
 'USA' 'Olivia'
 'USA' 'William'
```

The result is an alphabetized list sorted by both country and name.

Sort the names in the second column in descending order.

```
[C,index] = sortrows(A,[1 -2])
```

```
C =
```

```

'Germany' 'Lukas'
'Germany' 'Julia'
'Germany' 'Andreas'
'USA' 'William'
'USA' 'Olivia'
'USA' 'Andrew'

```

```
index =
```

```

1
6
4
2
5
3

```

The index vector, `index`, describes the rearrangement of the rows, such that `C = A(index,:)`.

### Sort Rows of Table

Sort the rows of a table by the variable values in ascending order.

Create a table with four variables listing patient information for five people.

```

LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];

```

## sortrows

---

```
tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table.

```
tblB = sortrows(tblA)
```

```
tblB =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Williams	38	64	131	125	83
Smith	38	71	176	124	93
Jones	40	67	133	117	75
Johnson	43	69	163	109	77
Brown	49	64	119	122	80

The `sortrows` function sorts the rows in ascending order first by the variable `Age`, and then it sorts by the variable `Height`.

### Sort Rows of Table by Row Names

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
```

```
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
tblA =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Sort the rows of the table by the row names and return an index vector, such that `tblB = tblA(index,:)`.

```
[tblB,index] = sortrows(tblA,'RowNames')
```

```
tblB =
```

	Age	Height	Weight	BloodPressure	
	---	-----	-----	-----	-----
Brown	49	64	119	122	80
Johnson	43	69	163	109	77
Jones	40	67	133	117	75
Smith	38	71	176	124	93
Williams	38	64	131	125	83

```
index =
```

```
5
2
4
1
3
```

The `sortrows` function sorts the rows in ascending order by the row names.

## Sort Rows of Table by Variables

Create a table with four variables listing patient information for five people.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
tblA = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```

# sound

---

## Purpose

Convert matrix of signal data to sound

## Syntax

```
sound(y)
sound(y,Fs)
sound(y,Fs,nBits)
```

## Description

`sound(y)` sends audio signal `y` to the speaker at the default sample rate of 8192 hertz.

`sound(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`sound(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

## Input Arguments

### **y** - Audio data

column vector |  $m$ -by-2 matrix

Audio data, specified as an  $m$ -by-1 column vector for single-channel (mono) audio, or an  $m$ -by-2 matrix for stereo playback, where  $m$  is the number of audio samples. If `y` is an  $m$ -by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

### Data Types

double

### **Fs** - Sample rate

8192 (default) | positive number

Sample rate, in hertz, of audio data `y`, specified as a positive number between 80 and 1000000.

### Data Types

single | double

### **nBits** - Bit depth of sample values

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

## Examples

### Play Sample Data at Default Sample Rate

Load the example file `gong.mat`, which contains sample data `y` and rate `Fs`, and listen to the audio.

```
load gong.mat;
sound(y);
```

### Play Sample Data at Specific Sample Rate

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
sound(y, 2*Fs);
```

### Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
sound(y, Fs, nBits);
```

MATLAB plays the audio with a bit depth of 16 bits per sample, if this is supported on your system.

## Tips

- The `sound` function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

# sound

---

## **Concepts**

- “Characteristics of Audio Files”
- “Play Audio”

**Purpose**

Scale data and play as sound

**Syntax**

```
soundsc(y)
soundsc(y,Fs)
soundsc(y,Fs,nBits)

soundsc(__ ,yRange)
```

**Description**

`soundsc(y)` scales the values of audio signal `y` to fit in the range from  $-1.0$  to  $1.0$ , and then sends the data to the speaker at the default sample rate of 8192 hertz. By first scaling the data, `soundsc` plays the audio as loudly as possible without clipping. The mean of the dynamic range of the data is set to zero.

`soundsc(y,Fs)` sends audio signal `y` to the speaker at sample rate `Fs`.

`soundsc(y,Fs,nBits)` uses `nBits` bits per sample for audio signal `y`.

`soundsc( __ ,yRange)`, where `yRange` is a vector of the form `[low,high]`, linearly scales the values in `y` between `low` and `high` to the full sound range `[-1.0,1.0]`. Values outside `[low,high]` are not clipped. You can use `yRange` with any of the input arguments in the above syntaxes.

**Input Arguments****y - Audio data**

column vector | m-by-2 matrix

Audio data, specified as an `m`-by-1 column vector for single-channel (mono) audio, or an `m`-by-2 matrix for stereo playback, where `m` is the number of audio samples. If `y` is an `m`-by-2 matrix, then the first column corresponds to the left channel, and the second column corresponds to the right channel. Stereo playback is available only if your system supports it.

**Data Types**

double

## **Fs - Sample rate**

8192 (default) | positive number

Sample rate, in hertz, of audio data  $y$ , specified as a positive number between 80 and 1000000.

## **Data Types**

single | double

## **nBits - Bit depth of sample values**

8 (default) | 16 | 24

Bit depth of the sample values, specified as an integer. Valid values depend on the audio hardware installed. Most platforms support bit depths of 8 bits or 16 bits.

## **yRange - Range of audio data to scale**

$[\min(y), \max(y)]$  (default) | two-element vector

Range of audio data to scale, specified as a two-element vector of the form  $[low, high]$ , where  $low$  and  $high$  are the lower and upper limits of the range.

**Example:**  $[-0.8, 0.8]$

## **Data Types**

double

## **Examples**

### **Play Sample Data at Default Sample Rate**

Load the example file `gong.mat`, which contains sample data  $y$  and rate  $F_s$ , and listen to the audio.

```
load gong.mat;
soundsc(y);
```

### **Play Sample Data at Specific Sample Rate**

Play an excerpt from Handel's "Hallelujah Chorus" at twice the recorded sample rate.

```
load handel.mat;
```

```
soundsc(y, 2*Fs);
```

### Play Sample Data with Specific Bit Depth

```
load handel.mat;
nBits = 16;
soundsc(y,Fs,nBits);
```

MATLAB plays the scaled audio with a bit depth of 16 bits per sample.

### Scale Selected Audio Data

```
load handel.mat;
yRange = [-0.7,0.7];
soundsc(y,yRange);
```

### Tips

- The sound function supports sound devices on all Windows and most UNIX platforms.
- Most sound cards support sample rates between 5 and 48 kilohertz. Specifying a sample rate outside this range might produce unexpected results.

# spalloc

---

**Purpose** Allocate space for sparse matrix

**Syntax** `S = spalloc(m,n,nzmax)`

**Description** `S = spalloc(m,n,nzmax)` creates an all zero sparse matrix `S` of size `m`-by-`n` with room to hold `nzmax` nonzeros. The matrix can then be generated column by column without requiring repeated storage allocation as the number of nonzeros grows.

`spalloc(m,n,nzmax)` is shorthand for

```
sparse([],[],[],m,n,nzmax)
```

**Examples** To generate efficiently a sparse matrix that has an average of at most three nonzero elements per column

```
S = spalloc(n,n,3*n);
for j = 1:n
 S(:,j) = [zeros(n-3,1)' round(rand(3,1))']';end
```

---

<b>Purpose</b>	Create sparse matrix
<b>Syntax</b>	<pre>S = sparse(A) S = sparse(i,j,s,m,n,nzmax) S = sparse(i,j,s,m,n) S = sparse(i,j,s) S = sparse(m,n)</pre>
<b>Description</b>	<p>The <code>sparse</code> function generates matrices in the MATLAB sparse storage organization.</p> <p><code>S = sparse(A)</code> converts a full matrix to sparse form by squeezing out any zero elements. If <code>S</code> is already sparse, <code>sparse(S)</code> returns <code>S</code>.</p> <p><code>S = sparse(i,j,s,m,n,nzmax)</code> uses vectors <code>i</code>, <code>j</code>, and <code>s</code> to generate an <code>m</code>-by-<code>n</code> sparse matrix such that <math>S(i(k),j(k)) = s(k)</math>, with space allocated for <code>nzmax</code> nonzeros. Vectors <code>i</code>, <code>j</code>, and <code>s</code> are all the same length. Any elements of <code>s</code> that are zero are ignored, along with the corresponding values of <code>i</code> and <code>j</code>. Any elements of <code>s</code> that have duplicate values of <code>i</code> and <code>j</code> are added together.</p> <hr/> <p><b>Note</b> If any value in <code>i</code> or <code>j</code> is larger than <math>2^{31}-1</math> for 32-bit platforms, or <math>2^{48}-1</math> on 64-bit platforms, then the sparse matrix cannot be constructed.</p> <hr/> <p>To simplify this six-argument call, you can pass scalars for the argument <code>s</code> and one of the arguments <code>i</code> or <code>j</code>—in which case they are expanded so that <code>i</code>, <code>j</code>, and <code>s</code> all have the same length.</p> <p><code>S = sparse(i,j,s,m,n)</code> uses <code>nzmax = length(s)</code>.</p> <p><code>S = sparse(i,j,s)</code> uses <code>m = max(i)</code> and <code>n = max(j)</code>. The maxima are computed before any zeros in <code>s</code> are removed, so one of the rows of <code>[i j s]</code> might be <code>[m n 0]</code>.</p> <p><code>S = sparse(m,n)</code> abbreviates <code>sparse([],[],[],m,n,0)</code>. This generates the ultimate sparse matrix, an <code>m</code>-by-<code>n</code> all zero matrix.</p>

## Tips

All of the MATLAB built-in arithmetic, logical, and indexing operations can be applied to sparse matrices, or to mixtures of sparse and full matrices. Operations on sparse matrices return sparse matrices and operations on full matrices return full matrices.

In most cases, operations on mixtures of sparse and full matrices return full matrices. The exceptions include situations where the result of a mixed operation is structurally sparse, for example,  $A * S$  is at least as sparse as  $S$ .

## Examples

`S = sparse(1:n,1:n,1)` generates a sparse representation of the  $n$ -by- $n$  identity matrix. The same  $S$  results from `S = sparse(eye(n,n))`, but this would also temporarily generate a full  $n$ -by- $n$  matrix with most of its elements equal to zero.

`B = sparse(10000,10000,pi)` is probably not very useful, but is legal and works; it sets up a 10000-by-10000 matrix with only one nonzero element. Don't try `full(B)`; it requires 800 megabytes of storage.

This dissects and then reassembles a sparse matrix:

```
[i,j,s] = find(S);
[m,n] = size(S);
S = sparse(i,j,s,m,n);
```

So does this, if the last row and column have nonzero entries:

```
[i,j,s] = find(S);
S = sparse(i,j,s);
```

## See Also

`diag` | `find` | `full` | `issparse` | `nnz` | `nonzeros` | `nzmax` | `spones` | `sprandn` | `sprandsym` | `spy`

**Purpose** Form least squares augmented system

**Syntax**  
 $S = \text{spaugment}(A, c)$   
 $S = \text{spaugment}(A)$

**Description**  $S = \text{spaugment}(A, c)$  creates the sparse, square, symmetric indefinite matrix  $S = [c \cdot I \ A; \ A' \ 0]$ . The matrix  $S$  is related to the least squares problem

$$\min \text{norm}(b - A \cdot x)$$

by

$$r = b - A \cdot x$$

$$S * [r/c; x] = [b; 0]$$

The optimum value of the residual scaling factor  $c$ , involves  $\min(\text{svd}(A))$  and  $\text{norm}(r)$ , which are usually too expensive to compute.

$S = \text{spaugment}(A)$  without a specified value of  $c$ , uses  $\max(\max(\text{abs}(A))) / 1000$ .

---

**Note** In previous versions of MATLAB product, the augmented matrix was used by sparse linear equation solvers, `\` and `/`, for nonsquare problems. Now, MATLAB software performs a least squares solve using the `qr` factorization of  $A$  instead.

**See Also** `spparms`

# spconvert

---

**Purpose** Import matrix from sparse matrix external format

**Syntax** `S = spconvert(D)`

**Description** `spconvert` is used to create sparse matrices from a simple sparse format easily produced by non-MATLAB sparse programs. `spconvert` is the second step in the process:

- 1 Load an ASCII data file containing `[i, j, v]` or `[i, j, re, im]` as rows into a MATLAB variable.
- 2 Convert that variable into a MATLAB sparse matrix.

`S = spconvert(D)` converts a matrix `D` with rows containing `[i, j, s]` or `[i, j, r, s]` to the corresponding sparse matrix. `D` must have an `nnz` or `nnz+1` row and three or four columns. Three elements per row generate a real matrix and four elements per row generate a complex matrix. A row of the form `[m n 0]` or `[m n 0 0]` anywhere in `D` can be used to specify `size(S)`. If `D` is already sparse, no conversion is done, so `spconvert` can be used after `D` is loaded from either a MAT-file or an ASCII file.

**Examples** Suppose the ASCII file `uphill.dat` contains

```
1 1 1.0000000000000000
1 2 0.5000000000000000
2 2 0.3333333333333333
1 3 0.3333333333333333
2 3 0.2500000000000000
3 3 0.2000000000000000
1 4 0.2500000000000000
2 4 0.2000000000000000
3 4 0.1666666666666667
4 4 0.142857142857143
4 4 0.0000000000000000
```

Then the statements

```
load uphill.dat
H = spconvert(uphill)
```

```
H =
(1,1) 1.0000
(1,2) 0.5000
(2,2) 0.3333
(1,3) 0.3333
(2,3) 0.2500
(3,3) 0.2000
(1,4) 0.2500
(2,4) 0.2000
(3,4) 0.1667
(4,4) 0.1429
```

recreate `sparse(triu(hilb(4)))`, possibly with roundoff errors. In this case, the last line of the input file is not necessary because the earlier lines already specify that the matrix is at least 4-by-4.

# spdiags

---

**Purpose** Extract and create sparse band and diagonal matrices

**Syntax**

```
B = spdiags(A)
[B,d] = spdiags(A)
B = spdiags(A,d)
A = spdiags(B,d,A)
A = spdiags(B,d,m,n)
```

**Description** The `spdiags` function generalizes the function `diag`. Four different operations, distinguished by the number of input arguments, are possible.

`B = spdiags(A)` extracts all nonzero diagonals from the  $m$ -by- $n$  matrix  $A$ .  $B$  is a  $\min(m,n)$ -by- $p$  matrix whose columns are the  $p$  nonzero diagonals of  $A$ .

`[B,d] = spdiags(A)` returns a vector  $d$  of length  $p$ , whose integer components specify the diagonals in  $A$ .

`B = spdiags(A,d)` extracts the diagonals specified by  $d$ .

`A = spdiags(B,d,A)` replaces the diagonals specified by  $d$  with the columns of  $B$ . The output is sparse.

`A = spdiags(B,d,m,n)` creates an  $m$ -by- $n$  sparse matrix by taking the columns of  $B$  and placing them along the diagonals specified by  $d$ .

---

**Note** In this syntax, if a column of  $B$  is longer than the diagonal it is replacing, and  $m \geq n$ , `spdiags` takes elements of super-diagonals from the lower part of the column of  $B$ , and elements of sub-diagonals from the upper part of the column of  $B$ . However, if  $m < n$ , then super-diagonals are from the upper part of the column of  $B$ , and sub-diagonals from the lower part. (See “Example 5A” on page 1-6402 and “Example 5B” on page 1-6404, below).

---

**Arguments** The `spdiags` function deals with three matrices, in various combinations, as both input and output.

- A An  $m$ -by- $n$  matrix, usually (but not necessarily) sparse, with its nonzero or specified elements located on  $p$  diagonals.
- B A  $\min(m, n)$ -by- $p$  matrix, usually (but not necessarily) full, whose columns are the diagonals of  $A$ .
- d A vector of length  $p$  whose integer components specify the diagonals in  $A$ .

Roughly,  $A$ ,  $B$ , and  $d$  are related by

```
for k = 1:p
 B(:,k) = diag(A,d(k))
end
```

Some elements of  $B$ , corresponding to positions outside of  $A$ , are not defined by these loops. They are not referenced when  $B$  is input and are set to zero when  $B$  is output.

### How the Diagonals of $A$ are Listed in the Vector $d$

An  $m$ -by- $n$  matrix  $A$  has  $m+n-1$  diagonals. These are specified in the vector  $d$  using indices from  $-m+1$  to  $n-1$ . For example, if  $A$  is 5-by-6, it has 10 diagonals, which are specified in the vector  $d$  using the indices -4, -3, ... 4, 5. The following diagram illustrates this for a vector of all ones.

# spdiags

---

## Examples

### Example 1

For the following matrix,

```
A=[0 5 0 10 0 0;...
0 0 6 0 11 0;...
3 0 0 7 0 12;...
1 4 0 0 8 0;...
0 2 5 0 0 9]
```

A =

0	5	0	10	0	0
0	0	6	0	11	0
3	0	0	7	0	12
1	4	0	0	8	0
0	2	5	0	0	9

the command

```
[B, d] =spdiags(A)
```

returns

B =

0	0	5	10
0	0	6	11
0	3	7	12
1	4	8	0
2	5	9	0

d =

```
-3
-2
1
```

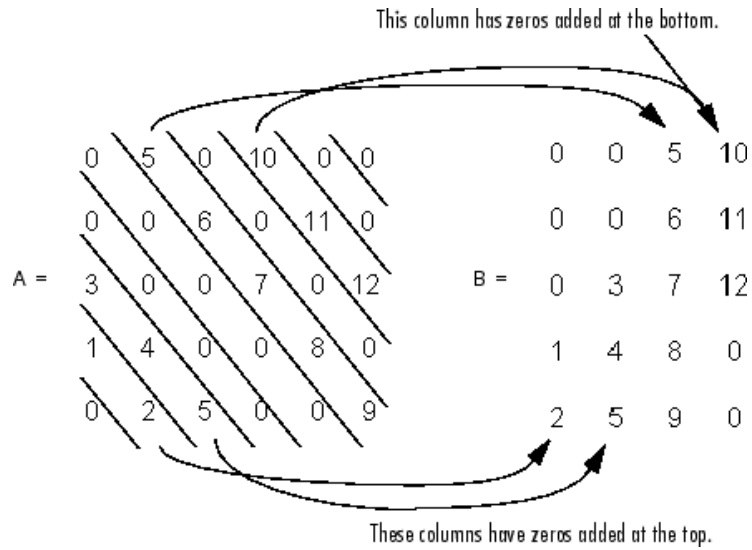

3

The columns of the first output **B** contain the nonzero diagonals of **A**. The second output **d** lists the indices of the nonzero diagonals of **A**, as shown in the following diagram. See “How the Diagonals of **A** are Listed in the Vector **d**” on page 1-6397.

Note that the longest nonzero diagonal in **A** is contained in column 3 of **B**. The other nonzero diagonals of **A** have extra zeros added to their corresponding columns in **B**, to give all columns of **B** the same length. For the nonzero diagonals below the main diagonal of **A**, extra zeros are added at the tops of columns. For the nonzero diagonals above the main diagonal of **A**, extra zeros are added at the bottoms of columns. This is illustrated by the following diagram.

## Example 2

This example generates a sparse tridiagonal representation of the classic second difference operator on  $n$  points.

```
e = ones(n,1);
A = spdiags([e -2*e e], -1:1, n, n)
```

Turn it into Wilkinson's test matrix (see gallery):

```
A = spdiags(abs(-(n-1)/2:(n-1)/2)', 0, A)
```

Finally, recover the three diagonals:

```
B = spdiags(A)
```

## Example 3

The second example is not square.

```
A = [11 0 13 0
 0 22 0 24]
```

```

 0 0 33 0
 41 0 0 44
 0 52 0 0
 0 0 63 0
 0 0 0 74]

```

Here  $m = 7$ ,  $n = 4$ , and  $p = 3$ .

The statement `[B,d] = spdiags(A)` produces `d = [-3 0 2]'` and

```

B = [41 11 0
 52 22 0
 63 33 13
 74 44 24]

```

Conversely, with the above `B` and `d`, the expression `spdiags(B,d,7,4)` reproduces the original `A`.

#### Example 4

This example shows how `spdiags` creates the diagonals when the columns of `B` are longer than the diagonals they are replacing.

```
B = repmat((1:6)', [1 7])
```

```
B =
```

```

 1 1 1 1 1 1 1
 2 2 2 2 2 2 2
 3 3 3 3 3 3 3
 4 4 4 4 4 4 4
 5 5 5 5 5 5 5
 6 6 6 6 6 6 6

```

```
d = [-4 -2 -1 0 3 4 5];
```

```
A = spdiags(B,d,6,6);
```

```
full(A)
```

```
ans =
```

```
1 0 0 4 5 6
1 2 0 0 5 6
1 2 3 0 0 6
0 2 3 4 0 0
1 0 3 4 5 0
0 2 0 4 5 6
```

## Example 5A

This example illustrates the use of the syntax `A = spdiags(B,d,m,n)`, under three conditions:

- `m` is equal to `n`
- `m` is greater than `n`
- `m` is less than `n`

The command used in this example is

```
A = full(spdiags(B, [-2 0 2], m, n))
```

where `B` is the 5-by-3 matrix shown below. The resulting matrix `A` has dimensions `m`-by-`n`, and has nonzero diagonals at `[-2 0 2]` (a sub-diagonal at -2, the main diagonal, and a super-diagonal at 2).

```
B =
 1 6 11
 2 7 12
 3 8 13
 4 9 14
 5 10 15
```

The first and third columns of matrix `B` are used to create the sub- and super-diagonals of `A` respectively. In all three cases though, these two outer columns of `B` are longer than the resulting diagonals of `A`. Because of this, only a part of the columns is used in `A`.

When `m == n` or `m > n`, `spdiags` takes elements of the super-diagonal in `A` from the lower part of the corresponding column of `B`, and elements

of the sub-diagonal in A from the upper part of the corresponding column of B.

When  $m < n$ , spdiags does the opposite, taking elements of the super-diagonal in A from the upper part of the corresponding column of B, and elements of the sub-diagonal in A from the lower part of the corresponding column of B.

**Part 1 – m is equal to n.**

A = full(spdiags(B, [-2 0 2], 5, 5))

Matrix B		== spdiags ==>		Matrix A
1    6    11				6    0    13    0    0
2    7    12				0    7    0    14    0
3    8    13				1    0    8    0    15
4    9    14				0    2    0    9    0
5    10   15				0    0    3    0    10

A(3,1), A(4,2), and A(5,3) are taken from the upper part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the lower part of B(:,3).

**Part 2 – m is greater than n.**

A = full(spdiags(B, [-2 0 2], 5, 4))

Matrix B		== spdiags ==>		Matrix A
1    6    11				6    0    13    0
2    7    12				0    7    0    14
3    8    13				1    0    8    0
4    9    14				0    2    0    9
5    10   15				0    0    3    0

Same as in Part A.

**Part 3 – m is less than n.**

A = full(spdiags(B, [-2 0 2], 4, 5))

Matrix B				Matrix A				
1	6	11		6	0	11	0	0
2	7	12		0	7	0	12	0
3	8	13	== spdiags ==>	3	0	8	0	13
4	9	14		0	4	0	9	0
5	10	15						

A(3,1) and A(4,2) are taken from the lower part of B(:,1).

A(1,3), A(2,4), and A(3,5) are taken from the upper part of B(:,3).

## Example 5B

Extract the diagonals from the first part of this example back into a column format using the command

```
B = spdiags(A)
```

You can see that in each case the original columns are restored (minus those elements that had overflowed the super- and sub-diagonals of matrix A).

## Part 1.

Matrix A						Matrix B		
6	0	13	0	0		1	6	0
0	7	0	14	0		2	7	0
1	0	8	0	15	== spdiags ==>	3	8	13
0	2	0	9	0		0	9	14
0	0	3	0	10		0	10	15

## Part 2.

Matrix A					Matrix B		
6	0	13	0		1	6	0
0	7	0	14		2	7	0
1	0	8	0	== spdiags ==>	3	8	13

```
0 2 0 9 0 9 14
0 0 3 0
```

### Part 3.

```
 Matrix A Matrix B
6 0 11 0 0 0 6 11

[diag](#) | [speye](#)

# specular

---

**Purpose** Calculate specular reflectance

**Syntax** `R = specular(Nx,Ny,Nz,S,V)`

**Description** `R = specular(Nx,Ny,Nz,S,V)` returns the reflectance of a surface with normal vector components `[Nx,Ny,Nz]`. `S` and `V` specify the direction to the light source and to the viewer, respectively. You can specify these directions as three vectors `[x,y,z]` or two vectors `[Theta Phi]` (in spherical coordinates).

The specular highlight is strongest when the normal vector is in the direction of  $(S+V)/2$  where `S` is the source direction, and `V` is the view direction.

The surface spread exponent can be specified by including a sixth argument as in `specular(Nx,Ny,Nz,S,V,spread)`.

<b>Purpose</b>	Sparse identity matrix
<b>Syntax</b>	<code>S = speye(m,n)</code> <code>S = speye([m n])</code> <code>S = speye(n)</code> <code>S = speye</code>
<b>Description</b>	<code>S = speye(m,n)</code> and <code>S = speye([m n])</code> form an m-by-n sparse matrix with 1s on the main diagonal. <code>S = speye(n)</code> abbreviates <code>speye(n,n)</code> . <code>S = speye</code> returns the sparse form of the 1-by-1 identity matrix.
<b>Examples</b>	<code>I = speye(1000)</code> forms the sparse representation of the 1000-by-1000 identity matrix, which requires only about 16 kilobytes of storage. This is the same final result as <code>I = sparse(eye(1000,1000))</code> , but the latter requires eight megabytes for temporary storage for the full representation.
<b>See Also</b>	<code>spalloc</code>   <code>spones</code>   <code>spdiags</code>   <code>sprand</code>   <code>sprandn</code>

# spfun

---

**Purpose** Apply function to nonzero sparse matrix elements

**Syntax** `f = spfun(fun,S)`

**Description** The `spfun` function selectively applies a function to only the *nonzero* elements of a sparse matrix `S`, preserving the sparsity pattern of the original matrix (except for underflow or if `fun` returns zero for some nonzero elements of `S`).

`f = spfun(fun,S)` evaluates `fun(S)` on the elements of `S` that are nonzero. `fun` is a function handle.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

**Tips** Functions that operate element-by-element, like those in the `elfun` directory, are the most appropriate functions to use with `spfun`.

**Examples** Given the 4-by-4 sparse diagonal matrix

```
S = spdiags([1:4]',0,4,4)
```

```
S =
 (1,1) 1
 (2,2) 2
 (3,3) 3
 (4,4) 4
```

Because `fun` returns nonzero values for all nonzero element of `S`, `f = spfun(@exp,S)` has the same sparsity pattern as `S`.

```
f =
 (1,1) 2.7183
 (2,2) 7.3891
 (3,3) 20.0855
 (4,4) 54.5982
```

whereas `exp(S)` has 1s where `S` has 0s.

```
full(exp(S))
```

```
ans =
```

```
 2.7183 1.0000 1.0000 1.0000
 1.0000 7.3891 1.0000 1.0000
 1.0000 1.0000 20.0855 1.0000
 1.0000 1.0000 1.0000 54.5982
```

**See Also**

```
function_handle
```

# sph2cart

---

**Purpose** Transform spherical coordinates to Cartesian

**Syntax** `[x,y,z] = sph2cart(azimuth,elevation,r)`

**Description** `[x,y,z] = sph2cart(azimuth,elevation,r)` transforms the corresponding elements of spherical coordinate arrays to Cartesian, or *xyz*, coordinates. *azimuth*, *elevation*, and *r* must all be the same size (or any of them can be scalar). *azimuth* and *elevation* are angular displacements in radians. *azimuth* is the counterclockwise angle in the *x-y* plane measured from the positive *x*-axis. *elevation* is the elevation angle from the *x-y* plane.

**Algorithms** The mapping from spherical coordinates to three-dimensional Cartesian coordinates is

```
x = r .* cos(elevation) .* cos(azimuth)
y = r .* cos(elevation) .* sin(azimuth)
z = r .* sin(elevation)
```

**See Also** `cart2pol` | `cart2sph` | `pol2cart`

## Purpose

Generate sphere

## Syntax

```
sphere
sphere(n)
[X,Y,Z] = sphere(n)
```

## Description

The `sphere` function generates the  $x$ -,  $y$ -, and  $z$ -coordinates of a unit sphere for use with `surf` and `mesh`.

`sphere` generates a sphere consisting of 20-by-20 faces.

`sphere(n)` draws a `surf` plot of an  $n$ -by- $n$  sphere in the current figure.

`[X,Y,Z] = sphere(n)` returns the coordinates of a sphere in three matrices that are  $(n+1)$ -by- $(n+1)$  in size. You draw the sphere with `surf(X,Y,Z)` or `mesh(X,Y,Z)`.

## Examples

### Plot Sphere

Generate and plot a sphere.

```
figure
sphere
```

# sphere

---

## Plot Multiple Spheres

Define  $x$ ,  $y$ , and  $z$  as coordinates of a sphere.

```
[x,y,z] = sphere;
```

Plot a sphere centered at the origin. Plot two more spheres centered at  $(3, -2, 0)$  and  $(0, 1, -3)$ .

```
figure
```

```
surf(x,y,z)

hold on
surf(x+3,y-2,z); % centered at (3,-2,0)
surf(x,y+1,z-3); % centered at (0,1,-3)
```

**See Also** [cylinder](#) | [axis](#)

# spinmap

---

**Purpose** Spin colormap

**Syntax** spinmap  
spinmap(t)  
spinmap(t,inc)  
spinmap('inf')

**Description** The spinmap function shifts the colormap RGB values by some incremental value. For example, if the increment equals 1, color 1 becomes color 2, color 2 becomes color 3, etc.

spinmap cyclically rotates the colormap for approximately five seconds using an incremental value of 2.

spinmap(t) rotates the colormap for approximately 10\*t seconds. The amount of time specified by t depends on your hardware configuration (e.g., if you are running MATLAB software over a network).

spinmap(t,inc) rotates the colormap for approximately 10\*t seconds and specifies an increment inc by which the colormap shifts. When inc is 1, the rotation appears smoother than the default (i.e., 2). Increments greater than 2 are less smooth than the default. A negative increment (e.g., -2) rotates the colormap in a negative direction.

spinmap('inf') rotates the colormap for an infinite amount of time. To break the loop, press **Ctrl+C**.

**See Also** colormap | colormapeditor

**Purpose** Cubic spline data interpolation

**Syntax**  
`yy = spline(x,Y,xx)`  
`pp = spline(x,Y)`

**Description** `yy = spline(x,Y,xx)` uses a cubic spline interpolation to find `yy`, the values of the underlying function `Y` at the values of the interpolant `xx`. For the interpolation, the independent variable is assumed to be the final dimension of `Y` with the breakpoints defined by `x`.

The sizes of `xx` and `yy` are related as follows:

- If `Y` is a scalar or vector, `yy` has the same size as `xx`.
- If `Y` is an array that is not a vector,
  - If `xx` is a scalar or vector, `size(yy)` equals `[d1, d2, ..., dk, length(xx)]`.
  - If `xx` is an array of size `[m1,m2,...,mj]`, `size(yy)` equals `[d1,d2,...,dk,m1,m2,...,mj]`.

`pp = spline(x,Y)` returns the piecewise polynomial form of the cubic spline interpolant for later use with `ppval` and the spline utility `unmkpp`. `x` must be a vector. `Y` can be a scalar, a vector, or an array of any dimension, subject to the following conditions:

- If `x` and `Y` are vectors of the same size, the not-a-knot end conditions are used.
- If `x` or `Y` is a scalar, it is expanded to have the same length as the other and the not-a-knot end conditions are used. (See Exceptions (1) below).
- If `Y` is a vector that contains two more values than `x` has entries, the first and last value in `Y` are used as the endslopes for the cubic spline. (See Exceptions (2) below.)

## Exceptions

- 1 If  $Y$  is a vector that contains two more values than  $x$  has entries, the first and last value in  $Y$  are used as the endslopes for the cubic spline. If  $Y$  is a vector, this means
  - $f(x) = Y(2:\text{end}-1)$
  - $df(\min(x)) = Y(1)$
  - $df(\max(x)) = Y(\text{end})$
- 2 If  $Y$  is a matrix or an  $N$ -dimensional array with  $\text{size}(Y,N)$  equal to  $\text{length}(x)+2$ , the following hold:
  - $f(x(j))$  matches the value  $Y(:, \dots, :, j+1)$  for  $j=1:\text{length}(x)$
  - $Df(\min(x))$  matches  $Y(:, :, \dots, 1)$
  - $Df(\max(x))$  matches  $Y(:, :, \dots, \text{end})$

---

**Note** You can also perform spline interpolation using the `interp1` function with the command `interp1(x,y,xx,'spline')`. Note that while `spline` performs interpolation on rows of an input matrix, `interp1` performs interpolation on columns of an input matrix.

---

## Examples

### Spline Interpolation of Sine Data

This generates a sine curve, then samples the spline over a finer mesh.

```
x = 0:10;
y = sin(x);
xx = 0:.25:10;
yy = spline(x,y,xx);
plot(x,y,'o',xx,yy)
```

### Spline Interpolation of Distribution and Specify Endpoint Slopes

This illustrates the use of clamped or complete spline interpolation where end slopes are prescribed. Zero slopes at the ends of an interpolant to the values of a certain distribution are enforced.

```
x = -4:4;
y = [0 .15 1.12 2.36 2.36 1.46 .49 .06 0];
cs = spline(x,[0 y 0]);
```

# spline

---

```
xx = linspace(-4,4,101);
plot(x,y,'o',xx,ppval(cs,xx),'-');
```

## Extrapolation Using Cubic Spline

The two vectors

```
t = 1900:10:1990;
p = [75.995 91.972 105.711 123.203 131.669 ...
 150.697 179.323 203.212 226.505 249.633];
```

represent the census years from 1900 to 1990 and the corresponding United States population in millions of people. The expression

```
spline(t,p,2000)
```

uses the cubic spline to extrapolate and predict the population in the year 2000. The result is

```
ans =
```

```
270.6060
```

### Spline Interpolation of Angular Data

The statements

```
x = pi*[0:.5:2];
y = [0 1 0 -1 0 1 0;
 1 0 1 0 -1 0 1];
pp = spline(x,y);
yy = ppval(pp, linspace(0,2*pi,101));
plot(yy(1,:),yy(2:,:), '-b',y(1,2:5),y(2,2:5),'or'), axis equal
```

generate the plot of a circle, with the five data points  $y(:,2), \dots, y(:,6)$  marked with o's. Note that this  $y$  contains two more values (i.e., two more columns) than does  $x$ , hence  $y(:,1)$  and  $y(:,end)$  are used as endslopes.

# spline

---

## Spline Interpolation of Sine and Cosine Data

The following code generates sine and cosine curves, then samples the splines over a finer mesh.

```
x = 0:.25:1;
Y = [sin(x); cos(x)];
xx = 0:.1:1;
YY = spline(x,Y,xx);
plot(x,Y(1,:), 'o',xx,YY(1,:), '-'); hold on;
```

```
plot(x,Y(2,:), 'o',xx,YY(2,:), ':'); hold off;
```

## Algorithms

A tridiagonal linear system (with, possibly, several right sides) is being solved for the information needed to describe the coefficients of the various cubic polynomials which make up the interpolating spline. `spline` uses the functions `ppval`, `mkpp`, and `unmkpp`. These routines form a small suite of functions for working with piecewise polynomials. For access to more advanced features, see the `interp1` reference page,

# spline

---

the command-line help for these functions, and the Curve Fitting Toolbox™ spline functions.

<b>Purpose</b>	Replace nonzero sparse matrix elements with ones
<b>Syntax</b>	$R = \text{spones}(S)$
<b>Description</b>	$R = \text{spones}(S)$ generates a matrix $R$ with the same sparsity structure as $S$ , but with 1's in the nonzero positions.
<b>Examples</b>	$c = \text{sum}(\text{spones}(S))$ is the number of nonzeros in each column. $r = \text{sum}(\text{spones}(S'))'$ is the number of nonzeros in each row. $\text{sum}(c)$ and $\text{sum}(r)$ are equal, and are equal to $\text{nnz}(S)$ .
<b>See Also</b>	<code>nnz</code>   <code>spalloc</code>   <code>spfun</code>

# spparms

---

**Purpose** Set parameters for sparse matrix routines

**Syntax**

```
spparms('key',value)
spparms
values = spparms
[keys,values] = spparms
spparms(values)
value = spparms('key')
spparms('default')
spparms('tight')
```

**Description** spparms('key',value) sets one or more of the *tunable* parameters used in the sparse routines. In ordinary use, you should never need to deal with this function.

The meanings of the key parameters are

'spumoni'	Sparse Monitor flag:
0	Produces no diagnostic output, the default
1	Produces information about choice of algorithm based on matrix structure, and about storage allocation
2	Also produces very detailed information about the sparse matrix algorithms
'thr_rel', 'thr_abs'	Minimum degree threshold is thr_rel*mindegree + thr_abs.
'exact_d'	Nonzero to use exact degrees in minimum degree. Zero to use approximate degrees.
'supernd'	If positive, minimum degree amalgamates the supernodes every supernd stages.
'rreduce'	If positive, minimum degree does row reduction every rreduce stages.

'wh_frac'	Rows with <code>density &gt; wh_frac</code> are ignored in <code>colmmd</code> .
'autommd'	Nonzero to use minimum degree (MMD) orderings with QR-based \ and /.
'autoamd'	Nonzero to use <code>colamd</code> ordering with the LU-based \ and /, and to use <code>amd</code> with Cholesky-based \ and /.
'piv_tol'	Pivot tolerance used by the LU-based \ and /.
'bandden'	Band density used by \ and / for banded matrices. Band density is defined as $(\# \text{ nonzeros in the band})/(\# \text{ nonzeros in a full band})$ . If <code>bandden = 1.0</code> , never use band solver. If <code>bandden = 0.0</code> , always use band solver. Default is <code>0.5</code> .
'umfpack'	Nonzero to use UMFPACK instead of the v4 LU-based solver in \ and /.
'sym_tol'	Symmetric pivot tolerance. See <code>lu</code> for more information about the role of the symmetric pivot tolerance.

`spparms`, by itself, prints a description of the current settings.

`values = spparms` returns a vector whose components give the current settings.

`[keys, values] = spparms` returns that vector, and also returns a character matrix whose rows are the keywords for the parameters.

`spparms(values)`, with no output argument, sets all the parameters to the values specified by the argument vector.

`value = spparms('key')` returns the current setting of one parameter.

`spparms('default')` sets all the parameters to their default settings.

`spparms('tight')` sets the minimum degree ordering parameters to their *tight* settings, which can lead to orderings with less fill-in, but which make the ordering functions themselves use more execution time.

The key parameters for `default` and `tight` settings are

# spparms

---

	<b>Keyword</b>	<b>Default</b>	<b>Tight</b>
values(1)	'spumoni'	0.0	
values(2)	'thr_rel'	1.1	1.0
values(3)	'thr_abs'	1.0	0.0
values(4)	'exact_d'	0.0	1.0
values(5)	'supernd'	3.0	1.0
values(6)	'rreduce'	3.0	1.0
values(7)	'wh_frac'	0.5	0.5
values(8)	'autommd'	1.0	
values(9)	'autoamd'	1.0	
values(10)	'piv_tol'	0.1	
values(11)	'bandden'	0.5	
values(12)	'umfpack'	1.0	
values(13)	'sym_tol'	0.001

<b>Purpose</b>	Sparse uniformly distributed random matrix
<b>Syntax</b>	<pre>R = sprand(S) R = sprand(m,n,density) R = sprand(m,n,density,rc)</pre>
<b>Description</b>	<p><code>R = sprand(S)</code> has the same sparsity structure as <code>S</code>, but uniformly distributed random entries.</p> <p><code>R = sprand(m,n,density)</code> is a random, <code>m</code>-by-<code>n</code>, sparse matrix with approximately <code>density*m*n</code> uniformly distributed nonzero entries (<code>0 &lt;= density &lt;= 1</code>).</p> <p><code>R = sprand(m,n,density,rc)</code> also has reciprocal condition number approximately equal to <code>rc</code>. <code>R</code> is constructed from a sum of matrices of rank one.</p> <p>If <code>rc</code> is a vector of length <code>lr</code>, where <code>lr &lt;= min(m,n)</code>, then <code>R</code> has <code>rc</code> as its first <code>lr</code> singular values, all others are zero. In this case, <code>R</code> is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• <code>sprand</code> uses the same random number generator as <code>rand</code>, <code>randi</code>, and <code>randn</code>. You control this generator with <code>rng</code>.</li></ul>
<b>See Also</b>	<code>sprandn</code>   <code>sprandsym</code>

# sprandn

---

**Purpose** Sparse normally distributed random matrix

**Syntax**  
R = sprandn(S)  
R = sprandn(m,n,density)  
R = sprandn(m,n,density,rc)

**Description** R = sprandn(S) has the same sparsity structure as S, but normally distributed random entries with mean 0 and variance 1.

R = sprandn(m,n,density) is a random, m-by-n, sparse matrix with approximately  $\text{density} * m * n$  normally distributed nonzero entries ( $0 \leq \text{density} \leq 1$ ).

R = sprandn(m,n,density,rc) also has reciprocal condition number approximately equal to rc. R is constructed from a sum of matrices of rank one.

If rc is a vector of length lr, where  $lr \leq \min(m,n)$ , then R has rc as its first lr singular values, all others are zero. In this case, R is generated by random plane rotations applied to a diagonal matrix with the given singular values. It has a great deal of topological and algebraic structure.

**Tips**

- sprandn uses the same random number generator as rand, randi, and randn. You control this generator with rng.

**See Also** sprand | sprandsym

<b>Purpose</b>	Sparse symmetric random matrix
<b>Syntax</b>	<pre>R = sprandsym(S) R = sprandsym(n,density) R = sprandsym(n,density,rc) R = sprandsym(n,density,rc,kind) R = sprandsym(S,[],rc,3)</pre>
<b>Description</b>	<p><code>R = sprandsym(S)</code> returns a symmetric random matrix whose lower triangle and diagonal have the same structure as <code>S</code>. Its elements are normally distributed, with mean 0 and variance 1.</p> <p><code>R = sprandsym(n,density)</code> returns a symmetric random, <code>n</code>-by-<code>n</code>, sparse matrix with approximately <code>density*n*n</code> nonzeros; each entry is the sum of one or more normally distributed random samples, and (<code>0 &lt;= density &lt;= 1</code>).</p> <p><code>R = sprandsym(n,density,rc)</code> returns a matrix with a reciprocal condition number equal to <code>rc</code>. The distribution of entries is nonuniform; it is roughly symmetric about 0; all are in <code>[-1,1]</code>.</p> <p>If <code>rc</code> is a vector of length <code>n</code>, then <code>R</code> has eigenvalues <code>rc</code>. Thus, if <code>rc</code> is a positive (nonnegative) vector then <code>R</code> is a positive (nonnegative) definite matrix. In either case, <code>R</code> is generated by random Jacobi rotations applied to a diagonal matrix with the given eigenvalues or condition number. It has a great deal of topological and algebraic structure.</p> <p><code>R = sprandsym(n,density,rc,kind)</code> is positive definite.</p> <ul style="list-style-type: none"><li>• If <code>kind = 1</code>, <code>R</code> is generated by random Jacobi rotation of a positive definite diagonal matrix. <code>R</code> has the desired condition number exactly.</li><li>• If <code>kind = 2</code>, <code>R</code> is a shifted sum of outer products. <code>R</code> has the desired condition number only approximately, but has less structure.</li></ul> <p><code>R = sprandsym(S,[],rc,3)</code> has the same structure as the matrix <code>S</code> and approximate condition number <code>1/rc</code>.</p>
<b>Tips</b>	<code>sprandsym</code> uses the same random number generator as <code>rand</code> , <code>randi</code> , and <code>randn</code> . You control this generator with <code>rng</code> .

# sprandsym

# sprintf

---

**Purpose** Format data into string

**Syntax**  
`str = sprintf(formatSpec,A1,...,An)`  
`[str,errmsg] = sprintf(formatSpec,A1,...,An)`

**Description** `str = sprintf(formatSpec,A1,...,An)` formats the data in arrays `A1,...,An` according to `formatSpec` in column order, and returns the results to string `str`.

`[str,errmsg] = sprintf(formatSpec,A1,...,An)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is empty.

## Input Arguments

### **formatSpec - Format of the output fields**

string

Format of the output fields, specified as a string.

The string can include a percent sign followed by a conversion character. The following table lists the available conversion characters and subtypes.

Value Type	Conversion	Details
Integer, signed	%d or %i	Base 10
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal), lowercase letters a–f
	%X	Same as %x, uppercase letters A–F

Value Type	Conversion	Details
Floating-point number	%f	Fixed-point notation
	%e	Exponential notation, such as 3.141593e+00
	%E	Same as %e, but uppercase, such as 3.141593E+00
	%g	The more compact of %e or %f, with no trailing zeros
	%G	The more compact of %E or %f, with no trailing zeros
	%bx or %bX %bo %bu	Double-precision hexadecimal, octal, or decimal value Example: %bx prints pi as 400921fb54442d18
	%tx or %tX %to %tu	Single-precision hexadecimal, octal, or decimal value Example: %tx prints pi as 40490fdb
Characters	%c	Single character
	%s	String of characters

The string can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

# sprintf

---

- Identifier

Order for processing inputs. Use the syntax *n*\$, where *n* represents the position of the value in the input list.

For example, '%3\$s %2\$s %1\$s %2\$s' prints inputs 'A', 'B', 'C' as follows: C B A B.

- Flags

' ' Left-justify. Example: %-5.2f

'+' Print sign character (+) for positive values. Example: %+5.2f

' ' Pad to field width with spaces before the value. Example: % 5.2f

'0' Pad to field width with zeros. Example: %05.2f

'#' Modify selected numeric conversions:

- For %o, %x, or %X, print 0, 0x, or 0X prefix.
- For %f, %e, or %E, print decimal point even when precision is 0.
- For %g or %G, do not remove trailing zeros or decimal point.

Example: %#5.0f

- Field width

Minimum number of characters to print. Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%12d', intmax) is equivalent to ('%\*d', 12, intmax).

- Precision

For %f, %e, or %E:      Number of digits to the right of the decimal point.  
 Example: '%6.4f' prints pi as '3.1416'

For %g or %G            Number of significant digits.  
 Example: '%6.4g' prints pi as ' 3.142'

Can be a number, or an asterisk (\*) to refer to an argument in the input list. For example, the input list ('%6.4f', pi) is equivalent to ('%\*.\*f', 6, 4, pi).

The string can also include combinations of the following:

- Literal text to print. To print a single quotation mark, include '' in formatSpec.
- Control characters, including:

%%	Percent character
\\	Backslash
\a	Alarm
\b	Backspace
\f	Form feed
\n	New line
\r	Carriage return
\t	Horizontal tab
\v	Vertical tab
\xN	Character whose ASCII code is the hexadecimal number, N
\N	Character whose ASCII code is the octal number, N

The following limitations apply to conversions:

# sprintf

---

- Numeric conversions print only the real component of complex numbers.
- If you specify a conversion that does not fit the data, such as a string conversion for a numeric value, MATLAB overrides the specified conversion, and uses %e.
- If you apply a string conversion (%s) to integer values, MATLAB converts values that correspond to valid character codes to characters. For example, '%s' converts [65 66 67] to ABC.

## **A1,...,An - Numeric or character arrays**

scalar | vector | matrix | multidimensional array

Numeric or character arrays, specified as a scalar, vector, matrix, or multidimensional array.

## **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char

## **Output Arguments**

### **str - Formatted text**

string

Formatted text, returned as a string.

### **errmsg - Error message**

string

Error message, returned as a string, when the operation is unsuccessful. Otherwise, errmsg is empty.

## **Tips**

- The sprintf function is similar to fprintf, but fprintf prints to a file or to the Command Window.
- Format specifiers for the reading functions sscanf and fscanf differ from the formats for the writing functions sprintf and fprintf. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

## Examples

### Floating-Point Formats

Format a floating-point number using %e, %f, and %g specifiers.

```
A = 1/eps;
str_e = sprintf('%0.5e',A)
str_f = sprintf('%0.5f',A)
str_g = sprintf('%0.5g',A)
```

```
str_e =
4.50360e+15
```

```
str_f =
4503599627370496.00000
```

```
str_g =
4.5036e+15
```

### Literal Text and Array Inputs

Combine literal text with array values to create a string.

```
formatSpec = 'The array is %dx%d.';
A1 = 2;
A2 = 3;
str = sprintf(formatSpec,A1,A2)
```

```
str =
The array is 2x3.
```

### Integer Format with Floating-Point Inputs

Explicitly convert double-precision values to integers.

```
str = sprintf('%d',round(pi))
```

```
str =
3
```

# sprintf

---

## Field Width

Specify the minimum width of the printed value.

```
str = sprintf('%025d',[123456])

str =
00000000000000000000000123456
```

The 0 flag in the %025d format specifier requests leading zeros in the output.

## Position Identifier (n\$)

Reorder the input values using the n\$ position identifier.

```
A1 = 'X';
A2 = 'Y';
A3 = 'Z';
formatSpec = ' %3$s %2$s %1$s';
str = sprintf(formatSpec,A1,A2,A3)

str =
 Z Y X
```

## Cell Array Inputs

Create a string from values in a cell array.

```
C = { 1, 2, 3 ;
 'AA', 'BB', 'CC' };

str = sprintf(' %d %s',C{:})

str =
 1 AA 2 BB 3 CC
```

The syntax C{:} creates a comma-separated list of arrays that contain the contents of each cell from C in column order. For example, C{1}==1 and C{2}=='AA'.

## Concepts

- “Formatting Strings”

**Purpose** Visualize sparsity pattern

**Syntax**

```
spy(S)
spy(S,markersize)
spy(S,'LineStyle')
spy(S,'LineStyle',markersize)
```

**Description** `spy(S)` plots the sparsity pattern of any matrix `S`.

`spy(S,markersize)`, where `markersize` is an integer, plots the sparsity pattern using markers of the specified point size.

`spy(S,'LineStyle')`, where `LineStyle` is a string, uses the specified plot marker type and color.

`spy(S,'LineStyle',markersize)` uses the specified type, color, and size for the plot markers.

`S` is usually a sparse matrix, but full matrices are acceptable, in which case the locations of the nonzero elements are plotted.

---

**Note** `spy` replaces `format +`, which takes much more space to display essentially the same information.

---

## Examples

### Plot Sparsity Pattern

This example plots the 60-by-60 sparse adjacency matrix of the connectivity graph of the Buckminster Fuller geodesic dome. This matrix also represents the soccer ball and the carbon-60 molecule.

```
B = bucky;
spy(B)
```

# sqrt

---

**Purpose** Square root

**Syntax** `B = sqrt(X)`

**Description** `B = sqrt(X)` returns the square root of each element of the array `X`. For the elements of `X` that are negative or complex, `sqrt(X)` produces complex results.

**Tips** See `sqrtm` for the matrix square root.

**Examples**

```
sqrt((-2:2)')
ans =
 0 + 1.4142i
 0 + 1.0000i
 0
 1.0000
 1.4142
```

**See Also** `nthroot` | `sqrtm` | `realsqrt`

<b>Purpose</b>	Matrix square root
<b>Syntax</b>	<pre>X = sqrtm(A) [X, resnorm] = sqrtm(A) [X, alpha, condest] = sqrtm(A)</pre>
<b>Description</b>	<p><math>X = \text{sqrtm}(A)</math> is the principal square root of the matrix <math>A</math>, i.e. <math>X^2 = A</math>. <math>X</math> is the unique square root for which every eigenvalue has nonnegative real part. If <math>A</math> has any eigenvalues with negative real parts then a complex result is produced. If <math>A</math> is singular then <math>A</math> may not have a square root. A warning is printed if exact singularity is detected.</p> <p><math>[X, \text{resnorm}] = \text{sqrtm}(A)</math> does not print any warning, and returns the residual, <math>\text{norm}(A - X^2, 'fro') / \text{norm}(A, 'fro')</math>.</p> <p><math>[X, \text{alpha}, \text{condest}] = \text{sqrtm}(A)</math> returns a stability factor <math>\text{alpha}</math> and an estimate <math>\text{condest}</math> of the matrix square root condition number of <math>X</math>. The residual <math>\text{norm}(A - X^2, 'fro') / \text{norm}(A, 'fro')</math> is bounded approximately by <math>n * \text{alpha} * \text{eps}</math> and the Frobenius norm relative error in <math>X</math> is bounded approximately by <math>n * \text{alpha} * \text{condest} * \text{eps}</math>, where <math>n = \max(\text{size}(A))</math>.</p>
<b>Tips</b>	<p>If <math>A</math> is real, symmetric and positive definite, or complex, Hermitian and positive definite, then so is the computed matrix square root.</p> <p>Some matrices, like <math>A = \begin{bmatrix} 0 &amp; 1 \\ 0 &amp; 0 \end{bmatrix}</math>, do not have any square roots, real or complex, and <code>sqrtm</code> cannot be expected to produce one.</p>
<b>Examples</b>	<p><b>Example 1</b></p> <p>A matrix representation of the fourth difference operator is</p> <pre>A =      5    -4     1     0     0     -4     6    -4     1     0      1    -4     6    -4     1      0     1    -4     6    -4      0     0     1    -4     5</pre>

This matrix is symmetric and positive definite. Its unique positive definite square root,  $Y = \text{sqrtm}(A)$ , is a representation of the second difference operator.

$$Y = \begin{bmatrix} 2 & -1 & -0 & -0 & -0 \\ -1 & 2 & -1 & 0 & -0 \\ 0 & -1 & 2 & -1 & 0 \\ -0 & 0 & -1 & 2 & -1 \\ -0 & -0 & -0 & -1 & 2 \end{bmatrix}$$

## Example 2

The matrix

$$A = \begin{bmatrix} 7 & 10 \\ 15 & 22 \end{bmatrix}$$

has four square roots. Two of them are

$$Y1 = \begin{bmatrix} 1.5667 & 1.7408 \\ 2.6112 & 4.1779 \end{bmatrix}$$

and

$$Y2 = \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}$$

The other two are  $-Y1$  and  $-Y2$ . All four can be obtained from the eigenvalues and vectors of  $A$ .

$$[V,D] = \text{eig}(A);$$
$$D = \begin{bmatrix} 0.1386 & 0 \\ 0 & 28.8614 \end{bmatrix}$$

The four square roots of the diagonal matrix D result from the four choices of sign in

$$S = \begin{pmatrix} -0.3723 & 0 \\ 0 & -5.3723 \end{pmatrix}$$

All four Ys are of the form

$$Y = V*S/V$$

The sqrtm function chooses the two plus signs and produces Y1, even though Y2 is more natural because its entries are integers.

# squeeze

---

**Purpose** Remove singleton dimensions

**Syntax** `B = squeeze(A)`

**Description** `B = squeeze(A)` returns an array `B` with the same elements as `A`, but with all singleton dimensions removed. A singleton dimension is any dimension for which `size(A,dim) = 1`. Two-dimensional arrays are unaffected by `squeeze`; if `A` is a row or column vector or a scalar (1-by-1) value, then `B = A`.

**Examples** Consider the 2-by-1-by-3 array `Y = rand(2,1,3)`. This array has a singleton column dimension — that is, there's only one column per page.

`Y =`

```
Y(:,:,1) = Y(:,:,2) =
 0.5194 0.0346
 0.8310 0.0535
```

```
Y(:,:,3) =
 0.5297
 0.6711
```

The command `Z = squeeze(Y)` yields a 2-by-3 matrix:

```
Z =
 0.5194 0.0346 0.5297
 0.8310 0.0535 0.6711
```

Consider the 1-by-1-by-5 array `mat= repmat(1,[1,1,5])`. This array has only one scalar value per page.

`mat =`

```
mat(:,:,1) = mat(:,:,2) =
 1 1
```

```
mat(:,:,3) = mat(:,:,4) =
 1 1
```

```
mat(:,:,5) =
 1
```

The command `squeeze(mat)` yields a 5-by-1 matrix:

```
squeeze(mat)
```

```
ans =
```

```
 1
 1
 1
 1
 1
```

```
size(squeeze(mat))
```

```
ans =
```

```
 5 1
```

## See Also

[reshape](#) | [shiftdim](#)

**Purpose** Convert state-space filter parameters to transfer function form

**Syntax** `[b,a] = ss2tf(A,B,C,D,iu)`

**Description** `ss2tf` converts a state-space representation of a given system to an equivalent transfer function representation.

`[b,a] = ss2tf(A,B,C,D,iu)` returns the transfer function

$$H(s) = \frac{B(s)}{A(s)} = C(sI - A)^{-1}B + D$$

of the system

$$\dot{x} = Ax + Bu$$

$$y = Cx + Du$$

from the `iu`-th input. Vector `a` contains the coefficients of the denominator in descending powers of  $s$ . The numerator coefficients are returned in array `b` with as many rows as there are outputs  $y$ . `ss2tf` also works with systems in discrete time, in which case it returns the  $z$ -transform representation.

The `ss2tf` function is part of the standard MATLAB language.

## Purpose

Read formatted data from string

## Syntax

```
A = sscanf(str, format)
A = sscanf(str, format, sizeA)
[A, count] = sscanf(...)
[A, count, errmsg] = sscanf(...)
[A, count, errmsg, nextindex] = sscanf(...)
```

## Description

`A = sscanf(str, format)` reads data from string `str`, converts it according to the `format`, and returns the results in array `A`. The `sscanf` function reapplies the `format` until either reaching the end of `str` or failing to match the `format`. If `sscanf` cannot match the `format` to the data, it reads only the portion that matches into `A` and stops processing. If `str` is a character array with more than one row, `sscanf` reads the characters in column order.

`A = sscanf(str, format, sizeA)` reads `sizeA` elements into `A`, where `sizeA` can be an integer or can have the form `[m,n]`.

`[A, count] = sscanf(...)` returns the number of elements that `sscanf` successfully reads.

`[A, count, errmsg] = sscanf(...)` returns an error message string when the operation is unsuccessful. Otherwise, `errmsg` is an empty string.

`[A, count, errmsg, nextindex] = sscanf(...)` returns one more than the number of characters scanned in `str`.

## Tips

- Format specifiers for the reading functions `sscanf` and `fscanf` differ from the formats for the writing functions `sprintf` and `fprintf`. The reading functions do not support a precision field. The width field specifies a minimum for writing but a maximum for reading.

## Input Arguments

### format

String enclosed in single quotation marks that describes each type of element (field). Includes one or more of the following specifiers.

Field Type	Specifier	Details
Integer, signed	%d	Base 10
	%i	Base determined from the values. Defaults to base 10. If initial digits are 0x or 0X, it is base 16. If initial digit is 0, it is base 8.
	%ld or %li	64-bit values, base 10, 8, or 16
Integer, unsigned	%u	Base 10
	%o	Base 8 (octal)
	%x	Base 16 (hexadecimal)
	%lu, %lo, %lx	64-bit values, base 10, 8, or 16
Floating-point number	%f	Floating-point fields can contain any of the following (not case sensitive): Inf, -Inf, NaN, or -NaN.
	%e	
	%g	
Character string	%s	Read series of characters, until find white space.
	%c	Read any single character, including white space. (To read multiple characters, specify field length.)
	%[...]	Read only characters in the brackets, until the first nonmatching character or white space.

Optionally:

- To skip fields, insert an asterisk (\*) after the percent sign (%). For example, to skip integers, specify %\*d.

- To specify the maximum width of a field, insert a number. For example, %10c reads exactly 10 characters at a time, including white space.
- To skip a specific set of characters, insert the literal characters in the *format*. For example, to read only the floating-point number from 'pi=3.14159', specify a *format* of 'pi=%f'.

**sizeA**

Dimensions of the output array *A*. Specify in one of the following forms:

- inf            Read to the end of the input string. (default)
- n*             Read at most *n* elements.
- [*m*,*n*]        Read at most *m*\**n* elements in column order. *n* can be inf, but *m* cannot.

When the *format* includes %s, *A* can contain more than *n* columns. *n* refers to elements, not characters.

**str**

Character string.

**Output Arguments**

**A**

An array. If the *format* includes:

- Only numeric specifiers, *A* is numeric. If *format* includes only 64-bit signed integer specifiers, *A* is of class int64. Similarly, if *format* includes only 64-bit unsigned integer specifiers, *A* is of class uint64. Otherwise, *A* is of class double. If *sizeA* is inf or *n*, then *A* is a column vector. If the input contains fewer than *sizeA* elements, MATLAB pads *A* with zeros.
- Only character or string specifiers (%c or %s), *A* is a character array. If *sizeA* is inf or *n*, *A* is a row vector. If the input contains fewer than *sizeA* characters, MATLAB pads *A* with char(0).

- A combination of numeric and character specifiers, *A* is numeric, of class `double`. MATLAB converts each character to its numeric equivalent. This conversion occurs even when the *format* explicitly skips all numeric values (for example, a *format* of `'%*d %s'`).

If MATLAB cannot match the input to the *format*, and the *format* contains both numeric and character specifiers, *A* can be numeric or character. The class of *A* depends on the values MATLAB reads before processing stops.

## **count**

Number of elements `sscanf` reads into *A*.

## **errmsg**

An error message string when `sscanf` cannot open the specified file. Otherwise, an empty string.

## **nextindex**

`sscanf` counts the number of characters `sscanf` reads from *str*, and then adds one.

## **Examples**

### **Example 1**

Read multiple floating-point values from a string:

```
s = '2.7183 3.1416';
A = sscanf(s, '%f ');
A =
 2.7183
 3.1416
```

### **Example 2**

Read an octal integer from a string, identified by the `'0'` prefix, using `%i` to preserve the sign:

```
sscanf('-010', '%i')
ans =
```

-8

### Example 3

Read numeric values from a two-dimensional character array. By default, `sscanf` reads characters in column order. To preserve the original order of the values, read one row at a time.

```
mixed = ['abc 45 6 ghi'; 'def 7 89 jkl'];

[nrows, ncols] = size(mixed);
for k = 1:nrows
 nums(k,:) = sscanf(mixed(k,:), '%*s %d %d %*s', [1, inf]);
end;

% type the variable name to see the result
nums =
 45 6
 7 89
```

### Example 4

`sscanf` finds one match for `%s`

```
[str count] = sscanf('ThisIsOneString', '%s')
str =
 ThisIsOneString
count =
 1
```

`sscanf` finds four matches for `%s`. Because it does not match space characters, there are no spaces in the output string:

```
[str count] = sscanf('These Are Four Strings', '%s')
str =
 TheseAreFourStrings
count =
 4
```

sscanf finds five word matches for %s and four space character matches for %c. Because the %c specifier does match a space character, the output string does include spaces:

```
[str count] = sscanf('Five strings and four spaces', '%s%c')
str =
 Five strings and four spaces
count =
 9
```

sscanf finds three word matches for %s and two numeric matches for %d. Because the format specifier has a mixed %d and %s format, sscanf converts all nonnumeric characters to numeric:

```
[str count] = sscanf('5 strings and 4 spaces', '%d%s%s%d%s');
str'
Columns 1 through 9
 5 115 116 114 105 110 103 115 97
Columns 10 through 18
 110 100 4 115 112 97 99 101 115
count
count =
 5
```

## Example 5

```
[str, count] = sscanf('one two three', '%c')
str =
 one two three
count =
 13
```

```
[str, count] = sscanf('one two three', '%13c')
str =
 one two three
count =
 1
```

```
[str, count] = sscanf('one two three', '%s')
str =
 onetwothree
count =
 3
```

```
[str, count] = sscanf('one two three', '%1s')
str =
 onetwothree
count =
 11
```

### Example 6

```
tempString = '78 F 72 F 64 F 66 F 49 F';

degrees = char(176);
tempNumeric = sscanf(tempString, ['%d' degrees 'F'])'
tempNumeric =
 78 72 64 66 49
```

fscanf | sprintf | textscan

# stack

---

**Purpose** Stack data from multiple variables into single variable

**Syntax**

```
T = stack(W,vars)
T = stack(W,vars,Name,Value)
[T,iw] = stack(___)
```

**Description** `T = stack(W,vars)` converts the wide table, `W`, into an equivalent table, `T`, that is in tall format. `stack` stacks up multiple variables from `W`, specified by `vars`, into a single variable in `T`. In general, `T` contains fewer variables, but more rows, than `W`.

The output table, `T`, contains a new categorical variable to indicate which variable in `W` the stacked data in each row came from. `stack` replicates data from the variables in `W` that are not stacked.

`T = stack(W,vars,Name,Value)` converts the table, `W`, to tall format with additional options specified by one or more `NAME,Value` pair arguments.

For example, you can specify variable names for the new and stacked variables in `W`.

`[T,iw] = stack( ___ )` also returns an index vector, `iw`, indicating the correspondence between rows in `T` and rows in `W`. You can use any of the previous input arguments.

## Input Arguments

### **W - Wide table**

table

Wide table, specified as a table.

### **vars - Variables in W to stack**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in `W` to stack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'NewDataVariableName', 'StackedData'` names the new data variable `StackedData`.

## **'ConstantVariables' - Variables other than vars to include in the output**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables other than `vars` to include in the output, specified as the comma-separated pair consisting of `'ConstantVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. `stack` replicates the data from the constant variables for each stacked entry from a row.

The default is all the variables in `W` not specified by `vars`. You can specify the `'ConstantVariables'` name-value pair argument to exclude variables not specified by `vars` or `'ConstantVariables'` from the output table, `T`.

## **'NewDataVariableName' - Name for the new data variable in T** string

Name for the new data variable in `T`, specified as the comma-separated pair consisting of `'NewDataVariableName'` and a string. The default is a concatenation of the names of the variables from `W` that are stacked up.

## **'IndexVariableName' - Name for the new indicator variable in T** string

Name for the new indicator variable in `T`, specified as the comma-separated pair consisting of `'IndexVariableName'` and a string. The default is a name based on `NewDataVariableName`.

## Output Arguments

### T - Tall table

table

Tall table, returned as a table. T contains a stacked data variable, a categorical indicator variable, and any constant variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

`stack` assigns the variable units and variable description property values from the first variable listed in `vars` to the corresponding `T.Properties.VariableUnits` and `T.Properties.VariableDescriptions` values for the new data variable.

### iw - Index to W

column vector

Index to W, returned as a column vector. The index vector, `iw`, identifies the row in the input table, W, containing the corresponding data. `stack` creates the `j`th row in the output table, T, using `W(iw(j), vars)`.

## Examples

### Stack Three Variables into One

Create a table containing test scores from three separate tests.

```
Test1 = [93;57;87;89];
```

```
Test2 = [89;77;92;86];
```

```
Test3 = [95;62;89;91];
```

```
W = table(Test1,Test2,Test3)
```

```
W =
```

Test1	Test2	Test3
93	89	95

```

57 77 62
87 92 89
89 86 91

```

The table contains four rows and three variables.

Stack the test scores into a single variable.

```
T = stack(W,1:3)
```

```
T =
```

Test1_Test2_Test3_Indicator	Test1_Test2_Test3
Test1	93
Test2	89
Test3	95
Test1	57
Test2	77
Test3	62
Test1	87
Test2	92
Test3	89
Test1	89
Test2	86
Test3	91

T contains twelve rows and two variables.

The categorical variable, Test1\_Test2\_Test3\_Indicator, identifies which test corresponds to the score in the stacked data variable, Test1\_Test2\_Test3.

### Stack Variables and Specify Variable Names

Create a table indicating the amount of snowfall at three locations from five separate storms.

```
Storm = [1;2;3;4;5];
Date = {'12/25/11';'1/2/12';'1/23/12';'2/7/12';'2/15/12'};
Natick = [20;5;13;0;17];
Boston = [18;9;21;5;12];
Worcester = [26;10;16;3;15];
```

```
W = table(Storm,Date,Natick,Boston,Worcester)
```

```
W =
```

Storm	Date	Natick	Boston	Worcester
1	'12/25/11'	20	18	26
2	'1/2/12'	5	9	10
3	'1/23/12'	13	21	16
4	'2/7/12'	0	5	3
5	'2/15/12'	17	12	15

The variables `Storm` and `Date` contain data that is constant at each location.

Stack the variables `Natick`, `Boston`, and `Worcester` into a single variable. Name the variable containing the stacked data, `Snowfall`, and name the new indicator variable, `Town`.

```
T = stack(W,{'Natick','Boston','Worcester'},...
 'NewDataVariableName','Snowfall',...
 'IndexVariableName','Town')
```

```
T =
```

Storm	Date	Town	Snowfall
1	'12/25/11'	Natick	20
1	'12/25/11'	Boston	18
1	'12/25/11'	Worcester	26

```

2 '1/2/12' Natick 5
2 '1/2/12' Boston 9
2 '1/2/12' Worcester 10
3 '1/23/12' Natick 13
3 '1/23/12' Boston 21
3 '1/23/12' Worcester 16
4 '2/7/12' Natick 0
4 '2/7/12' Boston 5
4 '2/7/12' Worcester 3
5 '2/15/12' Natick 17
5 '2/15/12' Boston 12
5 '2/15/12' Worcester 15

```

T contains three rows for each storm, and `stack` repeats the data in the constant variables, `Storm` and `Date`, accordingly.

The categorical variable, `Town`, identifies which variable in `W` contains the corresponding `Snowfall` data.

### Stack Variables and Output an Index Vector

Create a table containing estimated influenza rates along the east coast of the United States. Create a different variable for the Northeast, Mid Atlantic, and South Atlantic. Data Source: Google Flu Trends (<http://www.google.org/flutrends>).

```

Month = {'October'; 'November'; 'December'; ...
 'January'; 'February'; 'March'};
Year = [2005*ones(3,1); 2006*ones(3,1)];
NE = [1.1902; 1.3610; 1.5003; 1.7772; 2.1350; 2.2345];
MidAtl = [1.1865; 1.4120; 1.6043; 1.8830; 2.1227; 1.9920];
SAtl = [1.2730; 1.5820; 1.8625; 1.9540; 2.4803; 2.0203];

```

```
fluW = table(Month,Year,NE,MidAtl,SAtl)
```

```
fluW =
```

```

 Month Year NE MidAtl SAtl

```

'October'	2005	1.1902	1.1865	1.273
'November'	2005	1.361	1.412	1.582
'December'	2005	1.5003	1.6043	1.8625
'January'	2006	1.7772	1.883	1.954
'February'	2006	2.135	2.1227	2.4803
'March'	2006	2.2345	1.992	2.0203

The variables `Month` and `Year` contain data that is constant across the row.

Stack the variables `NE`, `MidAtl`, and `SAtl` into a single variable called `FluRate`. Name the new indicator variable `Region` and output an index vector, `ifluW`, to indicate the correspondence between rows in the input wide table, `fluW`, and the output tall table, `fluT`.

```
[fluT,ifluW] = stack(fluW,3:5,...
 'NewDataVariableName','FluRate',...
 'IndexVariableName','Region')
```

`fluT =`

Month	Year	Region	FluRate
'October'	2005	NE	1.1902
'October'	2005	MidAtl	1.1865
'October'	2005	SAtl	1.273
'November'	2005	NE	1.361
'November'	2005	MidAtl	1.412
'November'	2005	SAtl	1.582
'December'	2005	NE	1.5003
'December'	2005	MidAtl	1.6043
'December'	2005	SAtl	1.8625
'January'	2006	NE	1.7772
'January'	2006	MidAtl	1.883
'January'	2006	SAtl	1.954

'February'	2006	NE	2.135
'February'	2006	MidAtl	2.1227
'February'	2006	SAtl	2.4803
'March'	2006	NE	2.2345
'March'	2006	MidAtl	1.992
'March'	2006	SAtl	2.0203

```
ifluW =
```

```

1
1
1
2
2
2
3
3
3
4
4
4
5
5
5
6
6
6
```

`ifluW(5)` is 2. The fifth row in the output table, `fluT`, contains data from the second row in the input table `fluW`.

## Tips

- You can specify more than one group of data variables in `W`, and each group becomes a stacked data variable in `T`. Use a cell array to contain multiple values for `vars`, and a cell array of strings to contain multiple values for the `'NewDataVariableName'` name-value pair argument. All groups must contain the same number of variables.

# stack

---

[unstack](#) | [join](#)

**Purpose**

Stairstep graph

**Syntax**

```
stairs(Y)
stairs(X,Y)
stairs(____,LineStyleSpec)
stairs(____,Name,Value)

stairs(axes_handle, ____)

h = stairs(____)

[xb,yb] = stairs(____)
```

**Description**

`stairs(Y)` draws a stairstep graph of the elements in `Y`.

- If `Y` is a vector, then the `x`-axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stairs` draws one line per matrix column and the `x`-axis scale ranges from 1 to the number of rows in `Y`.

`stairs(X,Y)` plots the elements in `Y` at the locations specified in `X`. The inputs `X` and `Y` must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

`stairs( ____,LineStyleSpec)` specifies a line style, marker symbol, and color. Use this option with any of the input argument combinations in the previous syntaxes.

`stairs( ____,Name,Value)` specifies stairseries properties using one or more `Name,Value` pair arguments.

`stairs(axes_handle, ____)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

# stairs

---

`h = stairs( ___ )` returns a vector of stairseries object handles in `h`. When multiple stairseries are present, you can make changes to properties of a specific stairseries by specifying a particular handle.

`[xb,yb] = stairs( ___ )` does not create a plot, but returns matrices `xb` and `yb` of the same size, such that `plot(xb,yb)` plots the staircase graph.

## Input Arguments

### Y - Elements to plot

vector or matrix

Elements to plot, specified as a vector or matrix. When `Y` is a vector, `stairs` creates one stairseries. When `Y` is a matrix, `stairs` draws one line per matrix column and creates a separate stairseries for each column.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### X - Locations to plot elements in Y

vector or matrix

Locations to plot elements in `Y`, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### LineStyle - Line style, marker symbol, and color

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

**Example:** `':*r'`

### Data Types

char

### axes\_handle - Axes handle

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Marker','s','MarkerFaceColor','red'` plots the stairstep graph with red square markers.

For more information on `stairs` properties see `stairs`.

### 'LineStyle' - Line style

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
<code>'-'</code>	Solid line (default)
<code>'--'</code>	Dashed line
<code>':'</code>	Dotted line

Specifier	Line Style
'- . '	Dash-dot line
'none'	No line

**Example:** 'LineStyle', '- . '

### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar in points.

**Example:** 'LineWidth',0.75

### 'Color' - Color

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'Color', [0 1 0]

**Example:** 'Color', 'green'

**Example:** 'Color', 'g'

### 'Marker' - Marker symbol

'none' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

## 'MarkerEdgeColor' - Marker edge color

'auto' (default) | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

## 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

Example: 'MarkerFaceColor',[0 .8 1]

### 'MarkerSize' - Marker size

# stairs

---

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'MarkerSize',7

## Output Arguments

### **h - Stairseries object handle**

scalar or column vector

Stairseries object handle, specified as a scalar or column vector. This is a unique identifier, which you can use to query and modify the properties of a specific `stairs`.

### **xb - x values for use with plot**

vector or matrix

`x` values for use with `plot`, specified as a vector or matrix. `xb` contains the appropriate values such that `plot(xb,yb)` creates the staircase graph.

### **yb - y values for use with plot**

vector or matrix

`y` values for use with `plot`, specified as a vector or matrix. `yb` contains the appropriate values such that `plot(xb,yb)` creates the staircase graph.

## Examples

### **Plot Single Data Series**

Create a staircase plot of sine evaluated at 40 equally spaced values between 0 and  $4\pi$ .

```
X = linspace(0,4*pi,40);
Y = sin(X);
```

```
figure
stairs(Y)
```

The length of  $Y$  automatically determines and generates the  $x$ -axis scale.

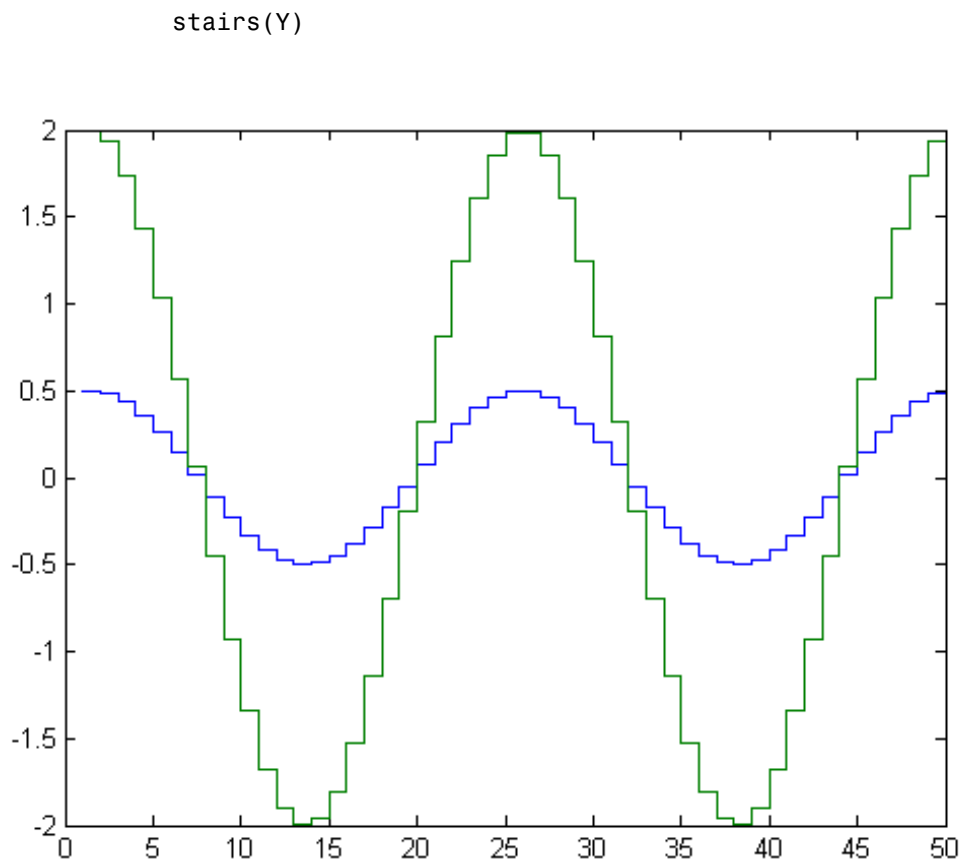

### Plot Multiple Data Series

Create a staircase plot of two cosine functions evaluated at 50 equally spaced values between 0 and  $4\pi$ .

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
```

```
figure
```

# stairs

The number of rows in  $Y$  automatically determines and generates the  $x$ -axis scale.

## Plot Single Data Series at Specified $x$ -Values

Create a staircase plot of a sine wave evaluated at equally spaced values between 0 and  $4\pi$ . Specify the set of  $x$ -values for the plot.

```
X = linspace(0,4*pi,40);
```

```
Y = sin(X);

figure
stairs(X,Y)
```

The entries in  $Y$  are plotted against the corresponding entries in  $X$ .

### Plot Multiple Data Series at Specified x-Values

Create a staircase plot of two cosine waves evaluated at equally spaced values between 0 and  $4\pi$ . Specify the set of  $x$ -values for the plot.

# stairs

---

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
```

```
figure
stairs(X,Y)
```

The first vector input,  $X$ , determines the  $x$ -axis positions for both data series.

### Plot Multiple Data Series at Unique Sets of x-Values

Create a staircase plot of two sine waves evaluated at different values. Specify a unique set of  $x$ -values for plotting each data series.

```
x1 = linspace(0,2*pi)';
x2 = linspace(0,pi)';
X = [x1,x2];
Y = [sin(5*x1),exp(x2).*sin(5*x2)];
```

```
figure
stairs(X,Y)
```

# stairs

Each column of X is plotted against the corresponding column of Y.

## **Specify Line Style, Marker Symbol and Color**

Create a staircase plot and set the line style to a dot-dashed line, the marker symbol to circles, and the color to red.

```
X = linspace(0,4*pi,20);
Y = sin(X);
```

```
figure
```

**Specify Additional Style Options**

Create a staircase plot and set the line width to 2, the marker symbols to diamonds, and the marker face color to cyan using Name, Value pair arguments.

```
X = linspace(0,4*pi,20);
Y = sin(X);
```

# stairs

```
figure
stairs(Y,'LineWidth',2,'Marker','d','MarkerFaceColor','c')
```

## Specify Axes for Stairstep Plots

Create a figure with two subplots and return the two axes handles, `s(1)` and `s(2)`. Create a stairstep plot in each subplot by referring to the axes handles.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

X = linspace(0,2*pi);
Y1 = 5*sin(X);
Y2 = sin(5*X);
stairs(s(1),X,Y1)
stairs(s(2),X,Y2)
```

## Set Marker Properties Using Stairseries Handle

Create a staircase plot of two data series and return the two stairseries handles in array h.

```
X = linspace(0,1,30)';
Y = [cos(10*X), exp(X).*sin(10*X)];
```

```
figure
h = stairs(X,Y);
```

Set the markers of the first series to small circles and the second series to magenta filled circles by referring to the handles.

```
set(h(1), 'Marker', 'o', 'MarkerSize', 4)
set(h(2), 'Marker', 'o', 'MarkerFaceColor', 'm')
```

# stairs

## Create a Stairstep Plot using plot Function

Evaluate two cosine functions at 50 equally spaced values between 0 and  $4\pi$  and create a stairstep plot using plot.

```
X = linspace(0,4*pi,50)';
Y = [0.5*cos(X), 2*cos(X)];
[xb,yb] = stairs(X,Y);
```

`stairs` returns two matrices of the same size, `xb` and `yb`, but no plot.

Use plot to create the staircase plot with xb and yb.

```
figure
plot(xb,yb)
```

# Stairseries Properties

---

**Purpose** Define stairseries properties

**Modifying Properties** You can set and query graphics object properties using the `set` and `get` commands or the Property Editor (`propertyeditor`).

Note that you cannot define default property values for stairseries objects.

See Plot Objects for information on stairseries objects.

## Stairseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

Annotation

`hg.Annotation` object (read-only)

*Control the display of stairseries objects in legends.* Specifies whether this stairseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stairseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the stairseries object in a legend as one entry, but not its children objects
off	Do not include the stairseries or its children in a legend (default)
children	Include only the children of the stairseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

### BeingDeleted

`on` | `{off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

### BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

# Stairseries Properties

---

*running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

The expression executes in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Children

array of graphics object handles

*Children of the stairseries object.* An array containing the handles of all line objects parented to the stairseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

ColorSpec

*Color of the object.* A three-element RGB vector or one of the MATLAB predefined names, specifying the object's color. The default value is `[0 0 0]` (black).

See the `ColorSpec` reference page for more information on specifying color. See “Adding Arrows and Lines to Graphs”.

# Stairseries Properties

---

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcb0`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

**DisplayName**  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the stairseries object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

**EraseMode**  
{normal} | none | xor | background

# Stairseries Properties

---

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property,

# Stairseries Properties

---

figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to on to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stairstep graph. If `HitTest` is off, clicking this object selects the object below it (which is usually the axes containing it).

`HitTestArea`  
`on | {off}`

Select the object by clicking lines or area of extent. Select plot objects by:

- Clicking lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is off, you must click the lines to select the object. When `HitTestArea` is on, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses the stairstep graph).

`Interruptible`  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.

# Stairseries Properties

---

- If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

BusyAction property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting Interruptible property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

LineStyle

{-} | -- | : | -. | none

*Line style of stairseries object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line

Specifier	Line Style
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

#### `LineWidth`

size in points

*Width of linear objects and edges of filled areas.* Specify in points. 1 point =  $\frac{1}{72}$  inch. The default is 0.5 points.

#### `Marker`

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

#### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond

# Stairseries Properties

---

Specifier	Marker Type
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' 'H'	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the Color property.

## MarkerFaceColor

ColorSpec | {none} | auto

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- ColorSpec — User-defined color.
- none — Makes the interior of the marker transparent, allowing the background to show through.
- auto — Sets the fill color to the axes Color property. If the axes Color property is none, sets the fill color to the figure Color.

MarkerSize  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the ' .' symbol) at one-third the specified size.

---

Parent  
handle of parent axes, hggroup, or hgtransform

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

Selected  
on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight  
{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

# Stairseries Properties

---

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag', 'area1'), 'FaceColor', 'red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stairseries objects, `Type` is `'hggroup'`. The following statement finds all the `hggroup` objects in the current axes object.

```
t = findobj(gca, 'Type', 'hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

- `on` — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- `off` — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-axis location of stairs.* The `stairs` function uses `XData` to label the *x*-axis. `XData` can be either a matrix equal in size to `YData` or a vector equal in length to the number of rows in `YData`. That is, `length(XData) == size(YData,1)`.

If you do not specify `XData` (which the input argument `X`), the `stairs` function uses the indices of `YData` to create the staircase graph. See the `XDataMode` property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify `XData` (by setting the `XData` property or specifying the `X` input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

# Stairseries Properties

---

If you set `XDataMode` to `auto` after specifying `XData`, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the `ZData`, overwriting any previous values for `XData`.

## `XDataSource`

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `XData`. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## `YData`

scalar | vector | matrix

*Stairs plot data.* `YData` contains the data plotted in the stairstep graph. Each value in `YData` is represented by a marker in the stairstep graph. If `YData` is a matrix, the `stairs` function creates a line for each column in the matrix.

The input argument `Y` in the `stairs` function calling syntax assigns values to `YData`.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the YData. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's YDataSource does not change the object's YData values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# standardizeMissing

---

**Purpose** Insert missing value indicators into table

**Syntax**  
B = standardizeMissing(A,id)  
B = standardizeMissing(A,id,'DataVariables',vars)

**Description** B = standardizeMissing(A,id) replaces all instances of the values specified in id occurring within table A with the standard missing value indicators. B is a table.

The standard missing value indicators depend on the data type:

- NaN for double and single floating-point arrays
- <undefined> for categorical arrays
- empty string, { ' ' }, for cell arrays of strings
- blank string, [ ' ' ], for character arrays

standardizeMissing checks double and single variables in A against numeric values from id and checks string and categorical variables in A against strings from id. The function standardizeMissing ignores integer data types because they cannot contain NaN.

B = standardizeMissing(A,id,'DataVariables',vars) replaces values only in variables specified by vars.

## Input Arguments

### A - Input table

table

Input table, specified as a table.

### id - Nonstandard missing value indicators

numeric vector | string | cell array containing numeric values and strings

Nonstandard missing value indicators, specified as a numeric vector, string, or cell array containing numeric values and strings.

### vars - Subset of variables to consider

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Subset of variables to consider, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

## Output Arguments

### B - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Replace All Instances of Specified Values

Create a table containing Inf and 'N/A' to represent missing values.

```
dblVar = [NaN;3;Inf;7;9];
cellstrVar = {'one';'three';'';'NA';'nine'};
charVar = ['A';'C';'E';' ';'I'];
categoryVar = categorical({'red';'yellow';'blue';'violet';''});
```

```
A = table(dblVar,cellstrVar,charVar,categoryVar)
```

A =

dblVar	cellstrVar	charVar	categoryVar
NaN	'one'	A	red
3	'three'	C	yellow
Inf	''	E	blue
7	'NA'		violet
9	'nine'	I	<undefined>

Replace all instances of Inf with NaN and replace all instances of 'NA' with the empty string, ''.

# standardizeMissing

---

```
B = standardizeMissing(A,{Inf,'NA'})
```

```
B =
```

dblVar	cellstrVar	charVar	categoryVar
NaN	'one'	A	red
3	'three'	C	yellow
NaN	''	E	blue
7	''		violet
9	'nine'	I	<undefined>

## Replace Only Values in Specified Variables

Replace instances of `Inf`, and `'N/A'`, occurring in specified variables of a table, with the standard missing value indicators.

Create a table containing `Inf` and `'N/A'` to represent missing values.

```
a = {'alpha';'bravo';'charlie';'';'N/A'};
x = [1;NaN;3;Inf;5];
y = [57;732;93;1398;Inf];
```

```
A = table(a,x,y)
```

```
A =
```

a	x	y
'alpha'	1	57
'bravo'	NaN	732
'charlie'	3	93
''	Inf	1398
'N/A'	5	Inf

For the variables `a` and `x`, replace instances of `Inf` with `NaN` and `'N/A'` with the empty string, `''`.

```
B = standardizeMissing(A,{Inf,'N/A'},'DataVariables',{ 'a', 'x' })
```

```
B =
```

a	x	y
'alpha'	1	57
'bravo'	NaN	732
'charlie'	3	93
''	NaN	1398
''	5	Inf

Inf in the variable y remains unchanged because y is not included in the 'DataVariables' name-value pair argument.

## Algorithms

`standardizeMissing` treats leading and trailing white space differently for cell arrays of strings, character arrays, and categorical arrays.

- For cell arrays of strings, `standardizeMissing` does not ignore white space. All strings must match exactly a string specified in `id`.
- For character arrays, `standardizeMissing` ignores trailing white space.
- For categorical arrays, `standardizeMissing` ignores leading and trailing white space.

# startup

---

**Purpose** Startup file for user-defined options

**Syntax** startup

**Description** startup executes commands of your choosing when the MATLAB program starts.

Create a `startup.m` file in your MATLAB “Startup Folder” on page 1-6508 and put in the file any commands you want executed at MATLAB startup. For example, your `startup.m` file might include physical constants, defaults for Handle Graphics properties, engineering conversion factors, or anything else you want predefined in your workspace.

**Algorithms** The MATLAB program executes the `matlabrc.m` file when it starts. `matlabrc.m` invokes `startup.m`, if it exists on the MATLAB search path.

You can extend this process to create additional startup files, if needed.

MathWorks does not recommend modifying the `matlabrc.m` file, except perhaps by system administrators in network configurations.

**Definitions** **Startup Folder**

The current folder in the MATLAB application when it starts. See “MATLAB Startup Folder”.

**See Also** finish | matlabrc | matlabroot | path | quit | userpath

**Concepts**

- “Specifying Startup Options in MATLAB Startup File”
- Preferences

**Purpose** Standard deviation

**Syntax**  
`s = std(X)`  
`s = std(X, flag)`  
`s = std(X, flag, dim)`

**Definitions** There are two common textbook definitions for the standard deviation `s` of a data vector `X`.

$$(1) s = \left( \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}}$$

$$(2) s = \left( \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^{\frac{1}{2}},$$

where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i$$

and  $n$  is the number of elements in the sample. The two forms of the equation differ only in  $n - 1$  versus  $n$  in the divisor.

**Description** `s = std(X)`, where `X` is a vector, returns the standard deviation using (1) above. The result `s` is the square root of an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

If `X` is a matrix, `std(X)` returns a row vector containing the standard deviation of the elements of each column of `X`. If `X` is a multidimensional array, `std(X)` is the standard deviation of the elements along the first nonsingleton dimension of `X`.

`s = std(X,flag)` for `flag = 0`, is the same as `std(X)`. For `flag = 1`, `std(X,1)` returns the standard deviation using (2) above, producing the second moment of the set of values about their mean.

`s = std(X,flag,dim)` computes the standard deviations along the dimension of `X` specified by scalar `dim`. Set `flag` to 0 to normalize `Y` by  $n-1$ ; set `flag` to 1 to normalize by  $n$ .

The input array, `X`, must be of type `double` or `single` for all syntaxes.

## Examples

For matrix `X`

```
X =
 1 5 9
 7 15 22
s = std(X,0,1)
s =
 4.2426 7.0711 9.1924
s = std(X,0,2)
s =
 4.000
 7.5056
```

## See Also

`corrcoef` | `cov` | `mean` | `median` | `var`

**Purpose** Plot discrete sequence data

**Syntax**

```
stem(Y)
stem(X,Y)
stem(__, 'fill')
stem(__, LineSpec)
stem(__, Name, Value)

stem(axes_handle, __)

h = stem(__)
```

**Description** `stem(Y)` plots the data sequence, `Y`, as stems that extend from a baseline along the  $x$ -axis. The data values are indicated by circles terminating each stem.

- If `Y` is a vector, then the  $x$ -axis scale ranges from 1 to `length(Y)`.
- If `Y` is a matrix, then `stem` plots all elements in a row against the same  $x$  value, and the  $x$ -axis scale ranges from 1 to the number of rows in `Y`.

`stem(X,Y)` plots the data sequence, `Y`, at values specified by `X`. The `X` and `Y` inputs must be vectors or matrices of the same size. Additionally, `X` can be a row or column vector and `Y` must be a matrix with `length(X)` rows.

- If `X` and `Y` are both vectors, then `stem` plots entries in `Y` against corresponding entries in `X`.
- If `X` is a vector and `Y` is a matrix, then `stem` plots each column of `Y` against the set of values specified by `X`, such that all elements in a row of `Y` are plotted against the same value.
- If `X` and `Y` are both matrices, then `stem` plots columns of `Y` against corresponding columns of `X`.

`stem(__, 'fill')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

# stem

---

`stem(___,LineStyleSpec)` specifies the line style, marker symbol, and color.

`stem(___,Name,Value)` specifies stemseries properties using one or more `Name,Value` pair arguments.

`stem(axes_handle,___)` plots into the axes specified by `axes_handle` instead of into the current axes (`gca`). The option, `axes_handle`, can precede any of the input argument combinations in the previous syntaxes.

`h = stem(___)` returns a vector of stemseries object handles in `h`. When multiple stemseries objects are present, you can make changes to properties of a specific stemseries by specifying a particular handle.

## Input Arguments

### **Y - Data sequence to display**

*vector or matrix*

Data sequence to display, specified as a vector or matrix. When `Y` is a vector, `stem` creates one stemseries. When `Y` is a matrix, `stem` creates a separate stemseries for each column.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### **X - Locations to plot data values in Y**

*vector or matrix*

Locations to plot data values in `Y`, specified as a vector or matrix. When `Y` is a vector, `X` must be a vector of the same size. When `Y` is a matrix, `X` must be a matrix of the same size, or a vector whose length equals the number of rows in `Y`.

#### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**LineStyle - Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

**Example:** `':*r'`

**Data Types**

char

**axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'LineStyle',':', 'MarkerFaceColor','red'` plots the stem as a dotted line and colors the marker face red.

For more information on these properties see `stemseries`.

**'LineStyle' - Line style**

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

**Example:** 'LineStyle','-.'

### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the stem and marker edge.

**Example:** 'LineWidth',0.75

### 'Color' - Color

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'Color', [0 1 0]

**Example:** 'Color', 'green'

**Example:** 'Color', 'g'

### 'Marker' - Marker symbol

'o' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle

Specifier	Marker Symbol
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

'auto' (default) | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

### 'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'MarkerSize',3.75

## Output Arguments

### h - Stemseries object handle

scalar or column vector

Stemseries object handle, returned as a scalar or column vector. This is a unique identifier, which you can use to query and modify the properties of a specific stemseries.

## Examples

### Plot Single Data Series

Create a stem plot of 50 data values between  $-2\pi$  and  $2\pi$ .

```
figure
Y = linspace(-2*pi,2*pi,50);
stem(Y)
```

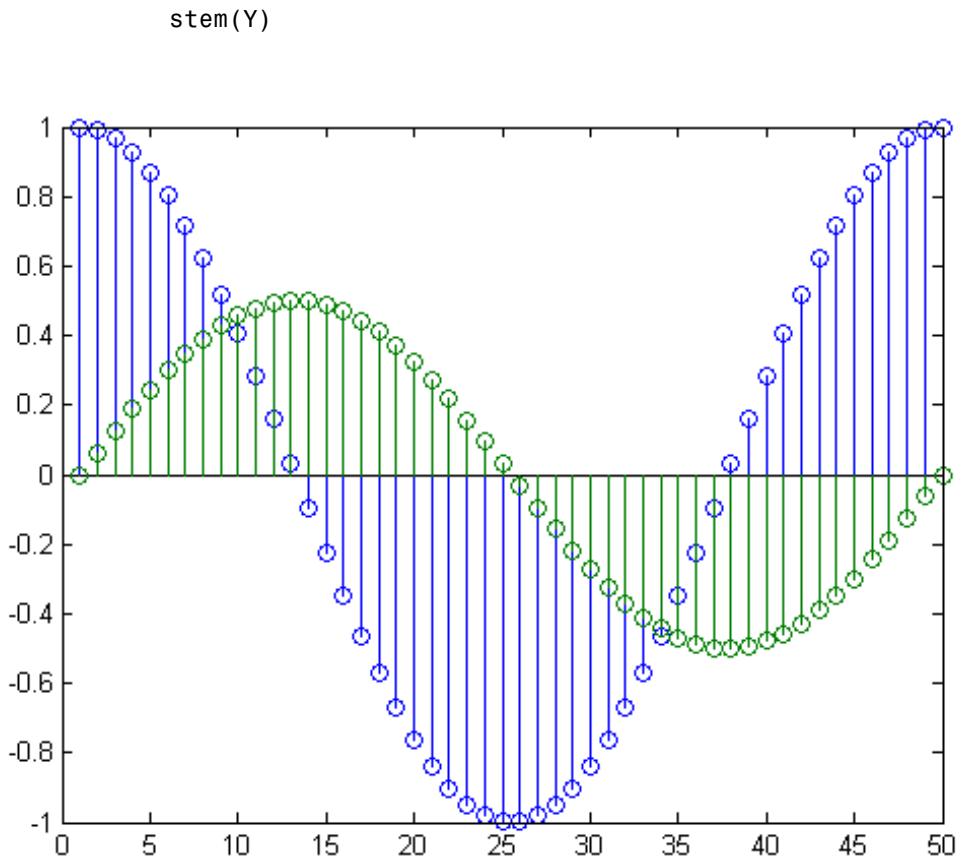

Data values are plotted as stems extending from the baseline and terminating at the data value. The length of  $Y$  automatically determines the position of each stem on the  $x$ -axis.

### Plot Multiple Data Series

Plot two data series using a two-column matrix.

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
```

# stem

Each column of  $Y$  is plotted as a separate series, and entries in the same row of  $Y$  are plotted against the same  $x$  value. The number of rows in  $Y$  automatically generates the position of each stem on the  $x$ -axis.

## Plot Single Data Series at Specified $x$ values

Plot 50 data values of cosine evaluated between 0 and  $2\pi$  and specify the set of  $x$  values for the stem plot.

```
figure
X = linspace(0,2*pi,50)';
Y = cos(X);
stem(X,Y)
```

The first vector input determines the position of each stem on the  $x$ -axis.

### Plot Multiple Data Series at Specified $x$ values

Plot 50 data values of sine and cosine evaluated between 0 and  $2\pi$  and specify the set of  $x$  values for the stem plot.

# stem

```
figure
X = linspace(0,2*pi,50)';
Y = [cos(X), 0.5*sin(X)];
stem(X,Y)
```

The vector input determines the  $x$ -axis positions for both data series.

## **Plot Multiple Data Series at Unique Sets of $x$ values**

Plot 50 data values of sine and cosine evaluated at different sets of  $x$  values. Specify the corresponding sets of  $x$  values for each series.

```
figure
x1 = linspace(0,2*pi,50)';
x2 = linspace(pi,3*pi,50)';
X = [x1, x2];
Y = [cos(x1), 0.5*sin(x2)];
stem(X,Y)
```

Each column of  $X$  is plotted against the corresponding column of  $Y$ .

# stem

---

## Fill in Plot Markers

Create a stem plot and fill in the circles that terminate each stem.

```
figure
X = linspace(0,10,20)';
Y = (exp(0.25*X));
stem(X,Y,'fill')
```

### Specify Stem and Marker Options

Create a stem plot and set the line style to a dotted line, the marker symbols to diamonds, and the color to red using the LineSpec option.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(X).*sin(X));
stem(X,Y,':diamondr')
```

To color the inside of the diamonds, use the 'fill' option.

## **Specify Additional Stem and Marker Options**

Create a stem plot and set the line style to a dot-dashed line, the marker face color to red, and the marker edge color to green using Name,Value pair arguments.

```
figure
X = linspace(0,2*pi,25)';
Y = (cos(2*X));
stem(X,Y,'LineStyle','-.-',...
 'MarkerFaceColor','red',...
 'MarkerEdgeColor','green')
```

The stem remains the default color.

### Specify Axes for Stem Plot

Create a figure with two subplots and return the handles to each axes, `s(1)` and `s(2)`. Create a stem plot in the lower subplot by referring to its axes handle, `s(2)`.

```
figure
s(1) = subplot(2,1,1);
```

# stem

---

```
s(2) = subplot(2,1,2);

X = 0:25;
Y = [exp(0.1*X); -exp(.05*X)]';
stem(s(2),X,Y)
```

## Return Stemseries Handle

Create a stem plot of multiple data series and return the handle to each stemseries.

```
figure
X = 0:25;
Y = [cos(X); exp(0.05*X)]';
h = stem(X,Y);
```

The `stem` function creates two `stemseries` objects, one for each column of data. The output argument, `h`, contains both `stemseries` handles.

Change the markers of the first series to blue circles and the second series to green squares using the handles.

# stem

```
set(h(1), 'MarkerFaceColor', 'blue')
set(h(2), 'MarkerFaceColor', 'green', 'Marker', 'square')
```

## Adjust Baseline Properties

Create a stem plot and change properties of the baseline.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
```

```
h = stem(X,Y);
```

Get the baseline handle, `hbase`. Adjust the style of the baseline by setting its `LineStyle` property.

```
hbase = get(h,'Baseline');
set(hbase,'LineStyle','--')
```

# stem

Make the baseline invisible by setting its `Visible` property to `'off'` .

```
set(hbase,'Visible','off')
```

### Change the Baseline Level

Create a stem plot and change the baseline level to 2.

```
figure
X = linspace(0,2*pi,50)';
Y = (exp(0.3*X).*sin(3*X));
h = stem(X,Y);
set(h,'BaseValue',2);
```

# stem

---

## Related Examples

- “Combine Stem Plot and Line Plot”

**Purpose** Plot 3-D discrete sequence data

**Syntax**

```
stem3(Z)
stem3(X,Y,Z)
stem3(__,'fill')
stem3(__,LineStyle)
stem3(__,Name,Value)

stem3(axes_handle, __)

h = stem3(__)
```

**Description** `stem3(Z)` plots entries in *Z* as stems extending from the *xy*-plane and terminating with circles at the entry values. The stem locations in the *xy*-plane are automatically generated.

`stem3(X,Y,Z)` plots entries in *Z* as stems extending from the *xy*-plane where *X* and *Y* specify the stem locations in the *xy*-plane. The inputs *X*, *Y*, and *Z* must be vectors or matrices of the same size.

`stem3(__,'fill')` fills the circles. Use this option with any of the input argument combinations in the previous syntaxes.

`stem3(__,LineStyle)` specifies the line style, marker symbol, and color.

`stem3(__,Name,Value)` specifies stemseries properties using one or more *Name,Value* pair arguments.

`stem3(axes_handle, __)` plots into the axes specified by *axes\_handle* instead of into the current axes (*gca*). The option, *axes\_handle*, can precede any of the input argument combinations in the previous syntaxes.

## Input Arguments

`h = stem3( ___ )` returns the stemseries handle `h`.

### **Z - Data sequence to display**

vector or matrix

Data sequence to display, specified as a vector or matrix. `stem3` plots each element in `Z` as a stem extending from the  $xy$ -plane and terminating at the data value.

- If `Z` is a row vector, `stem3` plots all elements against the same  $y$  value at equally spaced  $x$  values.
- If `Z` is a column vector, `stem3` plots all elements against the same  $x$  value at equally spaced  $y$  values.
- If `Z` is a matrix, `stem3` plots each row of `Z` against the same  $y$  value at equally spaced  $x$  values.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### **X - Locations to plot values of Z**

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

### **Y - Locations to plot values of Z**

vector or matrix

Locations to plot values of `Z`, specified as a vector or a matrix. Inputs `X`, `Y` and `Z` must be vectors or matrices of the same size.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical

**LineStyle - Line style, marker symbol, and color**

string

Line style, marker symbol, and color, specified as a string. For more information on line style, marker symbol, and color options see `LineStyle`.

**Example:** `':*r'`

**Data Types**

char

**axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'LineStyle',':', 'MarkerFaceColor','red'` plots the stem as a dotted line and sets the marker face color to red.

For more information on these properties see `stemseries`.

**'LineStyle' - Line style**

`'-'` (default) | `'--'` | `':'` | `'-.'` | `'none'`

Line style, specified as the comma-separated pair consisting of `'LineStyle'` and a line style specifier. This table lists supported line styles.

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

**Example:** 'LineStyle','-.'

### 'LineWidth' - Line width

0.5 (default) | scalar

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a scalar. The scalar sets the width size in points of the stem and marker edge.

**Example:** 'LineWidth',0.75

### 'Color' - Color

[0 0 1] (blue) (default) | three-element RGB vector | string

Color, specified as the comma-separated pair consisting of 'Color' and a three-element RGB vector or a string containing the short or long name of the color. The RGB vector is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

This table lists the predefined colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'Color', [0 1 0]

**Example:** 'Color', 'green'

**Example:** 'Color', 'g'

### 'Marker' - Marker symbol

'o' (default) | string

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and a marker specifier. This table lists supported marker symbols.

Specifier	Marker Symbol
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle

Specifier	Marker Symbol
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No marker

**Example:** 'Marker', '+'

**Example:** 'Marker', 'diamond'

### 'MarkerEdgeColor' - Marker edge color

'auto' (default) | 'none' | three-element RGB vector | string

Marker edge color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and a color value. The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as line color
'none'	Specifies no color, which makes unfilled markers invisible

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'

RGB Vector	Short Name	Long Name
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerEdgeColor',[1 .8 .1]

### 'MarkerFaceColor' - Marker face color

'none' (default) | 'auto' | three-element RGB vector | string

Marker face color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and a color value. MarkerFaceColor sets the fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles). The color value can be one of the supported strings or an RGB vector, listed in the following tables.

Specifier	Result
'auto'	Uses same color as marker edge color
'none'	Makes the interior of the marker transparent, allowing the background to show through (default)

For an RGB vector, use a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1]. This table lists the predefined string colors and their RGB equivalents.

# stem3

RGB Vector	Short Name	Long Name
[1 1 0]	'y'	'yellow'
[1 0 1]	'm'	'magenta'
[0 1 1]	'c'	'cyan'
[1 0 0]	'r'	'red'
[0 1 0]	'g'	'green'
[0 0 1]	'b'	'blue'
[1 1 1]	'w'	'white'
[0 0 0]	'k'	'black'

**Example:** 'MarkerFaceColor',[0 .8 1]

## 'MarkerSize' - Marker size

6 (default) | scalar

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a scalar in points.

**Example:** 'Markersize',12

## Output Arguments

### h - Stemseries object handle

scalar

Stemseries object handle, specified as a scalar. This is a unique identifier, which you can use to query and modify the properties of the stemseries.

## Examples

### Row Vector Input

Create a 3-D stem plot of cosine values between  $-\pi/2$  and  $\pi/2$  with a row vector input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = cos(X);
```

stem3 plots elements of Z against the same y value at equally space x values.

### Column Vector Input

Create a 3-D stem plot of cosine values between  $-\pi/2$  and  $\pi/2$  with a column vector input.

figure

## stem3

```
X = linspace(-pi/2,pi/2,40)';
Z = cos(X);
stem3(Z)
```

stem3 plots elements of Z against the same x value at equally spaced y values.

### Matrix Input

Create a 3-D stem plot of sine and cosine values between  $-\pi/2$  and  $\pi/2$  with a matrix input.

```
figure
X = linspace(-pi/2,pi/2,40);
Z = [sin(X); cos(X)];
stem3(Z)
```

## stem3

---

`stem3` plots each row of  $Z$  against the same  $y$  value at equally spaced  $x$  values.

### **Specify Stem Locations with Vector Inputs**

Create a 3-D stem plot and specify the stem locations along a curve. Use `view` to adjust the angle of the axes in the figure.

```
figure
X = linspace(-5,5,60);
Y = cos(X);
Z = X.^2;
stem3(X,Y,Z)
view(-8,30)
```

X and Y determine the stem locations. Z determines the marker heights.

### Specify Stem Locations with Matrix Inputs

Create a 3-D stem plot with matrix data and specify the stem locations in the  $xy$ -plane.

```
figure
[X,Y] = meshgrid(0:.1:1);
Z = exp(X+Y);
stem3(X,Y,Z)
```

## stem3

X and Y determine the stem locations. Z determines the marker heights.

### Fill in the Markers

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Use 'fill' to fill in the markers.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
```

```
stem3(Z,'fill')
```

### Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Use a dashed line style for the stem, set the marker symbols to stars, and set the color to magenta.

```
figure
X = linspace(-pi,pi,40);
```

## stem3

```
Z = cos(X);
stem3(Z, '--*m')
```

To specify only two of the three LineSpec options, omit the third option from the string. For example, '\*m' sets the marker symbol and the color and uses the default line style.

### Line Style, Marker Symbol, and Color Options

Create a 3-D stem plot and specify the stem locations along a circle. Set the stem to a dotted line style, the marker symbols to stars, and the color to magenta.

```
figure
theta = linspace(0,2*pi);
X = cos(theta);
Y = sin(theta);
Z = theta;
stem3(X,Y,Z,':*m')
```

## stem3

---

X and Y determine the stem locations. Z determines the marker heights.

### Additional Style Options

Create a 3-D stem plot of cosine values between  $-\pi$  and  $\pi$ . Set the marker symbols to squares with green faces and magenta edges.

```
figure
X = linspace(-pi,pi,40);
Z = cos(X);
stem3(Z,'Marker','s',...
```

```
'MarkerEdgeColor','m',...
'MarkerFaceColor','g')
```

### Axes Handles

Specify the axes for a 3-D stem plot.

Define vectors X, Y and Z.

```
X = linspace(-2,2,50);
```

## stem3

---

```
Y = X.^3;
Z = exp(X);
```

Create a figure with two subplots and return the handles to each axes, `s(1)` and `s(2)`. Plot a 3-D stem plot in the lower subplot by referring to its axes handle, `s(2)`. For comparison, plot a 2-D stem plot in the upper subplot by referring to its axes handle, `s(1)`.

```
figure
s(1) = subplot(2,1,1);
s(2) = subplot(2,1,2);

stem(s(1),X,Z)
stem3(s(2),X,Y,Z)
```

### Stemseries Handle

Create a 3-D stem plot and use the stemseries handle to adjust properties of the plot.

Get the handle for the stemseries.

```
figure
X = linspace(0,2);
Y = X.^3;
```

## stem3

```
Z = exp(X).*cos(Y);
h = stem3(X,Y,Z,'fill');
```

Set the color to magenta and the marker face color to yellow. Use `view` to adjust the angle of the axes in the figure.

```
set(h,'Color','m','MarkerFaceColor','y');
view(-10,35)
```

**See Also**

**Related Examples**

- “Combine Stem Plot and Line Plot”

# Stemseries Properties

---

## Purpose

Define stemseries properties

## Modifying Properties

You can set and query graphics object properties using the `set` and `get` commands or with the property editor (`propertyeditor`).

Note that you cannot define default properties for stemseries objects.

See Plot Objects for information on stemseries objects.

## Stemseries Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Control the display of stemseries objects in legends.* Specifies whether this stemseries object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the stemseries object is displayed in a figure legend.

IconDisplayStyle Value	Purpose
on	Include the stemseries object in a legend as one entry, but not its children objects
off	Do not include the stemseries or its children in a legend (default)
children	Include only the children of the stemseries as separate entries in the legend

## Setting the IconDisplayStyle Property

These commands set the `IconDisplayStyle` of a graphics object with handle `hobj` to `children`, which causes each child object to have an entry in the legend:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'children')
```

## Using the IconDisplayStyle Property

See “Control Legend Content” for more information and examples.

### BaseLine

handle

*Handle of the baseline object.* Handle of the line object used as the baseline. Set the properties of this line using its handle.

The following example makes the stem plot baseline a dashed, red line:

```
% Create stem plot
stem_handle = stem(randn(10,1));
% Obtain handle of baseline from stemseries object
baseline_handle = get(stem_handle, 'BaseLine');
% Set line properties
set(baseline_handle, 'LineStyle', '- -', 'Color', 'red')
```

### BaseValue

y-axis value

*Y-axis value where baseline is drawn.* Specify the value along the y-axis at which the MATLAB software draws the baseline.

### BeingDeleted

on | {off} (read-only)

# Stemseries Properties

---

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

`BusyAction`  
cancel | {queue}

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object. See the `HitTestArea` property for information about selecting objects of this type.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Children

array of graphics object handles

*Children of the stemseries object.* An array containing the handles of all line objects parented to the stemseries object (whether visible or not).

If a child object's `HandleVisibility` property is `callback` or `off`, its handle does not show up in this object's `Children` property. If you want the handle in the `Children` property, set the root `ShowHiddenHandles` property to `on`. For example:

```
set(0, 'ShowHiddenHandles', 'on')
```

## Clipping

{on} | off

# Stemseries Properties

---

*Clipping mode.* MATLAB clips graphs to the axes plot box by default. If you set `Clipping` to `off`, portions of graphs appear outside the axes plot box. This occurs if you create a plot object, set `hold` to `on`, freeze axis scaling (`axis manual`), and then create a larger plot object.

## Color

`ColorSpec`

*Color of stem lines.* A three-element RGB vector or one of the MATLAB predefined names, specifying the line color. See the `ColorSpec` reference page for more information on specifying color.

For example, the following statement creates a stem plot with red lines.

```
h = stem(randn(10,1),'Color','r');
```

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y,'CreateFcn',@CallbackFcn)
```

where `@CallbackFcn` is a function handle that references the callback function and `graphicfcn` is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

## DisplayName

string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the stemseries object in the legend. The default is an empty string.

# Stemseries Properties

---

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

## EraseMode

`{normal} | none | xor | background`

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- `normal` — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- `none` — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- `background` — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## `HandleVisibility`

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.

# Stemseries Properties

---

- **callback** — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- **off** — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

`{on}` | `off`

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the line objects that compose the stem plot. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## HitTestArea

`on` | `{off}`

*Select the object by clicking stem lines or area of extent.* Select plot objects by:

- Clicking stem lines (default).
- Clicking anywhere in the extent of the plot.

When `HitTestArea` is `off`, you must click the stem lines to select the object. When `HitTestArea` is `on`, you can select this object by clicking anywhere within the extent of the plot (that is, anywhere within a rectangle that encloses all the stem lines).

## Interruptible

`off` | `{on}`

# Stemseries Properties

---

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

**LineStyle**

{-} | -- | : | -. | none

*Line style of stemseries object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use **LineStyle** `none` when you want to place a marker at each point but do not want the points connected with a line (see the **Marker** property).

**LineWidth**

size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

# Stemseries Properties

---

## Marker

character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

### Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

ColorSpec | none | {auto}

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Specifies no color, which makes nonfilled markers invisible.
- `auto` — Uses same color as the `Color` property.

`MarkerFaceColor`

`ColorSpec` | `{none}` | `auto`

*Fill color for closed-shape markers.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `ColorSpec` — User-defined color.
- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Sets the fill color to the axes `Color` property. If the axes `Color` property is `none`, sets the fill color to the figure `Color`.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`Parent`

handle of parent axes, `hgggroup`, or `hgtransform`

# Stemseries Properties

---

*Parent of object.* Handle of the object's parent. The parent is normally the axes, hggroup, or hgtransform object that contains the object.

Selected

on | {off}

*Object selection state.* When you set this property to on, MATLAB displays selection handles at the corners and midpoints if the SelectionHighlight property is also on (the default). You can, for example, define the ButtonDownFcn callback to set this property to on, thereby indicating that this particular object is selected. This property is also set to on when an object is manually selected in plot edit mode.

SelectionHighlight

{on} | off

*Object highlighted when selected.*

- on — MATLAB indicates the selected state by drawing four edge handles and four corner handles.
- off — MATLAB does not draw the handles except when in plot edit mode and objects are selected manually.

Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the Tag property and the findobj function to manipulate specific objects within a plotting hierarchy.

For example, create a stemseries object and set the Tag property:

```
Y = linspace(-2*pi,2*pi,10);
t = stem(Y,'Tag','stem1')
```

To access the stemseries object, use `findobj` to find the object's handle. The following statement changes the `MarkerFaceColor` property of the object whose `Tag` is `stem1`.

```
set(findobj('Tag','stem1'),'MarkerFaceColor','red')
```

## Type

string (read-only)

*Type of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For stemseries objects, `Type` is `'hggroup'`. The following statement finds all `hggroup` objects in the current axes object.

```
t = findobj(gca,'Type','hggroup');
```

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## Visible

{on} | off

*Visibility of object and its children.*

# Stemseries Properties

---

- **on** — Object and all children of the object are visible unless the child object's `Visible` property is `off`.
- **off** — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

array

*X-axis location of stems.* The stem function draws an individual stem at each *x*-axis location in the XData array. XData can be either a matrix equal in size to YData or a vector equal in length to the number of rows in YData. That is, `length(XData) == size(YData,1)`. XData does not need to be monotonically increasing.

If you do not specify XData (which is the input argument X), the stem function uses the indices of YData to create the stem plot. See the XDataMode property for related information.

## XDataMode

{auto} | manual

*Use automatic or user-specified x-axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to `manual` and uses the specified values to label the *x*-axis.

If you set XDataMode to `auto` after specifying XData, MATLAB resets the *x*-axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h,'XDataSource','xdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

scalar | vector | matrix

*Stem plot data.* `YData` contains the data plotted as stems. Each value in `YData` is represented by a marker in the stem plot. If `YData` is a matrix, MATLAB creates a series of stems for each column in the matrix.

The input argument `Y` in the `stem` function calling syntax assigns values to `YData`.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h,'YDataSource','Ydatavariablename')
```

# Stemseries Properties

---

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

vector

*Z-coordinates.* A data defining the stems for 3-D stem graphs. `XData` and `YData` (if specified) must be the same size.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

# stopasync

---

<b>Purpose</b>	Stop asynchronous read and write operations
<b>Syntax</b>	<code>stopasync(obj)</code>
<b>Description</b>	<code>stopasync(obj)</code> stops any asynchronous read or write operation that is in progress for the serial port object, <code>obj</code> .

**Tips** You can write data asynchronously using the `fprintf` or `fwrite` function. You can read data asynchronously using the `readasync` function, or by configuring the `ReadAsyncMode` property to `continuous`. In-progress asynchronous operations are indicated by the `TransferStatus` property.

If `obj` is an array of serial port objects and one of the objects cannot be stopped, the remaining objects in the array are stopped and a warning is returned. After an object stops:

- Its `TransferStatus` property is configured to `idle`.
- Its `ReadAsyncMode` property is configured to `manual`.
- The data in its output buffer is flushed.

Data in the input buffer is not flushed. You can return this data to the MATLAB workspace using any of the synchronous read functions. If you execute the `readasync` function, or configure the `ReadAsyncMode` property to `continuous`, then the new data is appended to the existing data in the input buffer.

**See Also** `fprintf` | `fwrite` | `readasync` | `ReadAsyncMode` | `TransferStatus`

**Purpose** Convert string to double-precision value

**Syntax**  
`X = str2double('str')`  
`X = str2double(C)`

**Description** `X = str2double('str')` converts the string `str`, which should be an ASCII character representation of a real or complex scalar value, to the MATLAB double-precision representation. The string can contain digits, a comma (thousands separator), a decimal point, a leading + or - sign, an `e` preceding a power of 10 scale factor, and an `i` for a complex unit.

If `str` does not represent a valid scalar value, `str2double` returns NaN.

`X = str2double(C)` converts the strings in the cell array of strings `C` to double precision. The matrix `X` returned will be the same size as `C`.

**Examples** Here are some valid `str2double` conversions.

```
str2double('123.45e7')
str2double('123 + 45i')
str2double('3.14159')
str2double('2.7i - 3.14')
str2double({'2.71' '3.1415'})
str2double('1,200.34')
```

**See Also** `char` | `hex2num` | `num2str` | `str2num` | `cast`

# str2func

---

**Purpose** Construct function handle from function name string

**Syntax** `str2func('str')`

**Description** `str2func('str')` constructs a function handle `fhandle` for the function named in the string `'str'`. The contents of `str` can be the name of a file that defines a MATLAB function, or the name of an anonymous function.

You can create a function handle `fh` using any of the following four methods:

- Create a handle to a named function:

```
fh = @functionName;
fh = str2func('functionName');
```

- Create a handle to an anonymous function:

```
fh = @(x)functionDef(x);
fh = str2func('@(x)functionDef(x)');
```

You can create an array of function handles from strings by creating the handles individually with `str2func`, and then storing these handles in a cell array.

**Tips** Nested functions are not accessible to `str2func`. To construct a function handle for a nested function, you must use the function handle constructor, `@`.

Any variables and their values originally stored in a function handle when it was created are lost if you convert the function handle to a string and back again using the `func2str` and `str2func` functions.

## Examples **Example 1**

To convert the string, `'sin'`, into a handle for that function, type

```
fh = str2func('sin')
```

```
fh =
 @sin
```

### Example 2

If you pass a function name string in a variable, the function that receives the variable can convert the function name to a function handle using `str2func`. The example below passes the variable, `funcname`, to function `makeHandle`, which then creates a function handle. Here is the function:

```
function fh = makeHandle(funcname)
fh = str2func(funcname);
```

This is the code that calls `makeHandle` to construct the function handle:

```
makeHandle('sin')
ans =
 @sin
```

### Example 3

To call `str2func` on a cell array of strings, use the `cellfun` function. This returns a cell array of function handles:

```
fh_array = cellfun(@str2func, {'sin' 'cos' 'tan'}, ...
 'UniformOutput', false);
```

```
fh_array{2}(5)
ans =
 0.2837
```

### Example 4

In the following example, the `myminbnd` function expects to receive either a function handle or string in the first argument. If you pass a string, `myminbnd` constructs a function handle from it using `str2func`, and then uses that handle in a call to `fminbnd`:

```
function myminbnd(fhandle, lower, upper)
if ischar(fhandle)
```

```
 disp 'converting function string to function handle ...'
 fhandle = str2func(fhandle);
 end
 fminbnd(fhandle, lower, upper)
```

Whether you call `myminbnd` with a function handle or function name string, the function can handle the argument appropriately:

```
myminbnd('humps', 0.3, 1)
converting function string to function handle ...
ans =
 0.6370
```

## Example 5

The `dirByType` function shown here creates an anonymous function called `dirCheck`. What the anonymous function does depends upon the value of the `dirType` argument passed in to the primary function. The example demonstrates one possible use of `str2func` with anonymous functions:

```
function dirByType(dirType)
 switch(dirType)
 case 'class', leadchar = '@';
 case 'package', leadchar = '+';
 otherwise disp('ERROR: Unrecognized type'), return;
 end

 dirfile = @(fs)isdir(fs.name);
 dirCheckStr = ['@(fs)strcmp(fs.name(1,1),'', leadchar, '')'];
 dirCheckFun = str2func(dirCheckStr);
 s = dir; filecount = length(s);

 for k=1:filecount
 fstruct = s(k);
 if dirfile(fstruct) && dirCheckFun(fstruct)
 fprintf('%s folder: %s\n', dirType, fstruct.name)
 end
 end
end
```

Generate a list of class and package folders:

```
dirByType('class')
class folder: @Point
class folder: @asset
class folder: @bond

dirByType('package')
package folder: +containers
package folder: +event
package folder: +mypkg
```

[function\\_handle](#) | [func2str](#) | [functions](#)

# str2mat

---

**Purpose** Form blank-padded character matrix from strings

---

**Note** str2mat is not recommended. Use char instead.

---

**Syntax** S = str2mat(T1, T2, T3, ...)

**Description** S = str2mat(T1, T2, T3, ...) forms the matrix S containing the text strings T1, T2, T3, ... as rows. The function automatically pads each string with blanks in order to form a valid matrix. Each text parameter, Ti, can itself be a string matrix. This allows the creation of arbitrarily large string matrices. Empty strings are significant.

**Tips** str2mat differs from strvcat in that empty strings produce blank rows in the output. In strvcat, empty strings are ignored.

**Examples** x = str2mat('36842', '39751', '38453', '90307');

```
whos x
 Name Size Bytes Class
 x 4x5 40 char array
```

```
x(2,3)
```

```
ans =
```

```
7
```

**See Also** char

**Purpose** Convert string to number

**Syntax**

```
x = str2num('str')
[x, status] = str2num('str')
```

## Description

---

**Note** str2num uses the eval function to convert the input argument. Side effects can occur if the string contains calls to functions. Using str2double can avoid some of these side effects.

---

`x = str2num('str')` converts the string `str`, which is an ASCII character representation of a numeric value, to numeric representation. `str2num` also converts string matrices to numeric matrices. If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

The input string can contain one or more numbers separated by spaces, commas, or semicolons, such as '5', '10,11,12', or '5,10;15,20'. In addition to numerical values and delimiters, the input string can also include a decimal point, leading + or - signs, the letter e or d preceding a power of 10 scale factor, or the letter i or j indicating a complex or imaginary number.

The following table shows several examples of valid inputs to `str2num`:

String Input	Numeric Output	Output Class
'500'	500	1-by-1 scalar double
'500 250 125 67'	500, 250, 125, 67	1-by-4 row vector of double
'500; 250; 125; 62.5'	500.0000 250.0000 125.0000 62.5000	4-by-1 column vector of double

# str2num

String Input	Numeric Output	Output Class
'1 23 6 21; 53:56'	1 23 6 21 53 54 55 56	2-by-5 matrix of double
'12e-3 5.9e-3'	0.0120 0.0059	vector of double
'uint16(500)'	500	16-bit unsigned integer

---

**Note** `str2num` does not operate on cell arrays. To convert a cell array of strings to a numeric value, use `str2double`.

---

If the input string does not represent a valid number or matrix, `str2num(str)` returns the empty matrix in `x`.

`[x, status] = str2num('str')` returns the status of the conversion in logical `status`, where `status` equals logical 1 (true) if the conversion succeeds, and logical 0 (false) otherwise.

Space characters can be significant. For instance, `str2num('1+2i')` and `str2num('1 + 2i')` produce `x = 1+2i`, while `str2num('1 +2i')` produces `x = [1 2i]`. You can avoid these problems by using the `str2double` function.

## Examples

Input a character string that contains a single number. The output is a scalar double:

```
A = str2num('500')
A =
 500

class(A)
ans =
 double
```

Repeat this operation, but this time using an unsigned 16-bit integer:

```
A = str2num('uint16(500)')
A =
 500

class(A)
ans =
 uint16
```

Try three different ways of specifying a row vector. Each returns the same answer:

```
str2num('2 4 6 8') % Separate with spaces.
ans =
 2 4 6 8

str2num('2,4,6,8') % Separate with commas.
ans =
 2 4 6 8

str2num('[2 4 6 8]') % Enclose in brackets.
ans =
 2 4 6 8
```

Note that the first two of these commands do not need the MATLAB square bracket operator to create a matrix. The `str2num` function inserts the brackets for you if they are needed.

Use a column vector this time:

```
str2num('2; 4; 6; 8')
ans =
 2
 4
 6
 8
```

And now a 2-by-2 matrix:

# str2num

---

```
str2num('2 4; 6 8')
ans =
 2 4
 6 8
```

## See Also

[num2str](#) | [str2double](#) | [hex2num](#) | [sscanf](#) | [sparse](#) | [char](#) | [cast](#)  
| [special characters](#)

- Purpose** Concatenate strings horizontally
- Syntax** `combinedStr = strcat(s1,s2,...,sN)`
- Description** `combinedStr = strcat(s1,s2,...,sN)` horizontally concatenates strings in arrays. Inputs can be combinations of single strings, strings in scalar cells, character arrays with the same number of rows, and same-sized cell arrays of strings.
- If any input is a cell array, `combinedStr` is a cell array of strings. Otherwise, `combinedStr` is a character array.
  - For character array inputs, `strcat` removes trailing ASCII white-space characters: space, tab, vertical tab, newline, carriage return, and form-feed. For cell array inputs, `strcat` does not remove trailing white space.

## Examples

### Concatenate Two Strings

```
str = strcat('Good', 'morning')
```

```
str =
```

```
Goodmorning
```

### Concatenate Two Cell Arrays

```
a = {'abcde', 'fghi'};
```

```
b = {'jkl', 'mn'};
```

```
ab = strcat(a, b)
```

```
ab =
```

```
 'abcdejkl' 'fghimn'
```

## Concatenate Two Cell Arrays with Scalar Cell

```
a = {'abcde', 'fghi'};
b = {'jkl', 'mn'};
c = {'Q'};

abc = strcat(a, b, c)

abc =

 'abcdejklQ' 'fghimnQ'
```

## Input Arguments

### **s1,s2,...,sN** - Strings to horizontally concatenate

string | cell array of strings | character arrays

Strings to horizontally concatenate, specified as strings, cell arrays of strings, or character arrays with the same number of strings. When combining nonscalar cell arrays and multirow character arrays, cell arrays must be column vectors with the same number of rows as the character arrays.

### Data Types

char | cell

## Tips

- `strcat` strips trailing blank spaces. Adding a blank space at the end of the first string does not result in a blank space between the strings once concatenated.

```
str1 = strcat('Good ', 'morning')
```

```
str1 =
```

```
Goodmorning
```

Instead, add a blank space before the second string.

```
str2 = strcat('Good', ' morning')
```

```
str2 =
```

```
Good morning
```

- Strings can be horizontally concatenated using horizontal array concatenation. Horizontal array concatenation does not strip off trailing blank spaces from a string.

```
a = 'Good ';
b = 'Morning';

using_strcat = strcat(a, b)
using_arraycat = [a b] % Equivalent to horzcat(a, b)

using_strcat =

GoodMorning

using_arraycat =

Good Morning
```

**See Also**

cat | vertcat | horzcat | cellstr | strjoin | special character

# strcmp

---

**Purpose** Compare strings with case sensitivity

**Syntax** TF = strcmp(s1,s2)

**Description** TF = strcmp(s1,s2) compares two strings for equality. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or a scalar logical 0 for inequality. The comparison is case sensitive.

Inputs can be two strings, two same-sized cell arrays of strings, or a combination of a string and a cell array.

- If s1 , s2 are strings, TF is a logical scalar.
- If at least one input is a cell array of strings, TF is a logical array the same size as the cell array.

**Input Arguments** **s1,s2 - Strings or cell array of strings to compare**  
string | cell array of strings

Strings or cell array of strings to compare for equality, specified as two strings or a string and a cell array of strings or two equal-sized cell arrays of strings. The order of the inputs does not effect the comparison results.

**Data Types**  
char | cell

**Examples** **Compare Two Strings**

Use strcmp to compare two different strings.

```
strcmp('Yes' , 'No')
```

```
ans =
```

```
0
```

`strcmp` returns logical 0 (false) because the two strings are not equal. Use `strcmp` to compare two equal strings.

```
strcmp('Yes' , 'Yes')
```

```
ans =
```

```
1
```

The function `strcmp` returns logical 1 (true) because the two strings are equal.

### **Compare String and Cell Array of Strings**

Use `strcmp` to compare a string, 'upon', to each element of a cell array of strings.

```
a = 'upon';
b = {'Once' 'upon';
 'a' 'time'};
strcmp(a, b)
```

```
ans =
```

```
0 1
0 0
```

There is only one occurrence of string a in array b, and that occurs at element b{1, 2}.

### **Compare Two Cell Arrays of Strings**

Use `strcmp` to compare each element in a cell array of strings to the corresponding element in a second cell array of strings.

```
c = {'Time' 'flies' 'when';
 'you're' 'having' 'fun.'};
d = {'Time' 'drags' 'when';
 'you're' 'anxiously' 'waiting.'};
```

# strcmp

---

```
strcmp(c, d)
```

```
ans =
```

```
 1 0 1
 1 0 0
```

There are three instances of equal strings between `c` and `d`. These are 'Time' at indices {1, 1}, 'when' at indices {1, 3}, and 'you're' at indices {2, 1}.

## Tips

- The `strcmp` function is intended for comparison of character data. When you use it to compare numeric data, `strcmp` returns logical 0.
- For case insensitive string comparison, use `strcmpi` instead of `strcmp`.
- Any leading or trailing blanks are explicitly included in the comparison.
- The value returned by `strcmp` is not the same as the C language convention.
- `strcmp` supports international character sets.

## See Also

`regexp` | `regexpi` | `strcmpi` | `strfind` | `strncmp` | `strncmpi`

<b>Purpose</b>	Compare strings (case insensitive)
<b>Syntax</b>	TF = strcmpi(string,string) TF = strcmpi(string,cellstr) TF = strcmpi(cellstr,cellstr)
<b>Description</b>	<p>TF = strcmpi(string,string) compares two strings for equality, ignoring any differences in letter case. The strings are considered to be equal if the size and content of each are the same. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.</p> <p>TF = strcmpi(string,cellstr) compares a string with each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the cellstr input in which logical 1 represents equality. The order of the input arguments is not important.</p> <p>TF = strcmpi(cellstr,cellstr) compares each element of one cell array of strings with the same element of the other, ignoring letter case. The function returns a logical array the same size as the input arrays.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• The strcmpi function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.</li><li>• Use strcmp for case-sensitive string comparisons.</li><li>• Any leading and trailing blanks in either of the strings are explicitly included in the comparison.</li><li>• The value returned by strcmpi is not the same as the C language convention.</li><li>• strcmpi supports international character sets.</li></ul>
<b>Input Arguments</b>	<p><b>string</b> A single character string or n-by-1 array of strings.</p> <p><b>cellstr</b> A cell array of strings.</p>

# strcmpi

---

## Output Arguments

### TF

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

## Examples

Perform a simple case-insensitive comparison of two strings:

```
strcmpi('Yes', 'No')
ans =
 0
strcmpi('Yes', 'yes')
ans =
 1
```

---

Create two cell arrays of strings and call strcmpi to compare them:

```
A = {'Handle Graphics', 'Statistics'; ...
 'Toolboxes', 'MathWorks'};

B = {'Handle Graphics', 'Signal Processing'; ...
 'Toolboxes', 'MATHWORKS'};

match = strcmpi(A, B)
match =
 1 0
 0 1
```

The result of comparing the two cell arrays is:

- `match{1,1}` is 1 because “Handle Graphics” in `A{1,1}` matches the same text in `B{1,1}`.

- `match{1,2}` is 0 because “Statistics” in `A{1,2}` does not match “Signal Processing” in `B{1,2}`.
- `match{2,1}` is 0 because “ Toolboxes”, in `A{2,1}` contains leading space characters that are not in `B{2,1}`.
- `match{2,2}` is 1 because even though “MathWorks” in `A{2,2}` uses different letter case than “MATHWORKS” in `B{2,2}`, `strcmpi` performs the comparison without sensitivity to letter case.

# stream2

---

**Purpose** Compute 2-D streamline data

**Syntax**

```
XY = stream2(x,y,u,v,startx,starty)
XY = stream2(u,v,startx,starty)
XY = stream2(...,options)
```

**Description** `XY = stream2(x,y,u,v,startx,starty)` computes streamlines from vector data `u` and `v`.

The arrays `x` and `y`, which define the coordinates for `u` and `v`, must be monotonic, but do not need to be uniformly spaced. `x` and `y` must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XY` contains a cell array of vertex arrays.

`XY = stream2(u,v,startx,starty)` assumes the arrays `x` and `y` are defined as `[x,y] = meshgrid(1:n,1:m)` where `[m,n] = size(u)`.

`XY = stream2(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify a value, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream2`.

**Examples**

This example draws 2-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx,sy] = meshgrid(80,20:10:50);
streamline(stream2(x(:,:,5),y(:,:,5),u(:,:,5),v(:,:,5),sx,sy));
```

# stream3

---

**Purpose** Compute 3-D streamline data

**Syntax**

```
XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)
XYZ = stream3(U,V,W,startx,starty,startz)
XYZ = stream3(...,options)
```

**Description** `XYZ = stream3(X,Y,Z,U,V,W,startx,starty,startz)` computes streamlines from vector data `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`startx, starty, and startz` define the starting positions of the streamlines. The section "Specifying Starting Points for Stream Plots" provides more information on defining starting points.

The returned value `XYZ` contains a cell array of vertex arrays.

`XYZ = stream3(U,V,W,startx,starty,startz)` assumes the arrays `X, Y, and Z` are defined as `[X,Y,Z] = meshgrid(1:N,1:M,1:P)` where `[M,N,P] = size(U)`.

`XYZ = stream3(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB software uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 10000

Use the `streamline` command to plot the data returned by `stream3`.

**Examples**

This example draws 3-D streamlines from data representing air currents over regions of North America.

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamline(stream3(x,y,z,u,v,w,sx,sy,sz))
view(3)
```

# streamline

---

## Purpose

Plot streamlines from 2-D or 3-D vector data

## Syntax

```
streamline(X,Y,Z,U,V,W,startx,starty,startz)
streamline(U,V,W,startx,starty,startz)
streamline(XYZ)
streamline(X,Y,U,V,startx,starty)
streamline(U,V,startx,starty)
streamline(XY)
streamline(...,options)
streamline(axes_handle,...)
h = streamline(...)
```

## Description

`streamline(X,Y,Z,U,V,W,startx,starty,startz)` draws streamlines from 3-D vector data  $U$ ,  $V$ ,  $W$ .

The arrays  $X$ ,  $Y$ , and  $Z$ , which define the coordinates for  $U$ ,  $V$ , and  $W$ , must be monotonic, but do not need to be uniformly spaced.  $X$ ,  $Y$ , and  $Z$  must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, `startz` define the starting positions of the streamlines. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

`streamline(U,V,W,startx,starty,startz)` assumes the arrays  $X$ ,  $Y$ , and  $Z$  are defined as  $[X,Y,Z] = \text{meshgrid}(1:N,1:M,1:P)$ , where  $[M,N,P] = \text{size}(U)$ .

`streamline(XYZ)` assumes  $XYZ$  is a precomputed cell array of vertex arrays (as produced by `stream3`).

`streamline(X,Y,U,V,startx,starty)` draws streamlines from 2-D vector data  $U$ ,  $V$ .

The arrays  $X$  and  $Y$ , which define the coordinates for  $U$  and  $V$ , must be monotonic, but do not need to be uniformly spaced.  $X$  and  $Y$  must have the same number of elements, as if produced by `meshgrid`.

`startx` and `starty` define the starting positions of the streamlines. The output argument `h` contains a vector of line handles, one handle for each streamline.

`streamline(U,V,startx,starty)` assumes the arrays `X` and `Y` are defined as `[X,Y] = meshgrid(1:N,1:M)`, where `[M,N] = size(U)`.

`streamline(XY)` assumes `XY` is a precomputed cell array of vertex arrays (as produced by `stream2`).

`streamline(...,options)` specifies the options used when creating the streamlines. Define `options` as a one- or two-element vector containing the step size or the step size and the maximum number of vertices in a streamline:

```
[stepsize]
```

or

```
[stepsize, max_number_vertices]
```

If you do not specify values, MATLAB uses the default:

- Step size = 0.1 (one tenth of a cell)
- Maximum number of vertices = 1000

`streamline(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of the into current axes object (`gca`).

`h = streamline(...)` returns a vector of line handles, one handle for each streamline.

## Examples

### Draw Streamlines

Define arrays `x`, `y`, `u`, and `v`.

```
[x,y] = meshgrid(0:0.1:1,0:0.1:1);
u = x;
v = -y;
```

# streamline

Create a quiver plot of the data. Plot streamlines that start at different points along the line  $y = 1$ .

```
figure
quiver(x,y,u,v)

startx = 0.1:0.1:1;
starty = ones(size(startx));
streamline(x,y,u,v,startx,starty);
```

**How To**

- [Specifying Starting Points for Stream Plots](#)
- [Stream Line Plots of Vector Data](#)

# streamparticles

---

**Purpose** Plot stream particles

**Syntax**

```
streamparticles(vertices)
streamparticles(vertices,n)
streamparticles(...,'PropertyName',PropertyValue,...)
streamparticles(line_handle,...)
h = streamparticles(...)
```

**Description** `streamparticles(vertices)` draws stream particles of a vector field. Stream particles are usually represented by markers and can show the position and velocity of a streamline. `vertices` is a cell array of 2-D or 3-D vertices (as if produced by `stream2` or `stream3`).

`streamparticles(vertices,n)` uses `n` to determine how many stream particles to draw. The `ParticleAlignment` property controls how `n` is interpreted.

- If `ParticleAlignment` is set to `off` (the default) and `n` is greater than 1, approximately `n` particles are drawn evenly spaced over the streamline vertices.

If `n` is less than or equal to 1, `n` is interpreted as a fraction of the original stream vertices; for example, if `n` is 0.2, approximately 20% of the vertices are used.

`n` determines the upper bound for the number of particles drawn. The actual number of particles can deviate from `n` by as much as a factor of 2.

- If `ParticleAlignment` is `on`, `n` determines the number of particles on the streamline having the most vertices and sets the spacing on the other streamlines to this value. The default value is `n = 1`.

`streamparticles(...,'PropertyName',PropertyValue,...)` controls the stream particles using named properties and specified values. Any unspecified properties have default values. MATLAB ignores the case of property names.

## Stream Particle Properties

`Animate` — Stream particle motion [nonnegative integer]

The number of times to animate the stream particles. The default is 0, which does not animate. `Inf` animates until you enter **Ctrl+C**.

**FrameRate** — Animation frames per second [nonnegative integer]

This property specifies the number of frames per second for the animation. `Inf`, the default, draws the animation as fast as possible. Note that the speed of the animation might be limited by the speed of the computer. In such cases, the value of **FrameRate** cannot necessarily be achieved.

**ParticleAlignment** — Align particles with streamlines [on | {off}]

Set this property to `on` to draw particles at the beginning of each streamline. This property controls how `streamparticles` interprets the argument `n` (number of stream particles).

Stream particles are line objects. In addition to stream particle properties, you can specify any line object property, such as **Marker** and **EraseMode**. `streamparticles` sets the following line properties when called.

Line Property	Value Set by <code>streamparticles</code>
<code>EraseMode</code>	<code>xor</code>
<code>LineStyle</code>	<code>none</code>
<code>Marker</code>	<code>o</code>
<code>MarkerEdgeColor</code>	<code>none</code>
<code>MarkerFaceColor</code>	<code>red</code>

You can override any of these properties by specifying a property name and value as arguments to `streamparticles`. For example, this statement uses RGB values to set the `MarkerFaceColor` to medium gray:

```
streamparticles(vertices, 'MarkerFaceColor', [.5 .5 .5])
```

# streamparticles

---

`streamparticles(line_handle,...)` uses the line object identified by `line_handle` to draw the stream particles.

`h = streamparticles(...)` returns a vector of handles to the line objects it creates.

## Examples

This example combines streamlines with stream particle animation. The `interpstreamspeed` function determines the vertices along the streamlines where stream particles are drawn during the animation, thereby controlling the speed of the animation. Setting the figure `Renderer` property to `opengl` provides faster rendering.

```
load wind
figure('Renderer','opengl')
[sx,sy,sz] = meshgrid(80,20:1:55,5);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
sl = streamline(verts);
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.025);
axis tight manual; view(30,30); daspect([1 1 .125])
camproj perspective; camva(8)
box on
streamparticles(iverts,35,'animate',10,'ParticleAlignment','on')
```

The following picture is a static view of the animation.

This example uses the streamlines in the  $z = 5$  plane to animate the flow along these lines with streamparticles.

```
load wind
daspect([1,1,1]); view(2)
[verts,averts] = streamslice(x,y,z,u,v,w,[],[],[5]);
sl = streamline([verts averts]);
axis tight manual off;
set(sl,'Visible','off')
iverts = interpstreamspeed(x,y,z,u,v,w,verts,.05);
set(gca,'Position',[0 0 1 1],'ZLim',[4.9 5.1])
set(gcf,'Color','black')
streamparticles(iverts, 200, ...
 'Animate',100,'FrameRate',40, ...
 'MarkerSize',10,'MarkerFaceColor','yellow')
```

## How To

- [Creating Stream Particle Animations](#)
- [Specifying Starting Points for Stream Plots](#)

# streamribbon

---

**Purpose** 3-D stream ribbon plot from vector volume data

**Syntax**

```
streamribbon(X,Y,Z,U,V,W,startx,starty,startz)
streamribbon(U,V,W,startx,starty,startz)
streamribbon(vertices,X,Y,Z,cav,speed)
streamribbon(vertices,cav,speed)
streamribbon(vertices,twistangle)
streamribbon(...,width)
streamribbon(axes_handle,...)
h = streamribbon(...)
```

**Description** `streamribbon(X,Y,Z,U,V,W,startx,starty,startz)` draws stream ribbons from vector volume data `U`, `V`, `W`.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`.

`startx`, `starty`, and `startz` define the starting positions of the stream ribbons at the center of the ribbons. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The twist of the ribbons is proportional to the curl of the vector field. The width of the ribbons is calculated automatically.

`streamribbon(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamribbon(vertices,X,Y,Z,cav,speed)` assumes precomputed streamline vertices, curl angular velocity, and flow speed. `vertices` is a

cell array of streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, `cav`, and `speed` are 3-D arrays.

`streamribbon(vertices,cav,speed)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(cav)`.

`streamribbon(vertices,twistangle)` uses the cell array of vectors `twistangle` for the twist of the ribbons (in radians). The size of each corresponding element of `vertices` and `twistangle` must be equal.

`streamribbon(...,width)` sets the width of the ribbons to `width`.

`streamribbon(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamribbon(...)` returns a vector of handles (one per start point) to surface objects.

## Examples

This example uses stream ribbons to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream ribbons.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
axis tight
shading interp;
view(3);
camlight; lighting gouraud
```

# streamribbon

---

This example uses precalculated vertex data (`stream3`), curl average velocity (`curl1`), and speed  $\sqrt{u^2 + v^2 + w^2}$ . Using precalculated data enables you to use values other than those calculated from the single data source. In this case, the speed is reduced by a factor of 10 compared to the previous example.

figure

```
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
cav = curl(x,y,z,u,v,w);
spd = sqrt(u.^2 + v.^2 + w.^2).*0.1;
streamribbon(verts,x,y,z,cav,spd);
% Define viewing and lighting
axis tight
shading interp
view(3)
camlight; lighting gouraud
```

# streamribbon

---

This example specifies a twist angle for the stream ribbon.

```
figure
t = 0:.15:15;
verts = {[cos(t)' sin(t)' (t/3)']};
twistangle = {cos(t)'};
streamribbon(verts,twistangle);
% Define viewing and lighting
```

```
axis tight
shading interp;
view(3);
camlight; lighting gouraud
```

This example combines cone plots (coneplot) and stream ribbon plots in one graph.

# streamribbon

---

```
figure
% Define 3-D arrays x, y, z, u, v, w
xmin = -7; xmax = 7;
ymin = -7; ymax = 7;
zmin = -7; zmax = 7;
x = linspace(xmin,xmax,30);
y = linspace(ymin,ymax,20);
z = linspace(zmin,zmax,20);
[x y z] = meshgrid(x,y,z);
u = y; v = -x; w = 0*x+1;
[cx cy cz] = meshgrid(linspace(xmin,xmax,30),...
 linspace(ymin,ymax,30),[-3 4]);
h = coneplot(x,y,z,u,v,w,cx,cy,cz,'quiver');
set(h,'Color','k');

% Plot two sets of streamribbons
[sx sy sz] = meshgrid([-1 0 1],[-1 0 1],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);
[sx sy sz] = meshgrid([1:6],[0],-6);
streamribbon(x,y,z,u,v,w,sx,sy,sz);

% Define viewing and lighting
shading interp
view(-30,10) ; axis off tight
camproj perspective; camva(66); camlookat;
camdolly(0,0,.5,'fixtarget')
camlight
```

## How To

- “Volume Visualization”
- Displaying Curl with Stream Ribbons
- Specifying Starting Points for Stream Plots

# streamslice

---

## Purpose

Plot streamlines in slice planes

## Syntax

```
streamslice(X,Y,Z,U,V,W,startx,starty,startz)
streamslice(U,V,W,startx,starty,startz)
streamslice(X,Y,U,V)
streamslice(U,V)
streamslice(...,density)
streamslice(...,'arrowmode')
streamslice(...,'method')
streamslice(axes_handle,...)
h = streamslice(...)
[vertices arrowvertices] = streamslice(...)
```

## Description

`streamslice(X,Y,Z,U,V,W,startx,starty,startz)` draws well-spaced streamlines (with direction arrows) from vector data `U`, `V`, `W` in axis aligned  $x$ -,  $y$ -,  $z$ -planes at the points in the vectors `startx`, `starty`, `startz`. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The arrays `X`, `Y`, and `Z`, which define the coordinates for `U`, `V`, and `W`, must be monotonic, but do not need to be uniformly spaced. `X`, `Y`, and `Z` must have the same number of elements, as if produced by `meshgrid`. `U`, `V`, `W` must be  $m$ -by- $n$ -by- $p$  volume arrays.

Do not assume that the flow is parallel to the slice plane. For example, in a stream slice at a constant  $z$ , the  $z$  component of the vector field `W` is ignored when you are calculating the streamlines for that plane.

Stream slices are useful for determining where to start streamlines, stream tubes, and stream ribbons.

`streamslice(U,V,W,startx,starty,startz)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(X,Y,U,V)` draws well-spaced streamlines (with direction arrows) from vector volume data `U, V`.

The arrays `X` and `Y`, which define the coordinates for `U` and `V`, must be monotonic, but do not need to be uniformly spaced. `X` and `Y` must have the same number of elements, as if produced by `meshgrid`.

`streamslice(U,V)` assumes `X, Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamslice(...,density)` modifies the automatic spacing of the streamlines. `density` must be greater than 0. The default value is 1; higher values produce more streamlines on each plane. For example, 2 produces approximately twice as many streamlines, while 0.5 produces approximately half as many.

`streamslice(...,'arrowmode')` determines if direction arrows are present or not. `arrowmode` can be

- `arrows` — Draw direction arrows on the streamlines (default).
- `noarrows` — Do not draw direction arrows.

`streamslice(...,'method')` specifies the interpolation method to use. `method` can be

- `linear` — Linear interpolation (default)
- `cubic` — Cubic interpolation
- `nearest` — Nearest-neighbor interpolation

See `interp3` for more information on interpolation methods.

`streamslice(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

# streamslice

---

`h = streamslice(...)` returns a vector of handles to the line objects created.

`[vertices arrowvertices] = streamslice(...)` returns two cell arrays of vertices for drawing the streamlines and the arrows. You can pass these values to any of the streamline drawing functions (`streamline`, `streamribbon`, `streamtube`).

## Examples

### Plot Streamlines in Slice Plane

Load the wind data set. Draw a stream slice at  $z = 5$ .

```
load wind
```

```
figure
streamslice(x,y,z,u,v,w,[],[],[5])
axis tight
```

## See Also

[contourslice](#) | [slice](#) | [streamline](#) | [volumebounds](#) | [meshgrid](#) | [interp3](#) | [interp2](#) | [streamribbon](#) | [streamtube](#)

## How To

- [Specifying Starting Points for Stream Plots](#)

# streamtube

---

**Purpose** Create 3-D stream tube plot

**Syntax**

```
streamtube(X,Y,Z,U,V,W,startx,starty,startz)
streamtube(U,V,W,startx,starty,startz)
streamtube(vertices,X,Y,Z,divergence)
streamtube(vertices,divergence)
streamtube(vertices,width)
streamtube(vertices)
streamtube(...,[scale n])
streamtube(axes_handle,...)
h = streamtube(...z)
```

**Description** `streamtube(X,Y,Z,U,V,W,startx,starty,startz)` draws stream tubes from vector volume data `U, V, W`.

The arrays `X, Y, and Z`, which define the coordinates for `U, V, and W`, must be monotonic, but do not need to be uniformly spaced. `X, Y, and Z` must have the same number of elements, as if produced by `meshgrid`.

`startx, starty, and startz` define the starting positions of the streamlines at the center of the tubes. The section [Specifying Starting Points for Stream Plots](#) provides more information on defining starting points.

The width of the tubes is proportional to the normalized divergence of the vector field.

`streamtube(U,V,W,startx,starty,startz)` assumes `X, Y, and Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(U)`.

`streamtube(vertices,X,Y,Z,divergence)` assumes precomputed streamline vertices and divergence. `vertices` is a cell array of

streamline vertices (as produced by `stream3`). `X`, `Y`, `Z`, and divergence are 3-D arrays.

`streamtube(vertices,divergence)` assumes `X`, `Y`, and `Z` are determined by the expression

```
[X,Y,Z] = meshgrid(1:n,1:m,1:p)
```

where `[m,n,p] = size(divergence)`.

`streamtube(vertices,width)` specifies the width of the tubes in the cell array of vectors, `width`. The size of each corresponding element of `vertices` and `width` must be equal. `width` can also be a scalar, specifying a single value for the width of all stream tubes.

`streamtube(vertices)` selects the width automatically.

`streamtube(...,[scale n])` scales the width of the tubes by `scale`. The default is `scale = 1`. When the stream tubes are created, using start points or divergence, specifying `scale = 0` suppresses automatic scaling. `n` is the number of points along the circumference of the tube. The default is `n = 20`.

`streamtube(axes_handle,...)` plots into the axes object with the handle `axes_handle` instead of into the current axes object (`gca`).

`h = streamtube(...z)` returns a vector of handles (one per start point) to surface objects used to draw the stream tubes.

## Examples

This example uses stream tubes to indicate the flow in the wind data set. Inputs include the coordinates, vector field components, and starting location for the stream tubes.

```
figure
load wind
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
streamtube(x,y,z,u,v,w,sx,sy,sz);
% Define viewing and lighting
view(3)
axis tight
```

# streamtube

```
shading interp;
camlight; lighting gouraud
```

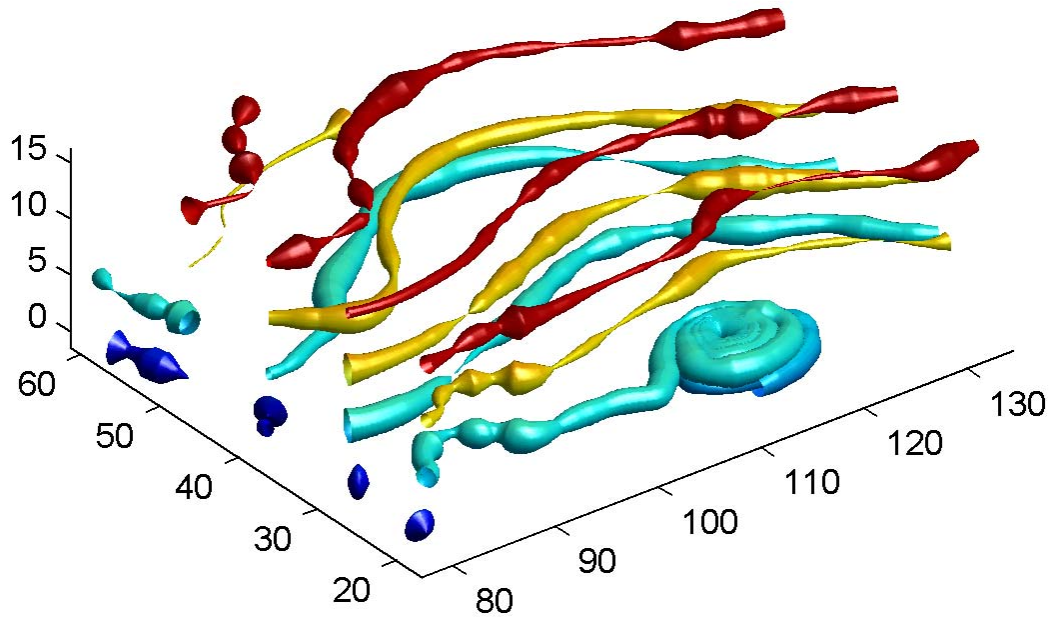

This example uses precalculated vertex data (`stream3`) and divergence (`divergence`).

```
figure
load wind
```

```
[sx sy sz] = meshgrid(80,20:10:50,0:5:15);
verts = stream3(x,y,z,u,v,w,sx,sy,sz);
div = divergence(x,y,z,u,v,w);
streamtube(verts,x,y,z,-div);
% Define viewing and lighting
view(3)
axis tight
shading interp
camlight; lighting gouraud
```

# streamtube

---

[divergence](#) | [streamribbon](#) | [streamline](#) | [stream3](#) | [meshgrid](#) | [stream3](#)

## How To

- [Displaying Divergence with Stream Tubes](#)
- [Specifying Starting Points for Stream Plots](#)

**Purpose** Find one string within another

**Syntax** `k = strfind(str, pattern)`

**Description** `k = strfind(str, pattern)` searches `str` for occurrences of `pattern`. The output, `k`, indicates the starting index of each occurrence of `pattern` in `str`. If `pattern` is not found `strfind` returns an empty array, `[]`. The `strfind` function executes a case sensitive search.

- If `str` is a string, `strfind` returns a vector of type `double`.
- If `str` is a cell array, `strfind` returns a cell array of vectors of type `double`.

### **Input Arguments**

#### **str - Data to be searched**

string | cell array of strings

Data to be searched, specified as a string or cell array of strings.

#### **Data Types**

char | cell

#### **pattern - Search pattern**

string

Search pattern, specified as a string.

#### **Data Types**

char

### **Output Arguments**

#### **k - Indices of occurrences of pattern**

array

Indices of occurrences of `pattern`, returned as an array. If `pattern` is not found, then `k` is an empty array, `[]`.

- If `str` is a string, `k` is an array of doubles indicating the index of each occurrence of `pattern`.

# strfind

---

- If `str` is a cell array of strings, `k` is a cell array with each element being an array of type `double` corresponding to the indices of each occurrence of `pattern` in the corresponding element of `str`.

## Examples

### Find String Pattern

Define string `S` as follows:

```
S = 'Find the starting indices of the pattern string';
```

Find the pattern `in` in string `S`.

```
k = strfind(S, 'in')
```

```
k =
```

```
 2 15 19 45
```

There are four instances of the substring, `in`, found in `S`.

Find the pattern `In` in string `S`.

```
k = strfind(S, 'In')
```

```
k =
```

```
 []
```

Since `strfind` is case sensitive, the string, `In`, is not found in `S`, `k` is an empty array.

Find the blank spaces in string `S`.

```
k = strfind(S, ' ')
```

```
k =
```

```
 5 9 18 26 29 33 41
```

There are seven occurrences of blank spaces in the string S.

### Find String in Cell Array of Strings

Define the cell array of strings, `cstr`, as follows:

```
cstr = {'How much wood would a woodchuck chuck';
 'if a woodchuck could chuck wood?'};
```

Find the pattern, `wood`, in cell array `cstr`.

```
idx = strfind(cstr, 'wood')
```

```
idx =
```

```
 [1x2 double]
 [1x2 double]
```

Examine the output cell array to find the instances of `wood`.

```
idx{:,:}
```

```
ans =
```

```
 10 23
```

```
ans =
```

```
 6 28
```

The pattern, `wood`, occurs at indices 10 and 23 in the first string and at indices 6 and 28 in the second string.

### Tips

- The `strfind` function does not find a pattern of empty strings, `''`, within `str`.

# strfind

---

## See Also

strtok | strcmp | strncmp | strcmpi | strncmpi | regexp | regexpi  
| regexprep | strrep | strsplit

**Purpose**

String handling

**Syntax**

```
S = 'Any Characters'
S = [S1 S2 ...]
C = {S1 S2 ...}
S = strcat(S1, S2, ...)
S = char(S1, S2, ...)
S = char(X)
X = double(S)
```

**Description**

`S = 'Any Characters'` creates a character array, or string. The string is actually a vector that contains the numeric codes for the characters (codes 0 to 127 are ASCII). The length of `S` is the number of characters. A quotation within the string is indicated by two quotation marks.

`S = [S1 S2 ...]` concatenates character arrays `S1`, `S2`, etc. into a new character array, `S`.

`C = {S1 S2 ...}` creates a cell array of strings. Separate each row of the cell array with a semicolon (;).

`S = strcat(S1, S2, ...)` horizontally concatenates `S1`, `S2`, etc., which can be character arrays or cell arrays of strings. If the inputs are character arrays, `strcat` removes trailing white space. For more information, see the `strcat` reference page.

`S = char(S1, S2, ...)` vertically concatenates character arrays `S1`, `S2`, etc., padding each input string as needed so that each row contains the same number of characters.

`S = char(X)` converts an array that contains positive integers representing numeric codes into a MATLAB character array.

`X = double(S)` converts the string to its equivalent integer numeric codes.

**Tips**

- To convert between character arrays and cell arrays of strings, use `char` and `cellstr`. Most string functions support both types.

# strings

---

- To determine whether S is a character array or cell array, call `ischar(S)` or `iscellstr(S)`.

## Examples

Create a simple string that includes a single quote.

```
msg = 'You're right!'
```

```
msg =
You're right!
```

Create the string name using two methods of concatenation.

```
name = ['Thomas' ' R. ' 'Lee']
name = strcat('Thomas', ' R.', ' Lee')
```

Create a character array of strings.

```
C = char('Hello', 'Goodbye', 'Yes', 'No')
```

```
C =
Hello
Goodbye
Yes
No
```

Create a cell array of strings.

```
S = {'Hello' 'Goodbye'; 'Yes' 'No'}
```

```
S =
 'Hello' 'Goodbye'
 'Yes' 'No'
```

## Concepts

- “Cell Arrays of Strings”

**Purpose** Join strings in cell array into single string

**Syntax**

```
str = strjoin(C)
str = strjoin(C,delimiter)
```

**Description** `str = strjoin(C)` constructs the string, `str`, by linking each string in the cell array, `C`, with a single space.

`str = strjoin(C,delimiter)` constructs the string, `str`, by linking each string of `C` with the elements in `delimiter`.

## Input Arguments

### **C - Input text**

1-by-n cell array of strings

Input text, specified as a 1-by-n cell array of strings. Each element in the cell array must contain a single string in a single row.

**Example:** {'The', 'rain', 'in', 'Spain'}

### **Data Types**

cell

### **delimiter - Delimiting characters**

string | 1-by-n cell array of strings

Delimiting characters, specified as a single string or a 1-by-n cell array of strings.

- If `delimiter` is a single string, then `strjoin` forms `str` by inserting `delimiter` between each element of `C`. The `delimiter` input can include any of these escape sequences:

<code>\\</code>	Backslash
<code>\0</code>	Null
<code>\a</code>	Alarm
<code>\b</code>	Backspace

# strjoin

---

<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab

- If `delimiter` is a cell array of strings, then it must contain one fewer element than `C`. Each element in the cell array must contain a single string in a single row. `strjoin` forms `str` by interleaving the elements of `delimiter` and `C`. All characters in `delimiter` are inserted as literal text, and escape sequences are not supported.

**Example:** `' , '`

**Example:** `{ ' , ' , ' ' }`

## Data Types

`char` | `cell`

## Examples

### Join List of Words with Whitespace

Join individual strings in a cell array of strings, `C`, with a single space.

```
C = {'one', 'two', 'three'};
str = strjoin(C)
```

```
str =
```

```
one two three
```

### Join Cell Array of Strings

```
C = {'Newton', 'Gauss', 'Euclid', 'Lagrange'};
str = strjoin(C, ', ')
```

```
str =
```

```
Newton, Gauss, Euclid, Lagrange
```

### **Join Strings with Multiple Different Delimiters**

Specify multiple different delimiters in a cell array of strings. The delimiter cell array must have one fewer element than C.

```
C = {'one', 'two', 'three'};
str = strjoin(C, {' + ', ' = '})
```

```
str =
```

```
one + two = three
```

### **See Also**

[strsplit](#) | [strcat](#) | [cellstr](#) | [regexp](#)

# strjust

---

**Purpose** Justify character array

**Syntax**

```
T = strjust(S)
T = strjust(S, 'right')
T = strjust(S, 'left')
T = strjust(S, 'center')
```

**Description** T = strjust(S) or T = strjust(S, 'right') returns a right-justified version of the character array S.

T = strjust(S, 'left') returns a left-justified version of S.

T = strjust(S, 'center') returns a center-justified version of S.

**See Also** deblank | strtrim

**Purpose** Find possible matches for string

---

**Note** `strmatch` is not recommended. Use `strncmp` or `validatestring`, depending on your requirements, instead. `strncmp` returns the numeric index of all array elements that begin with the specified string, whereas `validatestring` returns a single string that represents the best match to the specified string. See Example 2, below.

To find an exact match for a string, use `strcmp`.

---

**Syntax**

```
x = strmatch(str, strarray)
x = strmatch(str, strarray, 'exact')
```

**Description**

`x = strmatch(str, strarray)` looks through the rows of the character array or cell array of strings `strarray` to find strings that begin with the text contained in `str`, and returns the matching row indices. If `strmatch` does not find `str` in `strarray`, `x` is an empty matrix (`[]`). Any trailing space characters in `str` or `strarray` are ignored when matching. `strmatch` is fastest when `strarray` is a character array.

`x = strmatch(str, strarray, 'exact')` compares `str` with each row of `strarray`, looking for an exact match of the entire strings. Any trailing space characters in `str` or `strarray` are ignored when matching.

**Examples** **Example 1**

The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'))
```

returns `x = [1; 3]` since rows 1 and 3 begin with 'max'. The statement

```
x = strmatch('max', char('max', 'minimax', 'maximum'),'exact')
```

returns `x = 1`, since only row 1 matches 'max' exactly.

## Example 2

This example shows how to replace use of the `strmatch` function with `validatestring` or `strncmp`.

To start with, use `strmatch` to return the index of those elements for which there is a match:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = strmatch('max',list)
x =
 1
 3
 4
```

`validatestring` returns the string representing the best match. If multiple or no matches exist, this statement would return an error:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = validatestring('max', list)
x =
 max
```

`strncmp` returns a logical array indicating which strings match the specified string:

```
list = {'max', 'minimax', 'maximum', 'max'};
x = strncmp('max', list, 3)
x =
 1 0 1 1
```

If you prefer that MATLAB return the numeric indices of `list`, use `find` as follows:

```
list = {'max', 'minimax', 'maximum', 'max'}
x = find(strncmp(list, 'max', 3))
```

If your input to `strmatch` is a character matrix, then first convert the matrix to a cell array using `cellstr`. Then, pass the output from `cellstr` to `strncmp` or `validatestring`

| `regexprep`

# strncmp

---

**Purpose** Compare first *n* characters of strings (case sensitive)

**Syntax**  
TF = strncmp(string,string,n)  
TF = strncmp(string,cellstr,n)  
TF = strncmp(cellstr,cellstr,n)

**Description** TF = strncmp(string,string,n) compares the first *n* characters of two strings for equality. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

TF = strncmp(string,cellstr,n) compares the first *n* characters of a string with the first *n* characters of each element of a cell array of strings. The function returns a logical array the same size as the *cellstr* input in which logical 1 represents equality. The order of the first two input arguments is not important.

TF = strncmp(cellstr,cellstr,n) compares each element of one cell array of strings with the same element of the other. strncmp attempts to match only the first *n* characters of these strings. The function returns a logical array the same size as either input array.

- Tips**
- The strncmp function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
  - Use strncmpi for case-insensitive string comparisons.
  - Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
  - The value returned by strncmp is not the same as the C language convention.
  - strncmp supports international character sets.

**Input Arguments**

**string**  
Single character string or *n*-by-1 array of strings.

**cellstr**

Cell array of strings.

**n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

## **Output Arguments**

**TF**

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (true) if the size and content of both arrays are equal, and logical 0 (false) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (true) for those elements of the input arrays that are a match, and logical 0 (false) for those elements that are not.

## **Examples**

Before trying the `strncmp` function, use `strcmp` to perform a simple comparison of the two input strings. Because only the first 13 characters are the same, `strcmp` returns logical 0:

```
strcmp('Kansas City, KS', 'Kansas City, MO')
ans =
 0
```

Do the comparison again, but this time using `strncmp` and specifying the number of characters to compare:

```
chars2compare = length('Kansas City, KS') - 2
ans =
 13
strncmp('Kansas City, KS', 'Kansas City, MO', chars2compare)
ans =
 1
```

---

# strncmp

---

From a list of 10 MATLAB functions, find those that apply to using a camera:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
 'caxis' 'camtarget' 'cast' 'camorbit' ...
 'callib' 'cart2sph'};
```

```
strncmp(function_list, 'cam', 3)
ans =
 0 0 1 0 0 1 0 1 0 0
```

```
function_list{strncmp(function_list, 'cam', 3)}
ans =
 camdolly
ans =
 camtarget
ans =
 camorbit
```

---

Create two 5-by-10 string arrays `str1` and `str2` that are equal, except for the element at row 4, column 3. Using linear indexing, this is element 14:

```
str1 = ['AAAAAAAAA'; 'BBBBBBBBBB'; 'CCCCCCCCC'; ...
 'DDDDDDDDD'; 'EEEEEEEEEE']
```

```
str1 =
 AAAAAAAAAA
 BBBBBBBBBB
 CCCCCCCCCC
 DDDDDDDDDD
 EEEEEEEEEE
```

```
str2 = str1;
str2(4,3) = '-'
str2 =
 AAAAAAAAAA
```

```
BBBBBBBBBB
CCCCCCCCC
DD-DDDDDD
EEEEEEEEEE
```

Because MATLAB compares the arrays in linear order (that is, column by column rather than row by row), `strncmp` finds only the first 13 elements to be the same:

```
str1 A B C D E A B C D E A B C D E
str2 A B C D E A B C D E A B C - E
 |
 element 14
```

```
strncmp(str1, str2, 13)
ans =
 1
```

```
strncmp(str1, str2, 14)
ans =
 0
```

## See Also

`strcmp` | `strncmpi` | `strcmpi` | `strfind` | `regexp` | `regexpi`

# strncmpi

---

**Purpose** Compare first *n* characters of strings (case insensitive)

**Syntax**  
TF = strncmpi(string,string,n)  
TF = strncmpi(string,cellstr,n)  
TF = strncmpi(cellstr,cellstr,n)

**Description** TF = strncmpi(string,string,n) compares the first *n* characters of two strings for equality, ignoring any differences in letter case. The function returns a scalar logical 1 for equality, or scalar logical 0 for inequality.

TF = strncmpi(string,cellstr,n) compares the first *n* characters of a string with the first *n* characters of each element of a cell array of strings, ignoring letter case. The function returns a logical array the same size as the *cellstr* input in which logical 1 represents equality. The order of the input arguments is not important.

TF = strncmpi(cellstr,cellstr,n) compares each element of one cell array of strings with the same element of the other, ignoring letter case. strncmpi attempts to match only the first *n* characters of these strings. The function returns a logical array the same size as either input array.

- Tips**
- The strncmpi function is intended for comparison of character data. When used to compare numeric data, it returns logical 0.
  - Use strcmp for case-sensitive string comparisons.
  - Any leading and trailing blanks in either of the strings are explicitly included in the comparison.
  - The value returned by strncmpi is not the same as the C language convention.
  - strncmpi supports international character sets.

**Input Arguments** **string**  
A single character string or *n*-by-1 array of strings.

**cellstr**

A cell array of strings.

**n**

Maximum number of characters to compare. Must be a scalar, integer-valued double.

**Output Arguments****TF**

When both inputs are character arrays, TF is a scalar logical value. This value is logical 1 (**true**) if the size and content of both arrays are equal, and logical 0 (**false**) if they are not.

When either or both inputs are a cell array of strings, TF is an array of logical ones and zeros. This array is the same size as the input cell array(s), and contains logical 1 (**true**) for those elements of the input arrays that are a match, and logical 0 (**false**) for those elements that are not.

**Examples**

From a list of 10 MATLAB functions, find those that apply to using a camera. Do the comparison without sensitivity to letter case:

```
function_list = {'calendar' 'case' 'camdolly' 'circshift' ...
 'caxis' 'Camtarget' 'cast' 'camorbit' ...
 'callib' 'cart2sph'};
```

```
strncmpi(function_list, 'CAM', 3)
```

```
ans =
```

```
 0 0 1 0 0 1 0 1 0 0
```

```
function_list{strncmpi(function_list, 'CAM', 3)}
```

```
ans =
```

```
 camdolly
```

```
ans =
```

```
 Camtarget
```

```
ans =
```

```
 camorbit
```

# strncmpi

---

## See Also

`strcmpi` | `strncmp` | `strcmp` | `strfind` | `regexp` | `regexp`

**Purpose** Read formatted data from string

---

**Note** strread is not recommended. Use textscan instead.

---

## Syntax

```
A = strread('str')
[A, B, ...] = strread('str')
[A, B, ...] = strread('str', 'format')
[A, B, ...] = strread('str', 'format', N)
[A, B, ...] = strread('str', 'format', N, param, value, ...)
```

## Description

`A = strread('str')` reads numeric data from input string `str` into a 1-by-`N` vector `A`, where `N` equals the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 1” on page 1-6651 below.

`[A, B, ...] = strread('str')` reads numeric data from the string input `str` into scalar output variables `A`, `B`, and so on. The number of output variables must equal the number of whitespace-separated numbers in `str`. Use this form only with strings containing numeric data. See “Example 2” on page 1-6652 below.

`[A, B, ...] = strread('str', 'format')` reads data from `str` into variables `A`, `B`, and so on using the specified `format`. The number of output variables `A`, `B`, etc. must be equal to the number of format specifiers (e.g., `%s` or `%d`) in the `format` argument. You can read all of the data in `str` to a single output variable as long as you use only one format specifier in the command. See “Example 4” on page 1-6652 and “Example 5” on page 1-6653 below.

The table [Formats for strread](#) on page 1-6648 lists the valid format specifiers. More information on using formats is available under “Formats” on page 1-6651 in the “Tips” on page 1-6650 section below.

`[A, B, ...] = strread('str', 'format', N)` reads data from `str` using the format string `N` times, where `N` is an integer greater than zero. If `N` is -1, `strread` reads the entire string. When `str` contains

# strread

only numeric data, you can set `format` to the empty string ( `' '` ). See “Example 3” on page 1-6652 below.

`[A, B, ...] = strread('str', 'format', N, param, value, ...)` customizes `strread` using `param/value` pairs, as listed in the table Parameters and Values for `strread` on page 1-6649 below. When `str` contains only numeric data, you can set `format` to the empty string ( `' '` ). The `N` argument is optional and may be omitted entirely. See “Example 7” on page 1-6654 below.

## Formats for strread

Format	Action	Output
Literals (ordinary characters)	Ignore the matching characters. For example, in a string that has <code>Dept</code> followed by a number (for department number), to skip the <code>Dept</code> and read only the number, use <code>'Dept'</code> in the format string.	None
<code>%d</code>	Read a signed integer value.	Double array
<code>%u</code>	Read an integer value.	Double array
<code>%f</code>	Read a floating-point value.	Double array
<code>%s</code>	Read a white-space separated string.	Cell array of strings
<code>%q</code>	Read a double quoted string, ignoring the quotes.	Cell array of strings
<code>%c</code>	Read characters, including white space.	Character array
<code>%[...]</code>	Read the longest string containing characters specified in the brackets.	Cell array of strings

**Formats for stringstream (Continued)**

<b>Format</b>	<b>Action</b>	<b>Output</b>
%[ ^... ]	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
%*...	Ignore the characters following *. See “Example 8” on page 1-6654 below.	No output
%w...	Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision.	

**Parameters and Values for stringstream**

<b>param</b>	<b>value</b>	<b>Action</b>
whitespace	Any from the list below: \b Backspace \n New line \r Carriage return \t Horizontal tab \\ Backslash %% Percent sign ' Single quotation mark	Treats vector of characters, *, as white space. Default is \b\r\n\t.
delimiter	Delimiter character	Specifies delimiter character. Default is one or more whitespace characters.
expchars	Exponent characters	Default is eEdD.

## Parameters and Values for stream (Continued)

param	value	Action
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
emptyvalue	Value to return for empty numeric fields in delimited files	Default is NaN.

### Tips

If you terminate the input string with a newline character (`\n`), `stream` returns arrays of equal size by padding arrays of lesser size with the `emptyvalue` character:

```
[A,B,C] = stream(sprintf('5,7,1,9\n'),'%d%d%d', ...
 'delimiter', ',', 'emptyvalue',NaN)
A =
 5
 9
B =
 7
 NaN
C =
 1
 NaN
```

If you remove the `\n` from the input string of this example, array `A` continues to be a 2-by-1 array, but `B` and `C` are now 1-by-1.

### Delimiters

If your data uses a character other than a space as a delimiter, you must use the `strread` parameter `'delimiter'` to specify the delimiter. For example, if the string `str` used a semicolon as a delimiter, you would use this command:

```
[names, types, x, y, answer] = strread(str, '%s %s %f ...
 %d %s', 'delimiter', ';');
```

### Formats

The format string determines the number and types of return arguments. The number of return arguments must match the number of conversion specifiers in the format string.

The `strread` function continues reading `str` until the entire string is read. If there are fewer format specifiers than there are entities in `str`, `strread` reapplies the format specifiers, starting over at the beginning. See “Example 5” on page 1-6653 below.

The format string supports a subset of the conversion specifiers and conventions of the C language `fscanf` routine. White-space characters in the format string are ignored.

### Preserving White-Space

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
str = ' An example of preserving spaces ';

strread(str, '%s', 'whitespace', '')
ans =
 ' An example of preserving spaces '
```

## Examples

### Example 1

Read numeric data into a 1-by-5 vector:

# strread

---

```
a = strread('0.41 8.24 3.57 6.24 9.27')
a =
 0.4100 8.2400 3.5700 6.2400 9.2700
```

## Example 2

Read numeric data into separate scalar variables:

```
[a b c d e] = strread('0.41 8.24 3.57 6.24 9.27')
a =
 0.4100
b =
 8.2400
c =
 3.5700
d =
 6.2400
e =
 9.2700
```

## Example 3

Read the only first three numbers in the string, also formatting as floating point:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%4.2f', 3)
a =
 0.4100
 8.2400
 3.5700
```

## Example 4

Truncate the data to one decimal digit by specifying format `%3.1f`. The second specifier, `%*1d`, tells `strread` not to read in the remaining decimal digit:

```
a = strread('0.41 8.24 3.57 6.24 9.27', '%3.1f %*1d')
a =
```

```
0.4000
8.2000
3.5000
6.2000
9.2000
```

## Example 5

Read six numbers into two variables, reusing the format specifiers:

```
[a b] = strread('0.41 8.24 3.57 6.24 9.27 3.29', '%f %f')
```

```
a =
 0.4100
 3.5700
 9.2700
b =
 8.2400
 6.2400
 3.2900
```

## Example 6

Read string and numeric data to two output variables. Ignore commas in the input string:

```
str = 'Section 4, Page 7, Line 26';

[name value] = strread(str, '%s %d,')
name =
 'Section'
 'Page'
 'Line'
value =
 4
 7
 26
```

## Example 7

Read the string used in the last example, but this time delimiting with commas instead of spaces:

```
str = 'Section 4, Page 7, Line 26';

[a b c] = strread(str, '%s %s %s', 'delimiter', ',')
a =
 'Section 4'
b =
 'Page 7'
c =
 'Line 26'
```

## Example 8

Read selected portions of the input string:

```
str = '<table border=5 width="100%" cellpadding=0>';

[border width space] = strread(str, ...
 '%*s*s %c %*s "%4s" %*s %c', 'delimiter', '= ')
border =
 5
width =
 '100%'
space =
 0
```

## Example 9

Read the string into two vectors, restricting the Answer values to T and F. Also note that two delimiters (comma and space) are used here:

```
str = 'Answer_1: T, Answer_2: F, Answer_3: F';

[a b] = strread(str, '%s %[TF]', 'delimiter', ', ', ' ')
a =
 'Answer_1:'
```

```
 'Answer_2: '
 'Answer_3: '
b =
 'T'
 'F'
 'F'
```

# strrep

---

**Purpose** Find and replace substring

**Syntax** `modifiedStr = strrep(origStr, oldSubstr, newSubstr)`

**Description** `modifiedStr = strrep(origStr, oldSubstr, newSubstr)` replaces all occurrences of the string `oldSubstr` within string `origStr` with the string `newSubstr`.

- Tips**
- `strrep` accepts input combinations of single strings, strings in scalar cells, and same-sized cell arrays of strings. If any inputs are cell arrays, `strrep` returns a cell array.
  - The `strrep` function does not find empty strings for replacement. That is, when `origStr` and `oldSubstr` both contain the empty string (''), `strrep` does not replace '' with the contents of `newSubstr`.
  - Before replacing strings, `strrep` finds all instances of `oldSubstr` in `origStr`, like the `strfind` function. For overlapping patterns, `strrep` performs multiple replacements. See the final example in the Examples section.

## Examples

Replace text in a character array:

```
claim = 'This is a good example.';
new_claim = strrep(claim, 'good', 'great')
```

MATLAB returns:

```
new_claim =
This is a great example.
```

---

Replace text in a cell array:

```
c_files = {'c:\cookies.m'; ...
 'c:\candy.m'; ...
 'c:\calories.m'};
d_files = strrep(c_files, 'c:', 'd:')
```

MATLAB returns:

```
d_files =
 'd:\cookies.m'
 'd:\candy.m'
 'd:\calories.m'
```

---

Replace text in a cell array with values in a second cell array:

```
missing_info = {'Start: __'; ...
 'End: __'};

dates = {'01/01/2001'; ...
 '12/12/2002'};
```

```
complete = strrep(missing_info, '__', dates)
```

MATLAB returns:

```
complete =
 'Start: 01/01/2001'
 'End: 12/12/2002'
```

---

Compare the use of `strrep` and `regexprep` to replace a string with a repeated pattern:

```
repeats = 'abc 2 def 22 ghi 222 jkl 2222';
indices = strfind(repeats, '22')

using_strrep = strrep(repeats, '22', '*')
using_regexprep = regexprep(repeats, '22', '*')
```

MATLAB returns:

```
indices =
 11 18 19 26 27 28
```

# strrep

---

```
using_strrep =
abc 2 def * ghi ** jkl ***
```

```
using_regexprep =
abc 2 def * ghi *2 jkl **
```

## See Also

[strfind](#) | [regexprep](#)

**Purpose** Split string at specified delimiter

**Syntax**

```
C = strsplit(str)
C = strsplit(str,delimiter)
C = strsplit(str,delimiter,Name,Value)

[C,matches] = strsplit(__)
```

**Description** C = strsplit(str) splits the string, str, at whitespace into the cell array of strings, C. A whitespace character is equivalent to any sequence in the set {' ', '\f', '\n', '\r', '\t', '\v'}.

C = strsplit(str,delimiter) splits str at the delimiters specified by delimiter.

C = strsplit(str,delimiter,Name,Value) specifies additional delimiter options using one or more name-value pair arguments.

[C,matches] = strsplit( \_\_ ) additionally returns a cell array of strings, matches, using any of the input arguments in the previous syntaxes. matches contains all occurrences of delimiters upon which strsplit splits str.

## Input Arguments

**str - Input text**  
string

Input text, specified as a string.

**Data Types**  
char

**delimiter - Delimiting characters**  
string | 1-by-n cell array of strings

# strsplit

---

Delimiting characters, specified as a single string or a 1-by-n cell array of strings. Strings specified in `delimiter` do not appear in the string fragments of the output `C`.

Specify multiple delimiters in a cell array of strings. Each element of the cell array must contain a single string in a single row. The `strsplit` function splits `str` on the elements of `delimiter` in the order in which they appear in the cell array.

`delimiter` can include the following escape sequences:

<code>\\</code>	Backslash
<code>\0</code>	Null
<code>\a</code>	Alarm
<code>\b</code>	Backspace
<code>\f</code>	Form feed
<code>\n</code>	New line
<code>\r</code>	Carriage return
<code>\t</code>	Horizontal tab
<code>\v</code>	Vertical tab

**Example:** `' , '`

**Example:** `{ ' - ' , ' , ' }`

## Data Types

char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** 'DelimiterType', 'RegularExpression' instructs strsplit to treat delimiter as a regular expression.

### 'CollapseDelimiters' - Multiple delimiter handling

1 (true) (default) | 0 (false)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'CollapseDelimiters' and either true or false. If true, then consecutive delimiters in str are treated as one. If false, then consecutive delimiters are treated as separate delimiters, resulting in empty string '' elements between matched delimiters.

**Example:** 'CollapseDelimiters', true

### 'DelimiterType' - Delimiter type

'Simple' (default) | 'RegularExpression'

Delimiter type, specified as the comma-separated pair consisting of 'DelimiterType' and one of the following strings.

'Simple'	Except for escape sequences, strsplit treats delimiter as a literal string.
'RegularExpression'	strsplit treats delimiter as a regular expression.

In both cases, delimiter can include escape sequences.

## Output Arguments

### C - Parts of original string

cell array of strings

Parts of the original string, returned as a cell array of strings. C always contains one more element than matches contains. Consequently, if the original string, str, ends with a delimiter, then the last cell in C contains an empty string.

### matches - Identified delimiters

cell array of strings

# strsplit

---

Identified delimiters, returned as a cell array of strings. `matches` always contains one fewer element than output `C` contains.

## Examples

### Split String on Whitespace

```
str = 'The rain in Spain.';
C = strsplit(str)
```

```
C =
```

```
 'The' 'rain' 'in' 'Spain.'
```

`C` is a cell array containing 4 strings.

### Split String of Values on Specific Delimiter

Split a string of comma-separated values.

```
data = '1.21, 1.985, 1.955, 2.015, 1.885';
C = strsplit(data,', ')
```

```
C =
```

```
 '1.21' '1.985' '1.955' '2.015' '1.885'
```

Split a string of values, `data`, which contains the units `m/s` with an arbitrary number of white-space on either side of the text. The regular expression, `\s*`, matches any white-space character appearing zero or more times.

```
data = '1.21m/s1.985m/s 1.955 m/s2.015 m/s 1.885m/s';
[C,matches] = strsplit(data,'\s*m/s\s*',...
 'DelimiterType','RegularExpression')
```

```
C =
```

```
 '1.21' '1.985' '1.955' '2.015' '1.885' ''
```

```

matches =

 'm/s' 'm/s ' ' m/s' ' m/s ' 'm/s'

```

In this case, the last string in `C` is empty. This empty string is the string that follows the last matched delimiter.

### Split Path String on File Separator

```

myPath = 'C:\work\matlab';
C = strsplit(myPath,'\')

C =

 'C:' 'work' 'matlab'

```

### Split Text String with Multiple Delimiters

Split a string on ' ' and 'ain', treating multiple delimiters as one. Specify multiple delimiters in a cell array of strings.

```

str = 'The rain in Spain stays mainly in the plain.';
[C,matches] = strsplit(str,{' ','ain'},'CollapseDelimiters',true)

C =

 'The' 'r' 'in' 'Sp' 'stays' 'm' 'ly' 'in'

```

```

matches =

 ' ' 'ain ' ' ' 'ain ' ' ' 'ain' ' ' ' '

```

Split the same string on whitespace and on 'ain', using regular expressions and treating multiple delimiters separately.

```

[C,matches] = strsplit(str,{'\s','ain'},'CollapseDelimiters',...
 false, 'DelimiterType','RegularExpression')

C =

```

# strsplit

---

```
'The' 'r' '' 'in' 'Sp' '' 'stays' 'm' 'ly'

matches =
'' 'ain' '' ' ' 'ain' '' ' ' 'ain' ''
```

In this case, `strsplit` treats the two delimiters separately, so empty strings appear in output `C` between the consecutively matched delimiters.

## Split Text with Multiple, Overlapping Delimiters

Split text on the strings `'`, `'` and `'`, and `'`.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{' ', ',',' and '})

C =
 'bacon' 'lettuce' 'and tomato'

matches =
 ' ', ', ', ' ', ' ', ' ', ' ', ' ';
```

Because the command lists `'`, `'` first and `'`, and `'` contains `'`, `'`, the `strsplit` function splits `str` on the first delimiter and never proceeds to the second delimiter.

If you reverse the order of delimiters, `'`, and `'` takes priority.

```
str = 'bacon, lettuce, and tomato';
[C,matches] = strsplit(str,{' ', and ', ', ' '})

C =
```

```
'bacon' 'lettuce' 'tomato'
```

```
matches =
```

```
',' ' ' and '
```

## See Also

[strjoin](#) | [strfind](#) | [regexp](#)

## Concepts

- “Regular Expressions”

# strtok

---

**Purpose** Selected parts of string

**Syntax**

```
token = strtok(str)
token = strtok(str, delimiter)
[token, remain] = strtok(str, ...)
```

**Description** `token = strtok(str)` parses input string `str` from left to right, returning part or all of that string in `token`. Using the white-space character as a delimiter, the `token` output begins at the start of `str`, skipping any delimiters that might appear at the start, and includes all characters up to either the next delimiter or the end of the string. White-space characters include space (ASCII 32), tab (ASCII 9), and carriage return (ASCII 13).

The `str` argument can be a string of characters enclosed in single quotation marks, a cell array of strings each enclosed in single quotation marks, or a variable representing either of the two. If `str` is a cell array of `N` strings, then `token` is a cell array of `N` tokens, with `token{1}` derived from `str{1}`, `token{2}` from `str{2}`, and so on.

`token = strtok(str, delimiter)` is the same as the above syntax except that you specify the delimiting character(s) yourself using the `delimiter` character vector input. White-space characters are not considered to be delimiters when using this syntax unless you include them in the `delimiter` argument. If the `delimiter` input specifies more than one character, MATLAB treats each character as a separate delimiter; it does not treat the multiple characters as a delimiting string. The number and order of characters in the `delimiter` argument is unimportant. Do not use escape sequences as delimiters. For example, use `char(9)` rather than `'\t'` for tab.

`[token, remain] = strtok(str, ...)` returns in `remain` that part of `str`, if any, that follows `token`. The delimiter is included in `remain`. If no delimiters are found in the body of the input string, then the entire string (excluding any leading delimiting characters) is returned in `token`, and `remain` is an empty string (`' '`). If `str` is a cell array of strings, `token` is a cell array of tokens and `remain` is a cell array of string remainders.

## Examples

### Example 1

This example uses the default white-space delimiter. Note that space characters at the start of the string are not included in the token output, but the space character that follows token is included in remain:

```
s = ' This is a simple example.';
[token, remain] = strtok(s)
```

```
token =
This
remain =
 is a simple example.
```

### Example 2

Take a string of HTML code and break it down into segments delimited by the < and > characters. Write a while loop to parse the string and print each segment:

```
s = sprintf('%s%s%s%s', ...
'<ul class=continued><li class=continued>', ...
'<pre>token = strtok', ...
'('str', delimiter)', ...
'token = strtok('str')');
```

```
remain = s;
```

```
while true
 [str, remain] = strtok(remain, '<>');
 if isempty(str), break; end
 disp(sprintf('%s', str))
end
```

Here is the output:

```
ul class=continued
li class=continued
pre
```

# strtok

---

```
a name="13474"
/a
token = strtok('str', delimiter)
a name="13475"
/a
token = strtok('str')
```

## Example 3

Using `strtok` on a cell array of strings returns a cell array of strings in `token` and a character array in `remain`:

```
s = {'all in good time'; ...
 'my dog has fleas'; ...
 'leave no stone unturned'};

remain = s;

for k = 1:4
 [token, remain] = strtok(remain);
 token
end
```

Here is the output:

```
token =
 'all'
 'my'
 'leave'
token =
 'in'
 'dog'
 'no'
token =
 'good'
 'has'
 'stone'
token =
```

```
'time'
'fleas'
'unturned'
```

## See Also

[strfind](#) | [strncmp](#) | [strcmp](#) | [textscan](#) | [strsplit](#)

# strtrim

---

**Purpose** Remove leading and trailing white space from string

**Syntax**  
S = strtrim(str)  
C = strtrim(cstr)

**Description** S = strtrim(str) returns a copy of string str with all leading and trailing white-space characters removed. A white-space character is one for which the isspace function returns logical 1 (true).

C = strtrim(cstr) returns a copy of the cell array of strings cstr with all leading and trailing white-space characters removed from each string in the cell array.

**Examples** Remove the leading white-space characters (spaces and tabs) from str:

```
str = sprintf(' \t Remove leading white-space')
str =
 Remove leading white-space
```

```
str = strtrim(str)
str =
Remove leading white-space
```

Remove leading and trailing white-space from the cell array of strings:

```
cstr = {' Trim leading white-space';
 'Trim trailing white-space '};
```

```
cstr = strtrim(cstr)
cstr =
 'Trim leading white-space'
 'Trim trailing white-space'
```

**See Also** isspace | cellstr | deblank | strjust

**Purpose**

Create structure array

**Syntax**

```
s = struct
s = struct(field,value)
s = struct(field1,value1,...,fieldN,valueN)
s = struct([])

s = struct(obj)
```

**Description**

`s = struct` creates a scalar (1-by-1) structure with no fields.

`s = struct(field,value)` creates a structure array with the specified field and values.

- If `value` is *not* a cell array, then `s` is a scalar structure, where `s.(field) = value`.
- If `value` is a cell array, then `s` is a structure array with the same dimensions as `value`. Each element of `s` contains the corresponding element of `value`. For example, `s = struct('f',{'a','b'})` returns `s(1).f = 'a'` and `s(2).f = 'b'`.
- If `value` is an empty cell array `{}`, then `s` is an empty (0-by-0) structure.

`s = struct(field1,value1,...,fieldN,valueN)` creates a structure array with multiple fields. Any nonscalar cell arrays in the set `value1,...,valueN` must have the same dimensions.

- If none of the `value` inputs is a cell array, or all are scalar cell arrays, then `s` is a scalar structure.
- If any of the `value` inputs are nonscalar cell arrays, then `s` has the same dimensions as the nonscalar cell arrays. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.
- If any `value` input is an empty cell array, `{}`, then output `s` is an empty (0-by-0) structure.

# struct

---

`s = struct([])` creates an empty (0-by-0) structure with no fields.

`s = struct(obj)` creates a structure with field names and values that correspond to properties of `obj`. MATLAB does not convert `obj`, but rather creates `s` as a new structure. This structure does not retain the class information, so private, protected, and hidden properties become public fields in `s`. The `struct` function issues a warning when you use this syntax.

## Input Arguments

### field - Field name

string

Field name, specified as a string. Valid field names begin with a letter, and can contain letters, digits, and underscores. The maximum length of a field name is the value that the `namelengthmax` function returns.

### value - Values within structure field

cell array | scalar | vector | multidimensional array

Values within structure field, specified as a cell array or as a scalar, vector, or multidimensional array of any other data type.

If none of the `value` inputs is a cell array, or all of the `value` inputs are scalar cell arrays, then output `s` is a scalar structure. Otherwise, `value` inputs that are nonscalar cell arrays must have the same dimensions, and output `s` also has those dimensions. For any `value` that is a scalar cell array or an array of any other data type, `struct` inserts the contents of `value` in the relevant field for all elements of `s`.

If any `value` input is an empty cell array, {}, then output `s` is an empty structure array.

### Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char | struct | cell | function\_handle

**Complex Number Support:** Yes

### obj - Object

any nonfundamental class

Object of any class, except the fundamental data types such as double or char.

## Examples

### Structure with One Field

Create a nonscalar structure with one field, `f`.

```
field = 'f';
value = {'some text';
 [10, 20, 30];
 magic(5)};
s = struct(field,value)

s =
3x1 struct array with fields:
 f
```

View the contents each element.

```
s.f

ans =
some text

ans =
 10 20 30

ans =
 17 24 1 8 15
 23 5 7 14 16
 4 6 13 20 22
 10 12 19 21 3
 11 18 25 2 9
```

When you access a field of a nonscalar structure, such as `s.f`, MATLAB returns a comma-separated list. In this case, `s.f` is equivalent to `s(1).f`, `s(2).f`, `s(3).f`.

## Structure with Multiple Fields

Create a nonscalar structure with several fields.

```
field1 = 'f1'; value1 = zeros(1,10);
field2 = 'f2'; value2 = {'a', 'b'};
field3 = 'f3'; value3 = {pi, pi.^2};
field4 = 'f4'; value4 = {'fourth'};
```

```
s = struct(field1,value1,field2,value2,field3,value3,field4,value4)
```

```
s =
1x2 struct array with fields:
 f1
 f2
 f3
 f4
```

The cell arrays for `value2` and `value3` are 1-by-2, so `s` is also 1-by-2. Because `value1` is a numeric array and not a cell array, both `s(1).f1` and `s(2).f1` have the same contents. Similarly, because the cell array for `value4` has a single element, `s(1).f4` and `s(2).f4` have the same contents.

```
s(1)
```

```
ans =
 f1: [0 0 0 0 0 0 0 0 0 0]
 f2: 'a'
 f3: 3.1416
 f4: 'fourth'
```

```
s(2)
```

```
ans =
 f1: [0 0 0 0 0 0 0 0 0 0]
 f2: 'b'
 f3: 9.8696
 f4: 'fourth'
```

### Fields that Contain Cell Arrays

Create a structure with a field that contains a cell array.

```
field = 'mycell';
value = {'a','b','c'};
s = struct(field,value)

s =
 mycell: {'a' 'b' 'c'}
```

### Empty Structure Array

Create an empty structure with several fields.

```
s = struct('a', {}, 'b', {}, 'c', {})

s =
0x0 struct array with fields:
 a
 b
 c
```

Assign a value to a field in an empty structure.

```
s(1).a = 'a'

s =
 a: 'a'
 b: []
 c: []
```

### Nested Structure Array

Create a nested structure: a contains field b, which in turn contains fields c and d.

```
a.b = struct('c', {}, 'd', {})

a =
```

# struct

---

```
b: [0x0 struct]
```

View the names of the fields of nested structure a.b.

```
fieldnames(a.b)
```

```
ans =
 'c'
 'd'
```

# struct2table

---

**Purpose** Convert structure array to table

**Syntax**  
`T = struct2table(S)`  
`T = struct2table(S,Name,Value)`

**Description** `T = struct2table(S)` converts the structure array, `S`, to a table, `T`. Each field of `S` becomes a variable in `T`.

`T = struct2table(S,Name,Value)` creates a table from a structure array, `S`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names to include in the table.

## Input Arguments

### **S** - Structure array

structure array

Structure array, specified as a scalar structure array.

- If `S` is a scalar structure with `n` fields, all of which have `m` rows, then `T` is an `m`-by-`n` table.
- If `S` is a nonscalar `m`-by-1 structure array with `n` fields, then `T` is an `m`-by-`n` table.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `RowNames','{ 'row1','row2','row3' }` uses the row names, `row1`, `row2`, and `row3` for the table, `T`.

### **'RowNames' - Row names for T**

`{}` (default) | cell array of nonempty, distinct strings

Row names for T, specified as the comma-separated pair consisting of 'RowNames' and a cell array of nonempty, distinct strings.

## 'AsArray' - Indicator for how to treat scalar structure

false (default) | true | 0 | 1

Indicator for how to treat scalar structure, specified as the comma-separated pair consisting of 'AsArray' and either false, true, 0, or 1.

true	struct2table converts S to a table with one row and n variables. The variables can be different sizes.
false	struct2table converts a scalar structure array with n fields into an m-by-n table. Each field must have m rows. This is the default behavior

## Output Arguments

### T - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Convert Scalar Structure to Table

Convert a scalar structure to a table using the default options.

Create a structure array, S.

```
S.Name = {'CLARK'; 'BROWN'; 'MARTIN'};
S.Gender = {'M'; 'F'; 'M'};
S.SystolicBP = [124; 122; 130];
S.DiastolicBP = [93; 80; 92];
```

S

S =

# struct2table

---

```
 Name: {3x1 cell}
 Gender: {3x1 cell}
 SystolicBP: [3x1 double]
 DiastolicBP: [3x1 double]
```

The scalar structure, **S**, has four fields, each with three rows.

Convert the structure array to a table.

```
T = struct2table(S)
```

```
T =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'BROWN'	'F'	122	80
'MARTIN'	'M'	130	92

The structure field names in **S** become the variable names in the output table. The size of **T** is 3-by-4.

Change **Name** from a variable to row names by modifying the table property, **T.Properties.RowNames**, and then deleting the variable **Name**.

```
T.Properties.RowNames = T.Name;
T.Name = [];
```

```
T
```

```
T =
```

	Gender	SystolicBP	DiastolicBP
CLARK	'M'	124	93

```

 BROWN 'F' 122 80
 MARTIN 'M' 130 92

```

## Convert Nonscalar Structure Array to Table

Create a nonscalar structure array, S.

```

S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

```

```

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

```

```

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;

```

```
S
```

```
S =
```

3x1 struct array with fields:

```

 Name
 Gender
 SystolicBP
 DiastolicBP

```

S is a 3-by-1 structure array with four fields.

Convert the structure array to a table.

```
T = struct2table(S)
```

# struct2table

---

```
T =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'BROWN'	'F'	122	80
'MARTIN'	'M'	130	92

The structure field names in `S` become the variable names in the output table. The size of `T` is 3-by-4.

## Treat Scalar Structure As Array

Use `'AsArray'`, `true` to create a table from a scalar structure whose fields have different numbers of rows.

Create a scalar structure, `S`, with fields `name`, `billing`, and `test`.

```
S.name = 'John Doe';
S.billing = 127.00;
S.test = [79, 75, 73; 180, 178, 177.5; 220, 210, 205];
S
```

```
S =
```

```
 name: 'John Doe'
 billing: 127
 test: [3x3 double]
```

The fields have a different number of rows. Therefore, you cannot use `struct2table(S)`, which uses `'AsArray'`, `false` by default.

Treat the scalar structure as an array and convert it to a table.

```
T = struct2table(S, 'AsArray', true)
```

```
T =
```

<u>name</u>	<u>billing</u>	<u>test</u>
'John Doe'	127	[3x3 double]

T contains one row.

# structfun

---

**Purpose** Apply function to each field of scalar structure

**Syntax**  
`[A1,...,An] = structfun(func,S)`  
`[A1,...,An] = structfun(func,S,Name,Value)`

**Description** `[A1,...,An] = structfun(func,S)` applies the function specified by function handle `func` to each field of scalar structure `S`. Output arrays `A1,...,An`, where `n` is the number of outputs from function `func`, contain the outputs from the function calls.

`[A1,...,An] = structfun(func,S,Name,Value)` calls function `func` with additional options specified by one or more `Name,Value` pair arguments. Possible values for `Name` are `'UniformOutput'` or `'ErrorHandler'`.

## Input Arguments

### **func**

Handle to a function that accepts a single input argument and returns `n` output arguments.

If function `func` corresponds to more than one function file (that is, if `func` represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.

### **S**

Scalar structure.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'UniformOutput'**

Logical value, as follows:

- `true` (1) Indicates that for all inputs, each output from function `func` is a cell array or a scalar value that is always of the same type and size. The `structfun` function combines the outputs in arrays `A1, ..., An`, where `n` is the number of function outputs. Each output array is of the same type as the individual function outputs.
- `false` (0) Requests that the `structfun` function combine the outputs into scalar structures `A1, ..., An`, with the same fields as input structure `S`. The outputs of function `func` can be of any size or type.

**Default:** `true`

## 'ErrorHandler'

Handle to a function that catches any errors that occur when MATLAB attempts to execute function `func`. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Linear index corresponding to the element of the input cell array at the time of the error.

- The set of input arguments to function `func` at the time of the error.

## Output Arguments

### `A1, ..., An`

Arrays that collect the `n` outputs from function `func`.

If `UniformOutput` is `true` (the default):

# structfun

---

- The individual outputs from function `func` must be scalar values (numeric, logical, character, or structure) or cell arrays.
- The class of a particular output argument must be the same for each input. The class of the corresponding output array is the same as the class of the individual outputs from function `func`.
- Each array `A` is a column vector whose length equals the number of fields in `S`. The `structfun` function applies function `func` to the fields of `S` in the same order as that returned by the `fieldnames` function.

If `UniformOutput` is `false`, each array `A` is a scalar structure with the same fields as input `S`.

## Examples

Create a scalar structure, and count the number of characters in each field.

```
s.f1 = 'Sunday';
s.f2 = 'Monday';
s.f3 = 'Tuesday';
s.f4 = 'Wednesday';
s.f5 = 'Thursday';
s.f6 = 'Friday';
s.f7 = 'Saturday';
```

```
lengths = structfun(@numel, s)
```

---

Shorten the text in each field of `s`, created in the previous example. Because the output is nonscalar, set `UniformOutput` to `false`.

```
shortNames = structfun(@(x) (x(1:3)), s, 'UniformOutput', false)
```

The syntax `@(x)` creates an anonymous function.

---

Define and call a custom error handling function.

```
function result = errorfun(errorinfo, field)
```

```
 warning(errorinfo.identifier, errorinfo.message);
 result = NaN;
 end

mystruct.f1 = 'text';
myresult = structfun(@(x) x^2, mystruct, 'ErrorHandler', @errorfun)
```

## Tutorials

- “Anonymous Functions”

# strvcat

---

**Purpose** Concatenate strings vertically

---

**Note** `strvcat` is not recommended. Use `char` instead. Unlike `strvcat`, the `char` function does not ignore empty strings.

---

**Syntax** `S = strvcat(t1, t2, t3, ...)`  
`S = strvcat(c)`

**Description** `S = strvcat(t1, t2, t3, ...)` forms the character array `S` containing the text strings (or string matrices) `t1, t2, t3, ...` as rows. Spaces are appended to each string as necessary to form a valid matrix. Empty arguments are ignored.

`S = strvcat(c)` when `c` is a cell array of strings, passes each element of `c` as an input to `strvcat`. Empty strings in the input are ignored.

**Tips** If each text parameter, `ti`, is itself a character array, `strvcat` appends them vertically to create arbitrarily large string matrices.

**Examples** The command `strvcat('Hello', 'Yes')` is the same as `['Hello'; 'Yes']`, except that `strvcat` performs the padding automatically.

```
t1 = 'first'; t2 = 'string'; t3 = 'matrix'; t4 = 'second';
```

```
S1 = strvcat(t1, t2, t3) S2 = strvcat(t4, t2, t3)
```

```
S1 = S2 =
```

```
first second
string string
matrix matrix
```

```
S3 = strvcat(S1, S2)
```

```
S3 =
```

first  
string  
matrix  
second  
string  
matrix

# sub2ind

---

**Purpose** Convert subscripts to linear indices

**Syntax** `linearInd = sub2ind(matrixSize, rowSub, colSub)`  
`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)`

**Description** `linearInd = sub2ind(matrixSize, rowSub, colSub)` returns the linear index equivalent to the row and column subscripts `rowSub` and `colSub` for a matrix of size `matrixSize`. The `matrixSize` input is a 2-element vector that specifies the number of rows and columns in the matrix as `[nRows, nCols]`. The `rowSub` and `colSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscript pairs for the matrix. Example 3 demonstrates the use of vectors for the `rowSub` and `colSub` inputs.

`linearInd = sub2ind(arraySize, dim1Sub, dim2Sub, dim3Sub, ...)` returns the linear index equivalent to the specified subscripts for each dimension of an N-dimensional array of size `arraySize`. The `arraySize` input is an n-element vector that specifies the number of dimensions in the array. The `dimNSub` inputs are positive, whole number scalars or vectors that specify one or more row-column subscripts for the matrix.

All subscript inputs can be single, double, or any integer type. The `linearInd` output is always of class double.

If needed, `sub2ind` assumes that unspecified trailing subscripts are 1. See Example 2, below.

## Examples

### Example 1

This example converts the subscripts (2, 1, 2) for three-dimensional array A to a single linear index. Start by creating a 3-by-4-by-2 array A:

```
rng(0,'twister'); % Initialize random number generator.
A = rand(3, 4, 2)
```

```
A(:,:,1) =
 0.8147 0.9134 0.2785 0.9649
```

```

 0.9058 0.6324 0.5469 0.1576
 0.1270 0.0975 0.9575 0.9706
A(:, :, 2) =
 0.9572 0.1419 0.7922 0.0357
 0.4854 0.4218 0.9595 0.8491
 0.8003 0.9157 0.6557 0.9340

```

Find the linear index corresponding to (2, 1, 2):

```

linearInd = sub2ind(size(A), 2, 1, 2)
linearInd =
 14

```

Make sure that these agree:

```

A(2, 1, 2) A(14)
ans = and =
 0.4854 0.4854

```

## Example 2

Using the 3-dimensional array A defined in the previous example, specify only 2 of the 3 subscript arguments in the call to sub2ind. The third subscript argument defaults to 1.

The command

```

linearInd = sub2ind(size(A), 2, 4)
ans =
 11

```

is the same as

```

linearInd = sub2ind(size(A), 2, 4, 1)
ans =
 11

```

## Example 3

Using the same 3-dimensional input array A as in Example 1, accomplish the work of five separate `sub2ind` commands with just one.

Replace the following commands:

```
sub2ind(size(A), 3, 3, 2);
sub2ind(size(A), 2, 4, 1);
sub2ind(size(A), 3, 1, 2);
sub2ind(size(A), 1, 3, 2);
sub2ind(size(A), 2, 4, 1);
```

with a single command:

```
sub2ind(size(A), [3 2 3 1 2], [3 4 1 3 4], [2 1 2 2 1])
ans =
 21 11 15 19 11
```

Verify that these linear indices access the same array elements as their subscripted counterparts:

```
[A(3,3,2), A(2,4,1), A(3,1,2), A(1,3,2), A(2,4,1)]
ans =
 0.6557 0.1576 0.8003 0.7922 0.1576
```

```
A([21, 11, 15, 19, 11])
ans =
 0.6557 0.1576 0.8003 0.7922 0.1576
```

## See Also

`ind2sub` | `find` | `size`

**Purpose**

Create axes in tiled positions

**Syntax**

```
subplot(m,n,p)
subplot(m,n,p,'replace')
subplot(m,n,p,'align')
subplot('Position',positionVector)
subplot(__ ,Name,Value)
```

```
h = subplot(__)
```

```
subplot(h)
```

**Description**

`subplot(m,n,p)` divides the current figure into an *m*-by-*n* grid and creates an axes in the grid position specified by *p*. MATLAB numbers its grids by row, such that the first grid is the first column of the first row, the second grid is the second column of the first row, and so on.

`subplot(m,n,p,'replace')` deletes any existing axes in grid location *p* and creates a new axes.

`subplot(m,n,p,'align')` creates a new axes so that the plot boxes are aligned. This is the default behavior.

`subplot('Position',positionVector)` creates a new axes at the position specified by `positionVector`. The `positionVector` is a four-element vector of the form `[left,bottom,width,height]`, such that the entries are normalized values between 0.0 to 1.0. If the position vector specifies an axes that overlaps any previous axes, then the new axes replaces the existing ones.

`subplot( __ ,Name,Value)` specifies properties for the axes using any of the input argument combinations in the previous syntaxes and one or more `Name,Value` pair arguments.

# subplot

---

`h = subplot( __ )` returns the handle to the axes created by the `subplot` function.

`subplot(h)` makes the axes with handle `h` the current axes for subsequent plotting commands.

## Input Arguments

### **m - Number of grid rows**

1 (default) | positive integer

Number of grid rows, specified as a positive integer.

### **Data Types**

single | double

### **n - Number of grid columns**

1 (default) | positive integer

Number of grid columns, specified as a positive integer.

### **Data Types**

single | double

### **p - Grid position for new axes**

positive integer | vector

Grid position for the new axes, specified as a positive integer or a vector of positive integers.

- If `p` is a positive integer, then `subplot` creates a new axes in grid location `p`.
- If `p` is a vector of positive integers, then `subplot` creates a new axes that spans the grid locations listed in `p`. For example, `subplot(2,3,[2,5])` creates one axes spanning positions 2 and 5. Use `subplot(2,3,[2,6])` to create one axes spanning positions 2, 3, 5, and 6.

### **Data Types**

single | double

**positionVector - Normalized position for new axes**

four-element vector of values between 0.0 and 1.0

Normalized position for the new axes, specified as a four-element vector of values between 0.0 and 1.0 with the form `[left,bottom,width,height]`. The values are normalized with respect to the interior of the figure. The first two elements specify the position of the bottom-left corner of the axes in relation to the bottom-left corner of the figure. The last two elements specify the width and height of the new axes. Use this syntax to position an axes that does not align with grid positions.

**Example:** `[0.1, 0.1, 0.35, 0.35]`

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

You can set any axes properties for a subplot. Some plotting functions override existing axes property settings. Execute plotting functions before specifying axes properties to avoid overriding them. For a list of axes properties see [Axes Properties](#).

**Example:** `'XGrid','on'`

**Output Arguments****h - Handle to axes object**

scalar

Handle to axes object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of a specific axes object.

# subplot

---

## Examples

### Upper and Lower Subplots

Create a figure with two stacked subplots. Plot a sine wave in each axes.

```
x = linspace(0,10);
y1 = sin(x);
y2 = sin(5*x);
```

```
figure
subplot(2,1,1);
plot(x,y1)
```

```
subplot(2,1,2);
plot(x,y2)
```

### Quadrant of Subplots

Create a figure divided into four subplots.

Define the data.

```
x = linspace(0,10);
y1 = sin(x);
y2 = sin(2*x);
y3 = sin(4*x);
```

# subplot

---

```
y4 = sin(8*x);
```

Plot the four sine waves and title each subplot.

```
figure
subplot(2,2,1);
plot(x,y1);
title('Subplot 1: sin(x)')

subplot(2,2,2);
plot(x,y2);
title('Subplot 2: sin(2x)')

subplot(2,2,3)
plot(x,y3);
title('Subplot 3: sin(4x)')

subplot(2,2,4)
plot(x,y4);
title('Subplot 4: sin(8x)')
```

### Subplots with Different Sizes

Create a figure containing subplots with different sizes.

Define a vector of sine values and a vector of polynomial values.

```
x = linspace(-3.8,3.8);
y_cos = cos(x);
y_poly = 1 - x.^2./2 + x.^4./24;
```

# subplot

---

Plot the sine wave in the first subplot and the polynomial in the second subplot. Create a third subplot that spans the lower half of the figure and plot both vectors together. Add titles to each subplot.

```
figure
subplot(2,2,1);
plot(x,y_cos);
title('Subplot 1: Cosine')

subplot(2,2,2);
plot(x,y_poly,'g');
title('Subplot 2: Polynomial')

subplot(2,2,[3,4]);
plot(x,y_cos,'b',x,y_poly,'g');
title('Subplot 3 and 4: Both')
```

### Replacing Subplots

Replace an existing subplot with an empty axes.

Initialize the random number generator. Use a loop to create a figure with four stem plots of random data.

```
rng(0, 'twister');
figure
for k = 1:4
```

# subplot

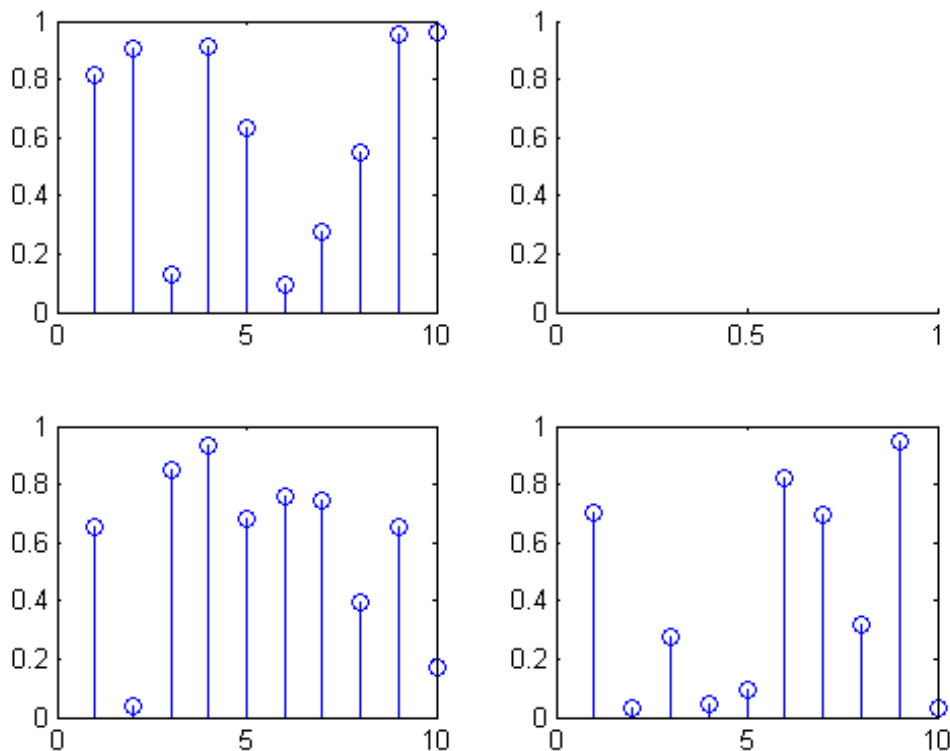

```
data = rand(1,10);
subplot(2, 2, k)
stem(data);
end
```

Replace the second subplot with an empty axes.

```
subplot(2,2,2, 'replace')
```

### Subplots at Specified Positions

Create a figure with two subplots that are not aligned.

Define  $y$  as data from the magic function.

```
y = magic(4);
```

Plot  $y$  in one subplot. Create a bar graph of  $y$  in a second subplot. Specify a custom position for each subplot.

# subplot

```
figure
positionVector1 = [0.1, 0.2, 0.3, 0.3];
subplot('Position',positionVector1)
plot(y)

positionVector2 = [0.5, 0.1, 0.4, 0.7];
subplot('Position',positionVector2)
bar(y)
```

## Return Subplot Axes Handle

Create a figure with two subplots and return the subplot axes handles, h1 and h2.

```
figure
h1 = subplot(2,1,1);
h2 = subplot(2,1,2);
```

# subplot

---

Store the data from the `peaks` function in matrix `Z`. Plot the first 20 rows of `Z` in the upper subplot by referring to its handle, `h1`. Plot the entire data set in the lower subplot.

```
Z = peaks;
plot(h1,Z(1:20,:))
plot(h2,Z);
```

Change the tick marks for the lower subplot using axes properties. Execute plotting functions before specifying axes properties to avoid overriding existing axes property settings.

```
set(h2, 'XTick', [0,10,25,40,50])
```

### **Make Axes the Current Axes**

Make a subplot the current axes using its axes handle.

# subplot

---

Create a figure with multiple subplots. Store the subplot axes handles in vector `h`.

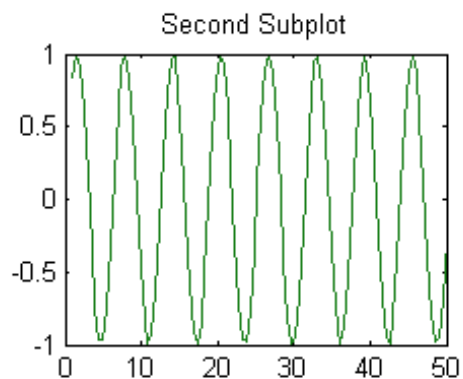

```
figure;
for k = 1:4
 h(k) = subplot(2,2,k);
end
```

Make the second subplot the current axes. Plot a sine wave and change the axis limits.

```
x = linspace(1,50);
y = sin(x);

subplot(h(2));
plot(x,y,'Color',[0.1, 0.5, 0.1]);
title('Second Subplot')
axis([0,50,-1,1])
```

# subplot

---

## Tips

- If the axes already exists, then the command `subplot(m,n,p)` makes the subplot in position `p` the current axes.
- `subplot(111)` is an exception and not identical in behavior to `subplot(1,1,1)`. For reasons of backwards compatibility, `subplot(111)` is a special case of `subplot` that does not immediately create an axes, but sets up the figure so that the next graphics command executes `clf reset`. The next graphics command deletes all the figure children and creates a new axes in the default position. `subplot(111)` does not return a handle and an error occurs if code specifies a return argument.
- If a new subplot axes overlaps an existing axes, then MATLAB deletes the existing axes. To overlay a new axes on top of existing subplots, use the `axes` command. For example, `subplot('Position',[.35 .35 .3 .3])` deletes any underlying subplots, but `axes('Position',[.35 .35 .3 .3])` positions a new axes in the middle of the figure without deleting any underlying axes.
- When using a script to create subplots, MATLAB does not finalize the `Position` property value until either a `drawnow` command is issued or MATLAB returns to await a user command. The `Position` property value for a subplot is subject to change until the script either refreshes the plot or exits.

<b>Purpose</b>	Subscripted assignment
<b>Syntax</b>	<code>A = subsasgn(A, S, B)</code>
<b>Description</b>	<p><code>A = subsasgn(A, S, B)</code> is called by MATLAB for the syntax <code>A(i) = B</code>, <code>A{i} = B</code>, or <code>A.i = B</code> when <code>A</code> is an object.</p> <p>MATLAB uses the built-in <code>subsasgn</code> function to interpret indexed assignment statements. Modify the indexed assignment behavior of classes by overloading <code>subsasgn</code> in the class.</p> <p>If <code>A</code> is a fundamental class (see “Fundamental MATLAB Classes”), then an indexed reference to <code>A</code> calls the built-in <code>subsasgn</code> function. It does not call a <code>subsasgn</code> method that you have overloaded for that class. Therefore, if <code>A</code> is an array of class <code>double</code>, and there is an <code>@double/subsasgn</code> method on your MATLAB path, the statement <code>A(I) = B</code> calls the MATLAB built-in <code>subsasgn</code> function.</p>
<b>Tips</b>	<p>Within a class’s own methods, MATLAB calls the built-in <code>subsasgn</code>, not the class defined <code>subsasgn</code>. This behavior enables to use the default <code>subsasgn</code> behavior when defining specialized indexing for your class. See “<code>subsref</code> and <code>subsasgn</code> Within Class Methods — Built-In Called” for more information.</p>
<b>Input Arguments</b>	<p><b>A</b> Object</p> <p><b>S</b> struct array with two fields, <code>type</code> and <code>subs</code>.</p> <ul style="list-style-type: none"> <li>• <code>type</code> is a string containing '()', '{}', or '.', where '()' specifies integer subscripts, '{}' specifies cell array subscripts, and '.' specifies subscripted structure fields.</li> <li>• <code>subs</code> is a cell array or string containing the actual subscripts.</li> </ul> <p><b>B</b></p>

# subsasgn

---

Assignment value (right-hand side)

## Output Arguments

**A**  
Result of evaluating assignment.

## Examples

See how MATLAB calls `subsasgn` for the expression:

```
A(1:2,:) = B;
```

The syntax `A(1:2,:) = B` calls `A = subsasgn(A,S,B)` where `S` is a 1-by-1 structure with `S.type = '()'` and `S.subs = {1:2, ':'}`. The string `':'` indicates a colon used as a subscript.

---

See how MATLAB calls `subsasgn` for the expression:

```
A{1:2} = B;
```

The syntax `A{1:2} = B` calls `A = subsasgn(A,S,B)` where `S.type = '{}'` and `S.subs = {[1 2]}`.

---

See how MATLAB calls `subsasgn` for the expression:

```
A.field = B;
```

The syntax `A.field = B` calls `A = subsasgn(A,S,B)` where `S.type = '.'` and `S.subs = 'field'`.

---

See how MATLAB calls `subsasgn` for the expression:

```
A(1,2).name(3:5)=B;
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscripting levels. For instance, `A(1,2).name(3:5)=B` calls `A=subsasgn(A,S,B)` where `S` is a 3-by-1 structure array with the following values:

```
S(1).type = '()' S(2).type = '.' S(3).type = '()'
S(1).subs = {1,2} S(2).subs = 'name' S(3).subs = {[3 4
 5]}
```

## Algorithms

In the assignment  $A(J,K,\dots) = B(M,N,\dots)$ , subscripts  $J, K, M, N$ , and so on, can be scalar, vector, or arrays, when all the following are true:

- The number of subscripts specified for  $B$ , excluding trailing subscripts equal to 1, does not exceed the value returned by `ndims(B)`.
- The number of nonscalar subscripts specified for  $A$  equals the number of nonscalar subscripts specified for  $B$ . For example,  $A(5, 1:4, 1, 2) = B(5:8)$  is valid because both sides of the equation use one nonscalar subscript.
- The order and length of all nonscalar subscripts specified for  $A$  matches the order and length of nonscalar subscripts specified for  $B$ . For example,  $A(1:4, 3, 3:9) = B(5:8, 1:7)$  is valid because both sides of the equation (ignoring the one scalar subscript 3) use a 4-element subscript followed by a 7-element subscript.

See `numel` for information concerning the use of `numel` with regards to the overloaded `subsasgn` function.

# subsindex

---

**Purpose**                 Subscript indexing with object

**Syntax**                 `ind = subsindex(A)`

**Description**           `ind = subsindex(A)` called by MATLAB for the expression `X(A)` when `A` is an object, unless such an expression results in a call to an overloaded `subsref` or `subsasgn` method for `X`. `subsindex` must return the value of the object as a zero-based integer index. (`ind` must contain integer values in the range 0 to `prod(size(X))-1`.) Call `subsindex` directly from an overloaded `subsref` or `subsasgn` method.

MATLAB invokes `subsindex` separately on all the subscripts in an expression, such as `X(A,B)`.

**See Also**                 `subsasgn` | `subsasgn`

**Tutorials**

- “Using Objects as Indices”

<b>Purpose</b>	Angle between two subspaces
<b>Syntax</b>	<code>theta = subspace(A,B)</code>
<b>Description</b>	<code>theta = subspace(A,B)</code> finds the angle between two subspaces specified by the columns of A and B. If A and B are column vectors of unit length, this is the same as <code>acos(abs(A'*B))</code> .
<b>Tips</b>	If the angle between the two subspaces is small, the two spaces are nearly linearly dependent. In a physical experiment described by some observations A, and a second realization of the experiment described by B, <code>subspace(A,B)</code> gives a measure of the amount of new information afforded by the second experiment not associated with statistical errors of fluctuations.
<b>Examples</b>	<p>Consider two subspaces of a Hadamard matrix, whose columns are orthogonal.</p> <pre>H = hadamard(8); A = H(:,2:4); B = H(:,5:8);</pre> <p>Note that matrices A and B are different sizes — A has three columns and B four. It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.</p> <pre>theta = subspace(A,B) theta =     1.5708</pre> <p>That A and B are orthogonal is shown by the fact that theta is equal to <math>\pi/2</math>.</p> <pre>theta - pi/2 ans =     0</pre>

# subsref

---

**Purpose** Redefine subscripted reference for objects

**Syntax** `B = subsref(A,S)`

**Description** `B = subsref(A,S)` is called by MATLAB for the syntax `A(i)`, `A{i}`, or `A.i` when `A` is an object. `S` is a struct array with two fields, `type` and `subs`.

The `type` field is string containing `'()'`, `'{}'`, or `','`, where `'()'` specifies integer subscripts, `'{}'` specifies cell array subscripts, and `','` specifies subscripted structure fields. The `subs` field is a cell array or a string containing the actual subscripts.

`B` is the result of the indexed expression.

MATLAB uses the built-in `subsref` function to interpret indexed references to objects. To modify the indexed reference behavior of objects, overload `subsref` in the class.

If `A` is a fundamental class (see “Fundamental MATLAB Classes”), then an indexed reference to `A` calls the built-in `subsref` function. It does not call a `subsref` method that you have overloaded for that class. Therefore, if `A` is an array of class `double`, and there is an `@double/subsref` method on your MATLAB path, the statement `A(I)` calls the MATLAB built-in `subsref` function.

**Tips** Within a class’s own methods, MATLAB calls the built-in `subsref`, not the class defined `subsref`. This behavior enables to use the default `subsref` behavior when defining specialized indexing for your class. See “`subsref` and `subsasgn` Within Class Methods — Built-In Called” for more information.

**Examples** See how MATLAB calls `subsref` for the expression:

```
A(1:2,:)
```

The syntax `A(1:2,:)` calls `B = subsref(A,S)` where `S` is a 1-by-1 structure with `S.type='()'` and `S.subs={1:2,','}`. The string `','` indicates a colon used as a subscript.

See how MATLAB calls `subsref` for the expression:

```
A{1:2}
```

The syntax `A{1:2}` calls `B = subsref(A,S)` where `S.type='{}'` and `S.subs={1 2}`.

See how MATLAB calls `subsref` for the expression:

```
A.field
```

The syntax `A.field` calls `B = subsref(A,S)` where `S.type='.'` and `S.subs='field'`.

See how MATLAB calls `subsref` for the expression:

```
A(1,2).name(3:5)
```

Simple calls combine in a straightforward way for more complicated indexing expressions. In such cases, `length(S)` is the number of subscript levels. For instance, `A(1,2).name(3:5)` calls `subsref(A,S)` where `S` is a 3-by-1 structure array with the following values:

<code>S(1).type='()'</code>	<code>S(2).type='.'</code>	<code>S(3).type='()'</code>
<code>S(1).subs={1,2}</code>	<code>S(2).subs='name'</code>	<code>S(3).subs={[3 4 5]}</code>

`numel` | `subsasgn` | `substruct`

## Tutorials

- “Indexed Reference and Assignment”

# substruct

---

**Purpose** Create structure argument for subsasgn or subsref

**Syntax** `S = substruct(type1, subs1, type2, subs2, ...)`

**Description** `S = substruct(type1, subs1, type2, subs2, ...)` creates a structure with the fields required by an overloaded `subsref` or `subsasgn` method. Each `type` string must be one of `'.'`, `'()'` , or `'{'`. The corresponding `subs` argument must be either a field name (for the `'.'` type) or a cell array containing the index vectors (for the `'()'`  or `'{'` types).

**Output Arguments** **S**  
struct with these fields:

- `type`: one of `'.'`, `'()'` , or `'{'`
- `subs`: subscript values (field name or cell array of index vectors)

**Examples** Call `subsref` with arguments equivalent to the syntax:

```
B = A(3,5).field;
```

where `A` is an object of a class that implements a `subsref` method

Use `substruct` to form the input struct, `S`:

```
S = substruct('()', {3,5}, '.', 'field');
```

Call the class method:

```
B = subsref(A,S);
```

The struct created by `substruct` in this example contains:

```
S(1)
```

```
ans =
```

```
type: '()'
subs: {[3] [5]}
```

S(2)

ans =

```
type: '.'
subs: 'field'
```

- “Indexed Reference and Assignment”

# subvolume

---

**Purpose** Extract subset of volume data set

**Syntax**  
`[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)`  
`[Nx,Ny,Nz,Nv] = subvolume(V,limits)`  
`Nv = subvolume(...)`

**Description** `[Nx,Ny,Nz,Nv] = subvolume(X,Y,Z,V,limits)` extracts a subset of the volume data set `V` using the specified axis-aligned `limits`. `limits = [xmin,xmax,ymin, ymax,zmin,zmax]` (Any NaNs in the limits indicate that the volume should not be cropped along that axis.)

The arrays `X`, `Y`, and `Z` define the coordinates for the volume `V`. The subvolume is returned in `NV` and the coordinates of the subvolume are given in `NX`, `NY`, and `NZ`.

`[Nx,Ny,Nz,Nv] = subvolume(V,limits)` assumes the arrays `X`, `Y`, and `Z` are defined as

```
[X,Y,Z] = meshgrid(1:N,1:M,1:P)
```

where `[M,N,P] = size(V)`.

`Nv = subvolume(...)` returns only the subvolume.

## Examples

This example uses a data set that is a collection of MRI slices of a human skull. The data is processed in a variety of ways:

- The 4-D array is squeezed (`squeeze`) into three dimensions and then a subset of the data is extracted (`subvolume`).
- The outline of the skull is an isosurface generated as a patch (`p1`) whose vertex normals are recalculated to improve the appearance when lighting is applied (`patch`, `isosurface`, `isonormals`).
- A second patch (`p2`) with interpolated face color draws the end caps (`FaceColor`, `isocaps`).
- The view of the object is set (`view`, `axis`, `daspect`).
- A 100-element grayscale colormap provides coloring for the end caps (`colormap`).

- Adding lights to the right and left of the camera illuminates the object (camlight, lighting).

```
load mri
D = squeeze(D);
[x,y,z,D] = subvolume(D,[60,80,nan,80,nan,nan]);
p1 = patch(isosurface(x,y,z,D, 5),...
 'FaceColor','red','EdgeColor','none');
isonormals(x,y,z,D,p1);
p2 = patch(isocaps(x,y,z,D, 5),...
 'FaceColor','interp','EdgeColor','none');
view(3); axis tight; daspect([1,1,.4])
colormap(gray(100))
camlight right; camlight left; lighting gouraud
```

<b>Purpose</b>	Sum of array elements
<b>Syntax</b>	<pre>S = sum(A) S = sum(A,dim) S = sum( __ , type)</pre>
<b>Description</b>	<p><code>S = sum(A)</code> returns the sum of the elements of <code>A</code> along the first array dimension whose size does not equal 1:</p> <ul style="list-style-type: none"><li>• If <code>A</code> is a vector, then <code>sum(A)</code> returns the sum of the elements.</li><li>• If <code>A</code> is a nonempty, nonvector matrix, then <code>sum(A)</code> treats the columns of <code>A</code> as vectors and returns a row vector whose elements are the sums of each column.</li><li>• If <code>A</code> is an empty 0-by-0 matrix, then <code>sum(A)</code> returns 0, a 1-by-1 matrix.</li><li>• If <code>A</code> is a multidimensional array, then <code>sum(A)</code> treats the values along the first array dimension whose size does not equal 1 as vectors and returns an array of row vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.</li></ul> <p><code>S = sum(A,dim)</code> sums the elements of <code>A</code> along dimension <code>dim</code>. The <code>dim</code> input is a positive integer scalar.</p> <p><code>S = sum( __ , type)</code> accumulates in and returns an array in the class specified by <code>type</code>, using any of the input arguments in the previous syntaxes. <code>type</code> can be 'double' or 'native'.</p>
<b>Input Arguments</b>	<p><b>A - Input array</b> scalar   vector   matrix   multidimensional array</p> <p>Input array, specified as a scalar, vector, matrix, or multidimensional array.</p> <p><b>Data Types</b> single   double   int8   int16   int32   int64   uint8   uint16   uint32   uint64   logical   char</p>

**Complex Number Support:** Yes

**dim - Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, A:

- `sum(A, 1)` works on successive elements in the columns of A and returns a row vector of the sums of each column.
- `sum(A, 2)` works on successive elements in the rows of A and returns a column vector of the sums of each row.

`sum` returns A if `dim` is greater than `ndims(A)`.

**Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

**type - Output class**

'double' | 'native'

Output class, specified as 'double' or 'native', defines the data type that the operation is performed in and returned in.

- If `type` is 'double', then `sum` computes and returns a double-precision array, regardless of the input data type. For example, if A is single,

then `sum` accumulates in and returns in `double`. This is the default behavior for integer data types when `type` is not specified.

- If `type` is `'native'`, `sum` accumulates natively and returns an array with the same data type as the input array `A`. For example, if `A` has data type `int8`, then `sum(A, 'native')` accumulates in and returns in `int8`. This is the default behavior for `single` and `double` data types when `type` is not specified.

### Data Types

`char`

## Output Arguments

### S - Sum array

`scalar` | `vector` | `matrix` | `multidimensional array`

Sum array, returned as a scalar, vector, matrix, or multidimensional array. The dimension of `A` acted on by `sum` has size 1 in `S`.

The class of `S` is as follows:

- If the `type` argument is not used and the input is not `single`, then the output is `double`.
- If the `type` argument is not used and the input is `single`, then the output is `single`.
- If the `type` argument specifies `'double'`, then the output is `double` regardless of the input data type.
- If the `type` argument specifies `'native'`, then the output is the same data type as the input.

## Examples

### Sum of Vector Elements

Create a vector and compute the sum of the elements.

```
A = 1:10;
S = sum(A)
```

```
S =
```

55

## Sum of Elements in Each Column

Create a 3-by-3 matrix.

A = [1 3 2; 4 2 5; 6 1 4]

A =

1	3	2
4	2	5
6	1	4

Compute the sum of the elements in each column.

S = sum(A)

S =

11	6	11
----	---	----

## Sum of Elements in Each Row

Create a 3-by-3 matrix.

A = [1 3 2; 4 2 5; 6 1 4]

A =

1	3	2
4	2	5
6	1	4

Compute the sum of the elements in each row.

S = sum(A,2)

S =

---

```
6
11
11
```

### Sum of Elements in Each Plane

Create a 4-by-2-by-3 multidimensional array of ones.

```
A = ones(4,2,3)
```

```
A(:,:,1) =
```

```
1 1
1 1
1 1
1 1
```

```
A(:,:,2) =
```

```
1 1
1 1
1 1
1 1
```

```
A(:,:,3) =
```

```
1 1
1 1
1 1
1 1
```

Compute the sum along the third (`dim = 3`) dimension.

```
S = sum(A,3)
```

```
S =
```

## sum

---

```
3 3
3 3
3 3
3 3
```

The length of the first dimension matches `size(A,1)`, the length of the second dimension matches `size(A,2)`, and the length of the third dimension is 1.

### Integer Overflow Due to Output Data Type

Create a vector of signed 8-bit integers and compute the sum of the elements.

```
A = int8(1:20);
S = sum(A)
```

```
S =
```

```
210
```

The output has data type `double` because of default behavior.

```
class(S)
```

```
ans =
```

```
double
```

To keep the same data type in the output as in the input, specify `type` as `'native'`.

```
S = sum(A, 'native')
```

```
S =
```

```
127
```

---

This disagrees with the double-precision value of 210 because the output has data type `int8` and is saturated.

```
class(S)
```

```
ans =
```

```
int8
```

**See Also**

`cumsum` | `diff` | `isfloat` | `prod`

# summary

---

**Purpose** Print summary of table or categorical array

**Syntax** `summary(T)`

`summary(A)`  
`summary(A,dim)`

**Description** `summary(T)` prints a summary of the table, `T`. The table summary displays the table description from `T.Properties.Description` followed by a summary of the table variables.

`summary(A)` prints a summary of the categorical array, `A`.

- If `A` is a vector, then `summary(A)` displays the category names along with the number of elements in each category (the category counts). Furthermore, the summary contains the number of elements that are undefined.
- If `A` is a matrix, then `summary` treats the columns of `A` as vectors and displays the category counts for each column of `A`.
- If `A` is a multidimensional array, then `summary` acts along the first array dimension whose size does not equal 1.

`summary(A,dim)` prints the category counts of the categorical array, `A`, along dimension `dim`.

For example, you can display the counts of each row in a categorical array using `counts(A,2)`.

## Input Arguments

### **T - Input table**

table

Input table, specified as a table.

### **A - Categorical array**

vector | matrix | multidimensional array

Categorical array, specified as a vector, matrix, or multidimensional array.

**dim - Dimension of A to operate along**

positive integer scalar

Dimension of A to operate to along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional categorical array, A:

If  $\text{dim} = 1$ , then  $\text{summary}(A, 1)$  displays the category counts for each column of A.

If  $\text{dim} = 2$ , then  $\text{summary}(A, 2)$  returns the category counts of each row of A.

# summary

---

If `dim` is greater than `ndims(A)`, then `summary(A)` returns an array the same size as `A` for each category. `summary` returns 1 for elements in the corresponding category and 0 otherwise.

## Examples

### Summary of Table

Create a table.

```
load patients
BloodPressure = [Systolic Diastolic];
T = table(Gender, Age, Smoker, BloodPressure, 'RowNames', LastName);
```

Add descriptions and units to table T.

```
T.Properties.Description = 'Simulated patient data';
T.Properties.VariableUnits = {'' 'Yrs' '' 'mm Hg'};
T.Properties.VariableDescriptions{4} = 'Systolic/Diastolic';
```

Print a summary of table T.

```
format compact
```

```
summary(T)
```

```
Description: Simulated patient data
Variables:
 Gender: 100x1 cell string
 Age: 100x1 double
 Units: Yrs
 Values:
 min 25
 median 39
 max 50
 Smoker: 100x1 logical
 Values:
 true 34
 false 66
 BloodPressure: 100x2 double
```

```

Units: mm Hg
Description: Systolic/Diastolic
Values:

```

	BloodPressure_1	BloodPressure_2
min	109	68
median	122	81.5
max	138	99

summary displays the minimum, median, and maximum values for each column of the variable BloodPressure.

### Summary of Categorical Vector

Create a 1-by-5 categorical vector.

```
A = categorical({'plane' 'car' 'train' 'car' 'plane'})
```

```
A =
```

```

 plane car train car plane

```

A has three categories, car, plane, and train.

Print a summary of A.

```
summary(A)
```

```

 car plane train
 2 2 1

```

car appears in two elements of A, plane appears in two elements, and train appears in one element.

Since A is a row vector, summary lists the occurrences of each category horizontally.

### Summary of Each Column in Categorical Array

Create a 3-by-2 categorical array, A, from a numeric array.

# summary

---

```
X = [1 3; 2 1; 3 1; 4 2];
valueset = 1:3;
catnames = {'red' 'green' 'blue'};

A = categorical(X,valueset,catnames)
```

```
A =

 red blue
 green red
 blue red
 <undefined> green
```

A has three categories, red, green, and blue. The value, 4, was not included in the valueset input to the categorical function. Therefore, the corresponding element, A(4,1), does not have a corresponding category and is undefined.

Print a summary of A.

```
summary(A)

 red 1 2
 green 1 1
 blue 1 1
 <undefined> 1 0
```

red appears in one element in the first column of A and two in the second column.

green appears in one element in the first column of A and none in the second column.

blue appears in one element in the first column of A and one in the second column.

A contains only one undefined element. It occurs in the first column.

**Category Counts of Each Row in Categorical Array**

Create a 3-by-2 categorical array, A, from a numeric array.

```
A = categorical([1 3; 2 1; 3 1],1:3,{'red' 'green' 'blue'})
```

A =

```

 red blue
 green red
 blue red

```

A has three categories, red, green, and blue.

Print a summary of A along the second dimension.

```
summary(A,2)
```

```

 red green blue
 1 0 1
 1 1 0
 1 0 1

```

red appears in one element in the first row of A, one in the second row, and one in the third row.

green appears in only one element. It occurs in the second row of A.

blue appears in one element in the first row of A and one in the third column.

**Definitions****Table Summary**

The table summary displays the table description from `T.Properties.Description` followed by information on the variables of T.

The summary contains the following information on the variables:

## summary

---

- Name: Size and Data Type — variable name from `T.Properties.VariableNames`, the size of the variable, and the data type of the variable.
- Units — variable's units from `T.Properties.VariableUnits`.
- Description — variable's description from `T.Properties.VariableDescriptions`.
- Values — only included for numeric variables, logical variables, or categorical variables.
  - numeric variables — minimum, median, and maximum values.
  - logical variables — number of values that are true and the number of values that are false.
  - categorical variables — number of elements from each category.

**Purpose**

Superclass names

**Syntax**

```
superclasses('ClassName')
superclasses(obj)
s = superclasses(...)
```

**Description**

`superclasses('ClassName')` displays the names of all visible superclasses of the MATLAB class with the name *ClassName*. Visible classes have a `Hidden` attribute value of `false` (the default).

`superclasses(obj)` `obj` is an instance of a MATLAB class. `obj` can be either a scalar object or an array of objects.

`s = superclasses(...)` returns the superclass names in a cell array of strings.

**Examples**

Get the name of the `hgsetget` class superclass:

```
superclasses('hgsetget')
```

Superclasses for class `hgsetget`:

```
handle
```

# superiorto

---

**Purpose** Establish superior class relationship

**Syntax** `superiorto('class1', 'class2', ...)`

**Description** `superiorto('class1', 'class2', ...)` establishes that the class invoking this function in its constructor has higher precedence than the classes in the argument list.

The `superiorto` function establishes a precedence that determines which object method MATLAB calls. Use this function only from a constructor that calls the `class` function to create an object. For classes defined with `classdef` statements, see “Class Precedence”.

**Examples** Show function dispatching:

`a` is an object of class `class_a`, `b` is an object of class `class_b`, and `c` is an object of class `class_c`. The constructor method for `class_c` contains the statement `superiorto('class_a')`. Then, either of the following two statements:

```
e = fun(a,c);
e = fun(c,a);
```

invokes `class_c/fun`.

If you call a function with two objects having an unspecified relationship, MATLAB considers the two objects to have equal precedence. In this case, MATLAB calls the left-most object method. So `fun(b,c)` calls `class_b/fun`, while `fun(c,b)` calls `class_c/fun`.

# surf

---

## Purpose

3-D shaded surface plot

## Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

## Description

`surf(Z)` creates a three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface. See [Coloring Mesh and Surface Plots](#) for information on defining  $C$ .

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`surf` does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c}
 i-1, j \\
 | \\
 i, j-1 - i, j - i, j+1 \\
 | \\
 i+1, j
 \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The shading function sets the shading. If the shading is `interp`, `C` must be the same size as `X`, `Y`, and `Z`; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local coordinates. If the shading is `faceted` (the default) or `flat`, `C(i, j)` specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i, j) & - & (i, j+1) \\ | & C(i, j) & | \\ (i+1, j) & - & (i+1, j+1) \end{array}$$

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of `XLimMode`, `YLimMode`, and `ZLimMode` axes properties determines the axis labels. You can also set these properties using `axis` function.

The range of `C` or the current setting of the `CLim` and `CLimMode` axes properties determines the color scaling. You can also set the properties using `caxis` function. The scaled color values are indices into the current colormap.

## Examples

### Surface Plot of Peaks Function

Use the `peaks` function to define `X`, `Y`, and `Z` as 25-by-25 matrices. Then, create a surface plot.

```
[X,Y,Z] = peaks(25);
```

```
figure
surf(X,Y,Z);
```

`surf` creates the surface plot from corresponding values in X, Y, and Z. If you do not define the color data C, then `surf` uses Z to determine the color, so color is proportional to surface height.

### **Sphere With Two Colors**

Create a sphere and color it using the pattern from a Hadamard matrix, which is a matrix that contains the values 1 and -1. Change the colors used in the plot by setting the colormap to an array of two RGB triplet values.

# surf

---

```
k = 5;
n = 2^k-1;
[x,y,z] = sphere(n);
c = hadamard(2^k);

figure
surf(x,y,z,c);
colormap([1 1 0; 0 1 1])
axis equal
```

- Coloring Mesh and Surface Plots

## Purpose

Contour plot under a 3-D shaded surface plot

## Syntax

```
surf(Z)
surf(Z,C)
surf(X,Y,Z)
surf(X,Y,Z,C)
surf(...,'PropertyName',PropertyValue)
surf(axes_handles,...)
h = surf(...)
```

## Description

`surf(Z)` creates a contour plot under the three-dimensional shaded surface from the  $z$  components in matrix  $Z$ , using  $x = 1:n$  and  $y = 1:m$ , where  $[m,n] = \text{size}(Z)$ . The height,  $Z$ , is a single-valued function defined over a geometrically rectangular grid.  $Z$  specifies the color data, as well as surface height, so color is proportional to surface height.

`surf(Z,C)` plots the height of  $Z$ , a single-valued function defined over a geometrically rectangular grid, and uses matrix  $C$ , assumed to be the same size as  $Z$ , to color the surface.

`surf(X,Y,Z)` uses  $Z$  for the color data and surface height.  $X$  and  $Y$  are vectors or matrices defining the  $x$  and  $y$  components of a surface. If  $X$  and  $Y$  are vectors,  $\text{length}(X) = n$  and  $\text{length}(Y) = m$ , where  $[m,n] = \text{size}(Z)$ . In this case, the vertices of the surface faces are  $(X(j), Y(i), Z(i,j))$  triples. To create  $X$  and  $Y$  matrices for arbitrary domains, use the `meshgrid` function.

`surf(X,Y,Z,C)` uses  $C$  to define color. MATLAB performs a linear transformation on this data to obtain colors from the current colormap.

`surf(...,'PropertyName',PropertyValue)` specifies surface Surfaceplot along with the data.

`surf(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = surf(...)` returns a handle to a Surfaceplot graphics object.

## Tips

`surf` does not accept complex inputs.

## Algorithms

Consider a parametric surface parameterized by two independent variables,  $i$  and  $j$ , which vary continuously over a rectangle; for example,  $1 \leq i \leq m$  and  $1 \leq j \leq n$ . The three functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  specify the surface. When  $i$  and  $j$  are integer values, they define a rectangular grid with integer grid points. The functions  $x(i, j)$ ,  $y(i, j)$ , and  $z(i, j)$  become three  $m$ -by- $n$  matrices,  $X$ ,  $Y$ , and  $Z$ . Surface color is a fourth function,  $c(i, j)$ , denoted by matrix  $C$ .

Each point in the rectangular grid can be thought of as connected to its four nearest neighbors.

$$\begin{array}{c}
 i-1, j \\
 | \\
 i, j-1 - i, j - i, j+1 \\
 | \\
 i+1, j
 \end{array}$$

This underlying rectangular grid induces four-sided patches on the surface. To express this another way, `[X(:) Y(:) Z(:)]` returns a list of triples specifying points in 3-D space. Each interior point is connected to the four neighbors inherited from the matrix indexing. Points on the edge of the surface have three neighbors. The four points at the corners of the grid have only two neighbors. This defines a mesh of quadrilaterals or a *quad-mesh*.

You can specify surface color in two different ways: at the vertices or at the centers of each patch. In this general setting, the surface need not be a single-valued function of  $x$  and  $y$ . Moreover, the four-sided surface patches need not be planar. For example, you can have surfaces defined in polar, cylindrical, and spherical coordinate systems.

The shading function sets the shading. If the shading is `interp`,  $C$  must be the same size as  $X$ ,  $Y$ , and  $Z$ ; it specifies the colors at the vertices. The color within a surface patch is a bilinear function of the local

coordinates. If the shading is `faceted` (the default) or `flat`, `C(i,j)` specifies the constant color in the surface patch:

$$\begin{array}{ccc} (i,j) & - & (i,j+1) \\ | & C(i,j) & | \\ (i+1,j) & - & (i+1,j+1) \end{array}$$

In this case, `C` can be the same size as `X`, `Y`, and `Z` and its last row and column are ignored. Alternatively, its row and column dimensions can be one less than those of `X`, `Y`, and `Z`.

The `surf` function specifies the viewpoint using `view(3)`.

The range of `X`, `Y`, and `Z` or the current setting of the axes `XLimMode`, `YLimMode`, and `ZLimMode` properties (also set by the `axis` function) determines the axis labels.

The range of `C` or the current setting of the axes `CLim` and `CLimMode` properties (also set by the `caxis` function) determines the color scaling. The scaled color values are used as indices into the current colormap.

## Examples

### Display Contour Plot Under Surface Plot

Display a contour plot under a surface plot of the `peaks` function.

```
[X,Y,Z] = peaks(30);
figure
surf(X,Y,Z)
```

# surf2patch

---

**Purpose** Convert surface data to patch data

**Syntax**

```
fvc = surf2patch(Z)
fvc = surf2patch(Z,C)
fvc = surf2patch(X,Y,Z)
fvc = surf2patch(X,Y,Z,C)
fvc = surf2patch(...,'triangles')
[f,v,c] = surf2patch(...)
```

**Description** `fvc = surf2patch(h)` converts the geometry and color data from the surface object identified by the handle `h` into patch format and returns the face, vertex, and color data in the struct `fvc`. You can pass this struct directly to the `patch` command.

`fvc = surf2patch(Z)` calculates the patch data from the surface's `ZData` matrix `Z`.

`fvc = surf2patch(Z,C)` calculates the patch data from the surface's `ZData` and `CData` matrices `Z` and `C`.

`fvc = surf2patch(X,Y,Z)` calculates the patch data from the surface's `XData`, `YData`, and `ZData` matrices `X`, `Y`, and `Z`.

`fvc = surf2patch(X,Y,Z,C)` calculates the patch data from the surface's `XData`, `YData`, `ZData`, and `CData` matrices `X`, `Y`, `Z`, and `C`.

`fvc = surf2patch(...,'triangles')` creates triangular faces instead of the quadrilaterals that compose surfaces.

`[f,v,c] = surf2patch(...)` returns the face, vertex, and color data in the three arrays `f`, `v`, and `c` instead of a struct.

**Examples** The first example uses the `sphere` command to generate the `XData`, `YData`, and `ZData` of a surface, which is then converted to a patch. Note that the `ZData` (`z`) is passed to `surf2patch` as both the third and fourth arguments — the third argument is the `ZData` and the fourth argument is taken as the `CData`. This is because the `patch` command does not

automatically use the  $z$ -coordinate data for the color data, as does the `surface` command.

Also, because `patch` is a low-level command, you must set the view to 3-D and shading to `faceted` to produce the same results produced by the `surf` command.

```
[x y z] = sphere;
patch(surf2patch(x,y,z,z));
shading faceted; view(3)
```

In the second example `surf2patch` calculates face, vertex, and color data from a surface whose handle has been passed as an argument.

```
s = surf(peaks);
pause
patch(surf2patch(s));
delete(s)
shading faceted; view(3)
```

## See Also

`patch` | `reducepatch` | `shrinkfaces` | `surface` | `surf`

# surface

---

**Purpose** Create surface object

**Syntax**

```
surface(Z)
surface(Z,C)
surface(X,Y,Z)
surface(X,Y,Z,C)
surface(x,y,Z)
surface(... 'PropertyName',PropertyValue,...)
h = surface(...)
```

**Properties** For a list of properties, see `Surface Properties`.

**Description** `surface` is the low-level function for creating surface graphics objects. Surfaces are plots of matrix data created using the row and column indices of each element as the  $x$ - and  $y$ -coordinates and the value of each element as the  $z$ -coordinate.

`surface(Z)` plots the surface specified by the matrix  $Z$ . Here,  $Z$  is a single-valued function, defined over a geometrically rectangular grid.

`surface(Z,C)` plots the surface specified by  $Z$  and colors it according to the data in  $C$  (see "Examples").

`surface(X,Y,Z)` uses  $C = Z$ , so color is proportional to surface height above the  $x$ - $y$  plane.

`surface(X,Y,Z,C)` plots the parametric surface specified by  $X$ ,  $Y$ , and  $Z$ , with color specified by  $C$ .

`surface(x,y,Z)`, `surface(x,y,Z,C)` replaces the first two matrix arguments with vectors and must have `length(x) = n` and `length(y) = m` where `[m,n] = size(Z)`. In this case, the vertices of the surface facets are the triples  $(x(j), y(i), Z(i,j))$ . Note that  $x$  corresponds to the columns of  $Z$  and  $y$  corresponds to the rows of  $Z$ . For a complete discussion of parametric surfaces, see the `surf` function.

`surface(... 'PropertyName',PropertyValue,...)` follows the  $X$ ,  $Y$ ,  $Z$ , and  $C$  arguments with property name/property value pairs to specify

additional surface properties. For a description of the properties, see `Surface Properties`.

`h = surface(...)` returns a handle to the created surface object.

## Tips

`surface` does not respect the settings of the figure and axes `NextPlot` properties. It simply adds the surface object to the current axes.

If you do not specify separate color data (C), MATLAB uses the matrix (Z) to determine the coloring of the surface. In this case, color is proportional to values of Z. You can specify a separate matrix to color the surface independently of the data defining the area of the surface.

You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see `set` and `get` for examples of how to specify these data types).

`surface` provides convenience forms that allow you to omit the property name for the `XData`, `YData`, `ZData`, and `CData` properties. For example,

```
surface('XData',X,'YData',Y,'ZData',Z,'CData',C)
```

is equivalent to

```
surface(X,Y,Z,C)
```

When you specify only a single matrix input argument,

```
surface(Z)
```

MATLAB assigns the data properties as if you specified

```
surface('XData',[1:size(Z,2)],...
 'YData',[1:size(Z,1)],...
 'ZData',Z,...
 'CData',Z)
```

The `axis`, `caxis`, `colormap`, `hold`, `shading`, and `view` commands set graphics properties that affect surfaces. You can also set and query

# surface

---

surface property values after creating them using the `set` and `get` commands.

## Examples

### Create Surface Plot

Plot the function  $z = xe^{-x^2-y^2}$  on the domain  $-2 \leq x \leq 2$  and  $-2 \leq y \leq 2$ . Use `meshgrid` to define `X` and `Y`. Then, define `Z` and create a surface plot. Change the view of the plot using `view`.

```
[X,Y] = meshgrid(-2:0.2:2,-2:0.2:2);
Z = X.*exp(-X.^2 - Y.^2);
figure
surface(X,Y,Z);
view(3)
```

`surface` creates the plot from corresponding values in X, Y, and Z. If you do not define the color data C, then `surface` uses Z to determine the color, so color is proportional to surface height.

### Display Image Along Surface Plot

Use the `peaks` function to define XD, YD, and ZD as 25-by-25 matrices.

```
[XD,YD,ZD] = peaks(25);
```

## surface

---

Load the clown data set to get the image data `X` and its associated colormap, `map`. Flip `X` using the `flipud` function and define the flipped image as the color data for the surface, `C`.

```
load clown
C = flipud(X);
```

Create a surface plot and display the image along the surface. Since the surface data `ZD` and the color data `C` have different dimensions, you must set the surface `FaceColor` to `'texturemap'`.

```
figure
surface(XD,YD,ZD,C,...
 'FaceColor','texturemap',...
 'EdgeColor','none',...
 'CDataMapping','direct')
colormap(map);
view(-35,45);
```

The clown data is typically viewed with the `image` function, which uses 'ij' axis numbering. This example reverses the image data in the vertical direction using `flipud`.

## Setting Default Properties

You can set default surface properties on the axes, figure, and root object levels:

```
set(0, 'DefaultSurfaceProperty', PropertyValue...)
set(gcf, 'DefaultSurfaceProperty', PropertyValue...)
set(gca, 'DefaultSurfaceProperty', PropertyValue...)
```

# surface

---

where *Property* is the name of the surface property whose default value you want to set and *PropertyValue* is the value you are specifying. Use `set` and `get` to access the surface properties.

## Tutorials

For examples, see [Representing a Matrix as a Surface](#).

## See Also

## Purpose

Surface properties

## Creating Surface Objects

Use `surface` to create surface objects.

## Modifying Properties

You can set and query graphics object properties in two ways:

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see [Setting Default Property Values](#).

See “Core Graphics Objects” for general information about this type of object.

## Surface Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`AlphaData`

`m-by-n matrix of double or uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)

# Surface Properties

---

- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

`AlphaDataMapping`

`none` | `direct` | `{scaled}`

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data.

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range (the default).
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values.
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

`AmbientStrength`

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the surface `DiffuseStrength` and `SpecularStrength` properties.

## Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this surface object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the surface object is displayed in a figure legend:

<b>IconDisplayStyle Value</b>	<b>Purpose</b>
on	Represent this surface object in a legend (default)
off	Do not include this surface object in a legend
children	Same as on because surface objects do not have children

## Setting the `IconDisplayStyle` property

Set the `IconDisplayStyle` of a graphics object with handle `hobj` to `off`:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

# Surface Properties

---

## Using the `IconDisplayStyle` property

See “Control Legend Content” for more information and examples.

`BackFaceLighting`  
`unlit | lit | {reverselit}`

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- `unlit` — Face not lit.
- `lit` — Face lit in normal way.
- `reverselit` — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

`BeingDeleted`  
`on | {off}` (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

`BusyAction`  
`cancel | {queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the surface object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src,evnt)
% src - the object that is the source of the event
```

# Surface Properties

---

```
% evnt - empty for this property
sel_typ = get(gcf,'SelectionType')
switch sel_typ
 case 'normal'
 disp('User clicked left-mouse button')
 set(src,'Selected','on')
 case 'extend'
 disp('User did a shift-click')
 set(src,'Selected','on')
 case 'alt'
 disp('User did a control-click')
 set(src,'Selected','on')
 set(src,'SelectionHighlight','off')
end
end
```

Suppose `h` is the handle of a surface object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h,'ButtonDownFcn',@button_down)
```

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

**CData**  
matrix (of type double)

*Vertex colors.* Values that specify the color at every point in `ZData`.

## Mapping CData to a Colormap

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see `caxis`) or interpreted directly as indices into the colormap, depending on the setting of the `CDataMapping` property.

## CData as True Color

True color defines an RGB value for each vertex. If the coordinate data (XData, for example) are contained in  $m$ -by- $n$  matrices, then CData must be an  $m$ -by- $n$ -by-3 array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

## Texturemapping the Surface FaceColor

If you set the FaceColor property to texturemap, CData does not need to be the same size as ZData, but must be of type double or uint8. In this case, MATLAB maps CData to conform to the surface defined by ZData.

CDataMapping  
{scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the surface. (If you use true color specification for CData, this property has no effect.)

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the caxis reference page for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to length(colormap). MATLAB maps values less than 1 to the first color in the colormap, and values greater than length(colormap) to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

Children  
matrix of handles

Always the empty matrix; surface objects have no children.

# Surface Properties

---

## Clipping

{on} | off

*Clipping to axes rectangle.* When `Clipping` is on, MATLAB does not display any portion of the surface that is outside the axes rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a surface object. You must define this property as a default value for surfaces or set the `CreateFcn` property during object creation.

For example, the following statement creates a surface (assuming `x`, `y`, `z`, and `c` are defined), and executes the function referenced by the function handle `@myCreateFcn`.

```
surface(x,y,z,c,'CreateFcn',@myCreateFcn)
```

MATLAB executes this routine after setting all surface properties. Setting this property on an existing surface object has no effect.

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DeleteFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Delete surface callback function.* Executes when you delete the surface object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
 obj_tp = get(src, 'Type');
 disp([obj_tp, ' object deleted'])
 disp('Its user data is:')
 disp(get(src, 'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## `DiffuseStrength`

scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is 0.6.

# Surface Properties

---

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the surface object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

`EdgeAlpha`  
{scalar = 1} | flat | interp

*Transparency of the surface edges.*

- scalar — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

## EdgeColor

`{ColorSpec} | none | flat | interp`

*Color of the surface edge.* Determines how MATLAB colors the edges of the individual faces that make up the surface.

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default value is `[0 0 0]` (black). See `ColorSpec` for more information on specifying color.
- `none` — Edges not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.

- `interp` — Linear interpolation of the `CData` values at the face vertices determines the edge color.

# Surface Properties

---

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on surface edges.

- none — Lights do not affect the edges of this object.
- flat — The effect of light objects is uniform across each edge of the surface.
- gouraud — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- phong — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase surface objects. Alternative erase modes are useful for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- normal — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- none — Do not erase the surface when it is moved or destroyed. While the object is still visible on the screen after erasing with EraseMode none, you cannot print it because MATLAB stores no information about its former location.

- `xor` — Draw and erase the surface by performing an exclusive OR (XOR) with each pixel index of the screen behind it. Erasing the surface does not damage the color of the objects behind it. However, surface color depends on the color of the screen behind it and is correctly colored only when over the axes background `Color`, or the figure background `Color` if the axes `Color` is none.
- `background` — Erase the surface by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is set to none. This damages objects that are behind the erased object, but surface objects are always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## FaceAlpha

`{scalar = 1} | flat | interp | texturemap`

*Transparency of the surface faces.*

- `scalar` — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).

# Surface Properties

---

- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

## `FaceColor`

`ColorSpec` | `none` | `{flat}` | `interp` | `texturemap`

*Color of the surface face.*

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See the `ColorSpec` reference page for more information on specifying color.
- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example.)

## `FaceLighting`

`none` | `{flat}` | `gouraud` | `phong`

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on the surface.

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## HandleVisibility

`{on} | callback | off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. This property is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching

# Surface Properties

---

the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* Determines if the surface can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking on the surface selects the object below it (which might be the axes containing it).

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is

the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

# Surface Properties

---

For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Line style of surface edges.*

### Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

## LineWidth

size in points

*Edge line width.* The width of the lines in points used to draw surface edges. The default width is 0.5 points. 1 point =  $\frac{1}{72}$  inch.

## Marker

character (see table)

*Marker symbol.* Specifies symbols that are displayed at vertices. You can set values for the Marker property independently from the LineStyle property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

### MarkerEdgeColor

none | {auto} | flat | ColorSpec

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.

# Surface Properties

---

- `ColorSpec` — Defines color to use.

`MarkerFaceColor`

`{none} | auto | flat | ColorSpec`

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surface.

`MarkerSize`

scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MeshStyle`

`{both} | row | column`

*Row and column lines.* Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

## NormalMode

{auto} | manual

*MATLAB generated or user-specified normal vectors.*

- **auto** — MATLAB calculates vertex normals based on the coordinate data
- **manual** — If you specify your own vertex normals, MATLAB sets this property to **manual** and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of axes, hggroup, or hgtransform

*Parent of surface object.* Contains the handle of the surface object's parent. The parent of a surface object is the axes, hggroup, or hgtransform object that contains it.

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays a dashed bounding box around the surface if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing a dashed bounding box around the surface. When `SelectionHighlight` is off, MATLAB does not draw the box.

## SpecularColorReflectance

scalar in the range 0 to 1

# Surface Properties

---

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

**SpecularExponent**

scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

**SpecularStrength**

scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the surface. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surface object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

**Tag**

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

**Type**

string (read-only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given

type within a plotting hierarchy. For surface objects, Type is always 'surface'.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the surface.* Assign this property the handle of a uicontextmenu object created in the same figure as the surface. Use the uicontextmenu function to create the context menu. MATLAB displays the context menu whenever you right-click over the surface.

## UserData

matrix

*User-specified data.* Data you want to associate with the surface object. The default value is an empty array. MATLAB does not use this data, but you can access it using the set and get commands.

## VertexNormals

vector | matrix

*Surface normal vectors.* The vertex normals for the surface. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

## Visible

{on} | off

*Surface object visibility.* By default, all surfaces are visible. When set to off, the surface is not visible, but still exists, and you can query and set its properties.

## XData

vector | matrix

# Surface Properties

---

*X-coordinates.* The  $x$ -position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of columns as `ZData`.

`YData`

vector | matrix

*Y-coordinates.* The  $y$ -position of the surface points. If you specify a row vector, `surface` replicates the row internally until it has the same number of rows as `ZData`.

`ZData`

matrix

*Z-coordinates.* The  $z$ -position of the surface data points. See the `Description` section for more information.

## See Also

`surface`

## Purpose

Define surfaceplot properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

Note that you cannot define default properties for surfaceplot objects.

See Plot Objects for information on surfaceplot objects.

## Surfaceplot Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

`AlphaData`

m-by-n matrix of `double` or `uint8`

*Transparency data.* A matrix of non-NaN values specifying the transparency of each face or vertex of the object. The `AlphaData` can be of class `double` or `uint8`.

MATLAB software determines the transparency in one of the following ways:

- Using the elements of `AlphaData` as transparency values (`AlphaDataMapping` set to `none`)
- Using the elements of `AlphaData` as indices into the current `alphamap` (`AlphaDataMapping` set to `direct`)
- Scaling the elements of `AlphaData` to range between the minimum and maximum values of the axes `ALim` property (`AlphaDataMapping` set to `scaled`, the default)

`AlphaDataMapping`

`none` | `direct` | `{scaled}`

# Surfaceplot Properties

---

*Transparency mapping method.* Determines how MATLAB interprets indexed alpha data. Values for this property are:

- `none` — The transparency values of `AlphaData` are between 0 and 1 or are clamped to this range.
- `scaled` — Transform the `AlphaData` to span the portion of the `alphamap` indicated by the axes `ALim` property, linearly mapping data values to alpha values (the default).
- `direct` — Use the `AlphaData` as indices directly into the `alphamap`. When not scaled, the data are usually integer values ranging from 1 to `length(alphamap)`. MATLAB maps values less than 1 to the first alpha value in the `alphamap`, and values greater than `length(alphamap)` to the last alpha value in the `alphamap`. Values with a decimal portion are fixed to the nearest, lower integer. If `AlphaData` is an array of `uint8` integers, then the indexing begins at 0 (that is, MATLAB maps a value of 0 to the first alpha value in the `alphamap`).

`AmbientStrength`

scalar  $\geq 0$  and  $\leq 1$

*Strength of ambient light.* Sets the strength of the ambient light, which is a nondirectional light source that illuminates the entire scene. You must have at least one visible light object in the axes for the ambient light to be visible. The axes `AmbientLightColor` property sets the color of the ambient light, which is therefore the same on all objects in the axes.

You can also set the strength of the diffuse and specular contribution of light objects. See the `surfaceplot` `DiffuseStrength` and `SpecularStrength` properties.

`Annotation`

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The Annotation property enables you to specify whether this surfaceplot object is represented in a figure legend.

Querying the Annotation property returns the handle of an hg.Annotation object. The hg.Annotation object has a property called LegendInformation, which contains an hg.LegendEntry object.

Once you have obtained the hg.LegendEntry object, you can set its IconDisplayStyle property to control whether the surfaceplot object is displayed in a figure legend:

IconDisplayStyle Value	Purpose
on	Represent this surfaceplot object in a legend (default)
off	Do not include this surfaceplot object in a legend
children	Same as on because surfaceplot objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle hobj to off:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Control Legend Content” for more information and examples.

# Surfaceplot Properties

---

## BackFaceLighting

unlit | lit | {reverselit}

*Face lighting control.* Determines how faces are lit when their vertex normals point away from the camera.

- unlit — Face not lit.
- lit — Face lit in normal way.
- reverselit — Face lit as if the vertex pointed towards the camera.

Use this property to discriminate between the internal and external surfaces of an object. See “Back Face Lighting” for an example.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object’s delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object’s delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-to-be-deleted object, it can check the object’s `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string | function handle

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over this object, but not over another graphics object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

This property can be:

- A string that is a valid MATLAB expression
- The name of a MATLAB file
- A function handle

Set this property to a function handle that references the callback. The expressions execute in the MATLAB workspace.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

# Surfaceplot Properties

---

## CData

matrix

*Vertex colors.* A matrix containing values that specify the color at every point in ZData. If you set the FaceColor property to texturemap, CData does not need to be the same size as ZData. In this case, MATLAB maps CData to conform to the surfaceplot defined by ZData.

You can specify color as indexed values or true color. Indexed color data specifies a single value for each vertex. These values are either scaled to map linearly into the current colormap (see caxis) or interpreted directly as indices into the colormap, depending on the setting of the CDataMapping property. Note that any non-texture data passed as an input argument must be of type double.

True color defines an RGB value for each vertex. If the coordinate data (XData, for example) are contained in m-by-n matrices, then CData must be an m-by-n-by-3 array. The first page contains the red components, the second the green components, and the third the blue components of the colors.

## CDataMapping

{scaled} | direct

*Direct or scaled color mapping.* Determines how MATLAB interprets indexed color data used to color the surfaceplot. (If you use true color specification for CData, this property has no effect.)

- **scaled** — Transform the color data to span the portion of the colormap indicated by the axes CLim property, linearly mapping data values to colors. See the caxis reference page for more information on this mapping.
- **direct** — Use the color data as indices directly into the colormap. The color data should then be integer values ranging from 1 to length(colormap). MATLAB maps values less than

1 to the first color in the colormap, and values greater than `length(colormap)` to the last color in the colormap. Values with a decimal portion are fixed to the nearest lower integer.

**CDataMode**  
{auto} | manual

*Use automatic or user-specified color data values.* If you specify `CData`, MATLAB sets this property to `manual` and uses the `CData` values to color the surfaceplot.

If you set `CDataMode` to `auto` after having specified `CData`, MATLAB resets the color data of the surfaceplot to that defined by `ZData`, overwriting any previous values for `CData`.

**CDataSource**  
string (MATLAB variable)

*Link CData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `CData`.

MATLAB reevaluates this property only when you set it. Therefore, a change to workspace variables appearing in an expression does not change `CData`.

You can use the `refreshdata` function to force an update of the object's data. `refreshdata` also enables you to specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`. See the `refreshdata` reference page for more information.

# Surfaceplot Properties

---

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## Children

matrix of handles

Always the empty matrix; surfaceplot objects have no children.

## Clipping

{on} | off

*Clipping to axes rectangle.* When Clipping is on, MATLAB does not display any portion of the surfaceplot that is outside the axes rectangle.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Defines a callback that executes when MATLAB creates an object. The default is an empty array.

You must specify the callback during the creation of the object. For example:

```
graphicfcn(y, 'CreateFcn', @CallbackFcn)
```

where @*CallbackFcn* is a function handle that references the callback function and *graphicfcn* is the plotting function which creates this object.

MATLAB executes this routine after setting all other object properties. Setting this property on an existing object has no effect.

The handle of the object whose `CreateFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## `DeleteFcn`

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback executed during object deletion.* Executes when this object is deleted (for example, this might happen when you issue a `delete` command on the object, its parent axes, or the figure containing it). MATLAB executes the callback before destroying the object's properties so the callback routine can query these values. The default is an empty array.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which can be queried using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

See the `BeingDeleted` property for related information.

## `DiffuseStrength`

scalar  $\geq 0$  and  $\leq 1$

*Intensity of diffuse light.* Sets the intensity of the diffuse component of the light falling on the surface. Diffuse light comes from light objects in the axes. Default value is 0.6.

# Surfaceplot Properties

---

You can also set the intensity of the ambient and specular components of the light on the object. See the `AmbientStrength` and `SpecularStrength` properties.

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the surfaceplot object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.
- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

`EdgeAlpha`  
{scalar = 1} | flat | interp

*Transparency of the patch and surface edges.*

- scalar — A single non-`NaN` scalar value between 0 and 1 that controls the transparency of all the edges of the object. 1 (the default) means fully opaque and 0 means completely transparent.

- `flat` — The alpha data (`AlphaData`) value for the first vertex of the face determines the transparency of the edges.
- `interp` — Linear interpolation of the alpha data (`AlphaData`) values at each vertex determines the transparency of the edge.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `EdgeAlpha`.

## `EdgeColor`

`{ColorSpec} | none | flat | interp`

*Color of the surfaceplot edge.* This property determines how MATLAB colors the edges of the individual faces that make up the surface:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for edges. The default `EdgeColor` is black. See `ColorSpec` for more information on specifying color.
- `none` — Edges are not drawn.
- `flat` — The `CData` value of the first vertex for a face determines the color of each edge.

# Surfaceplot Properties

---

- `interp` — Linear interpolation of the CData values at the face vertices determines the edge color.

## EdgeLighting

{none} | flat | gouraud | phong

*Algorithm used for lighting calculations.* Selects the algorithm used to calculate the effect of light objects on surfaceplot edges.

- `none` — Lights do not affect the edges of this object.
- `flat` — The effect of light objects is uniform across each edge of the surfaceplot.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the edge lines.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each edge line and calculating the reflectance at each pixel. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase objects. Use alternative erase modes for creating animated sequences, where control of the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to correctly render all objects. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the object when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the object by performing an exclusive OR (XOR) with the color of the screen beneath it. This mode does not damage the color of the objects beneath it. However, the object's color depends on the color of whatever is beneath it on the display.
- **background** — Erase the object by redrawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` property is `none`. This damages objects that are behind the erased object, but properly colors the erased object.

Set the axes background color with the axes `Color` property. Set the figure background color with the figure `Color` property.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

# Surfaceplot Properties

---

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## FaceAlpha

`{scalar = 1} | flat | interp | texturemap`

*Transparency of the surfaceplot faces.* This property can be any of the following:

- `scalar` — A single non-NaN scalar value between 0 and 1 that controls the transparency of all the faces of the object. 1 (the default) means fully opaque and 0 means completely transparent (invisible).
- `flat` — The values of the alpha data (`AlphaData`) determine the transparency for each face. The alpha data at the first vertex determine the transparency of the entire face.
- `interp` — Bilinear interpolation of the alpha data (`AlphaData`) at each vertex determines the transparency of each face.
- `texturemap` — Use transparency for the texture map.

Note that you must specify `AlphaData` as a matrix equal in size to `ZData` to use `flat` or `interp` `FaceAlpha`.

## FaceColor

`ColorSpec | none | {flat} | interp`

*Color of the surfaceplot face.* This property can be any of the following:

- `ColorSpec` — A three-element RGB vector or one of the MATLAB predefined names, specifying a single color for faces. See `ColorSpec` for more information on specifying color.

- `none` — Do not draw faces. Note that edges are drawn independently of faces.
- `flat` — The values of `CData` determine the color for each face of the surface. The color data at the first vertex determine the color of the entire face.
- `interp` — Bilinear interpolation of the values at each vertex (the `CData`) determines the coloring of each face.
- `texturemap` — Texture map the `CData` to the surface. MATLAB transforms the color data so that it conforms to the surface. (See the texture mapping example for `surface`.)

## FaceLighting

`none` | `{flat}` | `gouraud` | `phong`

*Algorithm used for lighting calculations.* This property selects the algorithm used to calculate the effect of light objects on the surface. Choices are

- `none` — Lights do not affect the faces of this object.
- `flat` — The effect of light objects is uniform across the faces of the surface. Select this choice to view faceted objects.
- `gouraud` — The effect of light objects is calculated at the vertices and then linearly interpolated across the faces. Select this choice to view curved surfaces.
- `phong` — The effect of light objects is determined by interpolating the vertex normals across each face and calculating the reflectance at each pixel. Select this choice to view curved surfaces. Phong lighting generally produces better results than Gouraud lighting, but takes longer to render.

## HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility`

# Surfaceplot Properties

---

is useful for preventing command-line users from accidentally accessing objects that you need to protect for some reason.

- `on` — Handles are always visible.
- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

## Functions Affected by Handle Visibility

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

## Properties Affected by Handle Visibility

When a handle's visibility is restricted using `callback` or `off`, the object's handle does not appear in its parent's `Children` property, figures do not appear in the root's `CurrentFigure` property, objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property, and axes do not appear in their parent's `CurrentAxes` property.

## Overriding Handle Visibility

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties. See also `findall`.

## Handle Validity

Hidden handles are still valid. If you know an object's handle, you can `set` and `get` its properties and pass it to any function that operates on handles.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## HitTest

{on} | off

*Selectable by mouse click.* Determines whether this object can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the surface. If `HitTest` is `off`, clicking this object selects the object below it (which is usually the axes containing it).

## Interruptible

off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

# Surfaceplot Properties

---

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

`LineStyle`  
{-} | -- | : | -. | none

*Line style of surfaceplot object.*

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

Use `LineStyle none` when you want to place a marker at each point but do not want the points connected with a line (see the `Marker` property).

`LineWidth`  
size in points

*Width of linear objects and edges of filled areas. Specify in points. 1 point =  $1/72$  inch. The default is 0.5 points.*

`Marker`  
character (see table)

*Marker symbol.* Specifies marks that display at data points. You can set values for the `Marker` property independently from the `LineStyle` property. For a list of supported marker symbols, see the following table.

## Marker Specifiers Table

Specifier	Marker Type
'+'	Plus sign
'o'	Circle

# Surfaceplot Properties

---

Specifier	Marker Type
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h' ' ' '	Six-pointed star (hexagram)
'none'	No marker (default)

## MarkerEdgeColor

none | {auto} | flat | ColorSpec

*Marker edge color.* The color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles).

- none — Specifies no color, which makes nonfilled markers invisible.
- auto — Uses same color as the EdgeColor property.
- flat — Uses the CData value of the vertex to determine the color of the marker edge.
- ColorSpec — Defines color to use.

## MarkerFaceColor

{none} | auto | flat | ColorSpec

*Marker face color.* The fill color for markers that are closed shapes (circle, square, diamond, pentagram, hexagram, and the four triangles).

- `none` — Makes the interior of the marker transparent, allowing the background to show through.
- `auto` — Uses the axes `Color` for the marker face color.
- `flat` — Uses the `CData` value of the vertex to determine the color of the face.
- `ColorSpec` — Defines a single color to use for all markers on the surfaceplot.

`MarkerSize`  
scalar

*Marker size.* Size of the marker in points. The default value is 6.

---

**Note** MATLAB draws the point marker (specified by the `'.'` symbol) at one-third the specified size.

---

`MeshStyle`  
{both} | row | column

*Row and column lines.* Specifies whether to draw all edge lines or just row or column edge lines.

- `both` — Draws edges for both rows and columns.
- `row` — Draws row edges only.
- `column` — Draws column edges only.

`NormalMode`  
{auto} | manual

*MATLAB generated or user-specified normal vectors.*

# Surfaceplot Properties

---

- `auto` — MATLAB calculates vertex normals based on the coordinate data
- `manual` — If you specify your own vertex normals, MATLAB sets this property to `manual` and does not generate its own data.

See also the `VertexNormals` property.

## Parent

handle of parent axes, `hggroup`, or `hgtransform`

*Parent of object.* Handle of the object's parent. The parent is normally the axes, `hggroup`, or `hgtransform` object that contains the object.

## Selected

`on` | `{off}`

*Object selection state.* When you set this property to `on`, MATLAB displays selection handles at the corners and midpoints if the `SelectionHighlight` property is also `on` (the default). You can, for example, define the `ButtonDownFcn` callback to set this property to `on`, thereby indicating that this particular object is selected. This property is also set to `on` when an object is manually selected in plot edit mode.

## SelectionHighlight

`{on}` | `off`

*Selected objects highlighted.*

- `on` — MATLAB indicates the selected state by drawing a dashed bounding box around the surface.
- `off` — MATLAB does not draw the bounding box except when in plot edit mode and objects are selected manually.

## SpecularColorReflectance

scalar in the range 0 to 1

*Color of specularly-reflected light.* When this property is 0, the color of the specularly-reflected light depends on both the color of the object from which it reflects and the color of the light source. When set to 1, the color of the specularly-reflected light depends only on the color of the light source (that is, the light object `Color` property). The proportions vary linearly for values in between.

**SpecularExponent**

scalar  $\geq 1$

*Harshness of specular reflection.* Controls the size of the specular spot. Most materials have exponents in the range of 5 to 20.

**SpecularStrength**

scalar  $\geq 0$  and  $\leq 1$

*Intensity of specular light.* Sets the intensity of the specular component of the light falling on the surfaceplot. Specular light comes from light objects in the axes.

You can also set the intensity of the ambient and diffuse components of the light on the surfaceplot object. See the `AmbientStrength` and `DiffuseStrength` properties. Also see the `material` function.

**Tag**

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

For example, create an `areaseries` object and set the `Tag` property.

```
t = area(Y, 'Tag', 'area1')
```

# Surfaceplot Properties

---

When you want to access objects of a given type, use `findobj` to find the object's handle. The following statement changes the `FaceColor` property of the object whose `Tag` is `area1`.

```
set(findobj('Tag','area1'),'FaceColor','red')
```

## Type

string (read only)

*Class of the graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For surfaceplot objects, `Type` is always the string `'surface'`.

## UIContextMenu

handle of `uicontextmenu` object

*Associate context menu with object.* Handle of a `uicontextmenu` object created in the object's parent figure. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the object. The default value is an empty array.

## UserData

array

*User-specified data.* Data you want to associate with this object (including cell arrays and structures). The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

## VertexNormals

vector | matrix

*Surfaceplot normal vectors.* Contains the vertex normals for the surfaceplot. MATLAB generates this data to perform lighting calculations. You can supply your own vertex normal data, even if it does not match the coordinate data. This can be useful to produce interesting lighting effects.

## Visible

{on} | off

*Visibility of object and its children.*

- on — Object and all children of the object are visible unless the child object's Visible property is off.
- off — Object not displayed. However, the object still exists and you can set and query its properties.

## XData

vector | matrix

*X-coordinates.* The  $x$ -position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of columns as ZData.

## XDataMode

{auto} | manual

*Use automatic or user-specified  $x$ -axis values.* If you specify XData (by setting the XData property or specifying the X input argument), MATLAB sets this property to manual and uses the specified values to label the  $x$ -axis.

If you set XDataMode to auto after specifying XData, MATLAB resets the  $x$ -axis ticks to `1:size(YData,1)` or to the column indices of the ZData, overwriting any previous values for XData.

## XDataSource

MATLAB variable, as a string

*Link XData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the XData. The default value is an empty array.

```
set(h, 'XDataSource', 'xdatablvariable')
```

# Surfaceplot Properties

---

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `XDataSource` does not change the object's `XData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## YData

vector | matrix

*Y-coordinates.* The *y*-position of the surfaceplot data points. If you specify a row vector, MATLAB replicates the row internally until it has the same number of rows as `ZData`.

## YDataMode

{auto} | manual

*Use automatic or user-specified y-axis values.* If you specify `XData`, MATLAB sets this property to `manual`.

If you set `YDataMode` to `auto` after having specified `YData`, MATLAB resets the *y*-axis ticks and *y*-tick labels to the row indices of the `ZData`, overwriting any previous values for `YData`.

## YDataSource

MATLAB variable, as a string

*Link YData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `YData`. The default value is an empty array.

```
set(h, 'YDataSource', 'Ydatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `YDataSource` does not change the object's `YData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

## ZData

matrix

*Z-coordinates.* The *z*-position of the surfaceplot data points. See the Description section for more information.

## ZDataSource

MATLAB variable, as a string

*Link ZData to MATLAB variable.* Set this property to a MATLAB variable that is evaluated in the base workspace to generate the `ZData`. The default value is an empty array.

```
set(h, 'ZDataSource', 'zdatavariablename')
```

MATLAB requires a call to `refreshdata` when you set this property. Changing workspace variables used as an object's `ZDataSource` does not change the object's `ZData` values, but you can use `refreshdata` to force an update of the object's data. `refreshdata` also lets you specify that the data source variable

# Surfaceplot Properties

---

be evaluated in the workspace of a function from which you call `refreshdata`.

---

**Note** If you change one data source property to a variable that contains data of a different dimension, you might cause the function to generate a warning and not render the graph until you have changed all data source properties to appropriate values.

---

**Purpose**

Surface plot with colormap-based lighting

**Syntax**

```
surf1(Z)
surf1(...,'light')
surf1(...,s)
surf1(X,Y,Z,s,k)
h = surf1(...)
```

**Description**

The `surf1` function displays a shaded surface based on a combination of ambient, diffuse, and specular lighting models.

`surf1(Z)` and `surf1(X,Y,Z)` create three-dimensional shaded surfaces using the default direction for the light source and the default lighting coefficients for the shading model. `X`, `Y`, and `Z` are vectors or matrices that define the  $x$ ,  $y$ , and  $z$  components of a surface.

`surf1(...,'light')` produces a colored, lighted surface using a MATLAB light object. This produces results different from the default lighting method, `surf1(...,'cdata')`, which changes the color data for the surface to be the reflectance of the surface.

`surf1(...,s)` specifies the direction of the light source. `s` is a two- or three-element vector that specifies the direction from a surface to a light source. `s = [sx sy sz]` or `s = [azimuth elevation]`. The default `s` is 45° counterclockwise from the current view direction.

`surf1(X,Y,Z,s,k)` specifies the reflectance constant. `k` is a four-element vector defining the relative contributions of ambient light, diffuse reflection, specular reflection, and the specular shine coefficient. `k = [ka kd ks shine]` and defaults to `[.55, .6, .4, 10]`.

`h = surf1(...)` returns a handle to a surface graphics object. If you specify the 'light' option, `h` contains the handle to the surface and the light objects.

## Tips

surf1 does not accept complex inputs.

For smoother color transitions, use colormaps that have linear intensity variations (e.g., gray, copper, bone, pink).

The ordering of points in the X, Y, and Z matrices defines the inside and outside of parametric surfaces. If you want the opposite side of the surface to reflect the light source, use `surf1(X',Y',Z')`. Because of the way surface normal vectors are computed, surf1 requires matrices that are at least 3-by-3.

## Examples

### Create Surface Plot With Colormap-Based Lighting

Create a surface plot of the `peaks` function using colormap-based lighting. Set the shading to `interp` to interpolate the colors across lines and faces.

```
[x,y] = meshgrid(-3:1/8:3);
z = peaks(x,y);
surf1(x,y,z);
shading interp
```

**See Also** [colormap](#) | [shading](#) | [light](#)

# surfnorm

---

**Purpose** Compute and display 3-D surface normals

**Syntax**

```
surfnorm(Z)
surfnorm(X,Y,Z)
surfnorm(axes_handle, ___)
surfnorm(___,Name,Value)
[Nx,Ny,Nz] = surfnorm(___)
```

**Description**

`surfnorm(Z)` plots a surface of the matrix `Z` with `surf` and displays its surface normals as radiating vectors.

`surfnorm(X,Y,Z)` plots a surface and its surface normals from the vectors or matrices `X`, `Y`, and matrix `Z`. `X`, `Y`, and `Z` must be the same size.

`surfnorm(axes_handle, ___)` plots into `axes_handle` instead of `gca` and it can include any of the input arguments in previous syntaxes.

`surfnorm( ___,Name,Value)` can be used to set the value of the specified Surface Properties.

`[Nx,Ny,Nz] = surfnorm( ___)` returns the components of the 3-D surface normals for the surface without plotting the surface or surface normals.

**Tips**

- `surfnorm` does not accept complex inputs.
- Reverse the direction of the normals by calling `surfnorm` with transposed arguments:  

```
surfnorm(X',Y',Z')
```
- The surface normals represent conditions at vertices and are not normalized. Normals for surface elements that face away from the viewer do not display.
- `surf1` uses `surfnorm` to compute surface normals when calculating the reflectance of a surface.

**Input Arguments****Z**

2-D array of real numbers representing a surface

**X**

2-D array of real numbers that defines the  $x$  component of the surface grid

**Y**

2-D array of real numbers that defines the  $y$  component of the surface grid

**axes\_handle**

Handle to the target axes in which to plot the surface

If you do not specify `axes_handle`, MATLAB uses current axes.

**Name,Value**

Specify optional comma-separated pairs of Name,Value arguments, where Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Property names and values of the surface object

See `Surface Properties` for description of property names and values.

**Output Arguments****[Nx,Ny,Nz]**

$x$ ,  $y$ , and  $z$  components of the three-dimensional surface normals for the surface

**Definitions****Surface Normal**

An imaginary line perpendicular to a flat surface or perpendicular to the tangent plane at a point on a non-flat surface

## Examples

### Display 3-D Surface Normals for Cone Plot

Compute and plot the normal vectors for a truncated cone. Set the axis limits using the axis function.

```
[x,y,z] = cylinder(1:10);
figure
surfnorm(x,y,z)
axis([-12 12 -12 12 -0.1 1])
```

### **Use Computed Surface Normals for Lighting**

Compute the normal vectors of an expression representing a surface.

```
[nx, ny, nz] = surfnorm(peaks);
```

Assign these normals to the `VertexNormals` property which MATLAB® uses to calculate the surface lighting. Set the lighting algorithm to `gouraud` and add a light using `camlight`.

```
b = reshape([nx ny nz], 49,49,3);
figure
surf(ones(49),'VertexNormals',b,'EdgeColor','none');
lighting gouraud
camlight
```

# surfnorm

---

## Algorithms

After performing a bicubic fit of the data in the  $x$ ,  $y$ , and  $z$  directions, diagonal vectors are computed and crossed to form the normal at each vertex.

## See Also

`surf` | `quiver3` | `surface` | `isonormals` | `surf1`

**Purpose** Singular value decomposition

**Syntax**

```
s = svd(X)
[U,S,V] = svd(X)
[U,S,V] = svd(X,0)
[U,S,V] = svd(X,'econ')
```

**Description** The svd command computes the matrix singular value decomposition. `s = svd(X)` returns a vector of singular values.

`[U,S,V] = svd(X)` produces a diagonal matrix `S` of the same dimension as `X`, with nonnegative diagonal elements in decreasing order, and unitary matrices `U` and `V` so that  $X = U*S*V'$ .

`[U,S,V] = svd(X,0)` produces the “economy size” decomposition. If `X` is `m`-by-`n` with `m > n`, then `svd` computes only the first `n` columns of `U` and `S` is `n`-by-`n`.

`[U,S,V] = svd(X,'econ')` also produces the “economy size” decomposition. If `X` is `m`-by-`n` with `m >= n`, it is equivalent to `svd(X,0)`. For `m < n`, only the first `m` columns of `V` are computed and `S` is `m`-by-`m`.

**Examples** For the matrix

```
X =
 1 2
 3 4
 5 6
 7 8
```

the statement

```
[U,S,V] = svd(X)
```

produces

```
U =
-0.1525 -0.8226 -0.3945 -0.3800
```

# svd

---

```
-0.3499 -0.4214 0.2428 0.8007
-0.5474 -0.0201 0.6979 -0.4614
-0.7448 0.3812 -0.5462 0.0407
```

```
S =
 14.2691 0
 0 0.6268
 0 0
 0 0
```

```
V =
 -0.6414 0.7672
 -0.7672 -0.6414
```

The economy size decomposition generated by

```
[U,S,V] = svd(X,0)
```

produces

```
U =
 -0.1525 -0.8226
 -0.3499 -0.4214
 -0.5474 -0.0201
 -0.7448 0.3812
```

```
S =
 14.2691 0
 0 0.6268
```

```
V =
 -0.6414 0.7672
 -0.7672 -0.6414
```

## Diagnostics

If the limit of 75 QR step iterations is exhausted while seeking a singular value, this message appears:

```
Solution will not converge.
```

**Purpose** Find singular values and vectors

**Syntax**

```
s = svds(A)
s = svds(A,k)
s = svds(A,k,sigma)
s = svds(A,k,'L')
s = svds(A,k,sigma,options)
[U,S,V] = svds(A,...)
[U,S,V,flag] = svds(A,...)
```

**Description** `s = svds(A)` computes the six largest singular values and associated singular vectors of matrix A. If A is m-by-n, `svds(A)` manipulates eigenvalues and vectors returned by `eigs(B)`, where `B = [sparse(m,m) A; A' sparse(n,n)]`, to find a few singular values and vectors of A. The positive eigenvalues of the symmetric matrix B are the same as the singular values of A.

`s = svds(A,k)` computes the k largest singular values and associated singular vectors of matrix A.

`s = svds(A,k,sigma)` computes the k singular values closest to the scalar shift sigma. For example, `s = svds(A,k,0)` computes the k smallest singular values and associated singular vectors.

`s = svds(A,k,'L')` computes the k largest singular values (the default).

`s = svds(A,k,sigma,options)` sets some parameters (see `eigs`):

### Option Structure Fields and Descriptions

Field name	Parameter	Default
<code>options.tol</code>	Convergence tolerance: $\text{norm}(AV-US,1) \leq \text{tol} * \text{norm}(A,1)$	1e-10
<code>options.maxit</code>	Maximum number of iterations	300
<code>options.disp</code>	Number of values displayed each iteration	0

`svds` checks the accuracy of the computed singular vectors. If the vectors are not accurate enough, then `svds` returns fewer singular values than requested. To obtain the requested number of singular values, try decreasing the error tolerance in the options structure.

`[U,S,V] = svds(A,...)` returns three output arguments, and if `A` is `m`-by-`n`:

- `U` is `m`-by-`k` with orthonormal columns
- `S` is `k`-by-`k` diagonal
- `V` is `n`-by-`k` with orthonormal columns
- `U*S*V'` is the closest rank `k` approximation to `A`

`[U,S,V,flag] = svds(A,...)` returns a convergence flag. If `eigs` converged, then `norm(A*V-U*S,1) <= tol*norm(A,1)` and `flag` is 0. If `eigs` did not converge, then `flag` is 1.

---

**Note** `svds` is best used to find a few singular values of a large, sparse matrix. To find all the singular values of such a matrix, `svd(full(A))` will usually perform better than `svds(A,min(size(A)))`.

---

## Algorithms

`svds(A,k)` uses `eigs` to find the `k` largest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`.

`svds(A,k,0)` uses `eigs` to find the `2k` smallest magnitude eigenvalues and corresponding eigenvectors of `B = [0 A; A' 0]`, and then selects the `k` positive eigenvalues and their eigenvectors.

## Examples

### Singular Values of Sparse Matrix

`west0479` is a real 479-by-479 sparse matrix. `svd` calculates all 479 singular values. `svds` picks out only the largest and smallest singular values.

```
load west0479
s = svd(full(west0479));
```

```
s1 = svds(west0479,4);
ss = svds(west0479,6,0);
```

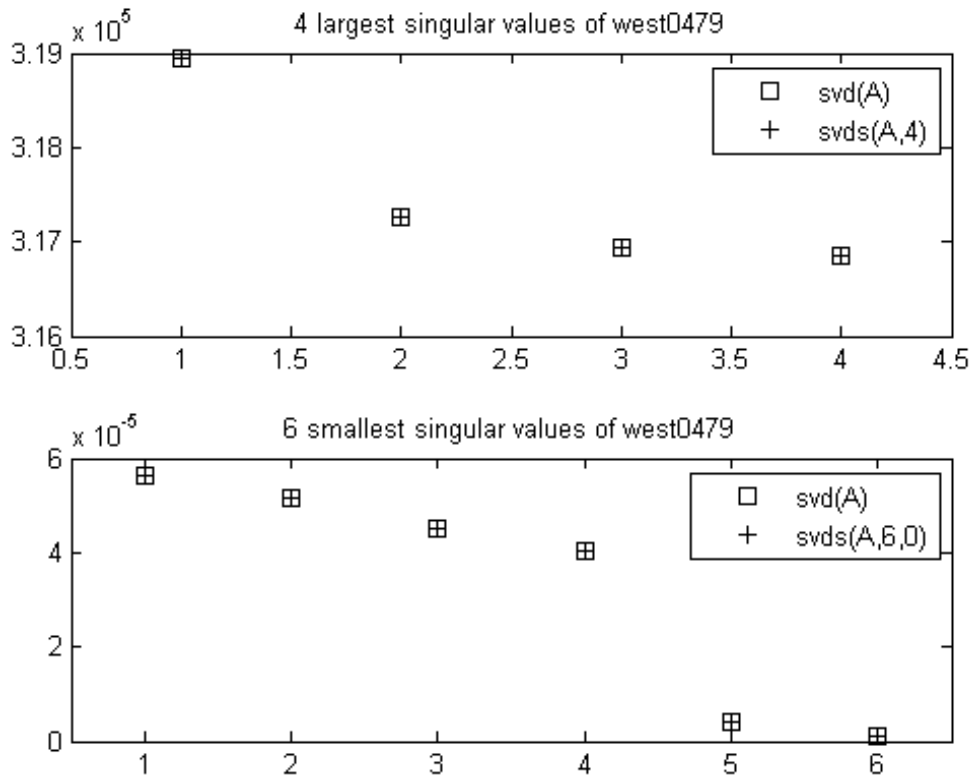

Warning: NORMEST did not converge for 100 iterations with tolerance 1e-10

These plots show some of the singular values of west0479 as computed by svd and svds.

```
subplot(2,1,1)
plot(s(1:4),'ks'), hold on
plot(s1,'k+'), hold off
title('4 largest singular values of west0479')
legend('svd(A)', 'svds(A,4)')
set(gca,'XLim',[0.5 4.5])

subplot(2,1,2)
plot(s(end-5:end),'ks'), hold on
plot(ss,'k+'), hold off
title('6 smallest singular values of west0479')
legend('svd(A)', 'svds(A,6,0)')
set(gca,'XLim',[0.5 6.5])
```

# svds

The largest singular value of west0479 can be computed a few different ways:

```
svds(west0479, 1)
max(svd(full(west0479)))
norm(full(west0479))
```

ans =

```
3.1895e+05
```

```
ans =
```

```
3.1895e+05
```

```
ans =
```

```
3.1895e+05
```

Or, to estimate the largest singular value:

```
normest(west0479)
```

```
Warning: NORMEST did not converge for 100 iterations with tolerance 1e-10
```

```
ans =
```

```
3.1854e+05
```

# swapbytes

---

**Purpose** Swap byte ordering

**Syntax** Y = swapbytes(X)

**Description** Y = swapbytes(X) reverses the byte ordering of each element in array X, converting little-endian values to big-endian (and vice versa). The input array must contain all full, noncomplex, numeric elements.

## **Examples** **Example 1**

Reverse the byte order for a scalar 32-bit value, changing hexadecimal 12345678 to 78563412:

```
A = uint32(hex2dec('12345678'));
```

```
B = dec2hex(swapbytes(A))
```

```
B =
 78563412
```

## **Example 2**

Reverse the byte order for each element of a 1-by-4 matrix:

```
X = uint16([0 1 128 65535])
```

```
X =
 0 1 128 65535
```

```
Y = swapbytes(X);
```

```
Y =
 0 256 32768 65535
```

Examining the output in hexadecimal notation shows the byte swapping:

```
format hex
```

```
X, Y
```

```
X =
 0000 0001 0080 ffff
```

```
Y =
 0000 0100 8000 ffff
```

### Example 3

Create a three-dimensional array A of 16-bit integers and then swap the bytes of each element:

```
format hex
```

```
A = uint16(magic(3) * 150);
A(:,:,2) = A * 40;
```

```
A
A(:,:,1) =
 04b0 0096 0384
 01c2 02ee 041a
 0258 0546 012c
A(:,:,2) =
 bb80 1770 8ca0
 4650 7530 a410
 5dc0 d2f0 2ee0
```

```
swapbytes(A)
ans(:,:,1) =
 b004 9600 8403
 c201 ee02 1a04
 5802 4605 2c01
ans(:,:,2) =
 80bb 7017 a08c
 5046 3075 10a4
 c05d f0d2 e02e
```

`typecast`

# switch, case, otherwise

---

**Purpose** Switch among several cases based on expression

**Syntax**

```
switch switch_expression
 case case_expression
 statements
 case case_expression
 statements
 ...
 otherwise
 statements
end
```

**Description** A switch block conditionally executes one set of statements from several choices. Each choice is a case.

An evaluated *switch\_expression* is a scalar or string. An evaluated *case\_expression* is a scalar, a string, or a cell array of scalars or strings. The switch block tests each case until one of the cases is true. A case is true when:

- For numbers, `eq(case_expression,switch_expression)`.
- For strings, `strcmp(case_expression,switch_expression)`.
- For objects that support the `eq` function, `eq(case_expression,switch_expression)`.
- For a cell array *case\_expression*, at least one of the elements of the cell array matches *switch\_expression*, as defined above for numbers, strings, and objects.

When a case is true, MATLAB executes the corresponding statements, and then exits the switch block.

*otherwise* is optional, and executes only when no case is true.

**Tips**

- Unlike the C language switch statement, the MATLAB switch does not fall through. If the first case statement is true, the other case

statements do not execute. Do not use a `break` statement within a `switch` block.

- A *case\_expression* cannot include relational operators such as `<` or `>` to compare against the *switch\_expression*. To test for inequality, use `if-elseif` statements.
- Because MATLAB executes only one case of any `switch` statement, variables defined within one case are not available for other cases. For example, if your current workspace does not contain a variable `x`, only cases that define `x` can use it:

```
switch choice
 case 1
 x = -pi:0.01:pi;
 case 2
 % does not know anything about x
end
```

## Examples

Conditionally display different text depending on a value entered at the command line:

```
mynumber = input('Enter a number:');
```

```
switch mynumber
 case -1
 disp('negative one');
 case 0
 disp('zero');
 case 1
 disp('positive one');
 otherwise
 disp('other value');
end
```

---

Decide which plot to create based on the value of the string `plottype`:

# switch, case, otherwise

---

```
x = [12, 64, 24];
plottype = 'pie3';

switch plottype
 case 'bar'
 bar(x)
 title('Bar Graph')
 case {'pie', 'pie3'}
 pie3(x)
 title('Pie Chart')
 legend('First', 'Second', 'Third')
 otherwise
 warning('Unexpected plot type. No plot created.');
```

---

In MATLAB switch blocks, only the first matching case executes:

```
result = 52;

switch(result)
 case 52
 disp('result is 52')
 case {52, 78}
 disp('result is 52 or 78')
end
```

This code returns

```
result is 52
```

<b>Purpose</b>	Solve Sylvester equation $AX + XB = C$ for $X$
<b>Syntax</b>	$X = \text{sylvester}(A,B,C)$
<b>Description</b>	<p><math>X = \text{sylvester}(A,B,C)</math> returns the solution, <math>X</math>, to the Sylvester equation.</p> <p>Input <math>A</math> is an <math>m</math>-by-<math>m</math> matrix, input <math>B</math> is an <math>n</math>-by-<math>n</math> matrix, and both <math>C</math> and <math>X</math> are <math>m</math>-by-<math>n</math> matrices.</p>
<b>Input Arguments</b>	<p><b>A,B,C - Input matrices</b> matrices</p> <p>Input matrices, specified as matrices. Input <math>A</math> is an <math>m</math>-by-<math>m</math> square matrix, input <math>B</math> is an <math>n</math>-by-<math>n</math> square matrix, and input <math>C</math> is an <math>m</math>-by-<math>n</math> rectangular matrix. The function returns an error if any input matrix is sparse.</p> <p><b>Data Types</b> single   double <b>Complex Number Support:</b> Yes</p>
<b>Output Arguments</b>	<p><b>X - Solution</b> matrix</p> <p>Solution, returned as a matrix of the same size as <math>C</math>. The function returns an error if the eigenvalues of <math>A</math> and <math>-B</math> are not distinct (in this case, the solution, <math>X</math>, is singular or not unique).</p>
<b>Examples</b>	<p><b>Solve Sylvester Equation with 3-by-3 Output</b></p> <p>Create the coefficient matrices <math>A</math> and <math>B</math>.</p> <pre>A = [1 -1 1; 1 1 -1; 1 1 1]; B = magic(3);</pre> <p>Define <math>C</math> as the 3-by-3 identity matrix.</p> <pre>C = eye(3);</pre>

Use the `sylvester` function to solve the Sylvester equation for these values of A, B, and C.

```
X = sylvester(A,B,C)
```

```
X =
```

```
 0.1223 -0.0725 0.0131
 -0.0806 -0.0161 0.1587
 -0.0164 0.1784 -0.1072
```

The result is a 3-by-3 matrix.

## **Solve Sylvester Equation with 4-by-2 Output**

Create a 4-by-4 coefficient matrix, A, and 2-by-2 coefficient matrix, B.

```
A = [1 0 2 3; 4 1 0 2; 0 5 5 6; 1 7 9 0];
```

```
B = [0 -1; 1 0];
```

Define C as a 4-by-2 matrix to match the corresponding sizes of A and B.

```
C = [1 0; 2 0; 0 3; 1 1]
```

```
C =
```

```
 1 0
 2 0
 0 3
 1 1
```

Use the `sylvester` function to solve the Sylvester equation for these values of A, B, and C.

```
X = sylvester(A,B,C)
```

```
X =
```

```
 0.4732 -0.3664
 -0.4006 0.3531
```

```
0.3305 -0.1142
0.0774 0.3560
```

The result is a 4-by-2 matrix.

## Definitions **Sylvester Equation**

The Sylvester equation is

$$AX + XB = C.$$

The equation has a unique solution when the eigenvalues of  $A$  and  $-B$  are distinct. In terms of the Kronecker tensor product,  $\otimes$ , the equation is

$$\left[ I \otimes A + B^T \otimes I \right] X(:) = C(:),$$

where  $I$  is the identity matrix, and  $X(:)$  and  $C(:)$  denote the matrices  $X$  and  $C$  as single column vectors.

# symamd

---

**Purpose** Symmetric approximate minimum degree permutation

**Syntax**  
`p = symamd(S)`  
`p = symamd(S,knobs)`  
`[p,stats] = symamd(...)`

**Description** `p = symamd(S)` for a symmetric positive definite matrix `S`, returns the permutation vector `p` such that `S(p,p)` tends to have a sparser Cholesky factor than `S`. To find the ordering for `S`, `symamd` constructs a matrix `M` such that `spones(M'*M) = spones(S)`, and then computes `p = colamd(M)`. The `symamd` function may also work well for symmetric indefinite matrices.

`S` must be square; only the strictly lower triangular part is referenced.

`p = symamd(S,knobs)` where `knobs` is a scalar. If `S` is `n`-by-`n`, rows and columns with more than `knobs*n` entries are removed prior to ordering, and ordered last in the output permutation `p`. If the `knobs` parameter is not present, then `knobs = spparms('wh_frac')`.

`[p,stats] = symamd(...)` produces the optional vector `stats` that provides data about the ordering and the validity of the matrix `S`.

<code>stats(1)</code>	Number of dense or empty rows ignored by <code>symamd</code>
<code>stats(2)</code>	Number of dense or empty columns ignored by <code>symamd</code>
<code>stats(3)</code>	Number of garbage collections performed on the internal data structure used by <code>symamd</code> (roughly of size <code>8.4*nnz(tril(S,-1)) + 9n</code> integers)
<code>stats(4)</code>	0 if the matrix is valid, or 1 if invalid
<code>stats(5)</code>	Rightmost column index that is unsorted or contains duplicate entries, or 0 if no such column exists
<code>stats(6)</code>	Last seen duplicate or out-of-order row index in the column index given by <code>stats(5)</code> , or 0 if no such row index exists
<code>stats(7)</code>	Number of duplicate and out-of-order row indices

Although, MATLAB built-in functions generate valid sparse matrices, a user may construct an invalid sparse matrix using the MATLAB C or Fortran APIs and pass it to `symamd`. For this reason, `symamd` verifies that `S` is valid:

- If a row index appears two or more times in the same column, `symamd` ignores the duplicate entries, continues processing, and provides information about the duplicate entries in `stats(4:7)`.
- If row indices in a column are out of order, `symamd` sorts each column of its internal copy of the matrix `S` (but does not repair the input matrix `S`), continues processing, and provides information about the out-of-order entries in `stats(4:7)`.
- If `S` is invalid in any other way, `symamd` cannot continue. It prints an error message, and returns no output arguments (`p` or `stats`).

The ordering is followed by a symmetric elimination tree post-ordering.

## Examples

### Compare Reverse Cuthill-McKee and Minimum Degree

Here is a comparison of reverse Cuthill-McKee and minimum degree on the Bucky ball example mentioned in the `symrcm` reference page.

```
B = bucky+4*speye(60);
r = symrcm(B);
p = symamd(B);
R = B(r,r);
S = B(p,p);
subplot(2,2,1), spy(R,4), title('B(r,r)')
subplot(2,2,2), spy(S,4), title('B(s,s)')
subplot(2,2,3), spy(chol(R),4), title('chol(B(r,r))')
subplot(2,2,4), spy(chol(S),4), title('chol(B(s,s))')
```

Even though this is a very small problem, the behavior of both orderings is typical. RCM produces a matrix with a narrow bandwidth which fills in almost completely during the Cholesky factorization. Minimum degree produces a structure with large blocks of contiguous zeros which do not fill in during the factorization. Consequently, the minimum degree ordering requires less time and storage for the factorization.

## References

The authors of the code for `symamd` are Stefan I. Larimore and Timothy A. Davis ([davis@cise.ufl.edu](mailto:davis@cise.ufl.edu)), University of Florida.

The algorithm was developed in collaboration with John Gilbert, Xerox PARC, and Esmond Ng, Oak Ridge National Laboratory. Sparse Matrix Algorithms Research at the University of Florida: <http://www.cise.ufl.edu/research/sparse/>

`colamd` | `colperm` | `spparms` | `symrcm` | `amd`

# symbfact

---

**Purpose** Symbolic factorization analysis

**Syntax**

```
count = symbfact(A)
count = symbfact(A, 'sym')
count = symbfact(A, 'col')
count = symbfact(A, 'row')
count = symbfact(A, 'lo')
[count,h,parent,post,R] = symbfact(...)
[count,h,parent,post,L] = symbfact(A,type,'lower')
```

**Description**

`count = symbfact(A)` returns the vector of row counts of  $R=\text{chol}(A)$ . `symbfact` should be much faster than `chol(A)`.

`count = symbfact(A, 'sym')` is the same as `count = symbfact(A)`.

`count = symbfact(A, 'col')` returns row counts of  $R=\text{chol}(A'*A)$  (without forming it explicitly).

`count = symbfact(A, 'row')` returns row counts of  $R=\text{chol}(A*A')$ .

`count = symbfact(A, 'lo')` is the same as `count = symbfact(A)` and uses `tril(A)`.

`[count,h,parent,post,R] = symbfact(...)` has several optional return values.

The flop count for a subsequent Cholesky factorization is `sum(count.^2)`

Return Value	Description
h	Height of the elimination tree
parent	The elimination tree itself
post	Postordering of the elimination tree
R	0-1 matrix having the structure of <code>chol(A)</code> for the symmetric case, <code>chol(A'*A)</code> for the 'col' case, or <code>chol(A*A')</code> for the 'row' case.

`symbfact(A)` and `symbfact(A, 'sym')` use the upper triangular part of  $A$  (`triu(A)`) and assume the lower triangular part is the transpose of the upper triangular part. `symbfact(A, 'lo')` uses `tril(A)` instead.

`[count,h,parent,post,L] = symbfact(A,type,'lower')` where `type` is one of `'sym'`, `'col'`, `'row'`, or `'lo'` returns a lower triangular symbolic factor  $L=R'$ . This form is quicker and requires less memory.

# symmlq

---

## Purpose

Symmetric LQ method

## Syntax

```
x = symmlq(A,b)
symmlq(A,b,tol)
symmlq(A,b,tol,maxit)
symmlq(A,b,tol,maxit,M)
symmlq(A,b,tol,maxit,M1,M2)
symmlq(A,b,tol,maxit,M1,M2,x0)
[x,flag] = symmlq(A,b,...)
[x,flag,relres] = symmlq(A,b,...)
[x,flag,relres,iter] = symmlq(A,b,...)
[x,flag,relres,iter,resvec] = symmlq(A,b,...)
[x,flag,relres,iter,resvec,resveccg] = symmlq(A,b,...)
```

## Description

`x = symmlq(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be symmetric but need not be positive definite. It should also be large and sparse. The column vector  $b$  must have length  $n$ . You can specify  $A$  as a function handle, `afun`, such that `afun(x)` returns  $A*x$ .

“Parameterizing Functions” explains how to provide additional parameters to the function `afun`, as well as the preconditioner function `mfun` described below, if necessary.

If `symmlq` converges, a message to that effect is displayed. If `symmlq` fails to converge after the maximum number of iterations or halts for any reason, a warning message is printed displaying the relative residual  $\text{norm}(b-A*x)/\text{norm}(b)$  and the iteration number at which the method stopped or failed.

`symmlq(A,b,tol)` specifies the tolerance of the method. If `tol` is `[]`, then `symmlq` uses the default,  $1e-6$ .

`symmlq(A,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]`, then `symmlq` uses the default,  $\min(n,20)$ .

`symmlq(A,b,tol,maxit,M)` and `symmlq(A,b,tol,maxit,M1,M2)` use the symmetric positive definite preconditioner  $M$  or  $M = M1*M2$  and effectively solve the system  $\text{inv}(\text{sqrt}(M))*A*\text{inv}(\text{sqrt}(M))*y =$

$\text{inv}(\text{sqrt}(M)) * b$  for  $y$  and then return  $x = \text{in}(\text{sqrt}(M)) * y$ . If  $M$  is  $[]$  then `symmlq` applies no preconditioner.  $M$  can be a function handle `mfun` such that `mfun(x)` returns  $M \backslash x$ .

`symmlq(A,b,tol,maxit,M1,M2,x0)` specifies the initial guess. If  $x_0$  is  $[]$ , then `symmlq` uses the default, an all-zero vector.

`[x,flag] = symmlq(A,b,...)` also returns a convergence flag.

Flag	Convergence
0	<code>symmlq</code> converged to the desired tolerance <code>tol</code> within <code>maxit</code> iterations.
1	<code>symmlq</code> iterated <code>maxit</code> times but did not converge.
2	Preconditioner $M$ was ill-conditioned.
3	<code>symmlq</code> stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during <code>symmlq</code> became too small or too large to continue computing.
5	Preconditioner $M$ was not symmetric positive definite.

Whenever `flag` is not 0, the solution  $x$  returned is that with minimal norm residual computed over all the iterations. No messages are displayed if the `flag` output is specified.

`[x,flag,relres] = symmlq(A,b,...)` also returns the relative residual  $\text{norm}(b - A * x) / \text{norm}(b)$ . If `flag` is 0, `relres`  $\leq$  `tol`.

`[x,flag,relres,iter] = symmlq(A,b,...)` also returns the iteration number at which  $x$  was computed, where  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = symmlq(A,b,...)` also returns a vector of estimates of the `symmlq` residual norms at each iteration, including  $\text{norm}(b - A * x_0)$ .

`[x,flag,relres,iter,resvec,resvecg] = symmlq(A,b,...)` also returns a vector of estimates of the conjugate gradients residual norms at each iteration.

## Examples

### Example 1

```
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -2*on],-1:1,n,n);
b = sum(A,2);
tol = 1e-10;
maxit = 50; M1 = spdiags(4*on,0,n,n);

x = symmlq(A,b,tol,maxit,M1);
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

### Example 2

This example replaces the matrix  $A$  in Example 1 with a handle to a matrix-vector product function `afun`. The example is contained in the function `run_symmlq` that:

- Calls `symmlq` with the function handle `@afun` as its first argument.
- Contains `afun` as a nested function, so that all variables in `run_symmlq` are available to `afun`.

The following shows the code for `run_symmlq`:

```
function x1 = run_symmlq
n = 100;
on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x1 = symmlq(@afun,b,tol,maxit,M1);

function y = afun(x)
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
```

```

 y(1:n-1) = y(1:n-1) - 2 * x(2:n);
 end
end

```

When you enter

```
x1=run_symmlq;
```

MATLAB software displays the message

```
symmlq converged at iteration 49 to a solution with relative
residual 4.3e-015
```

### Example 3

Use a symmetric indefinite matrix that fails with pcg.

```

A = diag([20:-1:1,-1:-1:-20]);
b = sum(A,2); % The true solution is the vector of all ones.
x = pcg(A,b); % Errors out at the first iteration.
pcg stopped at iteration 1 without converging to the desired
tolerance 1e-006 because a scalar quantity became too small or
too large to continue computing.
The iterate returned (number 0) has relative residual 1

```

However, symmlq can handle the indefinite matrix A.

```

x = symmlq(A,b,1e-6,40);
symmlq converged at iteration 39 to a solution with relative
residual 1.3e-007

```

<b>Purpose</b>	Sparse reverse Cuthill-McKee ordering
<b>Syntax</b>	<code>r = symrcm(S)</code>
<b>Description</b>	<p><code>r = symrcm(S)</code> returns the symmetric reverse Cuthill-McKee ordering of <code>S</code>. This is a permutation <code>r</code> such that <code>S(r,r)</code> tends to have its nonzero elements closer to the diagonal. This is a good reordering for LU or Cholesky factorization of matrices that come from long, skinny problems. The ordering works for both symmetric and nonsymmetric <code>S</code>.</p> <p>For a real, symmetric sparse matrix, <code>S</code>, the eigenvalues of <code>S(r,r)</code> are the same as those of <code>S</code>, but <code>eig(S(r,r))</code> probably takes less time to compute than <code>eig(S)</code>.</p>
<b>Algorithms</b>	The algorithm first finds a pseudoperipheral vertex of the graph of the matrix. It then generates a level structure by breadth-first search and orders the vertices by decreasing distance from the pseudoperipheral vertex. The implementation is based closely on the SPARSPAK implementation described by George and Liu.
<b>Examples</b>	<p><b>Reverse Cuthill-McKee Ordering</b></p> <p>The statement</p> <pre>B = bucky;</pre> <p>uses a function in the <code>demos</code> toolbox to generate the adjacency graph of a truncated icosahedron. This is better known as a soccer ball, a Buckminster Fuller geodesic dome (hence the name <code>bucky</code>), or, more recently, as a 60-atom carbon molecule. There are 60 vertices. The vertices have been ordered by numbering half of them from one hemisphere, pentagon by pentagon; then reflecting into the other hemisphere and gluing the two halves together.</p> <p>With this numbering, the matrix does not have a particularly narrow bandwidth, as the first spy plot shows:</p> <pre>figure();</pre>

```
subplot(1,2,1),spy(B),title('B')
```

The reverse Cuthill-McKee ordering is obtained with:

```
p = symrcm(B);
R = B(p,p);
```

The spy plot shows a much narrower bandwidth.

```
subplot(1,2,2),spy(R),title('B(p,p)')
```

This example is continued in the reference page for `symamd`.

The bandwidth can also be computed with:

```
[i,j] = find(B);
bw = max(i-j) + 1;
```

The bandwidths of `B` and `R` are 35 and 12, respectively.

**Purpose** Determine symbolic variables in expression

**Syntax** `symvar 'expr'`  
`s = symvar('expr')`

**Description** `symvar 'expr'` searches the expression, `expr`, for identifiers other than `i`, `j`, `pi`, `inf`, `nan`, `eps`, and common functions. `symvar` displays those variables that it finds or, if no such variable exists, displays an empty cell array, `{}`.

`s = symvar('expr')` returns the variables in a cell array of strings, `s`. If no such variable exists, `s` is an empty cell array.

**Examples** `symvar` finds variables `beta1` and `x`, but skips `pi` and the `cos` function.

```
symvar 'cos(pi*x - beta1)'
```

```
ans =
```

```
 'beta1'
```

```
 'x'
```

**See Also** `strfind`

**Purpose** Two ways to call MATLAB functions

**Description** You can call MATLAB functions using either *command syntax* or *function syntax*, as described below.

## **Command Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by spaces:

```
functionname arg1 arg2 ... argn
```

Command syntax does not allow you to obtain any values that might be returned by the function. Attempting to assign output from the function to a variable using command syntax generates an error. Use function syntax instead.

Examples of command syntax:

```
save mydata.mat x y z
import java.awt.Button java.lang.String
```

Arguments are treated as string literals. See the examples below, under “Argument Passing” on page 1-6851.

## **Function Syntax**

A function call in this syntax consists of the function name followed by one or more arguments separated by commas and enclosed in parentheses:

```
functionname(arg1, arg2, ..., argn)
```

You can assign the output of the function to one or more output values. When assigning to more than one output variable, separate the variables by commas or spaces and enclose them in square brackets ([ ]):

```
[out1,out2,...,outn] = functionname(arg1, arg2, ..., argn)
```

Examples of function syntax:

```
copyfile('srcfile', '..\mytests', 'writable')
[x1,x2,x3,x4] = deal(A{:})
```

Arguments are passed to the function by value. See the examples below, under “Argument Passing” on page 1-6851.

### Argument Passing

When calling a function using command syntax, MATLAB passes the arguments as string literals. When using function syntax, arguments are passed by value.

In the following example, assign a value to A and then call `disp` on the variable to display the value passed. Calling `disp` with command syntax passes the variable name, 'A':

```
A = pi;
disp A
 A
```

while function syntax passes the value assigned to A:

```
A = pi;
disp(A)
 3.1416
```

The next example passes two strings to `strcmp` for comparison. Calling the function with command syntax compares the variable names, 'str1' and 'str2':

```
str1 = 'one'; str2 = 'one';
strcmp str1 str2
ans =
 0 (unequal)
```

while function syntax compares the values assigned to the variables, 'one' and 'one':

```
str1 = 'one'; str2 = 'one';
strcmp(str1, str2)
```

```
ans =
 1 (equal)
```

## Passing Strings

When using the function syntax to pass a string literal to a function, you must enclose the string in single quotes, ('string'). For example, to create a new folder called `myapptests`, use

```
mkdir('myapptests')
```

On the other hand, variables that contain strings do not need to be enclosed in quotes:

```
folder = 'myapptests';
mkdir(folder)
```

`mlint`

## How To

- “Check Code for Errors and Warnings”

**Purpose** Execute operating system command and return output

**Syntax**

```
status = system(command)
[status,cmdout] = system(command)
[status,cmdout] = system(command, '-echo')
```

**Description** `status = system(command)` calls the operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = system(command)` additionally returns the output of the command to `cmdout`. This syntax is most useful for commands that do not require user input, such as `dir`.

`[status,cmdout] = system(command, '-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

## Input Arguments

### **command - Operating system command**

string

Operating system command, specified as a string. The command executes in a system shell, which might not be the shell from which you launched MATLAB.

**Example:** `'dir'`

**Example:** `'ls'`

## Output Arguments

### **status - Command exit status**

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If command includes the ampersand character (&), then status is the exit status upon command launch.
- If command does not include the ampersand character (&), then status is the exit status upon command completion.

## **cmdout - Output of operating system command**

string

Output of the operating system command, returned as a string.

## **Examples**

### **Display Windows Operating System Command Status and Output**

On a Windows system, display the current folder using the cd command.

```
command = 'cd';
[status,cmdout] = system(command)
```

```
status =
 0
cmdout =
C:\matlab\myfiles
```

A status of zero indicates that the command completed successfully. MATLAB returns a string containing the current folder in cmdout.

### **Save UNIX Command Exit Status and Output**

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = system(command);
status
```

```
status =
 0
```

---

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

## Limitations

- DOS does not support UNC path names. Therefore, if the current folder uses a UNC path name, then running `system` with a DOS command that relies on the current folder fails. To work around this limitation, change the folder to a mapped drive before calling `system`.

## Algorithms

On UNIX, MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

## Tips

- To execute the operating system command in the background, include the trailing character, `&`, in the command argument (for example, `'notepad &'` on a Windows platform, or `'emacs &'` on UNIX). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note** If command includes the trailing `&` character, `cmdout` is empty.

---

- On a UNIX system, the `system` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while the `system` function executes. This can lead to corrupted output when `system` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

## **Concepts**

- “Run External Commands, Scripts, and Programs”

**Purpose**

Create table from workspace variables

**Syntax**

```
T = table(var1,...,varN)
T = table(var1,...,varN,Name,Value)
T = table
```

**Description**

`T = table(var1,...,varN)` creates a table from the input variables, `var1,...,varN`. Variables can be of different sizes and data types, but all variables must have the same number of rows.

If the inputs are workspace variables, `table` uses the workspace variable names as variable names for the table. Otherwise, `table` uses strings of the form `'Var1',...,'VarN'` where `N` is the number of variables.

For more information on creating and using the `table` data type, see “Tables”.

`T = table(var1,...,varN,Name,Value)` includes additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify row names or variable names to include in the table.

`T = table` creates an empty 0-by-0 table.

**Input Arguments****var1,...,varN - Input variables**

arrays with the same number of rows

Input variables, specified as arrays with the same number of rows. The input variables can be of different sizes and different data types.

Common input variables are numeric arrays, logical arrays, character arrays, structure arrays, or cell arrays. Furthermore, input variables can be objects that are arrays that support indexing of the form `var(index1,...,indexN)`, where `index1` is a numeric or logical vector that corresponds to rows of the variable `var`. In addition, the array must implement a `vertcat` method and a `size` method with a `dim` argument.

# table

---

**Example:** `table([1:4]', ones(4,3,2), eye(4,2))` creates a table from variables with 4 rows, but different sizes.

**Example:** `table([1:3]', {'one'; 'two'; 'three'}, ['A'; 'B'; 'C'])` creates a table from variables with 3 rows, but different data types.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** `'RowNames', {'row1', 'row2', 'row3'}` names the rows `row1`, `row2`, and `row3`.

### **'RowNames' - Row names**

`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as the comma-separated pair consisting of `'RowNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of rows in the table.

### **'VariableNames' - Variable names**

cell array of nonempty, distinct strings

Variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a cell array of nonempty, distinct strings. The number of strings must equal the number of variables.

If the input variables, `var1`, ..., `varN`, are valid MATLAB identifiers, `table` uses the workspace variable names. Otherwise, `table` uses a cell array of `N` strings of the form `{'Var1', ..., 'VarN'}`, where `N` is the number of variables. You can determine valid MATLAB variable names using the function `isvarname`.

**Output Arguments****T - Output table**

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

**Examples****Create Table from Workspace Variables**

Define workspace variables with the same number of rows.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

Create a table, T, as a container for the workspace variables.

```
T = table(Age,Height,Weight,BloodPressure,...
 'RowNames',LastName)
```

T =

	Age	Height	Weight	BloodPressure	
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

table names the variables with the workspace variable names.

**Create Table and Specify Variable Names**

Create a table from arrays with different data types.

# table

---

```
T = table(['M';'F';'M'],[45;32;34],...
 {'NY';'CA';'MA'},logical([1;0;0]),...
 'VariableNames',{'Gender' 'Age' 'State' 'Vote'})
```

T =

Gender	Age	State	Vote
M	45	'NY'	true
F	32	'CA'	false
M	34	'MA'	false

Each variable in T contains 3 rows.

Gender is a character array, Age is a double-precision array, State is a cell array of strings, and Vote is a logical array. You can use the function `summary` to print the data type and other information about the variables in the table.

## Related Examples

- “Create a Table”
- “Modify Units, Descriptions and Table Variable Names”
- “Access Data in a Table”

**Purpose** Convert table to homogenous array

**Syntax** `A = table2array(T)`

**Description** `A = table2array(T)` converts the table, `T`, to a homogeneous array, `A`.

**Input Arguments** **T - Input table**

table

Input table, specified as a table. All variables in `T` must have sizes and data types that are compatible for horizontal concatenation. Specifically, the size of all variable dimensions greater than 2 must match.

- If `T` is an `m`-by-`n` table with variables that each have one column, then each variable becomes one column in `A`, and `A` is an `m`-by-`n` array.
- If `T` contains variables that consist of more than one column, those variables become multiple columns in `A`, and the size of `A` is greater than the size of `T`.
- If `T` contains variables with more than two dimensions, the number of dimensions of `A` is the same as the number of variable dimensions.

**Examples** **Convert Table of Numeric Data to Array**

Create a table, `T`, consisting of numeric data.

```
T = table([1;2;3],[2 8; 4 10; 6 12],[3 12 21; 6 15 24; 9 18 27],...
 'VariableNames',{'One' 'Two' 'Three'})
```

`T =`

	One	Two		Three	
	—	—————		—————	
1	2	8	3	12	21
2	4	10	6	15	24
3	6	12	9	18	27

# table2array

---

Convert table, T, to an array.

```
A = table2array(T)
```

```
A =
```

```
 1 2 8 3 12 21
 2 4 10 6 15 24
 3 6 12 9 18 27
```

A contains two columns from variable Two and three columns from variable Three.

## Convert Numeric Subset of Table to Array

Define the numeric subset of a table to convert to an array.

Create a table with nonnumeric data in the first variable.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [71;69;64;67;64],[176;163;131;133;119],...
 'VariableNames',{'Gender' 'Age' 'Height' 'Weight'})
```

```
T =
```

Gender	Age	Height	Weight
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

Convert T(:,2:4) to an array.

```
A = table2array(T(:,2:4))
```

```
A =
```

```

38 71 176
43 69 163
38 64 131
40 67 133
49 64 119

```

A does not include data from the variable Gender.

## Convert Table with Three-Dimensional Variables to Array

Create a table, T, with two rows and three variables where each variable has three dimensions.

```
T = table(ones(2,1,3),2*ones(2,2,3),3*ones(2,3,3),...
 'VariableNames',{'One' 'Two' 'Three'})
```

T =

One	Two	Three
[1x1x3 double]	[1x2x3 double]	[1x3x3 double]
[1x1x3 double]	[1x2x3 double]	[1x3x3 double]

The size of the table is 2-by-3.

Convert table T to an array.

```
A = table2array(T)
```

A(:, :, 1) =

```

1 2 2 3 3 3
1 2 2 3 3 3

```

A(:, :, 2) =

```

1 2 2 3 3 3

```

# table2array

---

```
 1 2 2 3 3 3
 1 2 2 3 3 3
 1 2 2 3 3 3
```

The size of A is 2-by-6-by-3.

## Algorithms

If T contains variables with different data types that are compatible for horizontal concatenation, `table2array` creates a homogeneous array, A, of the dominant data type. For example, if T contains `double` and `single` numeric data, `table2array(T)` returns an array with data type `single`.

## Tips

- `table2array` horizontally concatenates the variables in T to create A. If the variables in T are cell arrays, `table2array` does not concatenate their contents, and A is a cell array, equivalent to `table2cell(T)`. To create an array containing the contents of variables that are all cell arrays, use `cell2mat(table2cell(T))`.
- `table2array(T)` is equivalent to `T{:,:}`.

## See Also

`array2table` | `table2cell` | `table2struct` | `table`

## Concepts

- “Concatenating Objects of Different Classes”

**Purpose** Convert table to cell array

**Syntax** `C = table2cell(T)`

**Description** `C = table2cell(T)` converts the table, `T`, to a cell array, `C`. Each variable in `T` becomes a column of cells in `C`.

**Input Arguments** **T - Input table**  
table

Input table, specified as a table.

If `T` is an `m`-by-`n` table, then `C` is an `m`-by-`n` cell array.

**Examples** **Convert Table to Cell Array**

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [124 93;109 77; 125 83; 117 75; 122 80],...
 'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
 'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

`T =`

	Gender	Age	BloodPressure	
	_____	_____	_____	_____
Smith	M	38	124	93
Johnson	M	43	109	77
Williams	F	38	125	83
Jones	F	40	117	75
Brown	F	49	122	80

Convert `T` to a cell array.

```
C = table2cell(T)
```

# table2cell

---

```
C =

 'M' [38] [1x2 double]
 'M' [43] [1x2 double]
 'F' [38] [1x2 double]
 'F' [40] [1x2 double]
 'F' [49] [1x2 double]
```

C is a 5-by-3 cell array.

Vertically concatenate the table property, `T.Properties.VariableNames`, with C to include column headings for the cell array.

```
[T.Properties.VariableNames;C]
```

```
ans =

 'Gender' 'Age' 'BloodPressure'
 'M' [38] [1x2 double]
 'M' [43] [1x2 double]
 'F' [38] [1x2 double]
 'F' [40] [1x2 double]
 'F' [49] [1x2 double]
```

`T.Properties.VariableNames` is a cell array of strings.

## See Also

[cell2table](#) | [table2array](#) | [table2struct](#) | [table](#)

**Purpose** Convert table to structure array

**Syntax**

```
S = table2struct(T)
S = table2struct(T,'ToScalar',true)
```

**Description** `S = table2struct(T)` converts the table, `T`, to a structure array, `S`. Each variable of `T` becomes a field in `S`. If `T` is an `m`-by-`n` table, then `S` is a `m`-by-1 structure array with `n` fields.

`S = table2struct(T,'ToScalar',true)` converts the table, `T`, to a scalar structure `S`. Each variable of `T` becomes a field in `S`. If `T` is a `m`-by-`n` table, then `S` has `n` fields, each of which has `m` rows.

**Input Arguments**

**T - Input table**  
table

Input table, specified as a table.

**Examples**

**Convert Table to Structure Array**

Create a table, `T`, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [124 93;109 77; 125 83; 117 75; 122 80],...
 'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

`T =`

	Gender	Age	BloodPressure	
	M	38	124	93
	M	43	109	77
	F	38	125	83
	F	40	117	75
	F	49	122	80

# table2struct

---

Convert T to a structure array.

```
S = table2struct(T)
```

```
S =
```

```
5x1 struct array with fields:
```

```
 Gender
 Age
 BloodPressure
```

The structure is 5-by-1, corresponding to the five rows of the table, T. The three fields of S correspond to the three variables from T.

Display the field data for the first element of S.

```
S(1)
```

```
ans =
```

```
 Gender: 'M'
 Age: 38
 BloodPressure: [124 93]
```

The information corresponds to the first row of the table.

## Convert Table to Scalar Structure

Create a table, T, with five rows and three variables.

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [124 93;109 77; 125 83; 117 75; 122 80],...
 'VariableNames',{'Gender' 'Age' 'BloodPressure'})
```

```
T =
```

```
 Gender Age BloodPressure
 _____ _____ _____
```

M	38	124	93
M	43	109	77
F	38	125	83
F	40	117	75
F	49	122	80

Convert T to a scalar structure.

```
S = table2struct(T,'ToScalar',true)
```

```
S =
```

```
 Gender: [5x1 char]
 Age: [5x1 double]
 BloodPressure: [5x2 double]
```

The data in the fields of the scalar structure are 5-by-1, corresponding to the five rows in the table T.

Display the data for the field BloodPressure.

```
S.BloodPressure
```

```
ans =
```

124	93
109	77
125	83
117	75
122	80

The structure field BloodPressure contains all of the data that was in the variable of the same name from table T.

## Convert Table with Row Names to Structure

Create a table, T, that includes row names.

# table2struct

---

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [124 93;109 77; 125 83; 117 75; 122 80],...
 'VariableNames',{'Gender' 'Age' 'BloodPressure'},...
 'RowNames',{'Smith' 'Johnson' 'Williams' 'Jones' 'Brown'})
```

T =

	Gender	Age	BloodPressure	
	-----	-----	-----	-----
Smith	M	38	124	93
Johnson	M	43	109	77
Williams	F	38	125	83
Jones	F	40	117	75
Brown	F	49	122	80

Convert T to a scalar structure.

```
S = table2struct(T,'ToScalar',true)
```

S =

```
Gender: [5x1 char]
Age: [5x1 double]
BloodPressure: [5x2 double]
```

Add a field for the row names from the table.

```
S.RowNames = T.Properties.RowNames
```

S =

```
Gender: [5x1 char]
Age: [5x1 double]
BloodPressure: [5x2 double]
RowNames: {5x1 cell}
```

If `S` is a nonscalar structure, use `[S.RowNames] = T.Properties.RowNames{:}` to include a field with the row names from the table.

# Table Properties

---

## Purpose

Access and modify table metadata properties

## Access and Modify Properties

A table, *T*, has properties that store metadata such as its variable names, row names, descriptions, and variable units. *T.Properties* returns a summary of all of the table properties.

You can access a property using *T.Properties.PropName*, where *T* is the name of the table and *PropName* is one of the table properties. For example, to access the *VariableDescriptions* property of a table named *Patients*, use *Patients.Properties.VariableDescriptions*.

You can modify a property value using *T.Properties.PropName = P* where *T* is the name of the table, *PropName* is one of the table properties, and *P* is the desired property value. For example, to modify the *VariableUnits* property of a table named *Patients*, use *Patients.Properties.VariableUnits = P* where *P* is a cell array of strings containing the specified information.

In contrast, you can access and modify variables within a table using *T.Variable* or *T.Variable = V*, where *T* is the name of the table, *Variable* is the name of the variable you want to access or modify, and *V* is the variable value you want.

## Properties

### VariableNames - Variable names

cell array of nonempty, distinct strings

Variable names, specified as a cell array of nonempty, distinct strings. The number of strings must equal the number of variables. MATLAB removes any leading or trailing white space from the strings.

If valid MATLAB identifiers are not available for use as variable names, MATLAB uses a cell array of *N* strings of the form { 'Var1' . . . 'Var*N*' } where *N* is the number of variables. You can determine valid MATLAB variable names using the function *isvarname*.

The variable names are visible when viewing the table and when using the summary function. Furthermore, you can use the variable names within parentheses, within curly braces, or with dot indexing to access table data.

## Example

```
%% Create a table
```

```
T = table(['M';'M';'F';'F';'F'],[38;43;38;40;49],...
 [71;69;64;67;64],[176;163;131;133;119])
```

```
T =
```

Var1	Var2	Var3	Var4
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

```
%% Modify variable names
```

```
T.Properties.VariableNames = {'Gender' 'Age' 'Height' 'Weight'}
```

```
T =
```

Gender	Age	Height	Weight
M	38	71	176
M	43	69	163
F	38	64	131
F	40	67	133
F	49	64	119

```
%% Create a subtable
```

```
%
```

```
% Use variable names within parentheses to create a subtable.
```

```
% Include all the rows, but only the variables Age and Gender.
```

```
T(:,{'Age','Gender'})
```

```
ans =
```

# Table Properties

---

Age	Gender
38	M
43	M
38	F
40	F
49	F

```
%% Extract data from the table
%
% Use variable names within curly braces to extract the
% numeric data from the variables Height and Weight.
T(:,:,{'Height','Weight'})
```

```
ans =
```

71	176
69	163
64	131
67	133
64	119

```
% Use variable names with dot indexing to extract
% all the data from the variable Gender.
T.Gender
```

```
ans =
```

```
M
M
F
F
F
```

**RowNames - Row names**

`{}` (default) | cell array of nonempty, distinct strings

Row names, specified as a cell array of nonempty, distinct strings. This property can be empty, but if not empty, the number of strings must equal the number of rows in the table. MATLAB removes any leading or trailing white space from the strings. The default property value is an empty cell array.

The row names are visible when you view the table. Furthermore, you can use the row names within parentheses or curly braces to access the table data.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add row names
T.Properties.RowNames = LastName;

% Remove row names
T.Properties.RowNames = {};
```

## DimensionNames - Dimension names

`{'Row' `Variable'}` (default) | two-element cell array of strings

Dimension names, specified as a two-element cell array of strings.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic, ...
 'RowNames', LastName);

% Add dimension names
T.Properties.DimensionNames = {'Patient' 'Data'};
```

## Description - Table description

# Table Properties

---

'' (default) | string

Table description, specified as a string. This string is visible when using the summary function.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight);

% Add a table description
T.Properties.Description = 'Simulated patient data';

%View the summary
format compact
summary(T)
```

Description: Simulated patient data

Variables:

Gender: 100x1 char

Age: 100x1 double

Values:

min 25

median 39

max 50

Height: 100x1 double

Values:

min 60

median 67

max 72

Weight: 100x1 double

Values:

min 111

median 142.5

max 202

## VariableDescriptions - Variable descriptions

`{}` (default) | cell array of strings

Variable descriptions, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have a description.

The variable descriptions are visible when using the summary function.

## Example

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add variable descriptions
T.Properties.VariableDescriptions = {' ' ' ' ' ' ...
 'Has the patient ever been a smoker' ...
 'Systolic Pressure' 'Diastolic Pressure'};

% View the summary
format compact
summary(T)
```

```
Variables:
 Gender: 100x1 char
 Age: 100x1 double
 Values:
 min 25
 median 39
 max 50
 Height: 100x1 double
 Values:
 min 60
 median 67
 max 72
 Weight: 100x1 double
 Values:
```

# Table Properties

---

```
 min 111
 median 142.5
 max 202
Smoker: 100x1 logical
 Description: Has the patient ever been a smoker
 Values:
 true 34
 false 66
Systolic: 100x1 double
 Description: Systolic Pressure
 Values:
 min 109
 median 122
 max 138
Diastolic: 100x1 double
 Description: Diastolic Pressure
 Values:
 min 68
 median 81.5
 max 99
```

```
% Remove all the variable descriptions
T.Properties.VariableDescriptions = {};
```

## VariableUnits - Variable units

`{}` (default) | cell array of strings

Variable units, specified as a cell array of strings. This property can be an empty cell array, which is the default. If the cell array is not empty, the number of strings must equal the number of variables. You can specify an individual empty string within the cell array for a variable that does not have units.

The variable units are visible when using the summary function.

## Example

```
% Create a table
load patients
```

```
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add variable units
T.Properties.VariableUnits = {' ' 'Yrs' 'In' 'Lbs' ' ' 'mm Hg' 'mm Hg'};

% View the summary
format compact
summary(T)
```

```
Variables:
 Gender: 100x1 char
 Age: 100x1 double
 Units: Yrs
 Values:
 min 25
 median 39
 max 50
 Height: 100x1 double
 Units: In
 Values:
 min 60
 median 67
 max 72
 Weight: 100x1 double
 Units: Lbs
 Values:
 min 111
 median 142.5
 max 202
 Smoker: 100x1 logical
 Values:
 true 34
 false 66
 Systolic: 100x1 double
 Units: mm Hg
 Values:
 min 109
```

# Table Properties

---

```
 median 122
 max 138
Diastolic: 100x1 double
Units: mm Hg
Values:
 min 68
 median 81.5
 max 99
```

```
% Remove all the variable units
T.Properties.VariableUnits = {};
```

## **UserData - Additional table information**

`{}` (default) | variable containing information in any data type

Additional table information, specified as a variable containing information in any data type.

## **Example**

```
% Create a table
load patients
T = table(Gender, Age, Height, Weight, Smoker, Systolic, Diastolic);

% Add an anonymous function to the table metadata
formula = @(x) x.^2;
T.Properties.UserData = formula;
```

## **Concepts**

- “Access Data in a Table”

<b>Purpose</b>	Tangent of argument in radians
<b>Syntax</b>	$Y = \tan(X)$
<b>Description</b>	$Y = \tan(X)$ returns the tangent of each element of $X$ . The $\tan$ function operates element-wise on arrays. The function accepts both real and complex inputs. For real values of $X$ in the interval $[-\text{Inf}, \text{Inf}]$ , $\tan$ returns real values in the interval $[-\text{Inf}, \text{Inf}]$ . For complex values of $X$ , $\tan$ returns complex values. All angles are in radians.
<b>Input Arguments</b>	<b>X - Input angle in radians</b> scalar value   vector   matrix   N-D array  Input angle, specified as a real-valued or complex-valued scalar, vector, matrix or N-D array. The $\tan$ operation is element-wise when $X$ is non-scalar. <b>Data Types</b> single   double <b>Complex Number Support:</b> Yes
<b>Output Arguments</b>	<b>Y - Tangent of input angle</b> scalar value   vector   matrix   N-D array  Tangent of input angle, returned as a real-valued or complex-valued scalar, vector, matrix or N-D array.
<b>Examples</b>	<b>Plot Tangent Function</b>  Plot the tangent function over the domain $-\pi/2 \leq x \leq \pi/2$ .  <pre>x = (-pi/2)+0.01:0.01:(pi/2)-0.01; plot(x,tan(x)), grid on</pre>

# tan

## Tangent of Vector of Complex Angles

Calculate the tangent of the complex angles in vector x.

```
x = [-i pi+i*pi/2 -1+i*4];
y = tan(x)
```

y =

$$0.0000 - 0.7616i \quad -0.0000 + 0.9172i \quad -0.0006 + 1.0003i$$

**Definitions****Tangent Function**

The tangent of an angle,  $\alpha$ , defined with reference to a right angled triangle is

$$\text{tangent}(\alpha) = \frac{\text{opposite side}}{\text{adjacent side}} = \frac{a}{b}.$$

# tan

---

The tangent of a complex angle,  $\alpha$ , is

$$\text{tangent}(\alpha) = \frac{e^{i\alpha} - e^{-i\alpha}}{i(e^{i\alpha} + e^{-i\alpha})}.$$

---

<b>Purpose</b>	Compress files into tar file
<b>Syntax</b>	<pre>tar(<i>tarfilename</i>,<i>files</i>) tar(<i>tarfilename</i>,<i>files</i>,<i>rootfolder</i>) entrynames = tar(...)</pre>
<b>Description</b>	<p><code>tar(<i>tarfilename</i>,<i>files</i>)</code> creates a tar file named <i>tarfilename</i> from the list of files and folders specified in <i>files</i>. Folders recursively include all of their content. If <i>files</i> includes relative paths, the tar file also contains relative paths. The tar file does not include absolute paths.</p> <p><code>tar(<i>tarfilename</i>,<i>files</i>,<i>rootfolder</i>)</code> specifies the path for <i>files</i> relative to <i>rootfolder</i> rather than the current folder. Relative paths in the tar file reflect the relative paths in <i>files</i>, and do not include path information from <i>rootfolder</i>.</p> <p><code>entrynames = tar(...)</code> returns a string cell array of the names of the files contained in <i>tarfilename</i>. If <i>files</i> includes relative paths, <i>entrynames</i> also contains relative paths.</p>
<b>Tips</b>	tar cannot compress folders larger than 2 GB.
<b>Input Arguments</b>	<p><b>tarfilename</b></p> <p>String specifying the name of the tar file. If <i>tarfilename</i> has no extension, MATLAB appends the <code>.tar</code> extension. The <i>tarfilename</i> extension can end in <code>.tgz</code> or <code>.gz</code>. In this case, <i>tarfilename</i> is gzipped.</p> <p><b>files</b></p> <p>String or cell array of strings containing the list of files or folders included in <i>tarfilename</i>.</p> <p>Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.</p> <p>Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with <code>~/</code> or <code>~username/</code>,</p>

# tar

---

which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character `*` can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.

## **rootfolder**

String specifying the path for *files*.

## **Examples**

Tar all files in the current folder to the file `backup.tgz`.

```
tar('backup.tgz','.');
```

## **See Also**

`gzip` | `gunzip` | `untar` | `unzip` | `zip`

<b>Purpose</b>	Name of system's temporary folder
<b>Syntax</b>	<code>tmp_folder = tempdir</code>
<b>Description</b>	<code>tmp_folder = tempdir</code> returns the name of the system's temporary folder, if one exists. This function does not create a new folder.
<b>See Also</b>	<code>delete</code>   <code>recycle</code>   <code>tempname</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Create Temporary Files”</li></ul>

# tempname

---

**Purpose** Unique name for temporary file

**Syntax** tmpName = tempname

**Description** tmpName = tempname returns a string, tmpName, suitable for use as a temporary file path in your system's temporary folder.

## **Examples** Create Temporary File Name with Extension

Create a temporary file name that has the extension, .dat, by concatenating two strings.

```
tmpName = [tempname, '.dat'];
```

## **Write Data to Temporary File**

Create a temporary file name.

```
filename = tempname;
```

Create a new file with the temporary file name, and write data to the file.

```
fileID = fopen(filename, 'w');
fwrite(fileID, magic(5));
fclose(fileID);
```

**Limitations**

- In most cases, tempname generates a universally unique identifier (UUID). However, if you run MATLAB without JVM software, then tempname generates a random string using the CPU counter and time, and this string is not guaranteed to be unique. For more information about the MATLAB startup option that does not load JVM software, see “Commonly Used Startup Options”.

**See Also** tempdir

**Concepts**

- “Create Temporary Files”

**Purpose**

Tetrahedron mesh plot

**Syntax**

```
tetramesh(T,X,c)
tetramesh(T,X)
tetramesh(TR)
h = tetramesh(...)
tetramesh(...,'param','value','param','value'...)
```

**Description**

`tetramesh(T,X,c)` displays the tetrahedrons defined in the  $m$ -by-4 matrix  $T$  as mesh.  $T$  is usually the output of a Delaunay triangulation of a 3-D set of points. A row of  $T$  contains indices into  $X$  of the vertices of a tetrahedron.  $X$  is an  $n$ -by-3 matrix, representing  $n$  points in 3 dimension. The tetrahedron colors are defined by the vector  $C$ , which is used as indices into the current colormap.

`tetramesh(T,X)` uses  $C = 1:m$  as the color for the  $m$  tetrahedra. Each tetrahedron has a different color (modulo the number of colors available in the current colormap).

`tetramesh(TR)` displays the tetrahedra in a triangulation representation.

`h = tetramesh(...)` returns a vector of tetrahedron handles. Each element of  $h$  is a handle to the set of patches forming one tetrahedron. You can use these handles to view a particular tetrahedron by turning the patch 'Visible' property 'on' or 'off'.

`tetramesh(...,'param','value','param','value'...)` allows additional patch property name/property value pairs to be used when displaying the tetrahedrons. For example, the default transparency parameter is set to 0.9. You can overwrite this value by using the property name/property value pair ('FaceAlpha',value) where value is a number between 0 and 1. See Patch Properties for information about the available properties.

**Examples****Plot Tetrahedrons of 3-D Delaunay Triangulation**

Generate a 3-D Delaunay triangulation, then use `tetramesh` to visualize the tetrahedrons.

# tetramesh

---

```
d = [-1 1];
[x,y,z] = meshgrid(d,d,d); % a cube
x = [x(:);0];
y = [y(:);0];
z = [z(:);0];
```

[x,y,z] are corners of a cube plus the center.

```
DT = delaunayTriangulation(x,y,z);
tetramesh(DT);
camorbit(20,0)
```

# matlab.unittest.Test

---

**Superclasses** TestSuite

**Purpose** Specification of a single test method

**Description** The matlab.unittest.Test class holds the information needed for the TestRunner object to be able to run a single Test method of a TestCase class. A scalar Test instance is the fundamental element contained in TestSuite arrays. A simple array of Test instances is a commonly used form of a TestSuite array.

## Properties

### Name

Name of the Test element.

### Parameterization

Row vector of parameters required for the Test. The Parameterization property contains all the parameterized data needed by the TestRunner.

### SharedTestFixtures

Row vector of fixtures required for the Test. The SharedTestFixtures property contains all the fixtures specified by the SharedTestFixtures class-level attribute of the TestCase class.

## Examples

### Show Class of a TestSuite Array

Create a suite of Test objects of all test methods in the BankAccountTest class.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?BankAccountTest);

whos suite
```

Name	Size	Bytes	Class	Attributes
------	------	-------	-------	------------

```
suite 1x5 1636 matlab.unittest.Test
```

Each test is a `matlab.unittest.Test` object.

Display test method names.

```
{suite.Name}'
```

```
ans =
```

```
'BankAccountTest/testConstructor'
'BankAccountTest/testConstructorNotEnoughInputs'
'BankAccountTest/testDesposit'
'BankAccountTest/testWithdraw'
'BankAccountTest/testNotifyInsufficientFunds'
```

## See Also

[matlab.unittest.TestSuite](#) | [matlab.unittest.TestRunner](#) |  
[matlab.unittest.TestCase](#) | [matlab.unittest.fixtures](#)

# matlab.unittest.TestCase

---

**Purpose** Superclass of all `matlab.unittest` test classes

**Description** The `TestCase` class is the means by which a test is written in the `matlab.unittest` framework. It provides the means to write and identify test content, as well as test fixture setup and teardown routines. Creating such a test requires deriving from `TestCase` to produce a `TestCase` subclass. Then, subclasses can leverage the metadata attributes to specify tests and test fixtures.

**Construction** The `TestCase` constructor is used to create `TestCase` instances intended for interactive, command line use. When tests are run in the framework, `TestCase` instances are constructed by the `matlab.unittest.TestRunner`.

## Methods

<code>addTeardown</code>	Dynamically add teardown routine
<code>applyFixture</code>	Use fixture with <code>TestCase</code>
<code>forInteractiveUse</code>	Create <code>TestCase</code> for interactive use
<code>getSharedTestFixtures</code>	Provide access to shared test fixtures
<code>run</code>	Run <code>TestCase</code> test

## Inherited Methods

The `TestCase` class inherits methods from the following classes:

<code>matlab.unittest.qualifications.Assertions</code>	Qualification to validate preconditions of a test
<code>matlab.unittest.qualifications.Assertions</code>	Qualification to filter test content

`matlab.unittest.qualifications.FatalQualification` Qualification to abort test execution

`matlab.unittest.qualifications.VerificationQualification` Qualification to produce soft-failure conditions

## Attributes

### Class Attributes

TestCase objects support the following class level attributes. Specify class-level attributes in the `classdef` block before the class name.

<code>SharedTestFixtures</code>	Class block to contain shared test fixtures. You must define <code>SharedTestFixtures</code> as a cell array of <code>matlab.unittest.fixtures.Fixture</code> instances.
---------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------

### Method Attributes

Classes that derive from `TestCase` can define `methods` blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

<code>Test</code>	Method block to contain test methods.
<code>TestMethodSetup</code>	Method block to contain setup code.
<code>TestMethodTeardown</code>	Method block to contain teardown code.
<code>TestClassSetup</code>	Method block to contain class level setup code.

TestClassTeardown	Method block to contain class level teardown code.
ParameterCombination	Method block to contain parameterized testing code. This attribute accepts the following values: <ul style="list-style-type: none"><li>• 'exhaustive' (default): Test methods are invoked for all combinations of parameters.</li><li>• 'sequential': Test methods are invoked with corresponding values from each parameter. Each parameter must contain the same number of values.</li><li>• 'pairwise': Test methods are invoked for every pair of parameter values at least once.</li></ul>

## Property Attributes

Classes that derive from `TestCase` can define `properties` blocks which contain `matlab.unittest` framework-specific attributes to specify test content.

ClassSetupParameter	Property block to define parameterized testing properties for methods in the <code>TestClassSetup</code> block
MethodSetupParameter	Property block to define parameterized testing properties

for methods in the `MethodSetup` block

`TestParameter`

Property block to define parameterized testing properties for methods in the `Test` block

## Events

`AssertionFailed`

Triggered upon failing assertion. A `QualificationEventData` object is passed to listener callback functions.

`AssertionPassed`

Triggered upon passing assertion. A `QualificationEventData` object is passed to listener callback functions.

`AssumptionFailed`

Triggered upon failing assumption. A `QualificationEventData` object is passed to listener callback functions.

`AssumptionPassed`

Triggered upon passing assumption. A `QualificationEventData` object is passed to listener callback functions.

`FatalAssertionFailed`

Triggered upon failing fatal assertion. A `QualificationEventData` object is passed to listener callback functions.

# matlab.unittest.TestCase

---

FatalAssertionPassed	Triggered upon passing fatal assertion. A QualificationEventData object is passed to listener callback functions.
VerificationFailed	Triggered upon failing verification. A QualificationEventData object is passed to listener callback functions.
VerificationPassed	Triggered upon passing verification. A QualificationEventData object is passed to listener callback functions.
ExceptionThrown	Triggered by the TestRunner when an exception is thrown. An ExceptionEventData object is passed to listener callback functions.

## Examples

### Create Test Case Class

Create a test case class, `FigurePropertiesTest`, with `TestMethodSetup` and `TestMethodTeardown` methods.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

 properties
 TestFigure
 end

 methods(TestMethodSetup)
 function createFigure(testCase)
 testCase.TestFigure = figure;
 end
 end
end
```

```
 end
 end

 methods(TestMethodTeardown)
 function closeFigure(testCase)
 close(testCase.TestFigure);
 end
 end

 methods(Test)

 function defaultCurrentPoint(testCase)

 cp = get(testCase.TestFigure, 'CurrentPoint');
 testCase.verifyEqual(cp, [0 0], ...
 'Default current point is incorrect')
 end

 function defaultCurrentObject(testCase)
 import matlab.unittest.constraints.IsEmpty;

 co = get(testCase.TestFigure, 'CurrentObject');
 testCase.verifyThat(co, IsEmpty, ...
 'Default current object should be empty');
 end
 end

end

end
```

# matlab.unittest.TestCase.addTeardown

---

<b>Purpose</b>	Dynamically add teardown routine
<b>Syntax</b>	<code>addTeardown(testCase,tearDownFcn)</code> <code>addTeardown(testCase,tearDownFcn,arg1,...,argN)</code>
<b>Description</b>	<code>addTeardown(testCase,tearDownFcn)</code> adds the <code>tearDownFcn</code> function handle that defines fixture teardown code to the <code>testCase</code> instance. The teardown code is executed in the reverse order to which it is added. This is known as LIFO (or Last-In-First-Out). <code>addTeardown(testCase,tearDownFcn,arg1,...,argN)</code>
<b>Input Arguments</b>	<b>testCase</b> matlab.unittest.TestCase instance <b>tearDownFcn</b> Function, specified as a function handle, that defines the fixture teardown code <b>arg1,...,argN</b> Input arguments, 1 through N (if any), required by <code>tearDownFcn</code> , specified by any type. The argument type is specified by the function argument list.

## Examples **Call addTeardown in a TestMethodSetup Method**

```
classdef SomeTest < matlab.unittest.TestCase

 methods(TestMethodSetup)
 function createFixture(testCase)
 p = path;
 testCase.addTeardown(@path, p);
 addpath(fullfile(pwd, 'testHelpers'));
 end
 end
end
```

# matlab.unittest.TestCase.applyFixture

---

**Purpose** Use fixture with TestCase

**Syntax** `applyFixture(testCase, fixture)`

**Description** `applyFixture(testCase, fixture)` prepares the specified fixture for use with the TestCase. This method enables the use of a fixture within the scope of a single Test method or TestCase class. The life cycle of the fixture is tied to the TestCase. When the TestCase goes out of scope, the test framework tears down the fixture.

Call `applyFixture` within a Test method or TestMethodSetup method to use a fixture for the current test method alone. Use `applyFixture` within a TestClassSetup method to set up a fixture for the entire class.

## Input Arguments

### **testCase**

matlab.unittest.TestCase instance

### **fixture**

matlab.unittest.fixtures.Fixture instance

## Examples

### **Apply Fixtures to TestCase Class**

Create a temporary folder and make it the current working folder.

```
classdef applyFixtureTest < matlab.unittest.TestCase
 methods(TestMethodSetup)
 function addHelpers(testCase)
 import matlab.unittest.fixtures.TemporaryFolderFixture;
 import matlab.unittest.fixtures.CurrentFolderFixture;

 % Create a temporary folder and make it the current working
 % folder.
 tempFolder = testCase.applyFixture(TemporaryFolderFixture);
 testCase.applyFixture(CurrentFolderFixture(tempFolder.Folder));
 end
 end
end
```

Each test method can write files to the current working folder, which is the temporary folder. After each test method runs, the test framework restores the working folder to its previous state and deletes the temporary folder.

**See Also**

`matlab.unittest.fixtures`

# matlab.unittest.TestCase.forInteractiveUse

---

**Purpose** Create TestCase for interactive use

**Syntax** `tc = matlab.unittest.TestCase.forInteractiveUse`

**Description** `tc = matlab.unittest.TestCase.forInteractiveUse` creates a `TestCase` instance for interactive use. The `TestCase` is configured for experimentation at the command prompt. It reacts to qualification tests by printing messages to the screen for both passing and failing conditions.

## **Examples** **Verify Values Using Interactive TestCase**

Create a `TestCase` for interactive use.

```
import matlab.unittest.TestCase;
testCase = TestCase.forInteractiveUse;
```

Produce a passing verification.

```
testCase.verifyTrue(true, 'true should be true');
```

```
Interactive verification passed.
```

Produce a failing verification.

```
testCase.verifyTrue(false);
```

```
Interactive verification failed.
```

```

Framework Diagnostic:

verifyTrue failed.
--> The value must evaluate to "true".
```

```
Actual Value:
 0
```

# matlab.unittest.TestCase.forInteractiveUse

---

## See Also

[matlab.unittest.TestCase](#) | [matlab.unittest.qualifications](#)

# matlab.unittest.TestCase.getSharedTestFixtures

---

**Purpose** Provide access to shared test fixtures

**Syntax**

```
fixtures = getSharedTestFixtures(testCase)
fixtures = getSharedTestFixtures(testCase,fixtureClassName)
```

**Description**

`fixtures = getSharedTestFixtures(testCase)` provides access to the array of all shared test fixtures for `testCase`. `getSharedTestFixtures` returns an array of fixture objects, `fixtures`. Specify shared fixtures are using the `SharedTestFixtures` attribute for the `testCase` class.

`fixtures = getSharedTestFixtures(testCase,fixtureClassName)` returns only the shared fixtures that have the class name `fixtureClassName`.

**Input Arguments**

**testCase**  
matlab.unittest.TestCase instance

**fixtureClassName**  
Name of test fixture class, specified as a string

## Examples Obtain Array of All Shared Fixtures

Create the following class, `myTest`, on your MATLAB path. Two shared fixtures are used within the test method. This example assumes that the subfolder `helperFiles` exists in your working folder. Create the subfolder `helperFiles` in your working folder if it does not exist.

```
classdef (SharedTestFixtures={...
matlab.unittest.fixtures.PathFixture('helperFiles'),...
 matlab.unittest.fixtures.TemporaryFolderFixture}) ...
 myTest < matlab.unittest.TestCase
 methods(Test)
 function accessFixtures(testCase)
 myFixtures = testCase.getSharedTestFixtures
 end
 end
end
```

# matlab.unittest.TestCase.getSharedTestFixtures

---

```
end
```

At the command prompt, run the test.

```
run(myTest);
```

```
Setting up PathFixture.
```

```
Description: Adds 'H:\Documents\doc_examples\helperFiles' to the path.
```

---

```
Setting up TemporaryFolderFixture.
```

```
Description: Creates a temporary folder.
```

---

```
Running myTest
```

```
myFixtures =
```

```
 1x2 heterogeneous Fixture (PathFixture, TemporaryFolderFixture) array
```

```
.
```

```
Done myTest
```

---

```
Tearing down TemporaryFolderFixture.
```

```
Description: Deletes the temporary folder and all its contents.
```

---

```
Tearing down PathFixture.
```

```
Description: Restores the path to its previous state.
```

---

## Access Shared Fixtures of Particular Class

Create the class, `mySecondTest`, on your MATLAB path.

```
classdef (SharedTestFixtures={...
 matlab.unittest.fixtures.TemporaryFolderFixture})...
```

# matlab.unittest.TestCase.getSharedTestFixtures

---

```
 mySecondTest < matlab.unittest.TestCase
 methods(Test)
 function accessTemporaryFolderFixture(testCase)
 tempFolderFixture = testCase.getSharedTestFixtures...
 ('matlab.unittest.fixtures.TemporaryFolderFixture');
 temporaryFolder = tempFolderFixture.Folder
 end
 end
end
```

At the command prompt, run the test. The name of the temporary folder varies.

```
run(mySecondTest);
```

```
Setting up TemporaryFolderFixture.
Description: Creates a temporary folder.
```

```
Running mySecondTest
```

```
temporaryFolder =
```

```
C:\Temp\tpb92c9c67_02fa_4714_bfb0_b2127df0f31d
```

```
.
Done mySecondTest
```

```
Tearing down TemporaryFolderFixture.
Description: Deletes the temporary folder and all its contents.
```

## Concepts

- Class Attributes

## Purpose

Run `TestCase` test

## Syntax

```
result = run(testCase)
result = run(testCase, testMethod)
```

## Description

`result = run(testCase)` uses `testCase` as a prototype to run a `TestSuite` array created from all test methods in the class defining `testCase`. This suite is run using a `TestRunner` object configured for text output.

`result = run(testCase, testMethod)` uses `testCase` as a prototype to run a `TestSuite` array created from `testMethod`. This test is run using a `TestRunner` object configured for text output.

This is a convenience method to allow interactive experimentation of `TestCase` classes in MATLAB, yet running the tests contained in them using a supported `TestRunner` object.

## Input Arguments

### **testCase**

`matlab.unittest.TestCase` instance

### **testMethod**

Name of desired test method, specified as one of the following:

- string
- `meta.method` instance

The method must correspond to a valid Test method of the `testCase` instance.

## Output Arguments

### **result**

A `matlab.unittest.TestResult` object containing the result of the test run.

## Examples

### Run Test Directly from Test Case

Add the FigurePropertiesTest.m test case file to a folder on your MATLAB path.

```
classdef FigurePropertiesTest < matlab.unittest.TestCase

 properties
 TestFigure
 end

 methods(TestMethodSetup)
 function createFigure(testCase)
 %comment
 testCase.TestFigure = figure;
 end
 end

 methods(TestMethodTeardown)
 function closeFigure(testCase)
 close(testCase.TestFigure);
 end
 end

 methods(Test)

 function defaultCurrentPoint(testCase)

 cp = get(testCase.TestFigure, 'CurrentPoint');
 testCase.verifyEqual(cp, [0 0], ...
 'Default current point is incorrect')
 end

 function defaultCurrentObject(testCase)
 import matlab.unittest.constraints.IsEmpty;

 co = get(testCase.TestFigure, 'CurrentObject');
```

```
 testCase.verifyThat(co, IsEmpty, ...
 'Default current object should be empty');
 end
```

```
end
```

```
end
```

Create a testcase object.

```
tc = FigurePropertiesTest;
```

Run the tests.

```
tc.run;
```

```
Running FigurePropertiesTest
```

```
..
```

```
Done FigurePropertiesTest
```

---

All tests passed.

[matlab.unittest.TestSuite.run](#) |  
[matlab.unittest.TestRunner.run](#)

# matlab.unittest.TestResult

---

**Purpose** Result of running test suite

**Description** The `matlab.unittest.TestResult` class holds the information describing the result of running a test suite using the `matlab.unittest` framework. The results include information describing whether the test passed, failed, or ran to completion, as well as the duration of each test.

**Construction** `TestResult` arrays are created and returned by the test runner, and are of the same size as the suite which was run.

## Properties

### Duration

Time elapsed running test.

The `Duration` property indicates the amount of time taken to run a particular test, including the time taken setting up and tearing down any test fixtures.

Fixture setup time is accounted for in the duration of the first test suite array element that uses the fixture. Fixture teardown time is accounted for in the duration of the last test suite array element that uses the fixture.

The total run time for a suite of tests exceeds the sum of the durations for all the elements of the suite because the `Duration` property does not include all the overhead of the `TestRunner` object, nor any of the time consumed by test runner plugins.

### Failed

Logical value showing if test failed.

A `TRUE Failed` property indicates some form of test failure. When `Failed` is `FALSE`, then no failing conditions were encountered. A failing result can occur with a failure condition either in a test or in setting up and tearing down test fixtures. Failures can occur due to the following:

- Verification failures

- Assertion failures
- Uncaught MExceptions

Fatal assertions are also failing conditions, but in the event of a fatal assertion failure, the entire framework aborts and a `TestResult` object is never produced.

## **Incomplete**

Logical value showing if test did not run to completion.

A `TRUE` `Incomplete` property indicates a test did not run to completion. When it is `FALSE`, then no conditions were encountered that prevented the test from completing. In other words, when `FALSE` there were no stack disruptions out of the running test content. An incomplete result can occur with a stack disruption in either a test or when setting up and tearing down test fixtures. Incomplete tests can occur due to the following:

- Assertion failures
- Tests filtered through assumption
- Uncaught MExceptions

Fatal assertions are also conditions that prevent the completion of tests, but in the event of a fatal assertion failure the entire framework aborts and a `TestResult` object is never produced.

## **Name**

The name of the `TestSuite` object for the result.

The `Name` property is a string that holds the name of the test corresponding to this result.

## **Passed**

Logical value showing if the test passed.

# matlab.unittest.TestResult

---

When the `Passed` property is `TRUE`, then the test completed as expected without any failure. When it is `FALSE`, then the test did not run to completion and/or encountered a failure condition.

## Examples

### Use TestResult Object to Identify and Rerun Failed Tests

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;
```

Result display method provides a summary of the results

```
suite = TestSuite.fromClass(?SomeTestClass)
results = run(suite)
```

```
results =
```

```
 matlab.unittest.TestResult
```

```
 Test Suite Summary:
```

```
 12 Passed, 4 Failed, 0 Not Run To Completion.
```

```
 5.5091 seconds testing time.
```

Rerun only the failed tests.

```
failedTests = suite([results.Failed]);
failedResults = run(failedTests)
```

```
failedResults =
```

```
 matlab.unittest.TestResult
```

```
 Test Suite Summary:
```

```
 0 Passed, 4 Failed, 0 Not Run To Completion.
```

```
 1.2894 seconds testing time.
```

Make the fix and rerun results.

```
newResults = run(failedTests)

newResults =

 matlab.unittest.TestResult

Test Suite Summary:
 4 Passed, 0 Failed, 0 Not Run To Completion.
 1.1607 seconds testing time.
```

[TestRunner](#) | [TestSuite](#)

## Concepts

- [Property Attributes](#)

# matlab.unittest.TestRunner

---

**Purpose** Class for running tests in `matlab.unittest` framework

**Description** The `matlab.unittest.TestRunner` class is the fundamental API used to run a suite of tests in the `matlab.unittest` framework. It runs and operates on `TestSuite` arrays. Use this class to customize running tests. The `TestRunner` class is a sealed class; you cannot derive classes from the `TestRunner` class.

**Construction** To create a simple, silent `TestRunner` object, call the static `withNoPlugins` method.

```
runner = matlab.unittest.TestRunner.withNoPlugins
```

To create a `TestRunner` object to run tests from the MATLAB Command Window , call the static `withTextOutput` method.

```
runner = matlab.unittest.TestRunner.withTextOutput
```

To create a customized `TestRunner` object, call the `addPlugin` method.

```
runner = TestRunner.withNoPlugins;
runner.addPlugin(SomePlugin())
```

<b>Methods</b>		
<code>addPlugin</code>		Add plugin to <code>TestRunner</code> object
<code>run</code>		Run all tests in <code>TestSuite</code> array
<code>withNoPlugins</code>		Create simplest runner possible
<code>withTextOutput</code>		Create <code>TestRunner</code> object for command window output

## **Examples** **Create TestRunner Object Configured for Text Output**

Add `matlab.unittest` classes to the current import list.

```
import matlab.unittest.TestRunner;
```

```
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create the TestRunner object and run the suite.

```
runner = TestRunner.withTextOutput;
result = run(runner,suite);
```

## See Also

# matlab.unittest.TestRunner.addPlugin

---

<b>Purpose</b>	Add plugin to TestRunner object
<b>Syntax</b>	<code>addPlugin(runner,plugin)</code>
<b>Description</b>	<code>addPlugin(runner,plugin)</code> adds plugin to runner.
<b>Input Arguments</b>	<b>runner</b> matlab.unittest.TestRunner object. <b>plugin</b> Mechanism provided to customize the manner in which a TestSuite array is run, specified as a TestRunnerPlugin object.

## Examples **Run Test with Custom Plugin**

Add matlab.unittest classes to the current import list.

```
import matlab.unittest.TestRunner;
import matlab.unittest.TestSuite;
```

Create a TestSuite array.

```
suite = TestSuite.fromClass(?mypackage.MyTestClass);
```

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;
```

Add a custom plugin.

```
import matlab.unittest.plugins.DiagnosticsValidationPlugin;
runner.addPlugin(DiagnosticsValidationPlugin);
```

Run the test.

```
result = run(runner,suite);
```

<b>Purpose</b>	Run all tests in <code>TestSuite</code> array
<b>Syntax</b>	<code>result = run(runner,suite)</code>
<b>Description</b>	<p><code>result = run(runner,suite)</code> runs the <code>TestSuite</code> array defined by <code>suite</code> using the <code>TestRunner</code> object provided in <code>runner</code>, and returns the result in <code>result</code>.</p> <p>This method runs all of the appropriate methods of the <code>TestCase</code> class to set up fixtures and run test content. It handles errors and qualification failures and records the information in <code>result</code>.</p>
<b>Input Arguments</b>	<p><b>runner</b> matlab.unittest.TestRunner object.</p> <p><b>suite</b> Set of tests, specified as a matlab.unittest.TestSuite array.</p>
<b>Output Arguments</b>	<p><b>result</b> A matlab.unittest.TestResult object containing the result of the test run. <code>result</code> is the same size as <code>suite</code> and each element is the result of the corresponding element in <code>suite</code>.</p>
<b>Examples</b>	<p><b>Run All Tests in a Package</b></p> <p>Add matlab.unittest classes to the current import list.</p> <pre>import matlab.unittest.TestRunner; import matlab.unittest.TestSuite;</pre> <p>Create a test suite, and a test runner that displays text.</p> <pre>suite = TestSuite.fromClass(?mypackage.MyTestClass); runner = TestRunner.withTextOutput;</pre> <p>Run the test suite.</p>

# matlab.unittest.TestRunner.run

[matlab.unittest.TestSuite.run](#) | [matlab.unittest.TestCase.run](#)

# matlab.unittest.TestRunner.withNoPlugins

---

<b>Purpose</b>	Create simplest runner possible		
<b>Syntax</b>	<code>runner = matlab.unittest.TestRunner.withNoPlugins</code>		
<b>Description</b>	<p><code>runner = matlab.unittest.TestRunner.withNoPlugins</code> creates a <code>TestRunner</code> that is guaranteed to have no plugins installed and returns it in <code>runner</code>. It is the method one can use to create the simplest runner possible without violating the guarantees a test writer has when writing <code>TestCase</code> classes. This runner is a silent runner, meaning that regardless of passing or failing tests, this runner produces no command window output, although the results returned after running a test suite are accurate.</p> <p>This method can also be used when it is desirable to have complete control over which plugins are installed and in what order. It is the only method guaranteed to produce the minimal <code>TestRunner</code> with no plugins, so one can create it and add additional plugins as desired.</p>		
<b>Output Arguments</b>	<p><b>runner</b> matlab.unittest.TestRunner object.</p>		
<b>Attributes</b>	<table><tr><td>Static</td><td>true</td></tr></table> <p>To learn about attributes of methods, see <a href="#">Method Attributes</a> in the <a href="#">MATLAB Object-Oriented Programming</a> documentation.</p>	Static	true
Static	true		
<b>Examples</b>	<p><b>Create a Silent TestRunner Object with no Plugins</b></p> <p>Add <code>matlab.unittest</code> classes to the current import list.</p> <pre>import matlab.unittest.TestRunner; import matlab.unittest.TestSuite;</pre> <p>Create a <code>TestSuite</code> array.</p> <pre>suite = TestSuite.fromClass(?mypackage.MyTestClass);</pre>		

# matlab.unittest.TestRunner.withNoPlugins

---

Create a TestRunner object.

```
runner = TestRunner.withNoPlugins;

% Run the suite silently
result = run(runner,suite)
```

## Control Plugins

Using the TestRunner object created in the previous example, control which plugins are installed and in what order they are installed.

Add matlab.unittest class to the current import list.

```
import matlab.unittest.plugins;
```

Add specific plugins.

```
runner.addPlugin(DiagnosticsValidationPlugin);
runner.addPlugin(TestSuiteProgressPlugin);
```

Rerun the tests.

```
result = run(runner,suite)
```

# matlab.unittest.TestRunner.withTextOutput

---

<b>Purpose</b>	Create TestRunner object for command window output
<b>Syntax</b>	<code>runner = matlab.unittest.TestRunner.withTextOutput</code>
<b>Description</b>	<code>runner = matlab.unittest.TestRunner.withTextOutput</code> creates a TestRunner object that is configured for running tests from the MATLAB Command Window and returns it in <code>runner</code> . The output produced includes test progress as well as diagnostics in the event of test failures.
<b>Output Arguments</b>	<b>runner</b> matlab.unittest.TestRunner object.
<b>Attributes</b>	Static <span style="float: right;">true</span>  To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.
<b>Examples</b>	<b>Display Test Results in Command Window</b>  Add matlab.unittest classes to the current import list.  <pre>import matlab.unittest.TestRunner; import matlab.unittest.TestSuite;</pre> Create a TestSuite array.  <pre>suite = TestSuite.fromClass(?mypackage.MyTestClass);</pre> Create a TestRunner object that produced output to the Command Window.  <pre>runner = TestRunner.withTextOutput;</pre> <pre>% Run the suite</pre>

# matlab.unittest.TestRunner.withTextOutput

---

```
result = run(runner,suite)
```

**See Also** [run](#)

<b>Purpose</b>	Class for grouping tests to run																
<b>Description</b>	The <code>matlab.unittest.TestSuite</code> class is the fundamental interface used to group and run a set of tests in the unit test framework. The <code>matlab.unittest.TestRunner</code> object can only run arrays of <code>TestSuite</code> objects.																
<b>Construction</b>	<code>TestSuite</code> arrays are created using static methods of the <code>TestSuite</code> class. These methods may return subclasses of the <code>TestSuite</code> class depending on the method call and context.																
<b>Methods</b>	<table><tr><td><code>fromClass</code></td><td>Create suite from <code>TestCase</code> class</td></tr><tr><td><code>fromFile</code></td><td>Create <code>TestSuite</code> array from test file</td></tr><tr><td><code>fromFolder</code></td><td>Create <code>TestSuite</code> array from all tests in folder</td></tr><tr><td><code>fromMethod</code></td><td>Create <code>TestSuite</code> array from single test method</td></tr><tr><td><code>fromName</code></td><td>Create <code>Test</code> object from name of test element</td></tr><tr><td><code>fromPackage</code></td><td>Create <code>TestSuite</code> array from all tests in package</td></tr><tr><td><code>run</code></td><td>Run <code>TestSuite</code> array using <code>TestRunner</code> object configured for text output</td></tr><tr><td><code>selectIf</code></td><td>Select test suite elements that satisfy conditions</td></tr></table>	<code>fromClass</code>	Create suite from <code>TestCase</code> class	<code>fromFile</code>	Create <code>TestSuite</code> array from test file	<code>fromFolder</code>	Create <code>TestSuite</code> array from all tests in folder	<code>fromMethod</code>	Create <code>TestSuite</code> array from single test method	<code>fromName</code>	Create <code>Test</code> object from name of test element	<code>fromPackage</code>	Create <code>TestSuite</code> array from all tests in package	<code>run</code>	Run <code>TestSuite</code> array using <code>TestRunner</code> object configured for text output	<code>selectIf</code>	Select test suite elements that satisfy conditions

<code>run</code>	Run <code>TestSuite</code> array using <code>TestRunner</code> object configured for text output																
<code>selectIf</code>	Select test suite elements that satisfy conditions																

## Examples **Create Test Suite of Every Type of Test Set**

Add the `matlab.unittest.TestSuite` class to the current import list.

# matlab.unittest.TestSuite

---

```
import matlab.unittest.TestSuite;
```

Create test suites using a each method.

```
fileSuite = TestSuite.fromFile('SomeTestFile.m');
folderSuite = TestSuite.fromFolder(pwd);
packageSuite = TestSuite.fromPackage('mypackage.subpackage');
classSuite = TestSuite.fromClass(?mypackage.MyTestClass);
methodSuite = TestSuite.fromMethod(?SomeTestClass,'testMethod');
```

Concatenate the suites.

```
largeSuite = [fileSuite, folderSuite, packageSuite, classSuite, methodSuite];
```

Run the full suite.

```
result = run(largeSuite)
```

## See Also

[TestRunner](#) | [TestResult](#) | [Test](#)

## Purpose

Create suite from TestCase class

## Syntax

```
suite = matlab.unittest.TestSuite.fromClass(testClass)
suite = matlab.unittest.TestSuite.fromClass(testClass,s)
suite = matlab.unittest.TestSuite.fromClass(___,Name,Value)
```

## Description

`suite = matlab.unittest.TestSuite.fromClass(testClass)` creates a TestSuite array from all of the Test methods contained in `testClass` and returns that array in `suite`.

`suite = matlab.unittest.TestSuite.fromClass(testClass,s)` creates a TestSuite array from all of the Test methods contained in `testClass` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromClass( ___,Name,Value)` creates a TestSuite array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Tips

- `testClass` must be on the MATLAB path when using this method to create `suite`, as well as when `suite` is run.

## Input Arguments

### **testClass**

Class containing test methods, specified as a `meta.class` instance. Use the `?` operator to create a `meta.class` instance. `testClass` must derive from `matlab.unittest.TestCase`.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## Name-Value Pair Arguments

### **'Name'**

# matlab.unittest.TestSuite.fromClass

---

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

## **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

## **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

## **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

## **Output Arguments**

**suite**

Set of tests, specified as a `matlab.unittest.Test` array.

## **Attributes**

Static

true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Run Tests in a Package Class

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?mypackage.MyTestClass);
result = run(suite)
```

### Run Tests in a Class Without a Package

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromClass(?MyTestClass);
result = run(suite)
```

### Create Suite of Test Elements Using Selector

In your working folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single','double','uint16'};
 outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
```

# matlab.unittest.TestSuite.fromClass

---

```
 testCase.verifyClass(zeros, 'double');
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the test elements that tests the 'double' data type.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromClass(?testZeros, ...
 HasParameter('Property','type','Name','double'));
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from the test elements that tests the 'double' data type.

```
import matlab.unittest.TestSuite;
```

```
suite = TestSuite.fromClass(?testZeros, ...
 'ParameterProperty','type', 'ParameterName','double');
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## See Also

TestRunner | fromMethod | fromPackage |  
matlab.unittest.selectors

# matlab.unittest.TestSuite.fromFile

---

**Purpose** Create TestSuite array from test file

**Syntax**

```
suite = matlab.unittest.TestSuite.fromFile(file)
suite = matlab.unittest.TestSuite.fromFile(file,s)
suite = matlab.unittest.TestSuite.fromFile(___,Name,Value)
```

**Description** `suite = matlab.unittest.TestSuite.fromFile(file)` creates a TestSuite array from all of the Test methods in `file`.

When the test suite is run, MATLAB changes the current folder to the folder that defines the test content, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFile(file,s)` creates a TestSuite array from all of the Test methods in `file` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromFile(___,Name,Value)` creates a TestSuite array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Input Arguments

### **file**

Class file derived from `matlab.unittest.TestCase` containing test methods, specified as a string.

### **s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

## **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

## **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

## **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

## **Output Arguments**

### **suite**

Set of tests, specified as a `matlab.unittest.Test` array.

# matlab.unittest.TestSuite.fromFile

---

## Attributes

Static

true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## Examples

### Run Tests in Class File

Function for unit testing:

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.');
```

TestCase class containing test methods:

```
classdef Add5Test < matlab.unittest.TestCase
 methods (Test)
 function testDoubleOut(testCase)
 actOutput = add5(1);
 testCase.verifyClass(actOutput,'double');
 end
 function testNonNumericInput(testCase)
 testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
 end
 end
end
```

Create a test suite from the Add5Test class file.

```
suite = matlab.unittest.TestSuite.fromFile('Add5Test.m');
result = run(suite);
```

```
Running Add5Test
..
Done Add5Test
```

---

## Create Suite of Test Elements Using Selector

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single','double','uint16'};
 outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
 end
end
```

# matlab.unittest.TestSuite.fromFile

---

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized test methods in `testZeros.m` using the `HasParameter` selector.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromFile('testZeros.m', HasParameter)
```

```
suite =
```

```
 1x8 Test array with properties:
```

```
 Name
 Parameterization
 SharedTestFixtures
```

Create a test suite from only the test elements from the `testSize` method using the `HasName` selector with the `StartsWithSubstring` constraint.

```
import matlab.unittest.selectors.HasName;
import matlab.unittest.constraints.StartsWithSubstring;

suite = TestSuite.fromFile('testZeros.m',...
 HasName(StartsWithSubstring('testZeros/testSize')));
{suite.Name}'
```

```
ans =
```

```
 'testZeros/testSize(outSize=s2d) '
 'testZeros/testSize(outSize=s3d) '
```

The test suite contains the two parameterized tests from the `testSize` method.

## Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all test methods in `testZeros.m` that have a name starting with `'testZeros/testSize'`. This test suite contains parameterized tests from the `testSize` method.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFile('testZeros.m', 'Name', 'testZeros/testSize',
{suite.Name})

ans =

 'testZeros/testSize(outSize=s2d)'
 'testZeros/testSize(outSize=s3d)'
```

To ensure that a test suite is comprised of test elements associated with one particular test method, use the `fromMethod` method of `TestSuite`.

At the command prompt, create a test suite from all test methods in `testZeros.m` that have a name ending in `'Size'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFile('testZeros.m', 'Name', '*Size');
{suite.Name}

ans =

 'testZeros/testDefaultSize'
```

Note that elements from the `testSize` method are not included in the test suite. The name of these elements contains information about the parameterization, and therefore it does not end with `'Size'`.

Create a test suite of all tests that use the parameter name `'double'`.

# matlab.unittest.TestSuite.fromFile

---

```
suite = TestSuite.fromFile('testZeros.m', 'ParameterName', 'double');
{suite.Name}'
```

```
ans =
```

```
 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

To construct the same test suite using selectors,  
use `suite = TestSuite.fromFile('testZeros.m',  
HasParameter('Name','double'))`.

## See Also

[TestRunner](#) | [fromFolder](#) | [matlab.unittest.selectors](#)

## Purpose

Create TestSuite array from all tests in folder

## Syntax

```
suite = matlab.unittest.TestSuite.fromFolder(folder)
suite = matlab.unittest.TestSuite.fromFolder(folder,s)
suite =
matlab.unittest.TestSuite.fromFolder(___,Name,Value)
```

## Description

`suite = matlab.unittest.TestSuite.fromFolder(folder)` creates a TestSuite array from all of the Test methods of all concrete TestCase classes contained in `folder` and returns that array in `suite`. If tests are function-based, a Test file is included in the TestSuite array if it follows the naming convention of starting or ending in the word 'test', which is case-insensitive. Class-based tests do not need to follow this naming convention. The method is not recursive, returning only those tests directly in the specified folder.

When the test suite is run, MATLAB changes the current folder to the folder that defines the test content, and adds it to the path for the duration of the test run.

`suite = matlab.unittest.TestSuite.fromFolder(folder,s)` creates a TestSuite array from all of the Test methods contained in `folder` that satisfy the conditions specified by the selector, `s`.

`suite = matlab.unittest.TestSuite.fromFolder( ___,Name,Value)` creates a TestSuite array with additional options specified by one or more `Name,Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

## Input Arguments

### folder

Folder containing test methods, specified as a string. `folder` can be either an absolute or relative path to the desired folder.

**s**

# matlab.unittest.TestSuite.fromFolder

---

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## **Name-Value Pair Arguments**

### **'IncludingSubfolders'**

Include test methods from any `folder` subfolders, excluding package, class, and private folders. This property is `false` by default. You can specify it as `true` during construction.

### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For test classes defined in

packages, the base folder is the parent of the top-level package folder.

## Output Arguments

**suite**

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static

true

To learn about attributes of methods, see [Method Attributes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Run Tests in Current Folder

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder(pwd);
result = run(suite);
```

### Run Tests in Subfolders

```
suite = TestSuite.fromFolder(pwd, 'IncludingSubfolders', true);
result = run(suite);
```

### Create Suite of Test Elements Using Selector

In your working folder, create a new folder, `myTests`. In that folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single','double','uint16'};
 outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
 end
```

# matlab.unittest.TestSuite.fromFolder

---

```
methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests that use the parameter name 'double'.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromFolder('myTests', HasParameter('Name','double'));
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d)'
 'testZeros/testClass(type=double,outSize=s3d)'
```

## Create Suite of Test Elements Using Name-Value Arguments

Create the `myTests` folder and `testZeros.m` class from the previous example.

Create a test suite of all tests that use the parameter name `'double'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromFolder('myTests', 'ParameterName', 'double');
{suite.Name}'

ans =

 'testZeros/testClass(type=double,outSize=s2d) '
 'testZeros/testClass(type=double,outSize=s3d) '
```

## See Also

[TestRunner](#) | [fromFile](#) | [matlab.unittest.selectors](#)

# matlab.unittest.TestSuite.fromMethod

---

**Purpose** Create TestSuite array from single test method

**Syntax**

```
suite =
matlab.unittest.TestSuite.fromMethod(testClass, testMethod)
suite =
matlab.unittest.TestSuite.fromMethod(testClass, testMethod, s)
suite =
matlab.unittest.TestSuite.fromMethod(___, Name, Value)
```

**Description**

```
suite =
matlab.unittest.TestSuite.fromMethod(testClass, testMethod)
```

creates a TestSuite array from the test class described by `testClass` and the test method described by `testMethod` and returns it in `suite`.

```
suite =
matlab.unittest.TestSuite.fromMethod(testClass, testMethod, s)
```

creates a TestSuite array from all of the Test methods contained in `testMethod` that satisfy the conditions specified by the selector, `s`.

```
suite =
matlab.unittest.TestSuite.fromMethod(___, Name, Value)
```

creates a TestSuite array with additional options specified by one or more `Name, Value` pair arguments. You can use this syntax with any of the input arguments of the previous syntaxes.

**Tips**

- `testClass` must be on the MATLAB path when using this method to create `suite`, as well as when `suite` is run.

**Input Arguments**

**testClass**

Class describing the test methods, specified as a `meta.class` instance which must derive from `matlab.unittest.TestCase`.

**testMethod**

Test method, specified by either the `meta.method` instance or the name as a string. The method must be defined with a `Test` method attribute.

**s**

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

## **Name-Value Pair Arguments**

### **'Name'**

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterProperty'**

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For test classes defined in

# matlab.unittest.TestSuite.fromMethod

---

packages, the base folder is the parent of the top-level package folder.

## Output Arguments

**suite**

Set of tests, specified as a `matlab.unittest.Test` array.

## Attributes

Static

true

To learn about attributes of methods, see [Method Attributes](#) in the [MATLAB Object-Oriented Programming](#) documentation.

## Examples

### Run a Single Test Method

Add the `matlab.unittest.TestSuite` class to the current import list.

```
import matlab.unittest.TestSuite;

cls = ?mypackage.MyTestClass;

% Create the suite using the method name
suite = TestSuite.fromMethod(cls, 'testMethod');
result = run(suite)

% Create the suite using the meta.method instance
metaMethod = findobj(cls.MethodList, 'Name', 'testMethod');
suite = TestSuite.fromMethod(cls, metaMethod);
result = run(suite)
```

### Create Suite of Test Elements Using Selector

In your working folder, create the following `testZeros.m` test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
```

```
type = {'single','double','uint16'};
outSize = struct('s2d',[3 3], 's3d',[2 5 4]);
end

methods (Test)
function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize,type), type);
end

function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
end

function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
end
function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
end

function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
end
end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests from the `testClass` method that use the parameter name 'double'.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromMethod(?testZeros,'testClass', ...
 HasParameter('Name','single'));
```

# matlab.unittest.TestSuite.fromMethod

---

```
{suite.Name}'

ans =

 'testZeros/testClass(type=single,outSize=s2d) '
 'testZeros/testClass(type=single,outSize=s3d) '
```

## Create Suite of Test Elements Using Name-Value Arguments

Create the `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all parameterized tests from the `testClass` method that use the parameter name `'double'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromMethod(?testZeros,'testClass', ...
 'ParameterName','single');
{suite.Name}'

ans =

 'testZeros/testClass(type=single,outSize=s2d) '
 'testZeros/testClass(type=single,outSize=s3d) '
```

## See Also

[matlab.unittest.selectors](#)

# matlab.unittest.TestSuite.fromName

---

**Purpose** Create Test object from name of test element

**Syntax** `testObj = matlab.unittest.TestSuite.fromName(name)`

**Description** `testObj = matlab.unittest.TestSuite.fromName(name)` creates a scalar Test object, `testObj`, from the name of the test element, `name`.

**Input Arguments**

**name**

Name of the `matlab.unittest.Test` element, specified as a string. `name` contains the name of the `TestCase` class or function and the test method or local function, as well as information about test parameterization. The name argument corresponds to the `Name` property of the Test object.

The test class or function described by `name` must be on the MATLAB path when you are creating and running the `TestSuite`.

**Attributes**

Static true

To learn about attributes of methods, see [Method Attributes](#) in the MATLAB Object-Oriented Programming documentation.

**Examples**

**Create and Run Test from Test Suite Element**

Create a function to test, `add5`, in a file on your MATLAB path.

```
function res = add5(x)
%ADD5 Increment input by 5.
if ~isa(x,'numeric')
 error('add5:InputMustBeNumeric','Input must be numeric.');
```

end  
res = x + 5;  
end

# matlab.unittest.TestSuite.fromName

---

Create a file, `Add5Test.m`, on your MATLAB path that contains the following `TestCase` class.

```
classdef Add5Test < matlab.unittest.TestCase
 properties (TestParameter)
 Type = {'double','single','int8','int32'};
 end

 methods (Test)
 function testNonNumericInput(testCase)
 testCase.verifyError(@()add5('0'),'add5:InputMustBeNumeric');
 end
 function testResultType(testCase, Type)
 actOutput = add5(cast(1,Type));
 testCase.verifyClass(actOutput, Type);
 end
 end
end
```

At the command prompt, create a test object for the `testNonNumericInput` method in the `Add5Test` class.

```
import matlab.unittest.TestSuite;
testObj = TestSuite.fromName('Add5Test/testNonNumericInput');
```

Run the test

```
result = run(testObj);
```

```
Running Add5Test
.
Done Add5Test
```

---

Create a parameterized test for the `testResultType` method in the `Add5Test` class, and run the test.

# matlab.unittest.TestSuite.fromName

---

```
testObj = TestSuite.fromName('Add5Test/testResultType(Type=single)');
result = run(testObj);
```

```
Running Add5Test
.
Done Add5Test
```

---

You can use this syntax with any of the input arguments of the previous syntaxes.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• The root folder(s) where package is defined must be on the MATLAB path when creating suite using this method as well as when suite is run.</li></ul>
<b>Input Arguments</b>	<p><b>package</b> The name of the desired package to find tests, specified as a string.</p> <p><b>s</b> Selector, specified as an instance of a class from the matlab.unittest.selector package.</p>

## Name-Value Pair Arguments

### 'IncludingSubpackages'

Indicator for whether to include subpackages in the `TestSuite` array. This property is `false` by default. You can specify it as `true` during construction.

### 'Name'

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### 'ParameterProperty'

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### 'ParameterName'

String indicating the name of a parameter used by the test suite element. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### 'BaseFolder'

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

# matlab.unittest.TestSuite.fromPackage

---

## Output Arguments

**suite**

Set of tests, specified as a matlab.unittest.Test array.

## Attributes

Static

true

To learn about attributes of methods, see Method Attributes in the MATLAB Object-Oriented Programming documentation.

## Examples

### Run All Tests in a Package

Add the matlab.unittest.TestSuite class to the current import list.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromPackage('mypackage.subpackage');
result = run(suite)
```

Run tests in mypackage including all subpackages.

```
suite = TestSuite.fromPackage('mypackage', 'IncludingSubpackages', true);
result = run(suite)
```

### Create Suite of Test Elements Using Selector

In your working folder, create a new package by creating a new folder, +myPackage. In that folder, create the following testZeros.m test file. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
 testCase.verifyClass(zeros(outSize, type), type);
 end
 end
end
```

# matlab.unittest.TestSuite.fromPackage

---

```
end

function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
end

function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
end

function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
end

function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
end
end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from all parameterized tests that use the parameter property 'outSize'.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasParameter;

suite = TestSuite.fromPackage('myPackage', ...
 HasParameter('Property','outSize'));
{suite.Name}'

ans =

 'myPackage.testZeros/testClass(type=single,outSize=s2d)'
 'myPackage.testZeros/testClass(type=single,outSize=s3d)'
 'myPackage.testZeros/testClass(type=double,outSize=s2d)'
```

# matlab.unittest.TestSuite.fromPackage

---

```
'myPackage.testZeros/testClass(type=double,outSize=s3d)'
'myPackage.testZeros/testClass(type=uint16,outSize=s2d)'
'myPackage.testZeros/testClass(type=uint16,outSize=s3d)'
'myPackage.testZeros/testSize(outSize=s2d)'
'myPackage.testZeros/testSize(outSize=s3d)'
```

## Create Suite of Test Elements Using Name-Value Arguments

Create the `+myPackage` folder and `testZeros.m` class from the previous example.

At the command prompt, create a test suite from all parameterized tests that use the parameter property `'outSize'`.

```
import matlab.unittest.TestSuite;

suite = TestSuite.fromPackage('myPackage', ...
 'ParameterProperty', 'outSize');
{suite.Name}'

ans =

'myPackage.testZeros/testClass(type=single,outSize=s2d)'
'myPackage.testZeros/testClass(type=single,outSize=s3d)'
'myPackage.testZeros/testClass(type=double,outSize=s2d)'
'myPackage.testZeros/testClass(type=double,outSize=s3d)'
'myPackage.testZeros/testClass(type=uint16,outSize=s2d)'
'myPackage.testZeros/testClass(type=uint16,outSize=s3d)'
'myPackage.testZeros/testSize(outSize=s2d)'
'myPackage.testZeros/testSize(outSize=s3d)'
```

## Purpose

Select test suite elements that satisfy conditions

## Syntax

```
newsuite = selectIf(suite,s)
newsuite = selectIf(suite,Name,Value)
```

## Description

`newsuite = selectIf(suite,s)` selects from `suite` the test elements that satisfy the conditions specified by the selector, `s`, and returns them in the `TestSuite` array, `newsuite`.

`newsuite = selectIf(suite,Name,Value)` creates a `TestSuite` array with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### `suite`

Set of tests, specified as a `matlab.unittest.TestSuite` array.

### `s`

Selector, specified as an instance of a class from the `matlab.unittest.selector` package.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'Name'

String indicating the name of the suite element. To include a test element in the suite, the `Name` property of the test element must match the specified name. Use the wildcard character, `*`, to match any number of characters. Use the question mark character, `?`, to match to exactly one character.

### 'ParameterProperty'

# matlab.unittest.TestSuite.selectIf

---

String indicating the name of a property that defines a parameter used by the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character.

## **'ParameterName'**

String indicating the name of a parameter used by the test suite element. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character.

## **'BaseFolder'**

String indicating the name of the folder that contains the file defining the test class or function. For a test element to be included in the suite, the test element must be contained in the specified base folder. Use the wildcard character, \*, to match any number of characters. Use the question mark character, ?, to match to exactly one character. For test classes defined in packages, the base folder is the parent of the top-level package folder.

## **Examples**

### **Select Test Elements Using Selector**

In your working folder, create the file `ExampleTest.m` containing the following test class.

```
classdef (SharedTestFixtures={...
 matlab.unittest.fixtures.PathFixture(fullfile(...
 matlabroot, 'help', 'techdoc', 'matlab_oop', 'examples'))})...
 ExampleTest < matlab.unittest.TestCase
 methods(Test)
 function testPathAdd(testCase)
 % test code
 end
 function testOne(testCase)
 % test code
 end
 end
end
```

```
 function testTwo(testCase)
 % test code
 end
 end
end
```

At the command prompt, create a test suite from the ExampleTest class.

```
import matlab.unittest.TestSuite;
import matlab.unittest.selectors.HasSharedTestFixture;
import matlab.unittest.selectors.HasName;
import matlab.unittest.fixtures.PathFixture;
import matlab.unittest.constraints.EndsWithSubstring;
import matlab.unittest.constraints.ContainsSubstring;
```

```
suite = TestSuite.fromClass(?ExampleTest)
```

```
suite =
```

```
1x3 Test array with properties:
```

```
 Name
Parameterization
SharedTestFixtures
```

The test suite contains three test elements.

Create a filtered test suite of tests comprising tests with names that contain the case-insensitive substring 'pAtH'.

```
newSuite = selectIf(suite, HasName(ContainsSubstring('pAtH', 'IgnoringCase')))
```

```
newSuite =
```

```
Test with properties:
```

```
 Name: 'ExampleTest/testPathAdd'
Parameterization: []
```

# matlab.unittest.TestSuite.selectIf

---

```
SharedTestFixtures: [1x1 matlab.unittest.fixtures.PathFixture]
```

Only the `testPathAdd` test is part of the suite.

Alternatively, create the same suite using a name-value pair.

```
newSuite = selectIf(suite, 'Name', '*Path*');
```

However, unlike the `ContainsSubstring` constraint, the name-value pair does not have an option to ignore case.

Create a filtered suite of tests comprising tests that use a shared path fixture and do not have names ending with `'One'`.

```
newSuite = suite.selectIf(~HasName(EndsWithSubstring('One')) ...
 & HasSharedTestFixture(PathFixture(fullfile(matlabroot, 'help', ...
 'techdoc', 'matlab_oop', 'examples'))));
{newSuite.Name}
```

```
ans =
```

```
 'ExampleTest/testPathAdd' 'ExampleTest/testTwo'
```

The test suite contains two tests. All of the tests use the specified path fixture, but the test named `'testOne'` is excluded from the suite.

## Select Test Elements Using Parameterization

In your working folder, create `testZeros.m`. This class contains four test methods.

```
classdef testZeros < matlab.unittest.TestCase
 properties (TestParameter)
 type = {'single', 'double', 'uint16'};
 outSize = struct('s2d', [3 3], 's3d', [2 5 4]);
 end

 methods (Test)
 function testClass(testCase, type, outSize)
```

```
 testCase.verifyClass(zeros(outSize,type), type);
 end

 function testSize(testCase, outSize)
 testCase.verifySize(zeros(outSize), outSize);
 end

 function testDefaultClass(testCase)
 testCase.verifyClass(zeros, 'double');
 end
 function testDefaultSize(testCase)
 testCase.verifySize(zeros, [1 1]);
 end

 function testDefaultValue(testCase)
 testCase.verifyEqual(zeros,0);
 end
end
end
```

The test class contains two parameterized test methods, `testClass` and `testSize`.

At the command prompt, create a test suite from the file.

```
s = matlab.unittest.TestSuite.fromFile('testZeros.m');
{s.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
'testZeros/testSize(outSize=s2d)'
'testZeros/testSize(outSize=s3d)'
```

# matlab.unittest.TestSuite.selectIf

---

```
'testZeros/testDefaultClass'
'testZeros/testDefaultSize'
'testZeros/testDefaultValue'
```

The suite contains 11 test elements. Six from the parameterized `testClass` method, two from the parameterized `testSize` method, and one from each of the `testDefaultClass`, `testDefaultSize`, and `testDefaultValue` methods.

Select all of the test elements from parameterized test methods.

```
import matlab.unittest.selectors.HasParameter;

s1 = s.selectIf(HasParameter);
{s1.Name}'

ans =

'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
'testZeros/testSize(outSize=s2d)'
'testZeros/testSize(outSize=s3d)'
```

The suite contains the eight test elements from the two parameterized test methods.

Select all of the test elements from non-parameterized test methods.

```
s2 = s.selectIf(~HasParameter);
{s2.Name}'

ans =

'testZeros/testDefaultClass'
```

```
'testZeros/testDefaultSize'
'testZeros/testDefaultValue'
```

Select all test elements that are parameterized and have a property named 'type' with a parameter name 'double'.

```
s3 = s.selectIf('ParameterProperty','type','ParameterName','double'),
{s3.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
```

The resulting suite contains two elements. The `testClass` method is the only method in `testZeros` that uses the 'type' property, and selecting only 'double' from the parameters results in two test elements — one for each value of 'outSize'.

Select all test elements that are parameterized and have a parameters defined by a property starting with 't'.

```
s4 = s.selectIf('ParameterProperty','t*');
{s4.Name}'
```

```
ans =
```

```
'testZeros/testClass(type=single,outSize=s2d)'
'testZeros/testClass(type=single,outSize=s3d)'
'testZeros/testClass(type=double,outSize=s2d)'
'testZeros/testClass(type=double,outSize=s3d)'
'testZeros/testClass(type=uint16,outSize=s2d)'
'testZeros/testClass(type=uint16,outSize=s3d)'
```

The resulting suite contains the six parameterized test elements from the `testClass` method. The `testSize` method is parameterized, but the elements from the method are not included in the suite because the method does not use a property that starts with 't'.

# matlab.unittest.TestSuite.selectIf

---

Select all test elements that are parameterized and test the `zeros` function with a 2-D array. A parameter value representing a 2-D array will have a length of 1 (e.g. `zeros(3)`) or 2 (e.g. `zeros(2,3)`).

```
import matlab.unittest.constraints.HasLength;

s5 = s.selectIf(HasParameter('Property','outSize',...
 'Value', HasLength(1)|HasLength(2)));
{s5.Name}'
```

```
ans =

 'testZeros/testClass(type=single,outSize=s2d) '
 'testZeros/testClass(type=double,outSize=s2d) '
 'testZeros/testClass(type=uint16,outSize=s2d) '
 'testZeros/testSize(outSize=s2d) '
```

Select only the test element that tests that the output is a `double` data type and the has the correct size for a 2-D array.

```
s6 = s.selectIf(HasParameter('Property','type','Name','double')...
 & HasParameter('Property','outSize','Name','s2d'))
```

```
s6 =
```

```
Test with properties:
```

```
 Name: 'testZeros/testClass(type=double,outSize=s2d) '
Parameterization: [1x2 matlab.unittest.parameters.TestParameter]
SharedTestFixtures: []
```

## See Also

[matlab.unittest.constraints](#) | [matlab.unittest.selectors](#)

**Purpose** Format text into TeX string

**Syntax**  
`TeXString = texlabel(f)`  
`TeXString = texlabel(f, 'literal')`

**Description** `TeXString = texlabel(f)` converts the MATLAB expression `f` into the TeX equivalent for use in text strings. `texlabel` converts Greek variable names (for example, `lambda`, `delta`, and so on) into a string that is displayed as Greek letters. The TeXString output is useful as an argument to annotation functions such as `title`, `xlabel`, and `text`.

If TeXString is too long to fit into a figure window, then the center of the expression is replaced with a tilde ellipsis (~~~).

`TeXString = texlabel(f, 'literal')` interprets Greek variable names literally.

**Input Arguments** **f - Input MATLAB expression**  
string

Input MATLAB expression, specified as a string.

**Example:** `'theta (degrees)'`

**Data Types**  
char

**Examples** **Insert TeX String in Figure**

Create a figure and a TeX string for use in a text graphics object.

```
figure
plot((1:10).^2)
TeXString = texlabel('lambda 12^(3/2)/pi - pi*delta^(2/3)');
```

# texlabel

---

Add a text object containing the TeX string to the figure.

```
text(3,90,TeXString)
```

If you include the 'literal' argument, `texlabel` interprets Greek variable names literally. Add a text object containing the literal string.

```
text(4,60,texlabel('lambda12^(3/2)/pi - pi*delta^(2/3)','literal'))
```

# texlabel

---

## See Also

`text` | `title` | `xlabel` | `ylabel` | `zlabel` | `String`

**Purpose**

Create text object in current axes

**Syntax**

```
text(x,y,'string')
text(x,y,z,'string')
text(x,y,z,'string','PropertyName',PropertyValue....)
text('PropertyName',PropertyValue....)
h = text(...)
```

**Properties**

For a list of properties, see [Text Properties](#).

**Description**

`text` is the low-level function for creating text graphics objects. Use `text` to place character strings at specified locations.

`text(x,y,'string')` adds the string in quotes to the location specified by the point  $(x,y)$   $x$  and  $y$  must be numbers of class `double`.

`text(x,y,z,'string')` adds the string in 3-D coordinates.  $x$ ,  $y$  and  $z$  must be numbers of class `double`.

`text(x,y,z,'string','PropertyName',PropertyValue....)` adds the string in quotes to the location defined by the coordinates and uses the values for the specified text properties. For a description of the properties, see [Text Properties](#).

`text('PropertyName',PropertyValue....)` omits the coordinates entirely and specifies all properties using property name/property value pairs.

`h = text(...)` returns a column vector of handles to text objects, one handle per object. All forms of the `text` function optionally return this output argument.

See the [String](#) property for a list of symbols, including Greek letters.

**Tips****Position Text Within the Axes**

The default text units are the units used to plot data in the graph. Specify the text location coordinates (the  $x$ ,  $y$ , and  $z$  arguments) in the data units of the current graph (see “Examples” on page 1-6977). You can use other units to position the text by setting the `text Units`

property to normalized or one of the nonrelative units (pixels, inches, centimeters, points, or characters).

Note that the Axes Units property controls the positioning of the Axes within the figure and is not related to the axes data units used for graphing.

The Extent, VerticalAlignment, and HorizontalAlignment properties control the positioning of the character string with regard to the text location point.

If the coordinates are vectors, text writes the string at all locations defined by the list of points. If the character string is an array the same length as x, y, and z, text writes the corresponding row of the string array at each point specified.

## **Multiline Text**

When specifying strings for multiple text objects, the string can be:

- A cell array of strings
- A padded string matrix

Each element of the specified string array creates a different text object.

When specifying the string for a single text object, cell arrays of strings and padded string matrices result in a text object with a multiline string, while vertical slash characters are not interpreted as separators and result in a single line string containing vertical slashes.

## **Behavior of the Text Function**

text is a low-level function that accepts property name/property value pairs as input arguments. However, the convenience form:

```
text(x,y,z,'string')
```

is equivalent to:

```
text('Position',[x,y,z],'String','string')
```

You can specify other properties only as property name/property value pairs. For a description of each property, see `Text Properties`. You can specify properties as property name/property value pairs, structure arrays, and cell arrays (see the `set` and `get` reference pages for examples of how to specify these data types).

`text` does not respect the setting of the figure or axes `NextPlot` property. This allows you to add text objects to an existing axes without setting `hold` to on.

## Examples

### Label Point on Graph

Annotate the point  $(\pi, 0)$  with the string  $\sin(\pi)$ .

```
x = 0:pi/20:2*pi;
y = sin(x);

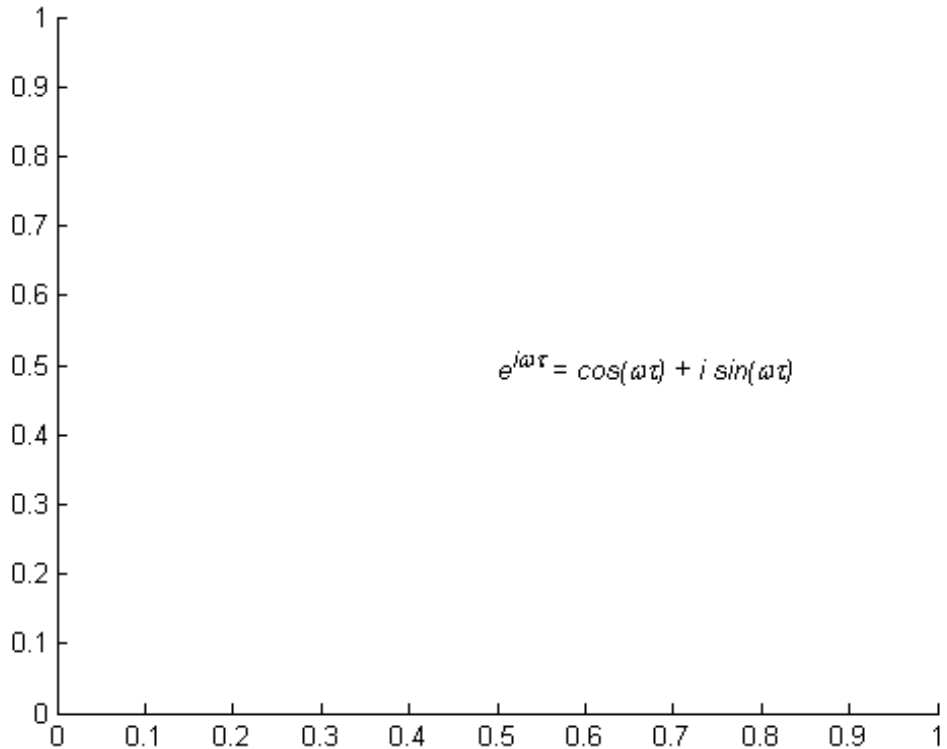

figure % new figure window
plot(x,y);
text(pi,0,' \leftarrow sin(\pi)')
```

### Display Equation with Greek Symbols

Use embedded TeX sequences to display an equation in an empty axes.

```
axes
text(0.5,0.5, '\ite^{i\omega\tau} = \cos(\omega\tau) + i \sin(\omega\tau)')
```

## Setting Default Properties

You can set default text properties on the axes, figure, and root object levels:

```
set(0, 'DefaulttextProperty', PropertyValue...)
set(gcf, 'DefaulttextProperty', PropertyValue...)
set(gca, 'DefaulttextProperty', PropertyValue...)
```

Where *Property* is the name of the text property and *PropertyValue* is the value you are specifying. Use `set` and `get` to access text properties.

# text

---

## **See Also**

annotation | gtext | int2str | num2str | strings | title | xlabel  
| ylabel | zlabel | Text Properties

## Purpose

Text properties

## Creating Text Objects

Use text to create text objects.

## Modifying Properties

You can set and query graphics object properties using the property editor or the `set` and `get` commands.

- Property Editor is an interactive tool that enables you to see and change object property values.
- The `set` and `get` commands enable you to set and query the values of properties.

To change the default values of properties, see [Setting Default Property Values](#).

See [Core Objects](#) for general information about this type of object.

## Text Property Descriptions

This section provides a description of properties. Curly braces { } enclose default values.

### Annotation

`hg.Annotation` object (read-only)

*Handle of Annotation object.* The `Annotation` property enables you to specify whether this text object is represented in a figure legend.

Querying the `Annotation` property returns the handle of an `hg.Annotation` object. The `hg.Annotation` object has a property called `LegendInformation`, which contains an `hg.LegendEntry` object.

Once you have obtained the `hg.LegendEntry` object, you can set its `IconDisplayStyle` property to control whether the text object is displayed in a figure legend:

# Text Properties

---

IconDisplayStyle Value	Purpose
on	Represent this text object in a legend (default)
off	Do not include this text object in a legend
children	Same as on because text objects do not have children

## Setting the IconDisplayStyle property

Set the IconDisplayStyle of a graphics object with handle `hobj` to off:

```
hAnnotation = get(hobj, 'Annotation');
hLegendEntry = get(hAnnotation, 'LegendInformation');
set(hLegendEntry, 'IconDisplayStyle', 'off')
```

## Using the IconDisplayStyle property

See “Control Legend Content” for more information and examples.

BackgroundColor  
ColorSpec | {none}

*Color of text extent rectangle.* Defines a color for the rectangle that encloses the text Extent plus the text Margin. For example, the following code creates a text object that labels a plot and sets the background color to light green.

```
text(3*pi/4, sin(3*pi/4), ...
 ['sin(3*pi/4) = ', num2str(sin(3*pi/4))], ...
 'HorizontalAlignment', 'center', ...
 'BackgroundColor', [.7 .9 .7]);
```

For additional features, see the following properties:

- `EdgeColor` — Color of the rectangle's edge (none by default).
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increase the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

See also [Drawing Text in a Box](#) in the MATLAB Graphics documentation for an example using background color with contour labels.

# Text Properties

---

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Button press callback function.* Executes whenever you press a mouse button while the pointer is over the text object.

See the figure's `SelectionType` property to determine if modifier keys were also pressed.

Set this property to a function handle that references the callback. The function must define at least two input arguments (handle of object associated with the button down event and an event structure, which is empty for this property).

The following example shows how to access the callback object's handle as well as the handle of the figure that contains the object from the callback function.

```
function button_down(src, evnt)
% src - the object that is the source of the event
% evnt - empty for this property
 sel_typ = get(gcf, 'SelectionType')
 switch sel_typ
 case 'normal'
 disp('User clicked left-mouse button')
 set(src, 'Selected', 'on')
 case 'extend'
 disp('User did a shift-click')
 set(src, 'Selected', 'on')
 case 'alt'
 disp('User did a control-click')
 set(src, 'Selected', 'on')
 set(src, 'SelectionHighlight', 'off')
 end
end
```

# Text Properties

---

Suppose `h` is the handle of a text object and the `button_down` function is on your MATLAB path. The following statement assigns the `button_down` function to the `ButtonDownFcn` property:

```
set(h, 'ButtonDownFcn', @button_down)
```

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## Children

matrix (read-only)

The empty matrix; text objects have no children.

## Clipping

on | {off}

*Clipping mode.* When `Clipping` is on, MATLAB does not display any portion of the text that is outside the axes.

## Color

ColorSpec

*Text color.* A three-element RGB vector or one of the predefined names, specifying the text color. The default value is `[0 0 0]` (black). See the [ColorSpec](#) reference page for more information on specifying color.

## CreateFcn

function handle | cell array containing function handle and additional arguments | string (not recommended)

*Callback function executed during object creation.* Executes when MATLAB creates a text object. You must define this property as a default value for `text` or in a call to the `text` function that creates a new text object. For example, the statement:

```
set(0, 'DefaultTextCreateFcn', @text_create)
```

defines a default value on the root level that sets the figure `Pointer` property to crosshairs whenever you create a text object. The callback function must be on your MATLAB path when you execute the above statement.

```
function text_create(src,evnt)
% src - the object that is the source of the event
% evnt - empty for this property
 set(gcf,'Pointer','crosshair')
end
```

MATLAB executes this function after setting all text properties. Setting this property on an existing text object has no effect. The function must define at least two input arguments (handle of object created and an event structure, which is empty for this property).

The handle of the object whose `CreateFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## DeleteFcn

```
function handle | cell array containing function handle and
additional arguments | string (not recommended)
```

*Delete text callback function.* Executes when you delete the text object (for example, when you issue a `delete` command or clear the axes `cla` or figure `clf`).

For example, the following function displays object property data before the object is deleted.

```
function delete_fcn(src,evnt)
% src - the object that is the source of the event
```

# Text Properties

---

```
% evnt - empty for this property
 obj_tp = get(src,'Type');
 disp([obj_tp, ' object deleted'])
 disp('Its user data is:')
 disp(get(src,'UserData'))
end
```

MATLAB executes the function before deleting the object's properties so these values are available to the callback function. The function must define at least two input arguments (handle of object being deleted and an event structure, which is empty for this property).

The handle of the object whose `DeleteFcn` is being executed is passed by MATLAB as the first argument to the callback function and is also accessible through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

`DisplayName`  
string

*String used by legend.* The `legend` function uses the `DisplayName` property to label the text object in the legend. The default is an empty string.

- If you specify string arguments with the `legend` function, MATLAB set `DisplayName` to the corresponding string and uses that string for the legend.
- If `DisplayName` is empty, `legend` creates a string of the form, `['data' n]`, where `n` is the number assigned to the object based on its location in the list of legend entries. However, `legend` does not set `DisplayName` to this string.
- If you edit the string directly in an existing legend, MATLAB set `DisplayName` to the edited string.

- If you specify a string for the `DisplayName` property and create the legend using the figure toolbar, then MATLAB uses the string defined by `DisplayName`.
- To add a legend programmatically that uses the `DisplayName` string, call `legend` with the `toggle` or `show` option.

See “Control Legend Content” for more information and examples.

## EdgeColor

ColorSpec | {none}

*Color of edge drawn around text extent rectangle plus margin.*  
Specifies the color of a box drawn around the text `Extent` plus the text `Margin`. For example, the following code draws a red rectangle around text that labels a plot.

```
text(3*pi/4, sin(3*pi/4), ...
'\leftarrow sin(t) = .707', ...
'EdgeColor', 'red');
```

For additional features, see the following properties:

# Text Properties

---

- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increases the size of the rectangle by adding a margin to the area defined by the text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

## Editing

on | {off}

*Enable or disable editing mode.* When this property is off (the default), you cannot edit the text string interactively (i.e., you must change the `String` property to change the text). When you set this property to on, MATLAB enables editing and places an insert cursor wherever the mouse is within the text. To apply the new text string, do any one of the following:

- Press the **Esc** key.
- Click anywhere away from the text string.
- Reset the `Editing` property to off.

MATLAB updates the `String` property to contain the new text and resets the `Editing` property to off. You must reset the `Editing` property to on to resume editing.

## EraseMode

{normal} | none | xor | background

*Erase mode.* Controls the technique MATLAB uses to draw and erase text objects. Alternative erase modes are useful for creating animated sequences where controlling the way individual objects are redrawn is necessary to improve performance and obtain the desired effect.

- **normal** — Redraw the affected region of the display, performing the three-dimensional analysis necessary to ensure that all objects are rendered correctly. This mode produces the most accurate picture, but is the slowest. The other modes are faster, but do not perform a complete redraw and are therefore less accurate.
- **none** — Do not erase the text when it is moved or destroyed. While the object is still visible on the screen after erasing with `EraseMode none`, you cannot print it because MATLAB stores no information about its former location.
- **xor** — Draw and erase the text by performing an exclusive OR (XOR) with each pixel index of the screen beneath it. When the text is erased, it does not damage the objects beneath it. However, when text is drawn in `xor` mode, its color depends on the color of the screen beneath it. It is correctly colored only when it is over axes background `Color`, or the figure background `Color` if the axes `Color` is `none`.
- **background** — Erase the text by drawing it in the axes background `Color`, or the figure background `Color` if the axes `Color` is `none`. This damages objects that are behind the erased text, but text is always properly colored.

## Printing with Nonnormal Erase Modes

MATLAB always prints figures as if the `EraseMode` of all objects is `normal`. This means graphics objects created with `EraseMode` set to `none`, `xor`, or `background` can look different on screen than on paper. On screen, MATLAB mathematically combines layers of colors (for example, performing an XOR on a pixel color with that of the pixel behind it) and ignore three-dimensional sorting

# Text Properties

---

to obtain greater rendering speed. However, these techniques are not applied to the printed output.

You can use the `getframe` command or other screen capture applications to create an image of a figure containing nonnormal mode objects.

## Extent

position rectangle (read-only)

*Position and size of text.* A four-element vector that defines the size and position of the text string:

```
[left,bottom,width,height]
```

If the `Units` property is `data` (the default), `left` and `bottom` are the  $x$ - and  $y$ -coordinates of the lower left corner of the text `Extent`.

For all other values of `Units`, `left` and `bottom` are the distance from the lower left corner of the axes `Position` rectangle to the lower left corner of the text `Extent`. `width` and `height` are the dimensions of the `Extent` rectangle. All measurements are in units specified by the `Units` property.

## FontAngle

```
{normal} | italic | oblique
```

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `italic` or `oblique` selects a slanted font.

## FontName

```
name (such as Courier) | FixedWidth
```

*Font family.* Specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports. The default font is `Helvetica`.

## Specifying a Fixed-Width Font

If you want text to use a fixed-width font that looks good in any locale, you should set `FontName` to the string `FixedWidth`:

```
set(text_handle, 'FontName', 'FixedWidth')
```

This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding (such as in Japan where multibyte character sets are used). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` (note that this string is case sensitive) and rely on `FixedWidthFontName` to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`.

Note that setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

Bitmapped fonts (e.g., Courier) cannot be rotated on the display. Therefore, when you specify a bitmapped font with the `FontName` property, this text might not be rotated correctly, for example, when used as the *y*-axis label. To avoid problems with bitmapped fonts, use TrueType fonts. For example, you might have a TrueType font named Courier New that you can use instead of Courier. See your system documentation for information on which fonts are installed on your system.

`FontSize`  
size in `FontUnits`

# Text Properties

---

*Font size.* Specifies the font size to use for text in units determined by the `FontUnits` property. The default is 10 points. 1 point =  $1/72$  inch.

## FontWeight

`{normal}` | `bold` | `light` | `demi`

*Weight of text characters.* MATLAB uses this property to select a font from those available on your particular system. Generally, setting this property to `bold` or `demi` causes MATLAB to use a bold font.

## FontUnits

`{points}` | `normalized` | `inches` | `centimeters` | `pixels`

*Font size units.* MATLAB uses this property to determine the units used by the `FontSize` property.

- `normalized` — Interpret `FontSize` as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen `FontSize` accordingly.
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $1/72$  inch.

Note that if you are setting both the `FontSize` and the `FontUnits` in one function call, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`.

## HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* Determines when an object's handle is visible in its parent's list of children. `HandleVisibility` is useful for preventing command-line users from accidentally drawing into or deleting a figure that contains only user interface devices (such as a dialog box).

- `on` — Handles are always visible.

- `callback` — Handles are visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have access to object handles.
- `off` — Handles are invisible at all times. Use this option when a callback invokes a function that could damage the GUI (such as evaluating a user-typed string). This option temporarily hides its own handles during the execution of that function.

When a handle is not visible in its parent's list of children, it cannot be returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`.

When a handle's visibility is restricted using `callback` or `off`,

- The object's handle does not appear in its parent's `Children` property.
- Figures do not appear in the root's `CurrentFigure` property.
- Objects do not appear in the root's `CallbackObject` property or in the figure's `CurrentObject` property.
- Axes do not appear in their parent's `CurrentAxes` property.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible regardless of their `HandleVisibility` settings (this does not affect the values of the `HandleVisibility` properties).

Handles that are hidden are still valid. If you know an object's handle, you can set and get its properties, and pass it to any function that operates on handles.

```
HitTest
{on} | off
```

# Text Properties

---

*Selectable by mouse click.* Determines if the text can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the text. If `HitTest` is `off`, clicking the text selects the object below it (which is usually the axes containing it).

For example, suppose you define the button down function of an image (see the `ButtonDownFcn` property) to display text at the location you click with the mouse.

First define the callback routine.

```
function bd_function
pt = get(gca,'CurrentPoint');
text(pt(1,1),pt(1,2),pt(1,3),...
 '\fontsize{20}\oplus The spot to label',...
 'HitTest','off')
```

Now display an image, setting its `ButtonDownFcn` property to the callback routine.

```
load earth
image(X,'ButtonDownFcn','bd_function'); colormap(map)
```

When you click the image, MATLAB displays the text string at that location. With `HitTest` set to `off`, existing text cannot intercept any subsequent button down events that occur over the text. This enables the image's button down function to execute.

`HorizontalAlignment`  
{left} | center | right

*Horizontal alignment of text.* Specifies the horizontal justification of the text string. It determines where MATLAB places the string with regard to the point specified by the `Position` property. The following picture illustrates the alignment options.

HorizontalAlignment viewed with the VerticalAlignment set to middle (the default).

See the Extent property for related information.

See “Text Alignment” for more information and examples.

Interpreter

latex | {tex} | none

*Interpret TeXinstructions.* Controls whether MATLAB interprets certain characters in the String property as TeX instructions (default) or displays all characters literally.

- latex — Supports a basic subset of the LaTeX markup language.
- tex — Supports a subset of plain TeX markup language. See the String property for a list of supported TeX instructions.
- none — Displays literal characters.

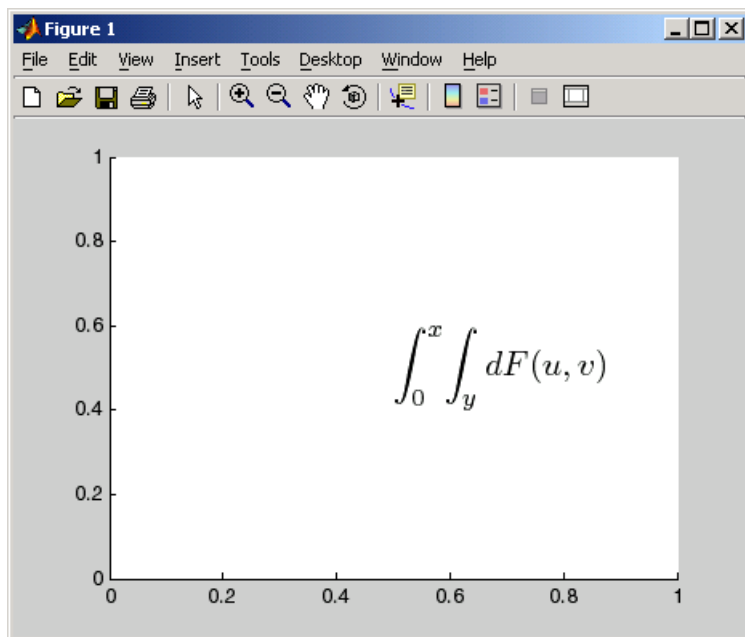

## LaTeX Interpreter

To enable the LaTeX interpreter for text objects, set the Interpreter property to latex. For example, the following statement displays an equation in a figure at the point [.5 .5], and enlarges the font to 16 points.

```
text('Interpreter','latex',...
 'String','$$\int_0^x \! \! \int_y dF(u,v)$$',...
 'Position',[.5 .5],...
 'FontSize',16)
```

# Text Properties

---

---

**Note** The maximum size of the string that you can use with the LaTeX interpreter is 1200 characters. For multiline strings, reduce this amount by about 10 characters per line.

---

## Information About Using TeX

The following references may be useful to people who are not familiar with TeX.

- Donald E. Knuth, *The T<sub>E</sub>Xbook*, Addison Wesley, 1986.
- The TeX Users Group home page: <http://www.tug.org>

Interruptible  
off | {on}

## *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For Graphics objects, the `Interruptible` property affects only the callbacks for the `ButtonDownFcn` property. A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both the callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

`BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting `Interruptible` property to on (default), allows a callback from other graphics objects to interrupt callback functions originating from this object.

# Text Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

## LineStyle

{-} | -- | : | -. | none

*Edge line type.* Specifies the line style used to draw the edges of the text Extent.

## Line Style Specifiers Table

Specifier	Line Style
'-'	Solid line (default)
'--'	Dashed line
':'	Dotted line
'-.'	Dash-dot line
'none'	No line

For example, the following code draws a red rectangle with a dotted line style around text that labels a plot.

```
text(3*pi/4,sin(3*pi/4),...
 '\leftarrow sin(t) = .707',...
 'EdgeColor','red',...
 'LineWidth',2,...
 'LineStyle',':');
```

For additional features, see the following properties:

- **BackgroundColor** — Color of the rectangle's interior (none by default)
- **EdgeColor** — Color of the rectangle's edge (none by default)
- **LineWidth** — Width of the rectangle's edge line (first set `EdgeColor`)
- **Margin** — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

**LineWidth**  
scalar (points)

# Text Properties

---

*Width of line used to draw text extent rectangle.* When you set the text `EdgeColor` property to a color (the default is none), MATLAB displays a rectangle around the text `Extent`. Use the `LineWidth` property to specify the width of the rectangle edge. For example, the following code draws a red rectangle around text that labels a plot and specifies a line width of 3 points:

```
text(3*pi/4,sin(3*pi/4),...
'\leftarrow sin(t) = .707',...
'EdgeColor','red',...
'LineWidth',3);
```

For additional features, see the following properties:

- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `EdgeColor` — Color of the rectangle's edge (none by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)

- **Margin** — Increases the size of the rectangle by adding a margin to the existing text extent rectangle. This margin is added to the text extent rectangle to define the text background area that is enclosed by the `EdgeColor` rectangle. Note that the text extent does not change when you change the margin; only the rectangle displayed when you set the `EdgeColor` property and the area defined by the `BackgroundColor` change.

## Margin

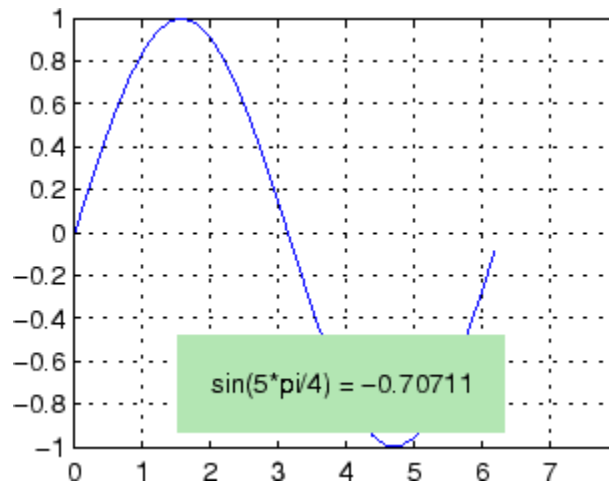

scalar (pixels)

*Distance between the text extent and the rectangle edge.* When you specify a color for the `BackgroundColor` or `EdgeColor` text properties, MATLAB draws a rectangle around the area defined by the text `Extent` plus the value specified by the `Margin`. For example, the following code displays a light green rectangle with a 10-pixel margin.

```
text(5*pi/4, sin(5*pi/4), ...
 ['sin(5*pi/4) = ', num2str(sin(5*pi/4))], ...
 'HorizontalAlignment', 'center', ...
 'BackgroundColor', [.7 .9 .7], ...
 'Margin', 10);
```

# Text Properties

---

For additional features, see the following properties:

- **BackgroundColor** — Color of the rectangle's interior (none by default)
- **EdgeColor** — Color of the rectangle's edge (none by default)
- **LineStyle** — Style of the rectangle's edge line (first set **EdgeColor**)
- **LineWidth** — Width of the rectangle's edge line (first set **EdgeColor**)

## See how margin affects text extent properties

This example enables you to change the values of the **Margin** property and observe the effects on the **BackgroundColor** area and the **EdgeColor** rectangle.

[Click to view in editor](#) — This link opens the MATLAB editor with the following example.

[Click to run example](#) — Use your scroll wheel to vary the **Margin**.

## Parent

handle of axes, hggroup, or hgtransform

*Parent of text object.* Handle of the text object's parent. The parent of a text object is the axes, hggroup, or hgtransform object that contains it.

## Position

[x,y,[z]]

*Location of text.* A two- or three-element vector, [x y [z]], that specifies the location of the text in three dimensions. If you omit the z value, it defaults to 0. All measurements are in units specified by the Units property. Initial value is [0 0 0].

## Rotation

scalar (default = 0)

*Text orientation.* Determines the orientation of the text string. Specify values of rotation in degrees (positive angles cause counterclockwise rotation).

## Selected

on | {off}

*Is object selected?* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also set to on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Objects are highlighted when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When SelectionHighlight is off, MATLAB does not draw the handles.

# Text Properties

---

String  
string

*Text string.* Specify this property as a quoted string for single-line strings, or as a cell array of strings, or a padded string matrix for multiline strings. MATLAB displays this string at the specified location. Vertical slash characters are not interpreted as line breaks in text strings, and are drawn as part of the text string. See Mathematical Symbols, Greek Letters, and TeX Characters for an example.

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a figure when quoted as a normal string. In order to display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

When the text Interpreter property is `tex` (the default), you can use a subset of TeX commands embedded in the string to produce special characters such as Greek letters and mathematical symbols. This table lists these characters and the character sequences used to define them.

Character Sequence	Symbol	Character Sequence	Symbol	Character Sequence	Symbol
<code>\alpha</code>	$\alpha$	<code>\upsilon</code>	$\upsilon$	<code>\sim</code>	$\sim$
<code>\angle</code>	$\angle$	<code>\phi</code>	$\Phi$	<code>\leq</code>	$\leq$
<code>\ast</code>	$*$	<code>\chi</code>	$\chi$	<code>\infty</code>	$\infty$
<code>\beta</code>	$\beta$	<code>\psi</code>	$\psi$	<code>\clubsuit</code>	$\clubsuit$
<code>\gamma</code>	$\gamma$	<code>\omega</code>	$\omega$	<code>\diamondsuit</code>	$\diamondsuit$
<code>\delta</code>	$\delta$	<code>\Gamma</code>	$\Gamma$	<code>\heartsuit</code>	$\heartsuit$
<code>\epsilon</code>	$\epsilon$	<code>\Delta</code>	$\Delta$	<code>\spadesuit</code>	$\spadesuit$

<code>\wedge</code>	∧	<code>\varpi</code>	ϖ	<code>\O</code>	∅
<code>\rceil</code>	⌈	<code>\rangle</code>	⟩	<code>\mid</code>	
<code>\vee</code>	∨			<code>\copyright</code>	©
<code>\langle</code>	⟨				

You can also specify stream modifiers that control font type and color. The first four modifiers are mutually exclusive. However, you can use `\fontname` in combination with one of the other modifiers:

- `\bf` — Bold font
- `\it` — Italic font
- `\sl` — Oblique font (rarely available)
- `\rm` — Normal font
- `\fontname{fontname}` — Specify the name of the font family to use.
- `\fontsize{fontsize}` — Specify the font size in FontUnits.
- `\color{colorSpec}` — Specify color for succeeding characters

Stream modifiers remain in effect until the end of the string or only within the context defined by braces { }.

## Specifying Text Color in TeX Strings

Use the `\color` modifier to change the color of characters following it from the previous color (which is black by default). Syntax is:

- `\color{colorname}` — Use for the eight basic named colors (red, green, yellow, magenta, blue, black, white), and plus the four Simulink colors (gray, darkGreen, orange, and lightBlue).

Note that short names (one-letter abbreviations) for colors are not supported by the `\color` modifier.

- `\color[rgb]{r g b}` — Use to specify an RGB triplet with values between 0 and 1 as a cell array

For example:

```
text(.1,.5,['\fontsize{16}black '...
 '{\color{magenta}magenta '...
 '\color[rgb]{0 .5 .5}teal '...
 '\color{red}red} black again'])
```

# Text Properties

---

## Specifying Subscript and Superscript Characters

The subscript character “`_`” and the superscript character “`^`” modify the character or substring defined in braces immediately following.

To print the special characters used to define the TeX strings when Interpreter is `tex`, prefix them with the backslash “`\`” character: `\{`, `\}`, `\_`, `\^`.

See the “Examples” on page 1-6977 in the text reference page for more information.

When Interpreter is `none`, no characters in the String are interpreted, and all are displayed when the text is drawn.

When Interpreter is `latex`, MATLAB provides a complete LaTeX interpreter for text objects. See the Interpreter property for more information.

## Tag

string

*User-specified object label.* Provides a means to identify graphics objects with a user-specified label. The default is an empty string.

Use the `Tag` property and the `findobj` function to manipulate specific objects within a plotting hierarchy.

## Type

string (read-only)

*Class of graphics object.* String that identifies the class of the graphics object. Use this property to find all objects of a given type within a plotting hierarchy. For text objects, `Type` is always 'text'.

## UIContextMenu

handle of uicontextmenu object

*Associate a context menu with the text.* The handle of a `uicontextmenu` object created in the same figure as the text. Use the `uicontextmenu` function to create the context menu. MATLAB displays the context menu whenever you right-click over the text.

## Units

pixels | normalized | inches |  
| characters | centimeters | points | {data}

*Units of measurement.* Specifies the units MATLAB uses to interpret the `Extent` and `Position` properties. All units are measured from the lower left corner of the axes plot box.

- `normalized` — Units map the lower left corner of the rectangle defined by the axes to (0,0) and the upper right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` — Absolute units. 1 point =  $\frac{1}{72}$  inch.

# Text Properties

---

- `characters` — Based on the size of characters in the default system font. The width of one `characters` unit is the width of the letter `x`, and the height of one `characters` unit is the distance between the baselines of two lines of text.
- `data` — Data units of the parent axes as determined by the data graphed (not the axes `Units` property, which controls the positioning of the axes within the figure window).

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`  
matrix

*User-specified data.* Data you want to associate with the text object. The default value is an empty array. MATLAB does not use this data, but you can access it using the `set` and `get` commands.

`VerticalAlignment`  
`top` | `cap` | `{middle}` | `baseline` |  
`bottom`

*Vertical alignment of text.* Specifies the vertical justification of the text string. It determines where MATLAB places the string vertically with regard to the points specified by the `Position` property.

- `top` — Place the top of the string's `Extent` rectangle at the specified  $y$ -position.
- `cap` — Place the string so that the top of a capital letter is at the specified  $y$ -position.
- `middle` — Place the middle of the string at the specified  $y$ -position.
- `baseline` — Place font baseline at the specified  $y$ -position.

- `bottom` — Place the bottom of the string’s Extent rectangle at the specified `y`-position.

The following picture illustrates the alignment options.

**Text VerticalAlignment property viewed with the HorizontalAlignment property set to left (the default).**

See “Text Alignment” for more information and examples.

`Visible`  
{on} | off

*Text visibility.* By default, all text is visible. When set to `off`, the text is not visible, but still exists, and you can query and set its properties.

**See Also**      `text`

# textread

---

## Purpose

Read data from text file; write to multiple outputs

---

**Note** textread is not recommended. Use textscan instead.

---

## Syntax

```
[A,B,C,...] = textread(filename,format)
[A,B,C,...] = textread(filename,format,N)
[...] = textread(...,param,value,...)
```

## Description

[A,B,C,...] = textread(filename,format) reads data from the file filename into the variables A,B,C, and so on, using the specified format, until the entire file is read. The filename and format inputs are strings, each enclosed in single quotes. textread is useful for reading text files with a known format. textread handles both fixed and free format files.

---

**Note** When reading large text files, reading from a specific point in a file, or reading file data into a cell array rather than multiple outputs, you might prefer to use the textscan function.

---

textread matches and converts groups of characters from the input. Each input field is defined as a string of non-white-space characters that extends to the next white-space or delimiter character, or to the maximum field width. Repeated delimiter characters are significant, while repeated white-space characters are treated as one.

The format string determines the number and types of return arguments. The number of return arguments is the number of items in the format string. The format string supports a subset of the conversion specifiers and conventions of the C language fscanf routine. Values for the format string are listed in the table below. White-space characters in the format string are ignored.

<b>format</b>	<b>Action</b>	<b>Output</b>
Literals (ordinary characters)	Ignore the matching characters. For example, in a file that has Dept followed by a number (for department number), to skip the Dept and read only the number, use 'Dept' in the format string.	None
%d	Read a signed integer value.	Double array
%u	Read an integer value.	Double array
%f	Read a floating-point value.	Double array
%s	Read a white-space or delimiter-separated string.	Cell array of strings
%q	Read a double quoted string, ignoring the quotes.	Cell array of strings
%c	Read characters, including white space.	Character array
%[...]	Read the longest string containing characters specified in the brackets.	Cell array of strings
%[^...]	Read the longest nonempty string containing characters that are not specified in the brackets.	Cell array of strings
%*... instead of %	Ignore the matching characters specified by *.	No output
%w... instead of %	Read field width specified by w. The %f format supports %w.pf, where w is the field width and p is the precision.	

[A,B,C,...] = textread(filename,format,N) reads the data, reusing the format string N times, where N is an integer greater than zero. If N is smaller than zero, textread reads the entire file.

[...] = textread(...,param,value,...) customizes textread using param/value pairs, as listed in the table below.

# textread

---

param	value	Action
bufsize	Positive integer	Specifies the maximum string length, in bytes. Default is 4095.
commentstyle	matlab	Ignores characters after %.
commentstyle	shell	Ignores characters after #.
commentstyle	c	Ignores characters between /* and */.
commentstyle	c++	Ignores characters after //.
delimiter	One or more characters	Act as delimiters between elements. Default is none.
emptyvalue	Scalar double	Value given to empty cells when reading delimited files. Default is 0.
endofline	Single character or '\r\n'	Character that denotes the end of a line. Default is determined from file
expchars	Exponent characters	Default is eEdD.
headerlines	Positive integer	Ignores the specified number of lines at the beginning of the file.
whitespace	Any from the list below: ' '           Space \b            Backspace \n            Newline \r            Carriage return \t            Horizontal tab	Treats vector of characters as white space. Default is '\b\t'.

---

**Note** When `textread` reads a consecutive series of `whitespace` values, it treats them as one white space. When it reads a consecutive series of `delimiter` values, it treats each as a separate delimiter.

---

**Tips**

If you want to preserve leading and trailing spaces in a string, use the `whitespace` parameter as shown here:

```
textread('myfile.txt', '%s', 'whitespace', '')
ans =
 ' An example of preserving spaces '
```

**Examples****Example 1 – Read All Fields in Free Format File Using %**

The first line of `mydata.dat` is

```
Sally Level1 12.34 45 Yes
```

Read the first line of the file as a free format file using the % format.

```
[names, types, x, y, answer] = textread('mydata.dat', ...
 '%s %s %f %d %s', 1)
```

returns

```
names =
 'Sally'
types =
 'Level1'
x =
 12.340000000000000
y =
 45
answer =
 'Yes'
```

**Example 2 – Read as Fixed Format File, Ignoring the Floating Point Value**

The first line of `mydata.dat` is

```
Sally Level1 12.34 45 Yes
```

Read the first line of the file as a fixed format file, ignoring the floating-point value.

```
[names, types, y, answer] = textread('mydata.dat', ...
'%9c %6s %*f %2d %3s', 1)
```

returns

```
names =
Sally
types =
 'Level1'
y =
 45
answer =
 'Yes'
```

`%*f` in the format string causes `textread` to ignore the floating point value, in this case, 12.34.

### **Example 3 – Read Using Literal to Ignore Matching Characters**

The first line of `mydata.dat` is

```
Sally Type1 12.34 45 Yes
```

Read the first line of the file, ignoring the characters `Type` in the second field.

```
[names, typenum, x, y, answer] = textread('mydata.dat', ...
'%s Type%d %f %d %s', 1)
```

returns

```
names =
 'Sally'
typenum =
 1
x =
 12.340000000000000
y =
 45
```

```
answer =
 'Yes'
```

Type%d in the format string causes the characters Type in the second field to be ignored, while the rest of the second field is read as a signed integer, in this case, 1.

#### Example 4 – Specify Value to Fill Empty Cells

For files with empty cells, use the emptyvalue parameter. Suppose the file data.csv contains:

```
1,2,3,4,,6
7,8,9,,11,12
```

Read the file using NaN to fill any empty cells:

```
data = textread('data.csv', '', 'delimiter', ',', ...
 'emptyvalue', NaN);
```

#### Example 5 – Read File into a Cell Array of Strings

Read the file fft.m into cell array of strings.

```
file = textread('fft.m', '%s', 'delimiter', '\n', ...
 'whitespace', '');
```

# textscan

---

**Purpose** Read formatted data from text file or string

**Syntax** `C = textscan(fileID,formatSpec)`  
`C = textscan(fileID,formatSpec,N)`

`C = textscan(str,formatSpec)`  
`C = textscan(str,formatSpec,N)`

`C = textscan( ___,Name,Value)`

`[C,position] = textscan( ___)`

**Description** `C = textscan(fileID,formatSpec)` reads data from an open text file into cell array, `C`. The text file is indicated by the file identifier, `fileID`. Use `fopen` to open the file and obtain the `fileID` value. When you finish reading from a file, close the file by calling `fclose(fileID)`.

`textscan` attempts to match the data in the file to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(fileID,formatSpec,N)` reads file data, using the `formatSpec` `N` times, where `N` is a positive integer. To read additional data from the file after `N` cycles, call `textscan` again using the original `fileID`. If you resume a text scan of a file by calling `textscan` with the same file identifier (`fileID`), then `textscan` automatically resumes reading at the point where it terminated the last read.

`C = textscan(str,formatSpec)` reads data from a string, `str` into cell array `C`. For strings, repeated calls to `textscan` restart the scan from the beginning each time. To restart a scan from the last position, request a `position` output.

`textscan` attempts to match the data in the string, `str`, to `formatSpec`, which is a string of conversion specifiers.

`C = textscan(str,formatSpec,N)` reads string data, using the `formatSpec` `N` times, where `N` is a positive integer.

`C = textscan( ___,Name,Value)` specifies options using one or more `Name,Value` pair arguments, in addition to any of the input arguments in the previous syntaxes.

`[C,position] = textscan( ___)` returns the file or string position at the end of the scan as the second output argument, using any of the input arguments in the previous syntaxes. For a file, this is the value that `ftell(fileID)` would return after calling `textscan`. For a string, `position` indicates how many characters `textscan` read.

## Input Arguments

### **fileID - File identifier**

numeric scalar

File identifier of an open text file, specified as a number. Before reading a file with `textscan`, you must use `fopen` to open the file and obtain the `fileID`.

### **Data Types**

double

### **formatSpec - Format of the data fields**

string

Format of the data fields, specified as a string of one or more conversion specifiers. When `textscan` reads a file or string, it attempts to match the data to the `formatSpec` string. If `textscan` fails to match a data field, it stops reading and returns all fields read before the failure.

The number of conversion specifiers determines the number of cells in output array, `C`.

### **Numeric Fields**

This table lists available conversion specifiers for numeric inputs.

<b>Numeric Input Type</b>	<b>Conversion Specifier</b>	<b>Output Class</b>
Integer, signed	%d	int32
	%d8	int8
	%d16	int16
	%d32	int32
	%d64	int64
Integer, unsigned	%u	uint32
	%u8	uint8
	%u16	uint16
	%u32	uint32
	%u64	uint64
Floating-point number	%f	double
	%f32	single
	%f64	double
	%n	double

## Character Fields

This table lists available conversion specifiers for character inputs.

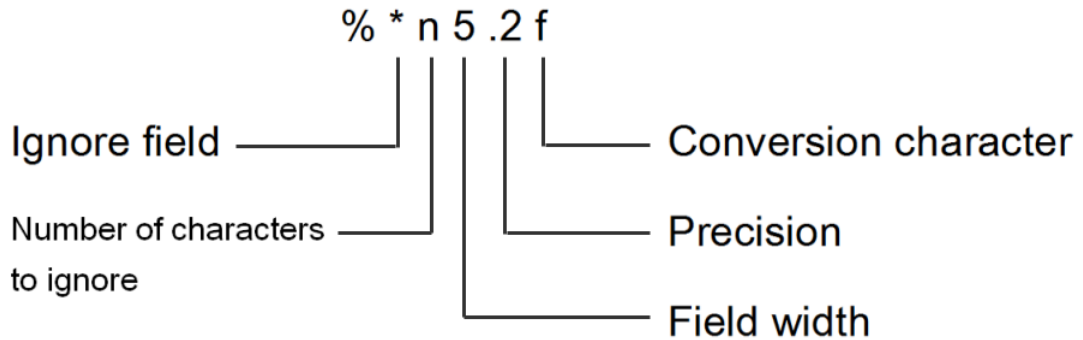

<b>Character Strings</b>	<b>Conversion Specifier</b>	<b>Details</b>
Characters	%s	String
	%q	String, where double quotation marks indicate text to keep together
	%c	Any single character, including a delimiter

Character Strings	Conversion Specifier	Details
Pattern-matching strings	%[...]	Read only the characters inside the brackets up to the first nonmatching character. To include ] in the set, specify it first: %[ ]...].  Example: %[mus] reads 'summer ' as 'summ'.
	%[^...]	Exclude characters inside the brackets, reading until the first matching character. To exclude ], specify it first: %[^ ]...].  Example: %[^xrg] reads 'summer ' as 'summe'.

**Optional Operators**

Conversion specifiers in formatSpec can include optional operators, which appear in the following order (includes spaces for clarity):

Optional operators include:

- Fields and Characters to Ignore

`textscan` reads all characters in your file in sequence, unless you tell it to ignore a particular field or a portion of a field.

Use the following operators to skip or read portions of fields.

Operator	Action Taken
<code>%*</code>	<p>Skip the field. <code>textscan</code> does not create an output cell for any field that it skips.</p> <p>Example: <code>'%s %*s %s %s %*s %*s %s'</code> (spaces are optional) converts the string <code>'Blackbird singing in the dead of night'</code> to four output cells with the strings <code>'Blackbird'</code> <code>'in'</code> <code>'the'</code> <code>'night'</code></p>
<code>%*n</code>	<p>Ignore <math>n</math> characters of the field, where <math>n</math> is an integer less than or equal to the number of characters in the field.</p> <p>Example: <code>%*4s</code> ignores 4 characters, so <code>'%*4s %s'</code> reads <code>'summer'</code> as <code>'er'</code>.</p>

- Field Width

`textscan` reads the number of characters or digits specified by the field width or precision, or up to the first delimiter, whichever comes first. A decimal point is counted as a digit. Specify the field width by inserting a number after the percent character (%) in the conversion specifier.

Example: `%5f` reads `'123.456'` as `123.4`.

---

**Note** When the field width operator is used with single characters (`%c`), `textscan` also reads delimiter characters.

Example: `%7c` reads 7 characters, including white-space, so `'Day and night'` reads as `'Day and'`.

---

- Precision

For floating-point numbers (`%n`, `%f`, `%f32`, `%f64`), you can specify the number of decimal digits to read.

Example: `%7.2f` reads `'123.456'` as `123.45`.

- Literal Text to Ignore

`textscan` ignores specified text appended to the `formatSpec` string.

Example: `Level%u8` reads `'Level1'` as `1`.

Example: `%u8Step` reads `'2Step'` as `2`.

### **N - Number of times to apply formatSpec**

integer

Number of times to apply `formatSpec`, specified as an integer.

### **Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### **str - Input string**

string

Input string to read.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Names are not case sensitive.

**Example:** `C =`

```
textscan(fileID,formatSpec,'HeaderLines',3,'Delimiter','(',')')
skips the first three lines of the data, and then reads the remaining
data, treating commas as a delimiter.
```

## **'CollectOutput' - Logical indicator determining data concatenation**

false (default) | true

Logical indicator determining data concatenation, specified as the comma-separated pair consisting of 'CollectOutput' and either true or false. If true, then textscan concatenates consecutive output cells of the same fundamental MATLAB class into a single array.

## **'CommentStyle' - Symbols designating text to ignore**

string | cell array of strings

Symbols designating text to ignore, specified as the comma-separated pair consisting of 'CommentStyle' and a string or cell array of strings.

For example, specify a string such as '%' to ignore characters following the string on the same line. Specify a cell array of two strings, such as {'/\*', '\*/'}, to ignore characters between the strings.

textscan checks for comments only at the start of each field, not within a field.

**Example:** 'CommentStyle',{'/\*', '\*/'}

## **'Delimiter' - Field delimiter characters**

{' ', '\b', '\t'} (default) | string | cell array of strings

Field delimiter characters, specified as the comma-separated pair consisting of 'Delimiter' and a string or a cell array of strings. Specify multiple delimiters in a cell array of strings.

**Example:** 'delimiter',{';', '\*'}

textscan interprets repeated delimiter characters as separate delimiters, and returns an empty value to the output cell.

Within each row of data, the default field delimiter is white space. White space can be any combination of space (' '), backspace ('\b'), or tab ('\t') characters. If you do not specify a delimiter, textscan interprets repeated white-space characters as a single delimiter.

When you specify one of the following escape sequences as a delimiter, textscan converts that sequence to the corresponding control character:

<code>\b</code>	Backspace
<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash ( <code>\</code> )

### **'EmptyValue' - Returned value for empty numeric fields**

`NaN` (default) | scalar

Returned value for empty numeric fields in delimited text files, specified as the comma-separated pair consisting of `'EmptyValue'` and a scalar.

### **'EndOfLine' - End-of-line characters**

string

End-of-line characters, specified as the comma-separated pair consisting of `'EndOfLine'` and a string. The default end-of-line sequence depends on the format of your file and can include a newline character (`'\n'`), a carriage return (`'\r'`), or a combination of the two (`'\r\n'`).

If there are missing values and an end-of-line sequence at the end of the last line in a file, then `textscan` returns empty values for those fields. This ensures that individual cells in output cell array, `C`, are the same size.

### **'ExpChars' - Exponent characters**

`'eEdD'` (default) | string

Exponent characters, specified as the comma-separated pair consisting of `'ExpChars'` and a string. The default exponent characters are `e`, `E`, `d`, and `D`.

### **'HeaderLines' - Number of header lines**

`0` (default) | positive integer

Number of header lines, specified as the comma-separated pair consisting of 'HeaderLines' and a positive integer. `textscan` skips the header lines, including the remainder of the current line.

### **'MultipleDelimsAsOne' - Multiple delimiter handling**

0 (false) (default) | 1 (true)

Multiple delimiter handling, specified as the comma-separated pair consisting of 'MultipleDelimsAsOne' and either true or false. If true, `textscan` treats consecutive delimiters as a single delimiter. Repeated delimiters separated by white-space are also treated as a single delimiter. You must also specify the `Delimiter` option.

**Example:** 'MultipleDelimsAsOne',1

### **'ReturnOnError' - Behavior when textscan fails to read or convert**

1 (true) (default) | 0 (false)

Behavior when `textscan` fails to read or convert, specified as the comma-separated pair consisting of 'ReturnOnError' and either true or false. If true, `textscan` terminates without an error and returns all fields read. If false, `textscan` terminates with an error and does not return an output cell array.

### **'TreatAsEmpty' - Strings to treat as empty value**

string | cell array of strings

Strings to treat as empty values, specified as the comma-separated pair consisting of 'TreatAsEmpty' and a single string or cell array of strings. This option only applies to numeric fields.

### **'Whitespace' - White-space characters**

' \b\t' (default) | string

White-space characters, specified as the comma-separated pair consisting of 'Whitespace' and a string of one or more characters. `textscan` adds a space character, `char(32)`, to any specified

Whitespace, unless Whitespace is empty ( ' ') and formatSpec includes any string conversion specifier.

When you specify one of the following escape sequences as any white-space character, textscan converts that sequence to the corresponding control character:

<code>\b</code>	Backspace
<code>\n</code>	Newline
<code>\r</code>	Carriage return
<code>\t</code>	Tab
<code>\\</code>	Backslash (\)

## Output Arguments

### **C - File or string data**

cell array

File or string data, returned as a cell array.

For each numeric conversion specifier in formatSpec, the textscan function returns a K-by-1 MATLAB numeric vector to the output cell array, C, where K is the number of times that textscan finds a field matching the specifier.

For each string conversion specifier in formatSpec, the textscan function returns a K-by-1 cell vector of strings, where K is the number of times that textscan finds a field matching the specifier. For each character conversion that includes a field width operator, textscan returns a K-by-M character array, where M is the field width.

### **position - File or string position**

integer

File or string position at the end of the scan, returned as an integer of class double. For a file, ftell(fileID) would return the same value after calling textscan. For a string, position indicates how many characters textscan read.

## Examples

### Read a String

Read a string of floating-point numbers.

```
str = '0.41 8.24 3.57 6.24 9.27';
```

```
C = textscan(str,'%f');
```

The formatSpec string '%f' tells textscan to match each field in str to a double-precision floating-point number.

Display the contents of cell array C.

```
celldisp(C)
```

```
C{1} =
```

```
 0.4100
 8.2400
 3.5700
 6.2400
 9.2700
```

Read the same string, truncating each value to one decimal digit.

```
C = textscan(str,'%3.1f %*1d');
```

The specifier %3.1f indicates a field width of 3 digits and a precision of 1. textscan reads a total of 3 digits, including the decimal point and the 1 digit after the decimal point. The specifier, %\*1d, tells textscan to skip the remaining digit.

Display the contents of cell array C.

```
celldisp(C)
```

```
C{1} =
```

```
 0.4000
```

```

8.2000
3.5000
6.2000
9.2000

```

### Read Different Types of Data

Using a text editor, create a file `scan1.dat` that contains data in the following form:

```

09/12/2005 Level1 12.34 45 1.23e10 inf Nan Yes 5.1+3i
10/12/2005 Level2 23.54 60 9e19 -inf 0.001 No 2.2-.5i
11/12/2005 Level3 34.90 12 2e5 10 100 No 3.1+.1i

```

Open the file, and read each column with the appropriate conversion specifier.

```

fileID = fopen('scan1.dat');
C = textscan(fileID, '%s %s %f32 %d8 %u %f %f %s %f');
fclose(fileID);
celldisp(C)

```

```
C{1}{1} =
```

```
09/12/2005
```

```
C{1}{2} =
```

```
10/12/2005
```

```
C{1}{3} =
```

```
11/12/2005
```

```
C{2}{1} =
```

Level1

C{2}{2} =

Level2

C{2}{3} =

Level3

C{3} =

12.3400

23.5400

34.9000

C{4} =

45

60

12

C{5} =

4294967295

4294967295

200000

C{6} =

Inf  
-Inf  
10

C{7} =

NaN  
0.0010  
100.0000

C{8}{1} =

Yes

C{8}{2} =

No

C{8}{3} =

No

C{9} =

5.1000 + 3.0000i  
2.2000 - 0.5000i  
3.1000 + 0.1000i

textscan returns a 1-by-9 cell array C.

View the MATLAB data type of each of the cells in C.

C

C =

Columns 1 through 5

{3x1 cell} {3x1 cell} [3x1 single] [3x1 int8] [3x1 uint32]

Columns 6 through 9

[3x1 double] [3x1 double] {3x1 cell} [3x1 double]

For example, C{1} and C{2} are cell arrays. C{5} is of data type uint32, so the first two elements of C{5} are the maximum values for a 32-bit unsigned integer, or intmax('uint32').

## Remove a Literal String

Remove the text 'Level' from each field in the second column of the data from the previous example.

Match the literal string in the formatSpec input.

```
fileID = fopen('scan1.dat');
C = textscan(fileID, '%s Level%d %f32 %d8 %u %f %f %s %f');
fclose(fileID);
C{2}
```

ans =

1  
2  
3

View the MATLAB data type of the second cell in C.

```
class(C{2})
```

```
ans =
```

```
int32
```

The second cell of the 1-by-9 cell array, `C`, is now of data type `int32`.

### Skip the Remainder of a Line

Read the first column of the file in the previous example into a cell array, skipping the rest of the line.

```
fileID = fopen('scan1.dat');
dates = textscan(fileID, '%s %*[^\\n]');
fclose(fileID);
dates{1}
```

```
ans =
```

```
 '09/12/2005'
```

```
 '10/12/2005'
```

```
 '11/12/2005'
```

`textscan` returns a 1-by-1 cell array `dates`.

### Specify Delimiter and Empty Value Conversion

Using a text editor, create a comma-delimited file, `data.csv`, that contains

```
1, 2, 3, 4, , 6
7, 8, 9, , 11, 12
```

Read the file, converting empty cells to `-Inf`.

```
fileID = fopen('data.csv');
C = textscan(fileID, '%f %f %f %f %u8 %f', ...
'delimiter', ',', 'EmptyValue', -Inf);
fclose(fileID);
```

```
column4 = C{4}, column5 = C{5}
```

```
column4 =
```

```
 4
 -Inf
```

```
column5 =
```

```
 0
 11
```

`textscan` returns a 1-by-6 cell array, `C`. The `textscan` function converts the empty value in `C{4}` to `-Inf`, where `C{4}` is associated with a floating-point format. Because MATLAB represents unsigned integer `-Inf` as 0, `textscan` converts the empty value in `C{5}` to 0, and not `-Inf`.

## Read Custom Empty Value Strings and Comments

Using a text editor, create a comma-delimited file, `data2.csv`, that contains the lines

```
abc, 2, NA, 3, 4
// Comment Here
def, na, 5, 6, 7
```

Designate the input that `textscan` should treat as comments or empty values.

```
fileID = fopen('data2.csv');
C = textscan(fileID, '%s %n %n %n %n', 'delimiter', ',', '...',
 'treatAsEmpty', {'NA', 'na'}, 'commentStyle', '//');
fclose(fileID);
celldisp(C)
```

```
C{1}{1} =
abc
```

```
C{1}{2} =
def
```

```
C{2} =
 2
 NaN
```

```
C{3} =
 NaN
 5
```

```
C{4} =
 3
 6
```

```
C{5} =
 4
 7
```

### Treat Repeated Delimiters as One

Using a text editor, create a file, `data3.csv`, that contains

```
1,2,3,,4
5,6,7,,8
```

To treat the repeated commas as a single delimiter, use the `MultipleDelimsAsOne` parameter, and set the value to 1 (true).

```
fileID = fopen('data3.csv');
C = textscan(fileID,'%f %f %f %f','delimiter','',...
'MultipleDelimsAsOne',1);
fclose(fileID);
celldisp(C)
```

```
C{1} =
 1
 5
```

```
C{2} =
 2
 6
```

```
C{3} =
 3
 7
```

```
C{4} =
 4
 8
```

## Collect Numeric Data

Using a text editor, create a file, `grades.txt`, that contains:

Student_ID	Test1	Test2	Test3
1	91.5	89.2	77.3
2	88.0	67.8	91.0
3	76.3	78.1	92.5
4	96.4	81.2	84.6

Read the column headers using the format `'%s'` four times.

```
fileID = fopen('grades.txt');

formatSpec = '%s';
N = 4;
C_text = textscan(fileID,formatSpec,N,'delimiter','|');
```

Read the numeric data in the file.

```
C_data0 = textscan(fileID,'%d %f %f %f')

C_data0 =
 [4x1 int32] [4x1 double] [4x1 double] [4x1 double]
```

The default value for `CollectOutput` is 0 (false), so `textscan` returns each column of the numeric data in a separate array.

Set `CollectOutput` to 1 (true) to collect the consecutive columns of the same class into a single array.

```
frewind(fileID);

C_text = textscan(fileID, '%s', N, 'delimiter', '|');

C_data1 = textscan(fileID, '%d %f %f %f', 'CollectOutput', 1)

C_data1 =
 [4x1 int32] [4x3 double]
```

The test scores, which are all double, are collected into a single 4-by-3 array.

Close the file, `grades.txt`.

```
fclose(fileID);
```

### Read Nondefault Control Characters

Use `sprintf` to convert nondefault escape sequences in your data.

Create a string that includes a form feed character, `\f`. Then, to read the string using `textscan`, call `sprintf` to explicitly convert the form feed.

```
lyric = sprintf('Blackbird\fsinging\fin\fthe\fddead\fof\fnight');
C = textscan(lyric, '%s', 'delimiter', sprintf('\f'));
C{1}
```

```
ans =

 'Blackbird'
 'singing'
 'in'
 'the'
```

```
'dead'
'of'
'night'
```

textscan returns a 1-by-1 cell array, C.

## Resume a Text Scan of a String

Resume a scan of a string from a position other than the beginning.

If you resume a text scan of a string, textscan reads from the beginning of the string each time. To resume a scan from any other position in the string, use the two-output argument syntax in your initial call to textscan.

For example, create a string called lyric. Read the first word of the string, and then resume the scan.

```
lyric = 'Blackbird singing in the dead of night';
[firstword,pos] = textscan(lyric,'%9c',1);
lastpart = textscan(lyric(pos+1:end),'%s');
```

## Algorithms

textscan converts numeric fields to the specified output type according to MATLAB rules regarding overflow, truncation, and the use of NaN, Inf, and -Inf. For example, MATLAB represents an integer NaN as zero. If textscan finds an empty field associated with an integer format specifier (such as %d or %u), it returns the empty value as zero and not NaN.

textscan does not include leading white-space characters in the processing of any data fields. When processing numeric data, textscan also ignores trailing white space.

textscan imports any complex number as a whole into a complex numeric field, converting the real and imaginary parts to the specified numeric type (such as %d or %f). Valid forms for a complex number are:

±<real>±<imag>i|j                      Example: 5.7-3.1i

±<imag>i|j                              Example: -7j

Do not include embedded white space in a complex number. `textscan` interprets embedded white space as a field delimiter.

# textwrap

---

**Purpose**            Wrapped string matrix for given uicontrol

**Syntax**            `outstring = textwrap(h,instring)`  
`outstring = textwrap(h,instring,columns)`  
`[outstring,position] = textwrap(...)`

**Description**      `outstring = textwrap(h,instring)` returns a wrapped string cell array, `outstring`, that fits inside the uicontrol with handle `h`. `instring` is a cell array, with each cell containing a single line of text. `outstring` is the wrapped string matrix in cell array format. Each cell of the input string is considered a paragraph.

`outstring = textwrap(h,instring,columns)` returns an `outstring` with each line wrapped at `columns` characters. Spaces are included in the character count.

`[outstring,position] = textwrap(...)` returns the recommended position of the uicontrol in the units of the uicontrol. `position` considers the extent of the multiline text in the *x* and *y* directions.

`textwrap` maintains the original line breaks in the input cell array and adds new ones. It can calculate uicontrol positions with any type of Units, including normalized units.

**Tips**                When programming a GUI, do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

**Examples**           Place two text-wrapped strings in text uicontrols. The left one has a `Position` calculated by `textwrap` in Units of pixels; the right one's `Position` is calculated manually in Units of characters:

```
figure('Position',[560 528 350 250]);
% Make a text uicontrol to wrap in Units of Pixels
% Create it in Units of Pixels, 100 wide, 10 high
pos = [10 100 100 10];
ht = uicontrol('Style','Text','Position',pos);
```

```
string = {'This is a string for the left text uicontrol.',...
 'to be wrapped in Units of Pixels,',...
 'with a position determined by TEXTWRAP.'};
% Wrap string, also returning a new position for ht
[outstring,newpos] = textwrap(ht,string) %#ok<NOPRT>

outstring =
 'This is a string for'
 'the left text'
 'uicontrol.'
 'to be wrapped in'
 'Units of Pixels,'
 'with a position'
 'determined by'
 'TEXTWRAP.'

newpos =
 10 100 91 124

set(ht,'String',outstring,'Position',newpos)

% Make another text uicontrol to wrap to a column width of 15
colwidth = 15;
% Create it in Units of Pixels, 100 wide, 10 high
pos1 = [150 100 100 10];
ht1 = uicontrol('Style','Text','Position',pos1);
string1 = {'This is a string for the right text uicontrol.',...
 'to be wrapped in Units of Characters,',...
 'into lines 15 columns wide.'};

set(ht1,'String',outstring1,'Position',newpos1)
```

## See Also

[align](#) | [uicontrol](#)

**Purpose** Transpose-free quasi-minimal residual method

**Syntax**

```
x = tfqmr(A,b)
x = tfqmr(afun,b)
x = tfqmr(a,b,tol)
x = tfqmr(a,b,tol,maxit)
x = tfqmr(a,b,tol,maxit,m)
x = tfqmr(a,b,tol,maxit,m1,m2,x0)
[x,flag] = tfqmr(A,B,...)
[x,flag,relres] = tfqmr(A,b,...)
[x,flag,relres,y]y(A,b,...)
[x,flag,relres,iter,resvec] = tfqmr(A,b,...)
```

**Description** `x = tfqmr(A,b)` attempts to solve the system of linear equations  $A*x=b$  for  $x$ . The  $n$ -by- $n$  coefficient matrix  $A$  must be square and the right-hand side column vector  $b$  must have length  $n$ .

`x = tfqmr(afun,b)` accepts a function handle, `afun`, instead of the matrix  $A$ . The function, `afun(x)`, accepts a vector input  $x$  and returns the matrix-vector product  $A*x$ . In all of the following syntaxes, you can replace  $A$  by `afun`. “Parameterizing Functions” explains how to provide additional parameters to the function `afun`.

`x = tfqmr(a,b,tol)` specifies the tolerance of the method. If `tol` is `[]` then `tfqmr` uses the default,  $1e-6$ .

`x = tfqmr(a,b,tol,maxit)` specifies the maximum number of iterations. If `maxit` is `[]` then `tfqmr` uses the default,  $\min(N,20)$ .

`x = tfqmr(a,b,tol,maxit,m)` and `x = tfqmr(a,b,tol,maxit,m1,m2)` use preconditioners  $m$  or  $m=m1*m2$  and effectively solve the system  $A*inv(M)*x = B$  for  $x$ . If  $M$  is `[]` then a preconditioner is not applied.  $M$  may be a function handle `mfun` such that `mfun(x)` returns  $m\backslash x$ .

`x = tfqmr(a,b,tol,maxit,m1,m2,x0)` specifies the initial guess. If `x0` is `[]` then `tfqmr` uses the default, an all zero vector.

`[x,flag] = tfqmr(A,B,...)` also returns a convergence flag:

Flag	Convergence
0	tfqmr converged to the desired tolerance tol within maxit iterations.
1	tfqmr iterated maxit times but did not converge.
2	Preconditioner m was ill-conditioned.
3	tfqmr stagnated. (Two consecutive iterates were the same.)
4	One of the scalar quantities calculated during tfqmr became too small or too large to continue computing.

`[x,flag,relres] = tfqmr(A,b,...)` also returns the relative residual norm  $\text{norm}(b-A*x)/\text{norm}(b)$ . If flag is 0, then  $\text{relres} \leq \text{tol}$ .

`[x,flag,relres,y]y(A,b,...)` also returns the iteration number at which x was computed:  $0 \leq \text{iter} \leq \text{maxit}$ .

`[x,flag,relres,iter,resvec] = tfqmr(A,b,...)` also returns a vector of the residual norms at each iteration, including  $\text{norm}(b-A*x_0)$ .

## Examples

### Using tfqmr with Matrix or Function Handle Input

This example shows how to use tfqmr with a matrix input and with a function input.

```
n = 100; on = ones(n,1);
A = spdiags([-2*on 4*on -on],-1:1,n,n);
b = sum(A,2);
tol = 1e-8;
maxit = 15;
M1 = spdiags([on/(-2) on],-1:0,n,n);
M2 = spdiags([4*on -on],0:1,n,n);
x = tfqmr(A,b,tol,maxit,M1,M2,[]);
```

You can also use a matrix-vector product function as input:

```
function y = afun(x,n)
```

```
y = 4 * x;
y(2:n) = y(2:n) - 2 * x(1:n-1);
y(1:n-1) = y(1:n-1) - x(2:n);
x1 = tfqmr(@(x)afun(x,n),b,tol,maxit,M1,M2);
```

If `applyOp` is a function suitable for use with `qmr`, it may be used with `tfqmr` by wrapping it in an anonymous function:

```
x1 = tfqmr(@(x)applyOp(x,'notransp'),b,tol,maxit,M1,M2);
```

### Using tfqmr with a Preconditioner

This example demonstrates the use of a preconditioner.

Load `A = west0479`, a real 479-by-479 nonsymmetric sparse matrix.

```
load west0479;
A = west0479;
```

Define `b` so that the true solution is a vector of all ones.

```
b = full(sum(A,2));
```

Set the tolerance and maximum number of iterations.

```
tol = 1e-12; maxit = 20;
```

Use `tfqmr` to find a solution at the requested tolerance and number of iterations.

```
[x0,f10,rr0,it0,rv0] = tfqmr(A,b,tol,maxit);
```

`f10` is 1 because `tfqmr` does not converge to the requested tolerance `1e-12` within the requested 20 iterations. The seventeenth iterate is the best approximate solution and is the one returned as indicated by `it0 = 17`. MATLAB® stores the residual history in `rv0`.

Plot the behavior of `tfqmr`.

```
semilogy(0:maxit,rv0(1:maxit+1)/norm(b),'-o');
```

```
xlabel('Iteration number');
ylabel('Relative residual');
```

Note that like `bicgstab`, `tfqmr` keeps track of half iterations. The plot shows that the solution does not converge. You can use a preconditioner to improve the outcome.

Create the preconditioner with `ilu`, since the matrix `A` is nonsymmetric.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-5));
```

Error using ilu

There is a pivot equal to zero. Consider decreasing the drop tolerance or consider using the 'udiag' option.

MATLAB cannot construct the incomplete LU as it would result in a singular factor, which is useless as a preconditioner.

You can try again with a reduced drop tolerance, as indicated by the error message.

```
[L,U] = ilu(A,struct('type','ilutp','droptol',1e-6));
[x1,f11,rr1,it1,rv1] = tfqmr(A,b,tol,maxit,L,U);
```

f11 is 0 because tfqmr drives the relative residual to  $4.1410e-014$  (the value of rr1). The relative residual is less than the prescribed tolerance of  $1e-12$  at the sixth iteration (the value of it1) when preconditioned by the incomplete LU factorization with a drop tolerance of  $1e-6$ . The output rv1(1) is norm(b), and the output rv1(7) is norm(b-A\*x2).

You can follow the progress of tfqmr by plotting the relative residuals at each iteration starting from the initial estimate (iterate number 0).

```
semilogy(0:0.5:it1,rv1/norm(b),'-o');
xlabel('Iteration number');
ylabel('Relative residual');
```

**Purpose** Issue exception and terminate function

**Syntax** `throw(exception)`

**Description** `throw(exception)` issues an exception based on the information contained in *exception*. The exception terminates the currently running function and returns control to its caller. The *exception* argument is scalar object of the MException class that contains information on the cause of the error and where it occurred. The `throw` function passes *exception* back to the caller of the currently running function, and eventually back to the Command Window when the program terminates. The exception is made available to any calling function by means of the `try`, `catch` function, and to the Command Window by means of the `MException.last` function.

Unlike `throwAsCaller` and `rethrow`, the `throw` function also sets the *stack* field of the *exception* to the location from which `throw` was called.

**Tips** There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

- 1** Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.
- 2** Reissue the original exception by throwing the initial exception unmodified. Use the MException `rethrow` method to do this.
- 3** Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the MException `addCause` and `throw` methods to do this.

# throw (MException)

---

- 4 Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

## Examples

### Example 1

This example tests the output of function `evaluate_plots` and throws an exception if it is not acceptable:

```
[minval, maxval] = evaluate_plots(p24, p28, p41);
if minval < lower_bound || maxval > upper_bound
 exception = MException('VerifyOutput:OutOfBounds', ...
 'Results are outside the allowable limits');
 throw(exception);
end
```

### Example 2

This example attempts to open a file in a folder that is not on the MATLAB path. It uses a nested try-catch block to give the user the opportunity to extend the path. If the file still cannot be found, the program issues an exception with the first error appended to the second using `addCause`:

```
function data = read_it(filename);
try
 % Attempt to open and read from a file.
 fid = fopen(filename, 'r');
 data = fread(fid);
catch exception1
 % If the error was caused by an invalid file ID, try
 % reading from another location.
 if strcmp(exception1.identifier, 'MATLAB:FileIO:InvalidFid')
 msg = sprintf(...
 '\nCannot open file %s. Try another location? ', ...
 filename);
 reply = input(msg, 's')
 if reply(1) == 'y'
 newFolder = input('Enter folder name: ', 's');
```

```
else
 throw(exception1);
end
oldpath = addpath(newFolder);
try
 fid = fopen(filename, 'r');
 data = fread(fid);
catch exception2
 exception3 = addCause(exception2, exception1)
 path(oldpath);
 throw(exception3);
end
path(oldpath);
end
end
fclose(fid);

try
 d = read_it('anytextfile.txt');
catch exception
end

exception
exception =
MException object with properties:

 identifier: 'MATLAB:FileIO:InvalidFid'
 message: 'Invalid file identifier. Use fopen
 to generate a valid file identifier.'
 stack: [1x1 struct]
 cause: {[1x1 MException]}
```

Cannot open file anytextfile.txt. Try another location?  
Enter folder name: xxxxxxx  
Warning: Name is nonexistent or not a directory: xxxxxxx.  
> In path at 110  
In addpath at 89

# throw (MException)

# throwAsCaller (MException)

---

**Purpose** Throw exception as if from calling function

**Syntax** `throwAsCaller(exception)`

**Description** `throwAsCaller(exception)` throws an exception from the currently running function based on the *exception* input, a scalar object of the `MException` class. The MATLAB software exits the currently running function and returns control to either the keyboard or an enclosing catch block in a calling function. Unlike the `throw` function, MATLAB omits the current stack frame from the `stack` field of the `MException`, thus making the exception look as if it is being thrown by the caller of the function.

In some cases, it is not relevant to show the person running your program the true location that generated an exception, but is better to point to the calling function where the problem really lies. You might also find `throwAsCaller` useful when you want to simplify the error display, or when you have code that you do not want made public.

## Tips

There are four ways to throw an exception in MATLAB (see the list below). Use the first of these when testing the outcome of some action for failure and reporting the failure to MATLAB. Use one of the remaining three techniques to throw an existing exception.

- 1** Test the result of some action taken by your program. If the result is found to be incorrect or unexpected, compose an appropriate message and message identifier, and pass these to MATLAB using the `error` function.
- 2** Reissue the original exception by throwing the initial exception unmodified. Use the `MException` `rethrow` method to do this.
- 3** Collect additional information on the cause of the error, store it in a new or modified exception, and issue a new exception based on that record. Use the `MException` `addCause` and `throw` methods to do this.

## throwAsCaller (MException)

---

- 4 Make it appear that the error originated in the caller of the currently running function. Use the MException throwAsCaller method to do this.

### Examples

The function `klein_bottle`, in this example, generates a Klein Bottle figure by revolving the figure-eight curve defined by `XYKLEIN`. It defines a few variables and calls the function `draw_klein`, which executes three functions in a `try`, `catch` block. If there is an error, the `catch` block issues an exception using either `throw` or `throwAsCaller`:

```
function klein_bottle(pq)
ab = [0 2*pi];
rtr = [2 0.5 1];
box = [-3 3 -3 3 -2 2];
vue = [55 60];
draw_klein(ab, rtr, pq, box, vue)

function draw_klein(ab, rtr, pq, box, vue)
clf
try
 tube('xyklein',ab, rtr, pq, box, vue);
 shading interp
 colormap(pink);
catch exception
 throw(exception)
% throwAsCaller(exception)
end
```

Call the `klein_bottle` function, passing a vector, and the function completes normally by drawing the figure.

```
klein_bottle([40 40])
```

Call the function again, this time passing a scalar value. Because the `catch` block issues the exception using `throw`, MATLAB displays error messages for line 16 of function `draw_klein`, and for line 6 of function `klein_bottle`:

## throwAsCaller (MException)

---

```
klein_bottle(40)
Error using klein_bottle>draw_klein (line 16)
Attempted to access pq(2); index out of bounds because numel(pq)=1.
```

```
Error in klein_bottle (line 6)
draw_klein(ab, rtr, pq, box, vue)
```

Run the function again, this time changing the `klein_bottle.m` file so that the `catch` block uses `throwAsCaller` instead of `throw`. This time, MATLAB only displays the error at line 6 of the main program:

```
klein_bottle(40)
Error using klein_bottle (line 6)
Attempted to access pq(2); index out of bounds because numel(pq)=1.
```

| assert | error | MException | try, catch
```

# tic

---

**Purpose** Start stopwatch timer

**Syntax**

```
tic
timerVal = tic
```

**Description** `tic` starts a stopwatch timer to measure performance. The function records the internal time at execution of the `tic` command. Display the elapsed time with the `toc` function.

`timerVal = tic` returns the value of the internal timer at the execution of the `tic` command, so that you can record time for simultaneous time spans.

- Tips**
- Consecutive `tic` commands overwrite the internally recorded starting time.
  - The `clear` function does not reset the starting time recorded by a `tic` command.
  - The following actions result in unexpected output:
    - Using `tic` and `toc` to time `timeit`
    - Using `tic` and `toc` within a function timed by `timeit`

**Output Arguments**

**timerVal**  
Value of the internal timer at the execution of the `tic` command. This value is used as an input argument for a subsequent call to `toc`. You should not rely on the meaning of this value.

**Examples** Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A' .* B';
```

---

```
toc
```

---

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
 A = rand(n,n);
 b = rand(n,1);
 tic;
 x = A\b;
 t(n) = toc;
end
plot(t)
```

---

Measure multiple time spans simultaneously using two pairs of tic/toc calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000; minTime = Inf; nsum = 10;
tic; % TIC, pair 1

for i=1:REPS
 tStart = tic; % TIC, pair 2
 total = 0;
 for j=1:nsum
 total = total + besselj(j,REPS);
 end

 tElapsed = toc(tStart); % TOC, pair 2
 minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS; % TOC, pair 1
```

## See Also

[clock](#) | [cputime](#) | [etime](#) | [profile](#) | [timeit](#) | [toc](#)

# timeit

---

**Purpose** Measure time required to run function

**Syntax**  
`t = timeit(f)`  
`t = timeit(f,numOutputs)`

**Description** `t = timeit(f)` measures the typical time (in seconds) required to run the function specified by the function handle `f`.

`t = timeit(f,numOutputs)` calls `f` with the desired number of outputs, `numOutputs`. By default, `timeit` calls the function `f` with one output (or no outputs, if the function does not return any outputs).

**Input Arguments** **f - function to be measured**  
function handle

Function to be measured, specified as a function handle. `f` is either a handle to a function that takes no input, or a handle to an anonymous function with an empty argument list.

**numOutputs - Number of desired outputs from f**  
integer

Number of desired outputs from `f`, specified as an integer. If the function specified by `f` has a variable number of outputs, `numOutputs` specifies which syntax `timeit` uses to call the function. For example, the `svd` function returns a single output, `s`, or three outputs, `[U,S,V]`. Set `numOutputs` to 1 to time the `s = svd(X)` syntax, or set it to 3 to time the `[U,S,V] = svd(X)` syntax.

**Algorithms** `timeit` calls the specified function multiple times, and computes the median of the measurements.

**Examples** **Determine Time to Obtain Current Date**

Use `timeit` to time a function call to `date`. This example uses a handle to a function that accepts no input.

```
f = @date;
t = timeit(f)
```

```
t =
```

```
1.3481e-04
```

### Determine Time to Compute Matrix Summation

Time the combination of several mathematical matrix operations: matrix transposition, element-by-element multiplication, and summation of columns.

```
A = rand(12000, 400);
B = rand(400, 12000);
f = @() sum(A.' .* B, 1);
timeit(f)
```

```
ans =
```

```
0.0427
```

### Compare Time to Run svd with Multiple Outputs

Determine how long it takes to run svd with one output argument, `s=svd(X)`.

```
X = [1 2; 3 4; 5 6; 7 8];
f = @() svd(X);
t1 = timeit(f)
```

```
t1 =
```

```
1.5427e-05
```

Compare the results to svd with three output arguments, `[U,S,V]=svd(X)`.

```
t2 = timeit(f,3)
```

```
t2 =

2.6695e-05
```

## Compare Time to Execute Custom Preallocation to Calling zeros

Create a short function to allocate a matrix using nested loops. Preallocating an array using a nested loop is inefficient, but is shown here for illustrative purposes.

```
function mArr = preAllocFcn(x,y)
for m = 1:x
 for n = 1:y
 mArr(m,n) = 0;
 end
end
end
```

Compare the time to allocate zeros to a matrix using nested loops and using the zeros function.

```
x = 1000;
y = 500;
g = @() preAllocFcn(x,y);
h = @() zeros(x,y);
diffRunTime = timeit(g)-timeit(h)
```

```
diffRunTime =

0.2004
```

## Tips

- The following actions result in unexpected output:
  - Using `timeit` between `tic` and `toc`
  - Using `timeit` to time a function that includes calls to `tic` and `toc`
  - Using `timeit` recursively

**See Also**

`function_handle` | `tic` | `toc` | `cputime`

**Concepts**

- Anonymous Functions
  - Analyzing Your Program's Performance
- MATLAB Performance Measurement White Paper on MATLAB Central File Exchange

**Purpose** Read elapsed time from stopwatch

**Syntax**

```
toc
elapsedTime = toc
toc(timerVal)
elapsedTime = toc(timerVal)
```

**Description** `toc` reads the elapsed time from the stopwatch timer started by the `tic` function. The function reads the internal time at the execution of the `toc` command, and displays the elapsed time since the most recent call to the `tic` function that had no output, in seconds.

`elapsedTime = toc` returns the elapsed time in a variable.

`toc(timerVal)` displays the time elapsed since the `tic` command corresponding to `timerVal`.

`elapsedTime = toc(timerVal)` returns the elapsed time since the `tic` command corresponding to `timerVal`.

## Tips

- Consecutive calls to the `toc` function with no input return the elapsed since the most recent `tic`. Therefore, you can take multiple measurements from a single point in time.

Consecutive calls to the `toc` function with the same `timerVal` input return the elapsed time since the `tic` function call that corresponds to that input.

- The following actions result in unexpected output:
  - Using `tic` and `toc` to time `timeit`
  - Using `tic` and `toc` within a function timed by `timeit`

## Input Arguments

### **timerVal**

Value of the internal timer saved from a previous call to the `tic` command.

## Output Arguments

### **elapsedTime**

Scalar double representing the time elapsed between `tic` and `toc` commands, in seconds.

## Examples

Measure time to generate two random matrices and compute element-by-element multiplication of their transposes.

```
tic
A = rand(12000, 4400);
B = rand(12000, 4400);
toc
C = A' .* B';
toc
```

---

Measure how the time required to solve a linear system varies with the order of a matrix:

```
t = zeros(1,100);
for n = 1:100
 A = rand(n,n);
 b = rand(n,1);
 tic;
 x = A\b;
 t(n) = toc;
end
plot(t)
```

---

Measure multiple time spans simultaneously using two pairs of `tic/toc` calls. To do this, measure the minimum and average time to compute a summation of Bessel functions:

```
REPS = 1000; minTime = Inf; nsum = 10;
tic; % TIC, pair 1
```

```
for i=1:REPS
 tStart = tic; % TIC, pair 2
 total = 0;
 for j=1:nsum
 total = total + besselj(j,REPS);
 end

 tElapsed = toc(tStart); % TOC, pair 2
 minTime = min(tElapsed, minTime);
end
averageTime = toc/REPS; % TOC, pair 1
```

## Purpose

MATLAB Gateway to LibTIFF library routines

## Description

The `Tiff` class represents a connection to a Tagged Image File Format (TIFF) file and provides access to many of the capabilities of the LibTIFF library. Use the methods of the `Tiff` object to call routines in the LibTIFF library. While you can use the `imread` and `imwrite` functions to read and write TIFF files, the `Tiff` class offers capabilities that these functions don't provide, such as reading subimages, writing tiles and strips of image data, and modifying individual TIFF tags.

In most cases, the syntax of the `Tiff` method is similar to the syntax of the corresponding LibTIFF library function. To get the most out of the `Tiff` object, you must be familiar with the LibTIFF API, as well as the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

MATLAB supports LibTIFF version 4.0.0.

For copyright information, see the `libtiffcopyright.txt` file.

## Construction

`obj = Tiff(filename,mode)` creates a `Tiff` object associated with the TIFF file `filename`. `mode` specifies the type of access to the file.

A TIFF file is made up of one or more image file directories (IFDs). An IFD contains image data and associated metadata. IFDs can also contain subIFDs which also contain image data and metadata. When you open a TIFF file for reading, the `Tiff` object makes the first IFD in the file the *current* IFD. `Tiff` methods operate on the current IFD. You can use `Tiff` object methods to navigate among the IFDs and the subIFDs in a TIFF file.

When you open a TIFF file for writing or appending, the `Tiff` object automatically creates a IFD in the file for writing subsequent data. This IFD has all the default values specified in TIFF Revision 6.0.

When creating a new TIFF file, before writing any image to the file, you must create certain required fields (tags) in the file. These tags include `ImageWidth`, `ImageHeight`, `BitsPerSample`, `SamplesPerPixel`, `Compression`, `PlanarConfiguration`, and `Photometric`. If the image data has a stripped layout, the IFD contains the `RowsPerStrip` tag. If

the image data has a tiled layout, the IFD contains the `TileWidth` and `TileHeight` tags. Use the `setTag` method to define values for these tags.

## Input Arguments

### filename

Text string specifying name of file.

### mode

One of the following text strings specifying the type of access to the TIFF file.

## Supported Values

Parameter	Description
'r'	Open file for reading (default)
'w'	Open file for writing; discard existing contents
'w8'	Open file for writing a BigTIFF file; discard existing contents
'a'	Open or create file for writing; append data to end of file.
'r+'	Open (do not create) file for reading and writing

## Properties

### Compression

Specify scheme used to compress image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

None
CCITTRLE (Read-only)
CCITTFax3
CCITTFax4
LZW
JPEG
CCITTRLEW (Read-only)
PackBits
SGILog
SGILog24
Deflate
AdobeDeflate (Same as deflate)

Example: Set the `Compression` tag to the value `JPEG`. Note how you use the property to specify the value.

```
tiffobj.setTag('Compression', Tiff.Compression.JPEG);
```

## ExtraSamples

Describe extra components

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This field is required if there are extra channels in addition to the usual colormetric channels.

## Supported Values

Value of ExtraSamples	Description
Unspecified	Unspecified data
AssociatedAlpha	Associated alpha (pre-multiplied)
UnassociatedAlpha	Unassociated alpha data

Example: Set the ExtraSamples tag to the value AssociatedAlpha. Note how you use the property to specify the value.

```
tiffobj.setTag('ExtraSamples', Tiff.ExtraSamples.AssociatedAlpha);
```

See Also “Specify Tiff object properties and describe alpha channel” on page 1-7081

## Group3Options

Options for Group 3 Fax Compression

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the setTag method. For more clarification, see the example.

This property is also referred to as Fax3 and T4Options. This value is a bit mask controlled by the first three bits.

## Supported Values

Supported values include the following.

Encoding2D	Bit 0 is 1. This specifies two-dimensional coding. If more than one strip is specified, each strip must begin with a one-dimensionally coded line. That is, RowsPerStrip should be a multiple of Parameter K, as documented in the CCITT specification.
Uncompressed	Bit 1 is 1. This specifies an uncompressed mode when encoding.
FillBits	Bit 2 is 1. Fill bits are added as necessary before EOL codes such that EOL always ends on a byte boundary. This ensures an EOL-sequence of 1 byte preceded by a zero nibble, for example, xxxx-0000 0000-0001.

Example:

```
mask = bitor(Tiff.Group3Options.Encoding2D,Tiff.Group3Options.Uncompressed);
tiffobj.setTag('Group3Options',mask);
```

### **InkSet**

Specify set of inks used in separated image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

In this context, separated refers to photometric interpretation, not the planar configuration.

## Supported Values

CMYK	Order of components: cyan, magenta, yellow, black. Usually, a value of 0 represents 0% ink coverage and a value of 255 represents 100% ink coverage for that component, but consult the TIFF specification for <code>DotRange</code> . When you specify CMYK, do not set the <code>InkNames</code> tag.
MultiInk	Any ordering other than CMYK. Consult the TIFF specification for <code>InkNames</code> field for a description of the inks used.

Example:

```
tiffobj.setTag('InkSet', Tiff.InkSet.CMYK);
```

## JPEGColorMode

Specify control of YCbCr/RGB conversion

Use these values only when the photometric interpretation is YCbCr.

This property should not be used for the purpose of reading YCbCr imagery as RGB. In this case, use the RGBA interface provided by the `readRGBAImage`, `readRGBAStrip`, and `readRGBATile` methods.

## Supported Values

Raw (default)	Keep input as separate Y, Cb, and Cr matrices.
RGB	Convert RGB input to YCbCr.

Example:

```
tiffobj.setTag('JPEGColorMode', Tiff/JPEGColorMode.RGB);
```

See also “Create YCbCr/JPEG image from RGB data” on page 1-7081

## Orientation

Specify visual orientation of the image data.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

The first row represents the top of the image, and the first column represents the left side. Support for this tag is for informational purposes only, and it does not affect how MATLAB reads or writes the image data.

## Supported Values

TopLeft
TopRight
BottomRight
BottomLeft
LeftTop
RightTop
RightBottom
LeftBottom

Example:

```
tiffobj.setTag('Orientation', Tiff.Orientation.TopRight);
```

## Photometric

Specify color space of image data

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

## Supported Values

MinIsWhite
MinIsBlack
RGB
Palette
Mask
Separated (CMYK)
YCbCr
CIELab
ICCLab
ITULab
LogL
LogLUV
CFA
LinearRaw

Example:

```
tiffobj.setTag('Photometric', Tiff.Photometric.RGB);
```

## PlanarConfiguration

Specifies how image data components are stored on disk

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

Chunky	Store component values for each pixel contiguously. For example, in the case of RGB data, the first three pixels would be stored in the file as RGBRGBRGB etc. Almost all TIFF images have contiguous planar configurations.
Separate	Store component values for each pixel separately. For example, in the case of RGB data, the red component would be stored separately in the file from the green and blue components.

Example:

```
tiffobj.setTag('PlanarConfiguration', Tiff.PlanarConfiguration.CHUNKY);
```

### ResolutionUnit

Specify unit of measure used to interpret the XResolution and YResolution tags.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

None (default)
Inch
Centimeter

Example: Set ResolutionUnit tag to the value Inch. Then, setting XResolution tag to 300 means pixels per inch.

```
tiffObj.setTag('ResolutionUnit', Tiff.ResolutionUnit.Inch);
tiffObj.setTag('XResolution', 300);
```

```
tiffObj.setTag('YResolution', 300);
```

## SampleFormat

Specify how to interpret each pixel sample

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the examples.

### Supported Values

UInt (default)
Int
IEEEFP

Void, ComplexInt, and ComplexIEEEFP are not supported.

Example:

```
tiffObj.setTag('SampleFormat', Tiff.SampleFormat.IEEFP);
```

## SGILogDataFmt

Specify control of client data for SGILog codec

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

These enumerated values should only be used when the photometric interpretation value is `LogL` or `LogLUV`. The `BitsPerSample`, `SamplesPerPixel`, and `SampleFormat` tags should not be set if the image type is `LogL` or `LogLuv`. The choice of `SGILogDataFmt` will set these tags automatically. The `Float` and `Bits8` settings imply a `SamplesPerPixel` value of 3 for `LogLUV` images, but only 1 for `LogL` images.

### Supported Values

Float	Single precision samples
Bits8	uint8 samples (read only)

This tag can be set only once per instance of a LogL/LogLuv Tiff image object instance.

Example:

```
tiffobj = Tiff('example.tif','r');
tiffobj.setDirectory(3); % image three is a LogLuv image
tiffobj.setTag('SGILogDataFmt', Tiff.SGILogDataFmt.Float);
imdata = tiffobj.read();
```

### SubFileType

Specify type of image

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

SubFileType is a bitmask that indicates the type of the image.

### Supported Values

Default	Default value for single image file or first image.
ReducedImage	The current image is a thumbnail or reduced-resolution image that typically would be found in a sub-IFD.
Page	The image is a single image of a multi-image (or multipage) file.
Mask	The image is a transparency mask for another image in the file. The photometric interpretation value must be Photometric.Mask.

Example:

```
tiffobj.setTag('SubFileType', Tiff.SubFileType.Mask);
```

## TagID

List of recognized TIFF tag names with their ID numbers

This property identifies all the supported TIFF tags with their ID numbers. Use this property to specify a tag when using the `setTag` method. For example, `Tiff.TagID.ImageWidth` returns the ID of the `ImageWidth` tag. To get a list of the names of supported tags, use the `getTagNames` method.

Example:

```
tiffobj.setTag(Tiff.TagID.ImageWidth, 300);
```

## Thresholding

Specifies technique used to convert from gray to black and white pixels.

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

### Supported Values

BiLevel (default)
HalfTone
ErrorDiffuse

Example:

```
tiffobj.setTag('Thresholding', Tiff.Thresholding.HalfTone);
```

## YCbCrPositioning

Specify relative positioning of chrominance samples

This property defines all the supported values for this tag. You use this property to specify the value you want to assign to the tag, using the `setTag` method. For more clarification, see the example.

This property identifies all supported values for the `YCbCrPositioning` tag.

### Supported Values

Centered	Specify for compatibility with industry standards such as PostScript Level 2
Cosited	Specify for compatibility with most digital video standards such as CCIR Recommendation 601-1.

Example:

```
tiffobj.setTag('YCbCrPositioning', Tiff.YCbCrPositioning.Centered)
```

## Methods

<code>close</code>	Close Tiff object
<code>computeStrip</code>	Index number of strip containing specified coordinate
<code>computeTile</code>	Index number of tile containing specified coordinates
<code>currentDirectory</code>	Index of current IFD
<code>getTag</code>	Value of specified tag
<code>getTagNames</code>	List of recognized TIFF tags
<code>getVersion</code>	LibTIFF library version
<code>isTiled</code>	Determine if tiled image
<code>lastDirectory</code>	Determine if current IFD is last in file
<code>nextDirectory</code>	Make next IFD current IFD

<code>numberOfStrips</code>	Total number of strips in image
<code>numberOfTiles</code>	Total number of tiles in image
<code>read</code>	Read entire image
<code>readEncodedStrip</code>	Read data from specified strip
<code>readEncodedTile</code>	Read data from specified tile
<code>readRGBAImage</code>	Read image using RGBA interface
<code>readRGBAStrip</code>	Read strip data using RGBA interface
<code>readRGBATile</code>	Read tile data using RGBA interface
<code>rewriteDirectory</code>	Write modified metadata to existing IFD
<code>setDirectory</code>	Make specified IFD current IFD
<code>setSubDirectory</code>	Make subIFD specified by byte offset current IFD
<code>setTag</code>	Set value of tag
<code>write</code>	Write entire image
<code>writeDirectory</code>	Create new IFD and make it current IFD
<code>writeEncodedStrip</code>	Write data to specified strip
<code>writeEncodedTile</code>	Write data to specified tile

## Examples

### Create New TIFF File Using `Tiff` object

Create a new file called `myfile.tif`. To run this example, your directory must be writable.

```
t = Tiff('myfile.tif', 'w');
```

Close the `Tiff` object.

```
t.close();
```

### **Specify Tiff object properties and describe alpha channel**

Create an array of data, `data`, that contains colormetric channels and an alpha channel.

```
rgb = imread('example.tif');
numrows = size(rgb,1);
numcols = size(rgb,2);
alpha = 255*ones([numrows numcols], 'uint8');
data = cat(3,rgb,alpha);
```

Create a Tiff object, `t`, and set the object properties. Set the value of the `ExtraSamples` tag because the data contains the alpha channel in addition to the colormetric channels.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.RGB);
t.setTag('Compression',Tiff.Compression.None);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',4);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ExtraSamples',Tiff.ExtraSamples.Unspecified);
t.setTag('ImageLength',numrows);
t.setTag('ImageWidth',numcols);
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write the data to the Tiff object.

```
t.write(data);
t.close();
```

### **Create YCbCr/JPEG image from RGB data**

Get RGB data.

# Tiff

---

```
rgb = imread('example.tif');
```

Create a Tiff object, `t`, and set the object properties. Specify RGB input data using the `JPEGColorMode` property.

```
t = Tiff('myfile.tif','w');
t.setTag('Photometric',Tiff.Photometric.YCbCr);
t.setTag('Compression',Tiff.Compression.JPEG);
t.setTag('YCbCrSubSampling',[2 2]);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',3);
t.setTag('SampleFormat',Tiff.SampleFormat.UInt);
t.setTag('ImageLength',size(rgb,1));
t.setTag('ImageWidth',size(rgb,2));
t.setTag('TileLength',32);
t.setTag('TileWidth',32);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
t.setTag('JPEGColorMode',Tiff.JPEGColorMode.RGB);
t.setTag('JPEGQuality',75);
```

Write the data to the Tiff object.

```
t.write(rgb);
t.close();
```

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose**

Create object to schedule execution of MATLAB commands

**Description**

Use a `timer` object to schedule the execution of MATLAB commands one or multiple times. If you schedule the timer to execute multiple times, you can define the time between executions and how to handle queuing conflicts.

The `timer` object uses callback functions to execute commands. Callback functions execute code during some event. For the `timer` object, you can specify the callback function as a function handle or as a string. If the callback function is a string, MATLAB evaluates it as executable code. The timer object supports callback functions when a timer starts (`StartFcn`), executes (`TimerFcn`), stops (`StopFcn`), or encounters an error (`ErrorFcn`).

---

**Note** The `timer` object is subject to the limitations of your hardware, operating system, and software. Avoid using timer objects for real-time applications.

---

**Construction**

`t = timer` creates an empty timer object to schedule execution of MATLAB commands. An error occurs if the timer starts and `TimerFcn` is not defined.

`t = timer(Name,Value)` creates a timer object with additional options that you specify using one or more `Name,Value` pair arguments.

**Input Arguments****Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

# timer

---

The argument name, `Name`, corresponds to a `timer` property name. In the constructor, the property values are specified using `Name, Value` pair arguments.

## **BusyMode**

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

<b>BusyMode Values</b>	<b>Behavior if Queue Empty</b>	<b>Behavior if Queue Not Empty</b>	<b>Notes</b>
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

## **ErrorFcn**

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls StopFcn.

**ExecutionMode**

String that defines how the timer object schedules timer events. When Running='on', ExecutionMode is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the Period property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

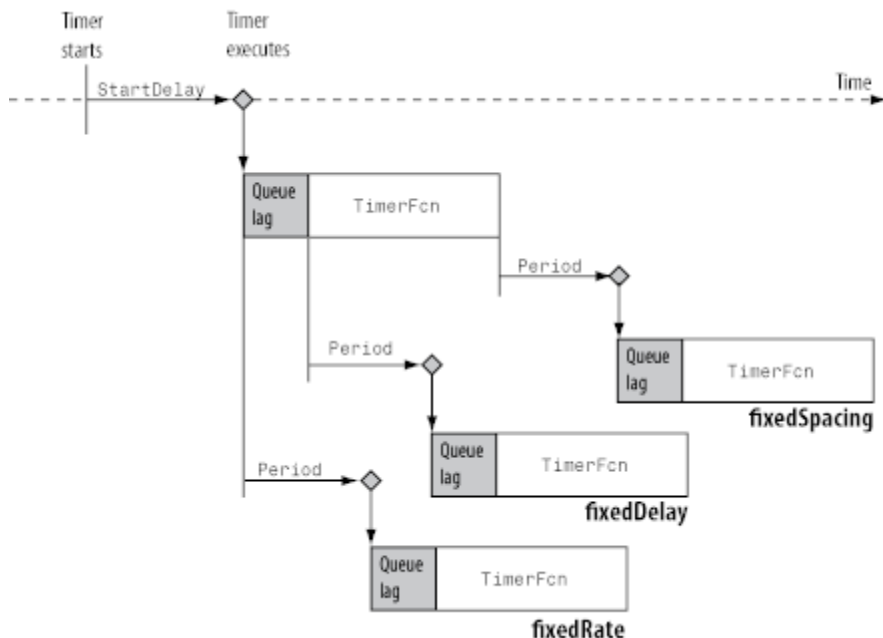

- 'singleShot' is the single execution mode for the timer class, and is the default value.

**singleShot**

# timer

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the Period property. The Period property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

## Name

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

**ObjectVisibility**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

**Period**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

**StartDelay**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

**StartFcn**

String, function handle, or cell array defining the function that executes when the timer starts.

**StopFcn**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer stop method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **Tag**

String that represents a label for the object.

## **TasksToExecute**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **TimerFcn**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

## **UserData**

Generic field for data that you want to add to the object.

## **Properties**

### **AveragePeriod**

Average time in seconds between `TimerFcn` executions since the timer started. Value is `NaN` until timer executes two timer callbacks.

**InstantPeriod**

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

**Running**

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

**TasksExecuted**

The number of times the timer called `TimerFcn` since the timer started.

**Type**

String that identifies the object type.

**Methods**

<code>delete</code>	Remove timer object from memory
<code>get</code>	Query property values for timer object
<code>isvalid</code>	Determine timer object validity
<code>set</code>	Set property values for timer object
<code>start</code>	Start timer object
<code>startat</code>	Schedule timer to fire at specified time
<code>stop</code>	Stop timer object
<code>timerfind</code>	Find timer object
<code>timerfindall</code>	Find timer object, regardless of visibility
<code>wait</code>	Block command prompt until timer stops running

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Display Message Using Timer

Display a message using an anonymous function as a callback function. It is important to note that the first two arguments the callback function passes are a handle to the timer object and an event structure. Even if the function doesn't use these arguments, the function definition requires them.

Wait 3 seconds, and then display the message '3 seconds have elapsed'.

```
t = timer;
t.StartDelay = 3;
t.TimerFcn = @(myTimerObj, thisEvent)disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Suppose the function does not require the timer or event object. Use the tilde (~) operator to ignore the inputs.

```
t.TimerFcn = @(~,~) disp('3 seconds have elapsed');
start(t)
```

```
3 seconds have elapsed
```

Delete the timer object.

```
delete(t)
```

### Execute Callback Function Multiple Times

Display the event and date/time output when the timer starts, fires, and stops. The timer callback function will be executed 3 times with 2 seconds between calls. The first two arguments the callback function passes are a handle to the timer object and an event structure. The event structure contains two fields: Type is a string that identifies the

type of event that caused the callback, and `Data` is a structure that contains a date time vector of when the event occurred.

```
t = timer;
t.StartFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
 datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.TimerFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
 datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.StopFcn = @(~,thisEvent)disp([thisEvent.Type ' executed '...
 datestr(thisEvent.Data.time,'dd-mmm-yyyy HH:MM:SS.FFF')]);
t.Period = 2;
t.TasksToExecute = 3;
t.ExecutionMode = 'fixedRate';
start(t)
```

```
StartFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:50.865
TimerFcn executed 14-Mar-2013 09:08:52.865
TimerFcn executed 14-Mar-2013 09:08:54.866
StopFcn executed 14-Mar-2013 09:08:54.869
```

Delete the timer object.

```
delete(t)
```

## Define Custom Callback Functions

Create a timer object to remind yourself to take 30-second ergonomic breaks every 10 minutes over the course of 8 hours.

Create a function in a file named `createErgoTimer.m` that returns a timer object. Have this file include three local functions to handle timer start, execute, and stop tasks.

```
function t = createErgoTimer()
secondsBreak = 30;
secondsBreakInterval = 600;
```

# timer

---

```
secondsPerHour = 60^2;
secondsWorkTime = 8*secondsPerHour;

t = timer;
t.UserData = secondsBreak;
t.StartFcn = @ergoTimerStart;
t.TimerFcn = @takeBreak;
t.StopFcn = @ergoTimerCleanup;
t.Period = secondsBreakInterval+secondsBreak;
t.StartDelay = t.Period-secondsBreak;
t.TasksToExecute = ceil(secondsWorkTime/t.Period);
t.ExecutionMode = 'fixedSpacing';
end
```

Using `StartDelay` allows the timer to start without directing you to take a break immediately. Set the execution mode to `'fixedSpacing'` so that 10 minutes and 30 seconds (`t.Period`) elapses after the completion of a `TimerFcn` execution. This allows you to stretch for 30 seconds before the start of the next 10 minute interval.

In the `createErgoTimer.m` file, add a local function to handle the tasks associated with starting the timer. By default, the `timer` object passes itself and event data to the callback function. The function disregards the event data.

```
function ergoTimerStart(mTimer,~)
secondsPerMinute = 60;
secondsPerHour = 60*secondsPerMinute;
str1 = 'Starting Ergonomic Break Timer. ';
str2 = sprintf('For the next %d hours you will be notified',...
 round(mTimer.TasksToExecute*(mTimer.Period + ...
 mTimer.UserData)/secondsPerHour));
str3 = sprintf(' to take a %d second break every %d minutes.',...
 mTimer.UserData, (mTimer.Period - ...
 mTimer.UserData)/secondsPerMinute);
disp([str1 str2 str3]);
end
```

Add a local function to handle the tasks associated with executing the timer. The `TimerFcn` callback should tell you to take a 30 second break.

```
function takeBreak(mTimer,~)
disp('Take a 30 second break.')
end
```

Add a local function to handle the tasks associated with stopping the timer.

```
function ergoTimerCleanup(mTimer,~)
disp('Stopping Ergonomic Break Timer. ');
delete(mTimer)
end
```

Deleting the timer object removes it from memory.

From the command line, call the `createErgoTimer` function to create and start a timer.

```
t = createErgoTimer;
start(t)
```

```
Starting Ergonomic Break Timer. For the next 8 hours you will be notified.
```

```
Every 10 minutes, you will be reminded to take a 30 second break.
```

```
Take a break.
```

You can leave the timer running for 8 hours or stop it manually. Recall that you included the task of deleting the timer from memory in the `StopFcn` callback.

```
stop(t)
```

```
Stopping Ergonomic Break Timer.
```

# timer

---

## Tips

- To force the execution of the callback functions in the event queue, include a call to the `drawnow` function in your code. The `drawnow` function flushes the event queue.

`function_handle`

## Concepts

- Timer Callback Functions
- “Handling Timer Queuing Conflicts”
- “Ignore Function Outputs”
- Property Attributes

<b>Purpose</b>	Remove timer object from memory
<b>Syntax</b>	<code>delete(t)</code>
<b>Description</b>	<p><code>delete(t)</code> removes the timer object, <code>t</code>, from memory. If <code>t</code> is an array of timer objects, <code>delete</code> removes all the objects from memory.</p> <p>When you delete a timer object, it becomes invalid and you cannot reuse it. If multiple references to a timer object exist in the workspace, deleting the timer object invalidates the remaining references. To remove invalid timer objects references from the workspace, use the <code>clear</code> command.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• Use the <code>isvalid</code> method to determine if a timer object exists in memory, but is not cleared from the workspace.</li><li>• Use the <code>timerfind</code> and <code>timerfindall</code> methods to return timer objects currently existing in memory. This approach is useful if the reference to the timer object is cleared from the workspace (using the <code>clear</code> command), but not deleted from memory.</li></ul>
<b>Input Arguments</b>	<p><b>t</b></p> <p>Object of class <code>timer</code>.</p>
<b>Examples</b>	<p><b>Delete a Timer</b></p> <p>Create and start a timer that generates a 10-by-10 array of random numbers.</p> <pre>t = timer('TimerFcn','rand(10);'); start(t)</pre> <p>Delete the timer from memory.</p> <pre>delete(t)</pre> <p>Call the <code>whos</code> function to see if a reference still exists in the workspace.</p>

# timer.delete

---

```
whos
```

Name	Size	Bytes	Class	Attributes
ans	10x10	800	double	
t	1x1	104	timer	

Try to restart the timer.

```
start(t)
```

```
Error using timer/start (line 27)
Invalid timer object. This object has been deleted and should be removed
```

The timer cannot be restarted.

Clear the timer object reference from the workspace.

```
clear t
```

## Delete Multiple Timers Using `timerfind`

Use `delete` with the `timerfind` method to remove all visible timers from memory. This is an alternative to deleting individual timers by variable name.

Create and start three timers that compute the sine, cosine and tangent of  $\pi/4$ .

```
t1 = timer('TimerFcn','sin(pi/4);');
t2 = timer('TimerFcn','cos(pi/4);');
t3 = timer('TimerFcn','tan(pi/4);');
```

Delete the timers from memory using `timerfind`. This removes all visible timer objects from memory.

```
delete(timerfind);
```

## See Also

[timer](#) | [isvalid](#) | [timerfind](#) | [timerfindall](#)

**Purpose** Query property values for timer object

**Syntax**

```
get(t)
V = get(t)
V = get(t,propName)
```

**Description** `get(t)` queries property values for timer object, `t`, and displays all property names and current values. `t` must be a scalar timer object.

`V = get(t)` queries property values for timer object, `t` and returns a structure, `V`, where each field name is the name of a property of `t` and each field contains the value of that property. If `t` is an M-by-1 vector of timer objects, `V` is an M-by-1 array of structures.

`V = get(t,propName)` returns the value, `V`, of the timer object property specified in `propName`. If `propNames` is a vector cell array of `N` property names, and `t` is a vector of `M` timer objects, `v` is an M-by-N cell array of property values.

**Input Arguments**

**t**  
Object of class `timer`.

**propName**

String enclosed in single quotation marks that specifies a `timer` property.

**Examples**      **Display All Properties of Timer**

```
t = timer;
get(t)

AveragePeriod: NaN
 BusyMode: 'drop'
 ErrorFcn: ''
ExecutionMode: 'singleShot'
```

```
InstantPeriod: NaN
 Name: 'timer-1'
ObjectVisibility: 'on'
 Period: 1
 Running: 'off'
StartDelay: 0
StartFcn: ''
StopFcn: ''
 Tag: ''
TasksExecuted: 0
TasksToExecute: Inf
TimerFcn: ''
 Type: 'timer'
UserData: []
```

Delete the timer from memory.

```
delete(t)
```

## **Obtain Properties for Array of Timers**

Create three timers.

```
t1 = timer;
t2 = timer;
t3 = timer;
```

Get properties of an array of timers.

```
V = get([t1,t2,t3])
```

```
V =
```

3x1 struct array with fields:

```
AveragePeriod
BusyMode
ErrorFcn
ExecutionMode
```

```
InstantPeriod
Name
ObjectVisibility
Period
Running
StartDelay
StartFcn
StopFcn
Tag
TasksExecuted
TasksToExecute
TimerFcn
Type
UserData
```

Delete the timers from memory.

```
delete([t1,t2,t3])
```

### **Obtain Single Property for Timer**

Create a timer and determine if it is running.

```
t = timer;
get(t,'Running')
```

```
ans =
```

```
off
```

Delete the timer from memory.

```
delete(t)
```

### **Obtain Specified Properties for Array of Timers**

Create three timers.

```
t1 = timer;
t2 = timer;
```

# timer.get

---

```
t3 = timer;
```

Obtain name, period, and running property values from the array of timers.

```
V = get([t1,t2,t3],{'Name','Running','Period'})
```

```
V =
```

```
 'timer-1' 'off' [1]
 'timer-2' 'off' [1]
 'timer-3' 'off' [1]
```

## Alternatives

You can also use dot notation can also be used to query timer object properties. For example, `t.Running` returns the same value as `get(t,'Running')`.

## See Also

[timer](#) | [set](#)

**Purpose** Determine timer object validity

**Syntax** `validCheck = isvalid(t)`

**Description** `validCheck = isvalid(t)` determines timer object validity and returns a logical array, `validCheck`, that contains a 0 where the elements of `t` are invalid timer objects and a 1 where the elements of `t` are valid timer objects.

An invalid timer object is an object that is deleted from memory using `delete` and cannot be reused. Use the `clear` command to remove an invalid timer object from the workspace.

**Tips**

- To return timer objects existing in memory, use the `timerfind` and `timerfindall` methods. This practice is useful if the reference to the timer object is cleared from the workspace (using the `clear` function), but the object has not been deleted from memory.

**Input Arguments**

`t`  
Object or array of objects of class `timer`

## Examples

### Check Timer Object Validity

Create a timer object. While this timer object is valid, it cannot start because a `TimerFcn` is not defined.

```
t = timer;
out = isvalid(t)
```

```
out =
```

```
 1
```

Delete the timer object, making it invalid.

```
delete(t)
out1 = isvalid(t)
```

# timer.isvalid

---

```
out1 =
0
```

## See Also

`timer` | `delete` | `timerfind` | `timerfindall`

**Purpose**

Set property values for timer object

**Syntax**

```
set(t)
propStruct = set(t)

set(t,Name)
propCell = set(t,Name)
set(t,Name,Value)
set(t,S)
set(t,PN,PV)
```

**Description**

`set(t)` displays the property names and their possible values for all configurable properties of timer object `t`.

`propStruct = set(t)` returns the values in a struct.

`set(t,Name)` displays the possible values for the specified property, `Name`, of timer object, `t`.

`propCell = set(t,Name)` returns the values in a cell.

`set(t,Name,Value)` sets the properties specified by one or more `Name,Value` pair arguments. `t` can be a single timer object or a vector of timer objects, in which case `set` configures the property values for all timer objects, `t`.

`set(t,S)` configures the properties of `t`, with the values specified in `S`, where `S` is a structure whose field names are object property names.

`set(t,PN,PV)` configures the properties specified in the cell array of strings, `PN`, to the corresponding values in the cell array `PV`, for the timer object `t`.

## Input Arguments

**t**

Object of class `timer`.

**S**

Structure whose field names are `timer` property names.

**PN,PV**

Cell array of strings, `PN`, and corresponding cell array of values, `PV`. The cell array of `PN` must be a 1-by-`N` or `N`-by-1 array. If `t` is an array of `timer` objects, `PV` can be an `M`-by-`N` cell array, where `M` is equal to the length of `t` and `N` is equal to the length of `PN`. In this case, each `timer` object is updated with a different set of values for the list of property names contained in `PN`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

<b>BusyMode Values</b>	<b>Behavior if Queue Empty</b>	<b>Behavior if Queue Not Empty</b>	<b>Notes</b>
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

#### **'ErrorFcn'**

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

#### **'ExecutionMode'**

String that defines how the timer object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

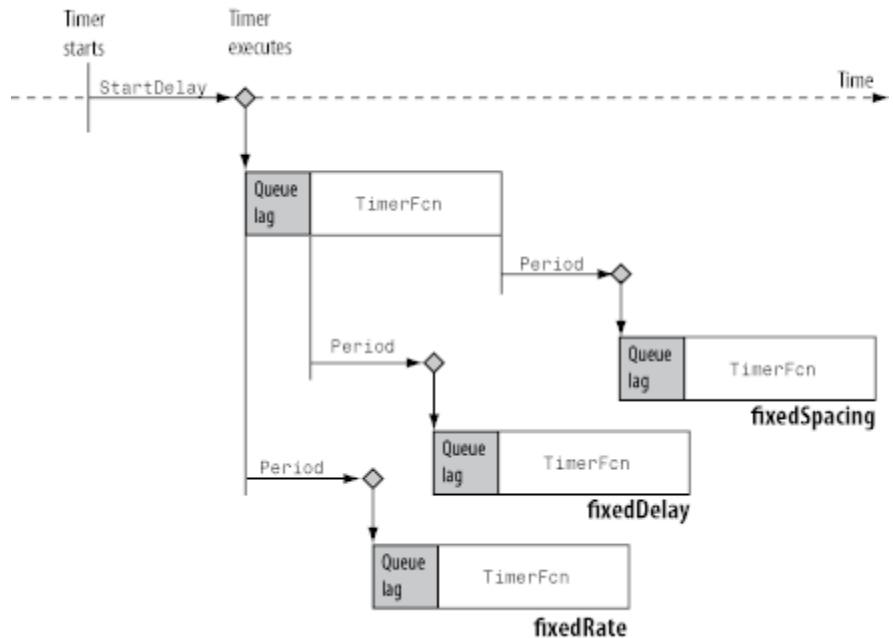

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the `timer` class, and is the default value.

### singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the `Period` property. The `Period` property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

## 'Name'

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## 'ObjectVisibility'

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the

timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

## **'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

## **'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

## **'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

## **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer stop method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.

- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

**'Tag'**

String that represents a label for the object.

**'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

**'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

**'UserData'**

Generic field for data that you want to add to the object.

## Output Arguments

**propStruct**

Configurable properties of `t`, returned as a structure. The field names of `propStruct` are the property names of `t`, and the associated values of `propStruct` are cell arrays of the possible property values. If the property in `t` does not have a finite set of possible values, the property value in `propStruct` is an empty cell array.

**propCell**

Possible values of a given property name, returned as cell array of strings. If the property does not have a finite set of possible string values, set returns an empty cell array.

## Examples

### Display Configurable Timer Object Properties

Instantiate a timer object and call the `set` method.

```
t = timer;
set(t)
```

```
BusyMode: [{drop} | queue | error]
ErrorFcn: string -or- function handle -or- cell array
ExecutionMode: [{singleShot} | fixedSpacing | fixedDelay | fixedRate
Name
ObjectVisibility: [{on} | off]
Period
StartDelay
StartFcn: string -or- function handle -or- cell array
StopFcn: string -or- function handle -or- cell array
Tag
TasksToExecute
TimerFcn: string -or- function handle -or- cell array
UserData
```

Some of the timer properties, such as `Running`, are not displayed because they are read only.

Use the `set` method to output a structure.

```
out = set(t)
```

```
out =
```

```
 BusyMode: {3x1 cell}
 ErrorFcn: {}
ExecutionMode: {4x1 cell}
 Name: {}
```

```
ObjectVisibility: {2x1 cell}
 Period: {}
 StartDelay: {}
 StartFcn: {}
 StopFcn: {}
 Tag: {}
TasksToExecute: {}
TimerFcn: {}
UserData: {}
```

Delete the timer object from memory.

```
delete(t)
```

### Display Possible Property Values

Instantiate a timer object and display possible values for the `BusyMode` property.

```
t = timer;
set(t, 'BusyMode')
```

```
[{drop} | queue | error]
```

The output shows the three possible values for `BusyMode`. The default value, `drop`, is indicated by curly braces.

Display the possible values for `ErrorFcn`.

```
set(t, 'ErrorFcn')
```

```
string -or- function handle -or- cell array
```

A description of the possible values is displayed since `ErrorFcn` does not have a set list of possible values.

Output the possible property values.

```
out1 = set(t, 'BusyMode')
out2 = set(t, 'ErrorFcn')
```

```
out1 =

 'drop'
 'queue'
 'error'
```

```
out2 =

 {}
```

While `set(t, 'ErrorFcn')` displays a description of the possible values, `out2 = set(t, 'ErrorFcn')` returns an empty cell.

Delete the timer from memory.

```
delete(t)
```

## Set Timer Object Property

Instantiate a timer object and make the object invisible. Display the object's visibility and delete the object.

```
t = timer;
set(t, 'ObjectVisibility', 'off');
get(t, 'ObjectVisibility')
delete(t)
```

```
ans =
```

```
off
```

## Set Timer Object Properties Using Structure

Construct a structure to modify several timer object properties.

```
s.BusyMode = 'queue';
s.ExecutionMode = 'fixedDelay';
s.ObjectVisibility = 'off'
```

```
s =
 BusyMode: 'queue'
 ExecutionMode: 'fixedDelay'
 ObjectVisibility: 'off'
```

Create a timer, display the properties in s, modify the timer, display the new values of the properties, and delete the timer.

```
t = timer;
get(t,{'BusyMode','ExecutionMode','ObjectVisibility'})
set(t,s);
get(t,{'BusyMode','ExecutionMode','ObjectVisibility'})
delete(t)
```

```
ans =
 'drop' 'singleShot' 'on'
```

```
ans =
 'queue' 'fixedDelay' 'off'
```

### Set Timer Objects Using Cell Arrays

Create a cell array of properties to modify, and a cell array of the values of the corresponding properties. Instantiate a timer, and display the initial values of the properties in the property name cell array, nameArr.

```
nameArr = {'BusyMode','ExecutionMode','Period'};
valArr = {'queue','fixedDelay',3};
t = timer;
get(t,nameArr)
```

```
ans =
 'drop' 'singleShot' [1]
```

## timer.set

---

Modify the timer object and display the new property values. Delete the timer.

```
set(t,nameArr,valArr)
get(t,nameArr)
delete(t)

ans =

 'queue' 'fixedDelay' [3]
```

Instantiate an array of three timers. Create a new property name cell array to modify the BusyMode, ExecutionMode, and UserData properties. Display the initial values of the properties for each timer.

```
tArr = [timer timer timer];
nameArr = {'BusyMode','ExecutionMode','UserData'};
get(tArr,nameArr)

ans =

 'drop' 'singleShot' []
 'drop' 'singleShot' []
 'drop' 'singleShot' []
```

Assign each property a different value in each timer. Create a cell array containing the new values. Each row indicates the values for the properties in the corresponding timer.

```
valArr = {'queue','fixedDelay',3;...
 'error','fixedSpacing',42;...
 'drop','fixedRate','hello'};
```

Modify the timer object properties and display the updated values.

```
set(tArr,nameArr,valArr)
get(tArr,nameArr)

ans =
```

```
'queue' 'fixedDelay' [3]
'error' 'fixedSpacing' [42]
'drop' 'fixedRate' 'hello'
```

Delete the timers from memory.

```
delete(tArr)
```

**Alternatives**

You can also use dot notation to set timer object properties. For example, `t.ObjectVisibility = 'off'` sets the property to the same value as `set(t, 'ObjectVisibility', 'off')`.

**See Also**

[timer | get](#)

# timer.start

---

**Purpose** Start timer object

**Syntax** start(t)

**Description** start(t) starts the timer object, t. If t is an array of timer objects, start starts all the timers.

The start method sets the Running property of the timer object to 'on', executes the StartFcn callback, and initiates TimerFcn callback .

**Input Arguments** t  
Object of class timer.

## Examples Start Timer

Create and start a timer that displays the message 'timer started.' as the StartFcn callback and generates a random number as the TimerFcn callback. Delete the timer.

```
t = timer('StartFcn',@(~,~)disp('timer started.'),'TimerFcn',@(~,~)disp(rand))
start(t)
delete(t)
```

```
timer started.
 0.9706
```

Your output from rand will vary.

## Start Several Timers

Create and start three timers that displays a message for the StartFcn callbacks and compute the sine, cosine, and tangent of  $\pi/4$  as the TimerFcn callbacks. Delete the timers.

```
t1 = timer('StartFcn',@(~,~)disp('t1 started.'),'TimerFcn',@(~,~)sin(pi/4))
t2 = timer('StartFcn',@(~,~)disp('t2 started.'),'TimerFcn',@(~,~)cos(pi/4))
t3 = timer('StartFcn',@(~,~)disp('t3 started.'),'TimerFcn',@(~,~)tan(pi/4))
start([t1 t2 t3]);
```

```
delete([t1 t2 t3]);
```

```
t1 started.
t2 started.
t3 started.
```

## See Also

timer | delete | stop | startat

# timer.startat

---

**Purpose** Schedule timer to fire at specified time

**Syntax**  
`startat(t, firingTime)`  
`startat(t, Y, M, D)`  
`startat(t, Y, M, D, H, MI, S)`

**Description** `startat(t, firingTime)` schedules timer, `t`, to fire at specified time, `firingTime`. A timer fires by executing the callback function, `timerFcn`. `firingTime` must be within 25 days of the current time.

- If `t` is an array of timer objects and `firingTime` is a scalar, `startat` sets all the timers to fire at the specified time.
- If `t` is an array of timer objects and `firingTime` is an array of the same size as `t`, `startat` sets each timer to fire at the corresponding time.

`startat(t, Y, M, D)` starts the timer and schedules execution of `TimerFcn` at the year (Y), month (M), and day (D) specified.

`startat(t, Y, M, D, H, MI, S)` also specifies the hour (H), minute (MI), and second (S) specified.

- Algorithms**
- The `startat` method specifies when the timer object executes the `TimerFcn` callback, not when the timer starts running. The timer starts running with the call to the `startat` method.
  - Based on the specified time, `startat` computes and sets the required `StartDelay` property of the timer object, `t`. Additionally, it sets the `Running` property of the timer object to 'on', and executes the `StartFcn` callback.
  - `startat` modifies the timer object's `startDelay` property. As such, `startat` overrides specified values of the timer's `startDelay` property.

**Input Arguments****t**

Object of class `timer`.

**firingTime**

Time at which the timer object is to fire, specified as a serial date number, date string, or a date vector. `firingTime` can be a single date or an array of dates with the same number of rows as timer objects in `t`.

- A serial date number indicates the number of days that have elapsed since 1-Jan-0000 (starting at 1). See `datenum` for additional information about serial date numbers.
- To specify date strings, use the following date formats defined by the `datestr` function: 0, 1, 2, 6, 13, 14, 15, 16, or 23. These numeric identifiers correspond to formats defined by the `formatOut` property of the `datestr` function. Date strings with two-character years are interpreted to be within the 100 years centered on the current year.
- Date vectors are specified as an `m-by-6` or `m-by-3` matrix containing `m` full or partial date vectors, respectively. A full date vector has six elements indicating year, month, day, hour, minute, and second, in that order. A partial date vector has three elements indicating year, month, and day, in that order.

**Y,M,D**

Time at which the timer object is to fire, specified as numbers indicating the year (Y), month (M), and day (D). Month values less than 1 are set to 1; other arguments can wrap and have negative values.

**Y,M,D,H,MI,S**

Time at which the timer object is to fire, specified as numbers indicating the year (Y), month (M), day (D), hour (H), minute (MI), and second (S) specified. Month values less than 1 are set to 1; other arguments can wrap and have negative values.

## Examples

### Start Timer in 2 Seconds

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
 'StartFcn', @(~,~)disp('Started.'));
```

Set the timer to fire 2 seconds from the present time using a serial date. A serial date is specified in days.

```
two = 2/(60^2*24); % two seconds in serial time
fTime = now + two
startat(t,fTime);
```

```
fTime =

 7.3527e+05
```

```
Started.
Fired.
```

Wait for the timer to fire, and then delete the timer.

```
delete(t)
```

### Start Timer Using Year, Month, Day

Create a timer that displays messages at start time and firing time.

```
t = timer('TimerFcn', @(~,~)disp('Fired.'), ...
 'StartFcn', @(~,~)disp('Started.'));
```

Schedule the timer to start 2 days from present at 00:00:00

```
[Y, M, D, H, MI, S] = datevec(now+2);
startat(t,Y,M,D)
```

```
Started.
```

Manually stop and delete the timer.

stop(t)  
delete(t)

## See Also

timer | delete | start | stop

## Concepts

- “Carryover in Date Vectors and Strings”

# timer.stop

---

**Purpose** Stop timer object

**Syntax** stop(t)

**Description** stop(t) stops the timer object, t. If t is an array of timer objects, the stop method stops each timer.

The stop method sets the Running property of the timer object to 'off' and executes the StopFcn callback .

**Tips**

- Use the stop method to stop a timer manually. The timer automatically stops when the TimerFcn callback executes the number of times specified by the ExecutionMode and TasksToExecute properties or when an error occurs while executing a TimerFcn callback.

**Input Arguments**

**t**  
Object of class timer.

## Examples

### Stop Timer

Create a timer object that generates 100 random numbers and executes one million times. Define a StopFcn callback that displays the message 'Timer has stopped.' Start the timer and verify the timer is running

```
t = timer('TimerFcn','rand(100,1);',...
 'ExecutionMode','fixedSpacing','TasksToExecute',1e6,...
 'StopFcn','disp(''Timer has stopped.'')');
start(t)
t.Running

ans =

on
```

Manually stop the timer and verify it is no longer running. Delete the timer.

```
stop(t)
t.Running
delete(t)
```

```
Timer has stopped.
```

```
ans =
```

```
off
```

## See Also

```
timer | delete | start | startat
```

# timer.timerfind

---

## Purpose

Find timer object

## Syntax

```
out = timerfind
out = timerfind(Name,Value)
out = timerfind(t,Name,Value)
out = timerfind(S)
```

## Description

`out = timerfind` finds the “visible timer objects” on page 1-7130 and returns an array, `out`.

`out = timerfind(Name,Value)` finds “visible timer objects” on page 1-7130 with property values matching those passed as `Name, Value` pair arguments and returns an array, `out`.

`out = timerfind(t,Name,Value)` matches `Name, Value` pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfind(S)` matches property values defined in the structure, `S`, and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

## Tips

- `timerfind` only finds “visible timer objects” on page 1-7130. Visible timer objects are those that are in memory and have the `ObjectVisibility` property set to 'on'. To find objects that are hidden, but still valid, use `timerfindall`.

## Input Arguments

**t**

Array of objects of class `timer`

**S**

Structure with field names corresponding to `timer` object property names. Field values are the corresponding property values.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

BusyMode Values	Behavior if Queue Empty	Behavior if Queue Not Empty	Notes
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

# timer.timerfind

---

## 'ErrorFcn'

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

## 'ExecutionMode'

String that defines how the timer object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

Execution Mode	Time Period Start Point
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

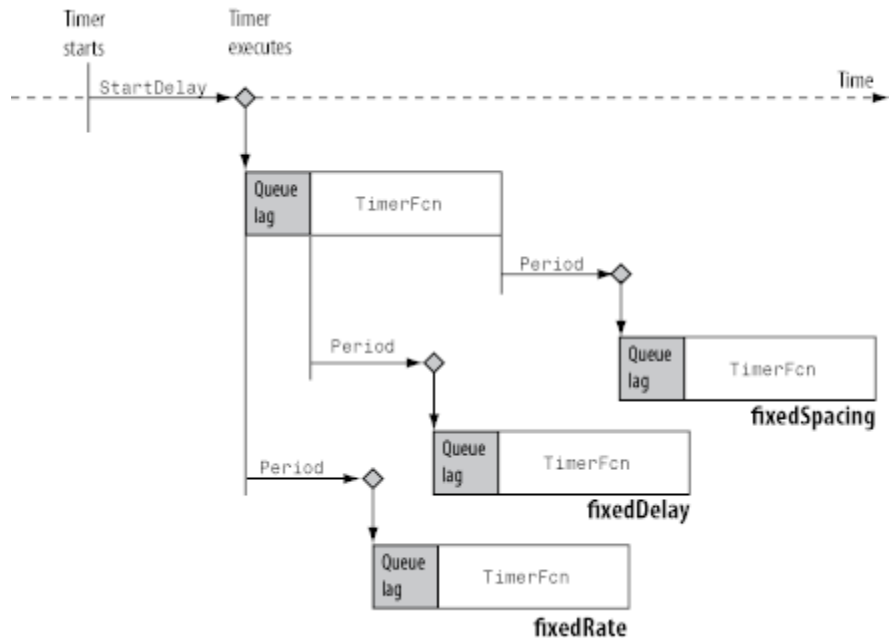

- 'singleShot' is the single execution mode for the timer class, and is the default value.

## singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the Period property. The Period property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

# timer.timerfind

---

## **'Name'**

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## **'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

## **'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

## **'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

## **'StartFcn'**

String, function handle, or cell array defining the function that executes when the timer starts.

## **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer `stop` method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

## **'UserData'**

# timer.timerfind

---

Generic field for data that you want to add to the object.

## Read Only Name-Value Pair Arguments

### AveragePeriod

Average time in seconds between `TimerFcn` executions since the timer started. Value is NaN until timer executes two timer callbacks.

### InstantPeriod

The time in seconds between the last two executions of `TimerFcn`. Value is NaN until timer executes two timer callbacks.

### Running

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

### TasksExecuted

The number of times the timer called `TimerFcn` since the timer started.

### Type

String that identifies the object type.

## Definitions

### visible timer objects

*Visible timer objects* are timer objects that are in memory and have the `ObjectVisibility` property set to 'on'.

## Examples

### Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress','UserData','Monday');
t2 = timer('Tag', 'displayProgress','UserData','Monday');
timerArr = [timer('Tag', 'broadcastProgress','UserData','Tuesday');
 timer('Tag', 'displayProgress','UserData','Tuesday');
 timer('Tag', 'displayProgress','UserData','Wednesday');];
```

Find all the timers in memory.

```
out1 = timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	timer-4
5	singleShot	1	''	timer-5

Find only those timers in memory that have the string value, 'displayProgress', as the Tag property.

```
out2 = timerfind('Tag','displayProgress')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-2
2	singleShot	1	''	timer-4
3	singleShot	1	''	timer-5

Limit the search for timers with the string value, 'displayProgress', as the Tag property to timer objects in timerArr.

```
out3 = timerfind(timerArr,'Tag','displayProgress')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-4
2	singleShot	1	''	timer-5

Define a struct containing the Tag and UserData properties of interest.

# timer.timerfind

---

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')

searchStruct =

 Tag: 'broadcastProgress'
 UserData: 'Monday'
```

Use the struct as the search criteria to find timer objects in memory.

```
out4 = timerfind(searchStruct)
```

```
Timer Object: timer-1

Timer Settings
 ExecutionMode: singleShot
 Period: 1
 BusyMode: drop
 Running: off

Callbacks
 TimerFcn: ''
 ErrorFcn: ''
 StartFcn: ''
 StopFcn: ''
```

Delete the timer objects.

```
delete(t1); delete(t2); delete(timerArr)
```

## Delete Timer by Name

Simulate having existing timers in memory by creating an array of timers. Create a new timer with a custom name. List all visible timers.

```
existingTimers = [timer timer timer];

myTimerName = 'myTimer';
anotherTimer = timer('Name',myTimerName);
```

```
timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3
4	singleShot	1	''	myTimer

Delete the specified timer and list all visible timers.

```
delete(timerfind('Name',myTimerName));
timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1
2	singleShot	1	''	timer-2
3	singleShot	1	''	timer-3

Delete all visible timers from memory.

```
delete(timerfind)
```

## Find Valid Timer Objects Cleared from Workspace

Use `timerfind` to find 'lost' timer object references. References are lost when you clear the timer object from the workspace, but do not delete it from memory.

Create two timer objects. Since the callback function does not require the timer or event object, you can use the tilde (~) operator to ignore the inputs in the function handle.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
whos
```

# timer.timerfind

---

Name	Size	Bytes	Class	Attributes
t1	1x1	104	timer	
t2	1x1	104	timer	

Clear one of the timer objects from the workspace. To actually remove the timer from memory, you need to both clear it and delete it.

```
clear t1
whos
```

Name	Size	Bytes	Class	Attributes
t2	1x1	104	timer	

Try to delete the timer, t1.

```
delete(t1)
```

```
Undefined function or variable 't1'.
```

The timer, t1, can not be removed from memory using delete because its reference has been cleared.

Find valid timer objects in memory.

```
out = timerfind
```

```
Timer Object Array
```

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1
2	singleShot	1	1x1 function_handle	arraytimer-2

Since two timers were found, determine which timer does not exist in the workspace.

```
out ~= t2
```

```
ans =

 1 0
```

The first timer object in `out` is not equal to `t2`. This was previously `t1`. It is reassigned to `t1`. Since it is still valid, the timer can be started.

```
t1 = out(1);
start(t1);
```

```
Timer 1 Fired!
```

Delete timer objects. `timerfind` provides a way of accessing timer objects in memory. It does not copy the objects; therefore you do not need to delete `out` from memory. To verify, use `timerfind`.

```
delete(t1); delete(t2);
timerfind
```

```
ans =

 []
```

## Delete All Timer Objects in Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Clear two timers from the workspace.

```
clear t2 t3
```

Pass `timerfind` to `delete` to remove all timer objects from memory, whether or not they exist in the workspace.

# timer.timerfind

---

```
delete(timerfind)
timerfind
```

```
ans =
```

```
 []
```

## See Also

timer | delete | timerfindall

**Purpose** Find timer object, regardless of visibility

**Syntax**

```
out = timerfindall
out = timerfindall(Name,Value)
out = timerfindall(t,Name,Value)
out = timerfindall(S)
```

**Description** `out = timerfindall` finds timer objects existing in memory, regardless of visibility and returns an array, `out`. Use the `ObjectVisibility` property to set the object's visibility.

`out = timerfindall(Name,Value)` finds timer objects existing in memory, regardless of visibility whose property values match those passed as `Name,Value` pair arguments and returns an array, `out`.

`out = timerfindall(t,Name,Value)` matches `Name,Value` pair arguments to the timer objects listed in `t`, where `t` can be an array of timer objects, and returns an array, `out`.

`out = timerfindall(S)` matches property values defined in the structure, `S` and returns an array, `out`. The field names of `S` are timer object property names and the field values are the corresponding property values.

**Tips**

- `timerfindall` finds timer objects in memory, regardless of the value of the `ObjectVisibility` property. To limit the search to objects with `ObjectVisibility` set to 'on', use `timerfind`.

**Input Arguments**

**t**  
Array of objects of class `timer`.

**S**  
Structure with field names corresponding to timer object property names. Field values are the corresponding property values.

# timer.timerfindall

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

## 'BusyMode'

String that indicates action taken when a timer has to execute `TimerFcn` before the completion of previous execution of the `TimerFcn`. When `Running='on'`, `BusyMode` is read only. This table summarizes the busy modes.

<b>BusyMode Values</b>	<b>Behavior if Queue Empty</b>	<b>Behavior if Queue Not Empty</b>	<b>Notes</b>
'drop'	Adds task to queue	Drops task	Possible skipping of <code>TimerFcn</code>
'error'	Adds task to queue	Completes task; throws error specified by <code>ErrorFcn</code> ; stops timer	Stops timer after completing task in execution queue
'queue'	Adds task to queue	Waits for queue to clear, and then enters task in queue	Adjusts <code>Period</code> property to manage tasks in execution queue

See “Handling Timer Queuing Conflicts” for more information.

**Default:** 'drop'

**'ErrorFcn'**

String, function handle, or cell array defining the function that the timer executes when an error occurs. If there is an error, this function executes, and then calls `StopFcn`.

**'ExecutionMode'**

String that defines how the `timer` object schedules timer events. When `Running='on'`, `ExecutionMode` is read only. This table summarizes the execution modes.

<b>Execution Mode</b>	<b>Time Period Start Point</b>
'singleShot'	In this mode, the timer callback function is only executed once. Therefore, the <code>Period</code> property has no effect. This is the default execution mode.
'fixedRate'	Starts immediately after the timer callback function is added to the MATLAB execution queue
'fixedDelay'	Starts when the timer function callback restarts execution after a time lag due to delays in the MATLAB execution queue
'fixedSpacing'	Starts when the timer callback function finishes executing.

- 'singleShot' is the single execution mode for the timer class, and is the default value.

# timer.timerfindall

## singleShot

- 'fixedDelay', 'fixedRate', and 'fixedSpacing' are the three supported multiexecution modes. These modes define the starting point of the Period property. The Period property specifies the amount of time between executions, which remains the same. Only the point at which execution begins is different.

**Default:** 'singleShot'

## **'Name'**

String representing the timer name.

**Default:** 'timer-*i*', where *i* is a number indicating the *i*th timer object created this session. To reset *i* to 1, execute the `clear classes` command.

## **'ObjectVisibility'**

String with possible values of 'on' or 'off', that provides a way for you to discourage end-user access to the timer objects your application creates. The `timerfind` function does not return an object whose `ObjectVisibility` property is set to 'off'. Objects that are not visible are still valid. To retrieve a list of all the timer objects in memory, including the invisible ones, use the `timerfindall` function.

**Default:** 'on'

## **'Period'**

Number greater than 0.001 that specifies the delay, in seconds, between executions of `TimerFcn`. For the timer to use `Period`, you must set `ExecutionMode` and `TasksToExecute` to schedule multiple timer object callback events.

**Default:** 1.0

## **'StartDelay'**

Number greater than or equal to 0 that specifies the delay, in seconds, between the start of the timer and the first execution of the function specified in `TimerFcn`. When `Running = 'on'`, `StartDelay` is read only.

**Default:** 0

## **'StartFcn'**

# timer.timerfindall

---

String, function handle, or cell array defining the function that executes when the timer starts.

## **'StopFcn'**

String, function handle, or cell array defining the function that executes when the timer stops. The timer stops when

- You call the timer stop method.
- The timer finishes executing `TimerFcn`. In other words, the value of `TasksExecuted` reaches the limit set by `TasksToExecute`.
- An error occurs. The `ErrorFcn` callback is called first, followed by the `StopFcn` callback.

You can use `StopFcn` to define clean up actions, such as deleting the timer object from memory.

## **'Tag'**

String that represents a label for the object.

## **'TasksToExecute'**

Number greater than 0, indicating the number of times the timer object is to execute the `TimerFcn` callback. Use the `TasksToExecute` property to set the number of executions. To use `TasksToExecute`, you must set `ExecutionMode` to schedule multiple timer callback events.

**Default:** `Inf`

## **'TimerFcn'**

String, function handle, or cell array defining the timer callback function. You must define this property before you can start the timer.

## **'UserData'**

Generic field for data that you want to add to the object.

## Read Only Name-Value Pair Arguments

### AveragePeriod

Average time in seconds between TimerFcn executions since the timer started. Value is NaN until timer executes two timer callbacks.

### InstantPeriod

The time in seconds between the last two executions of TimerFcn. Value is NaN until timer executes two timer callbacks.

### Running

String defined as 'off' or 'on', indicating whether the timer is currently executing callback functions.

### TasksExecuted

The number of times the timer called TimerFcn since the timer started.

### Type

String that identifies the object type.

## Examples

### Find and Delete All Timers From Memory

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers t2 and t4 to be invisible.

```
t2.ObjectVisibility = 'off';
t4.ObjectVisibility = 'off';
```

# timer.timerfindall

---

Clear timers t1 and t2 from the workspace.

```
clear t1 t2
whos
```

Name	Size	Bytes	Class	Attributes
t3	1x1	104	timer	
t4	1x1	104	timer	

Find all visible timers in memory.

```
timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1
2	singleShot	1	1x1 function_handle	arraytimer-3

timerfind finds only timers t1 and t2, since they are visible. Timer t2 is still valid and in memory even though it was cleared from the workspace

Find all timers in memory.

```
timerfindall
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle	arraytimer-1
2	singleShot	1	1x1 function_handle	arraytimer-2
3	singleShot	1	1x1 function_handle	arraytimer-3
4	singleShot	1	1x1 function_handle	arraytimer-4

timerfindall finds all four valid timers in memory even though t2 and t4 are invisible and t1 and t2 were cleared from the workspace.

Delete all timers from memory.

```
delete(timerfindall)
```

## Find Timer Objects Existing in Memory

Create several individual timers and an array of timers.

```
t1 = timer('Tag', 'broadcastProgress', 'UserData', 'Monday');
t2 = timer('Tag', 'displayProgress', 'UserData', 'Monday');
timerArr = [timer('Tag', 'broadcastProgress', 'UserData', 'Tuesday');
 timer('Tag', 'displayProgress', 'UserData', 'Tuesday');
 timer('Tag', 'displayProgress', 'UserData', 'Wednesday')];
```

Make timer t1 and timerArr(2) invisible.

```
t1.ObjectVisibility = 'off';
timerArr(2).ObjectVisibility = 'off';
```

Find all the timers in memory using timerfind.

```
out1 = timerfind
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-2
2	singleShot	1	''	timer-3
3	singleShot	1	''	timer-5

timerfind does not find the hidden timers.

Find all the timers in memory using timerfindall.

```
out2 = timerfindall
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	''	timer-1

# timer.timerfindall

---

```
2 singleShot 1 '' timer-2
3 singleShot 1 '' timer-3
4 singleShot 1 '' timer-4
5 singleShot 1 '' timer-5
```

timerfindall finds all timers, even the invisible ones.

Find only those timers in memory that have the string value, 'displayProgress', as the Tag property.

```
out3 = timerfindall('Tag','displayProgress')
```

Timer Object Array

```
Index: ExecutionMode: Period: TimerFcn: Name:
1 singleShot 1 '' timer-2
2 singleShot 1 '' timer-4
3 singleShot 1 '' timer-5
```

Limit the search for timers that have the string value, 'displayProgress', as the Tag property to timer objects in timerArr.

```
out4 = timerfindall(timerArr,'Tag','displayProgress')
```

Timer Object Array

```
Index: ExecutionMode: Period: TimerFcn: Name:
1 singleShot 1 '' timer-4
2 singleShot 1 '' timer-5
```

Define a struct containing the Tag and UserData properties of interest.

```
searchStruct = struct('Tag','broadcastProgress','UserData','Monday')
```

```
searchStruct =
```

```
Tag: 'broadcastProgress'
UserData: 'Monday'
```

Use the struct as the search criteria to find timer objects in memory.

```
out5 = timerfindall(searchStruct)
```

```
Timer Object: timer-1
```

```
Timer Settings
```

```
 ExecutionMode: singleShot
```

```
 Period: 1
```

```
 BusyMode: drop
```

```
 Running: off
```

```
Callbacks
```

```
 TimerFcn: ''
```

```
 ErrorFcn: ''
```

```
 StartFcn: ''
```

```
 StopFcn: ''
```

Delete the timer objects.

```
delete(timerfindall)
```

## Find Invisible Timers

Create four timer objects.

```
t1 = timer('TimerFcn',@(~,~)disp('Timer 1 Fired!'));
```

```
t2 = timer('TimerFcn',@(~,~)disp('Timer 2 Fired!'));
```

```
t3 = timer('TimerFcn',@(~,~)disp('Timer 3 Fired!'));
```

```
t4 = timer('TimerFcn',@(~,~)disp('Timer 4 Fired!'));
```

Set timers t2 and t4 to be invisible, and clear timers t1 and t2 from the workspace.

```
t2.ObjectVisibility = 'off';
```

```
t4.ObjectVisibility = 'off';
```

```
clear t1 t2;
```

```
whos
```

# timer.timerfindall

---

Name	Size	Bytes	Class	Attributes
t3	1x1	104	timer	
t4	1x1	104	timer	

Find all valid invisible timers.

```
out = timerfindall('ObjectVisibility','off')
```

Timer Object Array

Index:	ExecutionMode:	Period:	TimerFcn:	Name:
1	singleShot	1	1x1 function_handle array	timer-2
2	singleShot	1	1x1 function_handle array	timer-4

Both valid invisible timers were found by `timerfindall`, regardless of whether they were in the workspace.

`timer` | `delete` | `timerfind`

<b>Purpose</b>	Block command prompt until timer stops running
<b>Syntax</b>	<code>wait(t)</code>
<b>Description</b>	<p><code>wait(t)</code> blocks the command prompt until timer, <code>t</code>, stops running. If <code>t</code> is an array of timer objects, <code>wait</code> blocks the MATLAB command line until each timer in <code>t</code> has stopped running.</p> <p>To block the command line, the timer object must first start via <code>start</code> or <code>startat</code> before calling the <code>wait</code> method. If the timer is not running, <code>wait</code> returns immediately.</p>
<b>Input Arguments</b>	<p><b>t</b></p> <p>Array of timer objects</p>

## Examples

### Block Command Prompt While Timer Runs

Create a timer that waits 10 seconds, and then displays a message. Start the timer and wait for it to finish.

```
T = timer('TimerFcn',@(~,~)disp('Fired.'), 'StartDelay',10);
start(T);
```

```
Fired.
```

Notice that after the timer starts, the MATLAB prompt returns.

Start the timer and use the `wait` method to block anyone from entering commands at the MATLAB command line. You must start the timer before calling the `wait` command.

```
start(T);
wait(T);
```

```
Fired.
```

Notice that after the timer starts, the MATLAB prompt disappears until the timer stops.

# timer.wait

---

Delete the timer.

```
delete(T)
```

[mtimes](#)

**Purpose**

Add title to current axes

**Syntax**

```
title(str)
title(str,Name,Value)

title(axes_handle, ___)

h = title(___)
```

**Description**

`title(str)` adds the title consisting of a string, `str`, at the top and in the center of the current axes. Each axes graphics object has one predefined title.

`title(str,Name,Value)` additionally specifies the title properties using one or more `Name,Value` pair arguments.

`title(axes_handle, ___ )` adds the title to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a title. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = title( ___ )` returns the handle to the text object used as the title. The handle is useful when making future modifications to the title.

**Input Arguments****str - Text to display as title**

string

Text to display as a title, specified as a string. You also can specify the name of a function that returns a string.

**Example:** 'myTitle'

**Example:** date

---

**Note** The words `default`, `factory`, and `remove` are reserved words that will not appear in a title when quoted as a normal string. To display any of these words individually, type `'\reserved_word'` instead of `'reserved_word'`.

---

## **axes\_handle - Axes handle**

`handle`

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Color','red','FontSize',14` adds a title with red, 14-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

## **'Color' - Text color**

`[0 0 0]` (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0 1]`.

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### **'FontAngle' - Character slant**

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### **'FontName' - Font name**

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to

hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName', 'Courier'

## **'FontSize' - Font size**

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize', 12.5

## **'FontUnits' - Font size units**

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $\frac{1}{72}$  inch

---

**Note** When setting both the `FontSize` and the `FontUnits`, you must set the `FontUnits` property first so that MATLAB can correctly interpret the specified `FontSize`. For example, to set the font size to 0.3 inches, call `'FontUnits','inches','FontSize',0.3` in the argument list.

---

### **'FontWeight' - Weight of text characters**

`'normal'` (default) | `'bold'` | `'light'` | `'demi'`

Weight of text characters, specified as the comma-separated pair consisting of `'FontWeight'` and one of the following strings:

- `'normal'`
- `'bold'`
- `'light'`
- `'demi'`

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to `'bold'` or `'demi'` causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

### **'Interpreter' - Character interpretation**

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of `'Interpreter'` and one of the following strings.

# title

---

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** `'Interpreter', 'latex'`

## Output Arguments

### **h** - Handle to text object

scalar

Handle to the text object, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the title.

## Examples

### **Add Title to Current Figure**

Create a figure and display a title in the current axes.

```
figure
plot((1:10).^2)
title('My Title')
```

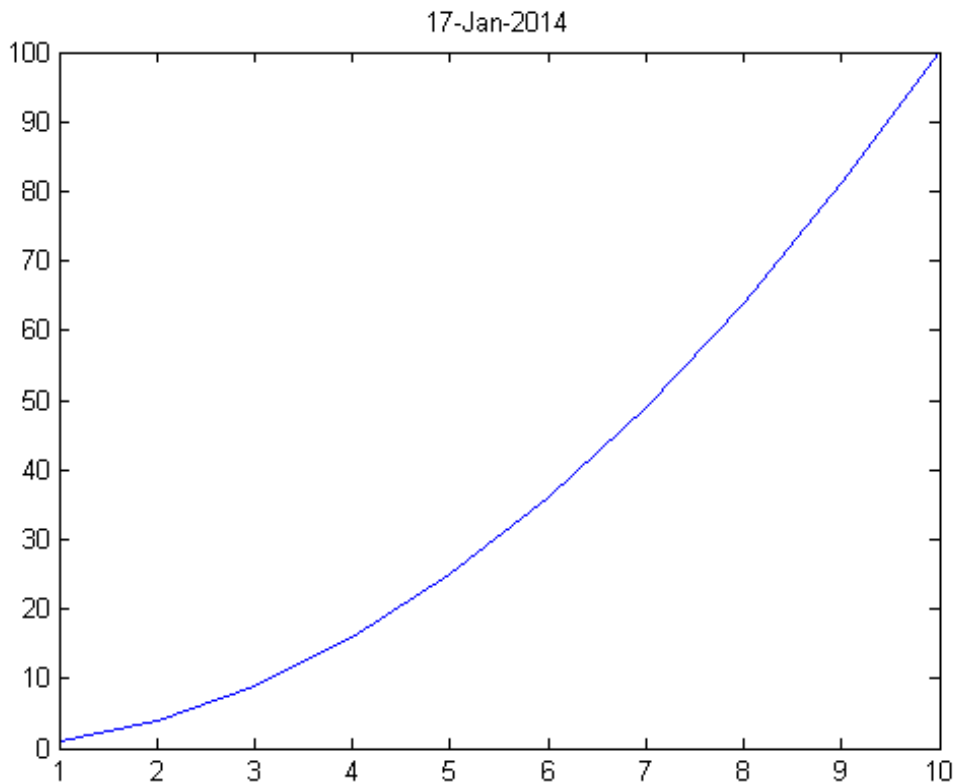

You also can call `title` with a function that returns a string. For example, the `date` function returns a string containing today's date.

```
title(date)
```

# title

---

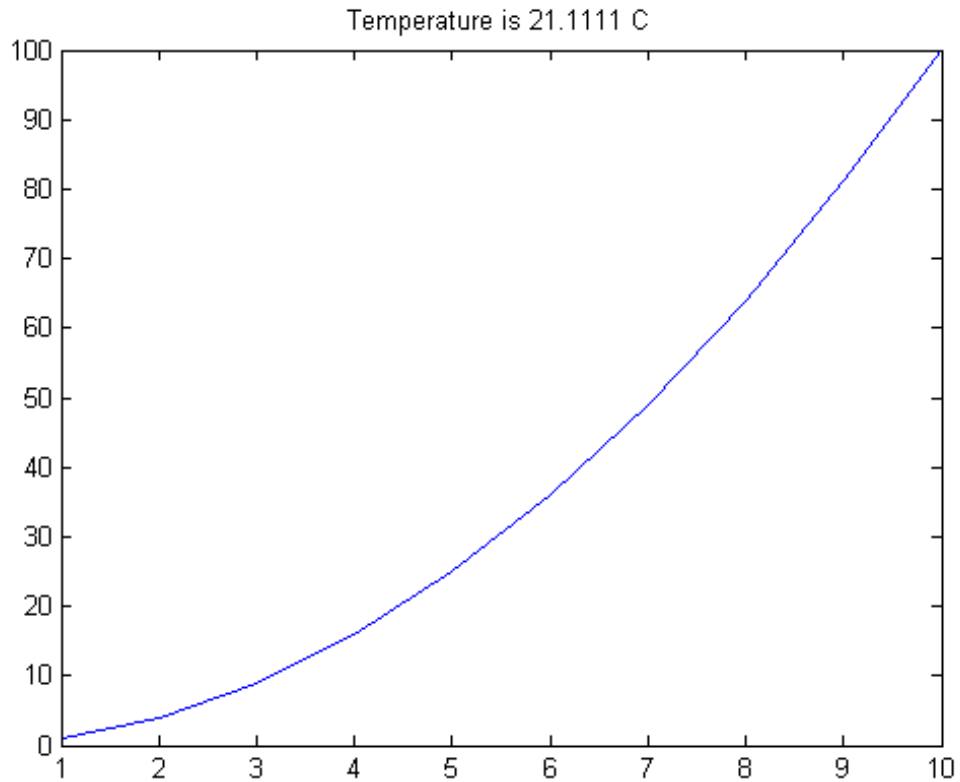

MATLAB® sets the output of `date` as the axes title.

## Include Variable's Value in Title

Include the value of variable `c` in a title.

```
figure
plot((1:10).^2)
f = 70;
c = (f-32)/1.8;
title(['Temperature is ', num2str(c), ' C'])
```

### Create Multicolored Title Using TeX Markup

In a TeX string, use the color modifier `\color` to change the color of characters following it from the previous color.

```
figure
plot((1:10).^2)
title(['\fontsize{16}black {\color{magenta}magenta '...
'\color[rgb]{0.5.5}teal \color{red}red} black again'])
```

# title

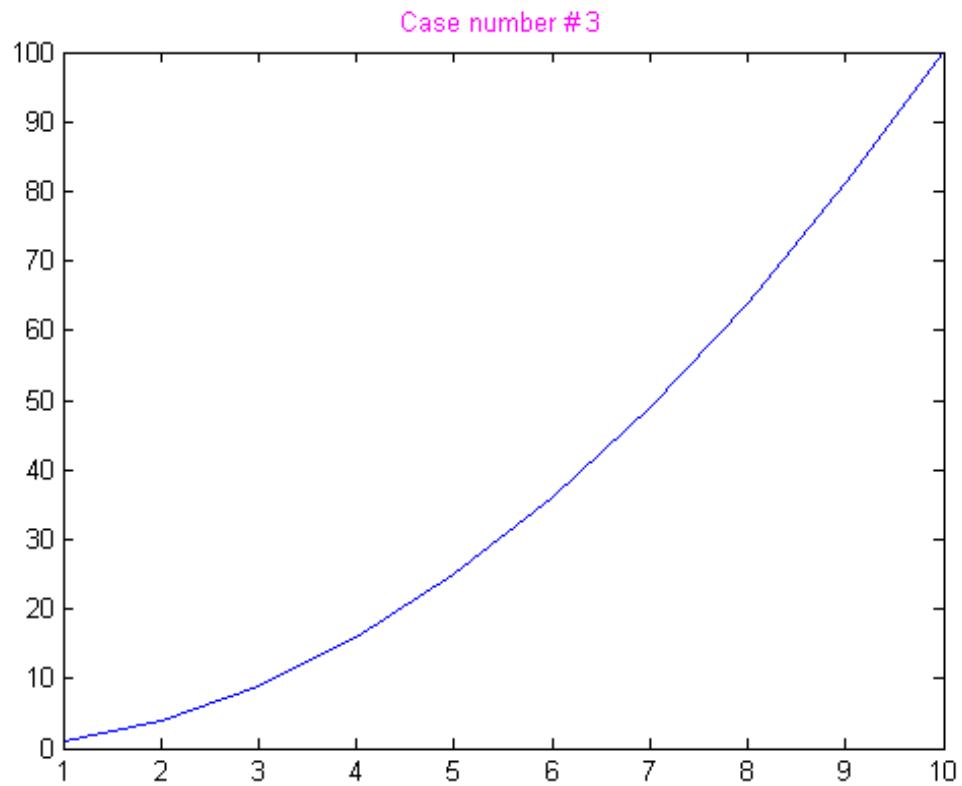

---

## Create Colored Title Using Name,Value Pair Argument

Use the Name,Value pair 'Color', 'm' to set the color of the title to magenta.

```
figure
plot((1:10).^2)
title('Case number # 3','Color', 'm')
```

### Include Greek Symbols in Title

Use a TeX string to include Greek symbols in a title.

```
t = (0:0.01:0.2);
y = exp(-25*t);
figure
plot(t,y)
title('y = \ite^{\lambda t}','Color','b')
```

# title

---

The 'Interpreter' property must be 'tex' (the default).

## **Include Superscript or Subscript Character in Title**

```
figure
plot((1:10).^2)
title('\alpha^2 and X_1')
```

The superscript character, "^", and the subscript character, "\_", modify the character or substring defined in braces immediately following.

### Create Multiline Title

Create a multiline title using a multiline cell array.

```
figure
plot((1:10).^2)
title({'First line'; 'Second line'})
```

# title

---

## Display Text As Typed

Set the Interpreter property as 'none' so that the string `X_1` is displayed in the figure as typed, without making 1 a subscript of X.

```
figure
plot((1:10).^2)
title('X_1','Interpreter','none')
```

MATLAB® displays the string  $X_1$  in the title of the figure.

### Add Title to Specific Axes

Create two subplots and return the handles to the axes objects,  $s(1)$  and  $s(2)$ .

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
```

# title

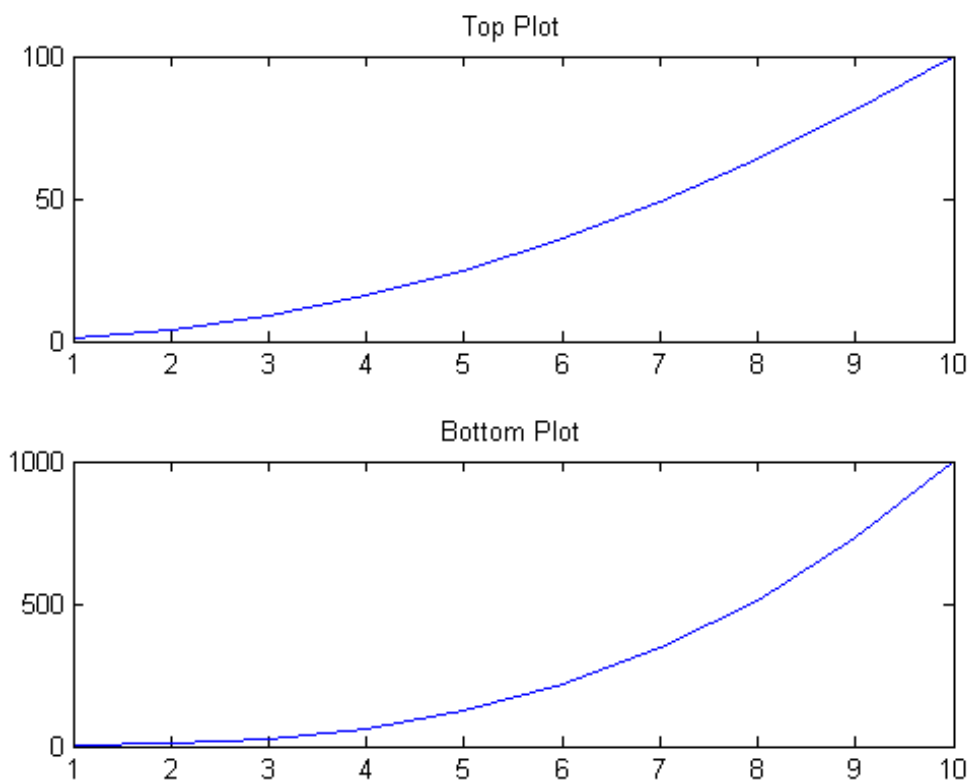

---

```
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Add a title to each subplot by referring to its axes handle, `s(1)`, or `s(2)`.

```
title(s(1), 'Top Plot')
title(s(2), 'Bottom Plot')
```

### Add Title and Return Text Handle

Add a title to a plot and return the handle to the text object used as the title.

```
figure
plot((1:10).^2)
h = title('My Title');
```

# title

---

MATLAB® returns the handle in the output variable, `h`.

Set the color of the title to red, using the handle.

```
set(h, 'Color', 'red')
```

**See Also**

**Concepts**

- Adding Titles to Graphs
- Text Properties

# todatenum

---

**Purpose** Convert CDF epoch object to MATLAB datenum

**Syntax** `n = todatenum(obj)`

**Description** `n = todatenum(obj)` converts the CDF epoch object `ep_obj` into a MATLAB serial date number. Note that a CDF epoch is the number of milliseconds since 01-Jan-0000 whereas a MATLAB datenum is the number of days since 00-Jan-0000.

**Examples** Construct a CDF epoch object from a date string, and then convert the object back into a MATLAB date string:

```
dstr = datestr(today)
dstr =
 08-Oct-2003

obj = cdfepoch(dstr)
obj =
 cdfepoch object:
 08-Oct-2003 00:00:00

dstr2 = datestr(todatenum(obj))
dstr2 =
 08-Oct-2003
```

**See Also** `cdfepoch` | `cdfinfo` | `cdfread` | `datenum`

**Purpose** Toeplitz matrix

**Syntax** `T = toeplitz(c,r)`  
`T = toeplitz(r)`

**Description** A *Toeplitz* matrix is defined by one row and one column. A *symmetric Toeplitz* matrix is defined by just one row. `toeplitz` generates Toeplitz matrices given just the row or row and column description.

`T = toeplitz(c,r)` returns a nonsymmetric Toeplitz matrix `T` having `c` as its first column and `r` as its first row. If the first elements of `c` and `r` are different, a message is printed and the column element is used.

For a real vector `r`, `T = toeplitz(r)` returns the symmetric Toeplitz matrix formed from vector `r`, where `r` defines the first row of the matrix. For a complex vector `r` with a real first element, `T = toeplitz(r)` returns the Hermitian Toeplitz matrix formed from `r`, where `r` defines the first row of the matrix and `r'` defines the first column. When the first element of `r` is not real, the resulting matrix is Hermitian off the main diagonal, i.e.,  $T_{ij} = \text{conj}(T_{ji})$  for  $i \neq j$ .

**Examples** A Toeplitz matrix with diagonal disagreement is

```
c = [1 2 3 4 5];
r = [1.5 2.5 3.5 4.5 5.5];
toeplitz(c,r)
Column wins diagonal conflict:
ans =
 1.000 2.500 3.500 4.500 5.500
 2.000 1.000 2.500 3.500 4.500
 3.000 2.000 1.000 2.500 3.500
 4.000 3.000 2.000 1.000 2.500
 5.000 4.000 3.000 2.000 1.000
```

**See Also** `hankel` | `kron`

# toolboxdir

---

**Purpose** Root folder for specified toolbox

**Syntax**

```
toolboxdir('tbxFolderName')
s = toolboxdir('tbxFolderName')
s = toolboxdir tbxFolderName
```

**Description** `toolboxdir('tbxFolderName')` returns a string that is the absolute path to the specified toolbox, `tbxFolderName`, where `tbxFolderName` is the folder name for the toolbox.

`s = toolboxdir('tbxFolderName')` returns the absolute path to the specified toolbox to the output argument, `s`.

`s = toolboxdir tbxFolderName` is the command form of the syntax.

**Tips** `toolboxdir` is particularly useful for MATLAB Compiler software. The base folder of all toolboxes installed with MATLAB software is:

```
matlabroot/toolbox/tbxFolderName
```

However, in deployed mode, the base folders of the toolboxes are different. `toolboxdir` returns the correct root folder, whether running from MATLAB or from an application deployed with the MATLAB Compiler software.

To determine the folder name for a given toolbox, run the following code, substituting the name of a product function for *toolboxfcn*:

```
n = 'toolboxfcn';
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+';
regexp(which(n), pat, 'match', 'once')
```

For example, to determine the product name for Control System Toolbox set `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss'
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+'
regexp(which(n), pat, 'match', 'once')
```

control

## Examples

Obtain the path for the Control System Toolbox software:

```
s = toolboxdir('control')
```

MATLAB returns:

```
s = C:\Program Files\MATLAB\R2012a\toolbox\control
```

## See Also

# trace

---

<b>Purpose</b>	Sum of diagonal elements
<b>Syntax</b>	<code>b = trace(A)</code>
<b>Description</b>	<code>b = trace(A)</code> is the sum of the diagonal elements of the matrix A.
<b>Algorithms</b>	<code>t = sum(diag(A));</code>
<b>See Also</b>	<code>det</code>   <code>eig</code>

<b>Purpose</b>	Transpose
<b>Syntax</b>	<code>b = a.'</code> <code>b = transpose(a)</code>
<b>Description</b>	<code>b = a.'</code> computes the non-conjugate transpose of matrix <code>a</code> and returns the result in <code>b</code> . <code>b = transpose(a)</code> is called for the syntax <code>a.'</code> when <code>a</code> is an object.
<b>See Also</b>	<code>ctranspose</code>   <code>permute</code>

# trapez

---

**Purpose** Trapezoidal numerical integration

**Syntax**  
`Q = trapz(Y)`  
`Q = trapz(X,Y)`  
`Q = trapz( __ ,dim)`

**Description** `Q = trapz(Y)` returns the approximate integral of `Y` via the trapezoidal method with unit spacing. The size of `Y` determines the dimension to integrate along:

- If `Y` is a vector, then `trapz(Y)` is the approximate integral of `Y`.
- If `Y` is a matrix, then `trapz(Y)` integrates over each column and returns a row vector of integration values.
- If `Y` is a multidimensional array, then `trapz(Y)` integrates over the first dimension whose size does not equal 1. The size of this dimension becomes 1, and the sizes of other dimensions remain unchanged.

`Q = trapz(X,Y)` integrates `Y` with spacing increment `X`. By default, `trapz` operates on the first dimension of `Y` whose size does not equal 1. `length(X)` must be equal to the size of this dimension. If `X` is a scalar, then `trapz(X,Y)` is equivalent to `X*trapz(Y)`.

`Q = trapz( __ ,dim)` integrates along the dimension `dim` using any of the previous syntaxes. You must specify `Y`, and optionally can specify `X`. The length of `X`, if specified, must be the same as `size(Y,dim)`. For example, if `Y` is a matrix, then `trapz(X,Y,2)` integrates each row of `Y`.

## **Input Arguments**

**Y - Numeric data**  
vector | matrix | multidimensional array

Numeric data, specified as a vector, matrix, or multidimensional array. By default, `trapz` integrates along the first dimension of `Y` whose size does not equal 1.

**Data Types**

single | double

**Complex Number Support:** Yes

**X - Point spacing**

1 (default) | uniform scalar spacing | vector of nonuniform spacings

Point spacing, specified as 1 (default), a uniform scalar spacing, or a vector of nonuniform spacings. If X is a vector, then `length(X)` must be the same as the size of the integration dimension in Y.

**Data Types**

single | double

**Complex Number Support:** Yes

**dim - Dimension to operate along**

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If no value is specified, the default is the first array dimension whose size does not equal 1.

Consider a two-dimensional input array, Y:

- `trapz(Y,1)` works on successive elements in the columns of Y and returns a row vector of integration values.

- `trapz(Y,2)` works on successive elements in the rows of Y and returns a column vector of integration values.

If `dim` is greater than `ndims(Y)`, then `trapz` returns an array of zeros of the same size as `Y`.

## Examples

### Integrate Vector of Data with Unit Spacing

Create a numeric vector of data.

```
Y = [1 4 9 16 25];
```

`Y` contains five evenly spaced points from the function  $f(x) = x^2$ .

Use `trapz` to integrate the data points with unit spacing.

```
Q = trapz(Y)
```

```
Q =
```

```
42
```

This approximate integration yields a value of 42. In this case, the

exact answer is a little less,  $41\frac{1}{3}$ . The `trapz` function overestimates the value of the integral because  $f(x)$  is concave up.

### Integrate Vector of Data with Nonunit Spacing

Create a domain vector, `X`.

```
X = 0:pi/100:pi;
```

Calculate the sine of `X` and store the result in `Y`.

```
Y = sin(X);
```

Integrate the function values contained in Y using trapz.

```
Q = trapz(X,Y)
```

```
Q =
```

```
1.9998
```

When the spacing between points is constant, but not equal to 1, you can multiply by the spacing value, in this case  $\pi/100 \cdot \text{trapz}(Y)$ . The answer is the same if you pass the value directly to the function with `trapz(X,Y)`.

### Integrate Matrix with Nonuniform Spacing

Create a vector of time values, X. Also create a matrix, Y, containing values evaluated at the irregular intervals in X.

```
X = [1 2.5 7 10]';
```

```
Y = [5.2 4.8 4.9 5.1; 7.7 7.0 6.5 6.8; 9.6 10.5 10.5 9.0; 13.2 14.5 15.2 15.2];
```

```
Y =
```

```
5.2000 4.8000 4.9000 5.1000
7.7000 7.0000 6.5000 6.8000
9.6000 10.5000 10.5000 9.0000
13.2000 14.5000 13.8000 15.2000
```

The columns of Y represent velocity data, taken at the times contained in X, for several different trials.

Use trapz to integrate each column independently and find the total distance traveled in each trial. Since the function values are not evaluated at constant intervals, specify X to indicate the spacing between the data points.

```
Q = trapz(X,Y)
```

```
Q =

 82.8000 85.7250 83.2500 80.7750
```

The result is a row vector of integration values, one for each column in  $Y$ . By default, `trapz` integrates along the first dimension of  $Y$  whose size does not equal 1.

Alternatively, you can integrate the rows of a matrix by specifying `dim = 2`.

In this case, use `trapz` on  $Y'$ , which contains the velocity data in the rows.

```
dim = 2;
Q1 = trapz(X,Y',dim)
```

```
Q1 =

 82.8000
 85.7250
 83.2500
 80.7750
```

The result is a column vector of integration values, one for each row in  $Y'$ .

## Multiple Numerical Integrations

Created a grid of domain values.

```
x = -3:.1:3;
y = -5:.1:5;
[X,Y] = meshgrid(x,y);
```

Calculate the function  $f(x,y) = x^2 + y^2$  over the grid.

```
F = X.^2 + Y.^2;
```

trapz integrates numeric data rather than functional expressions, so in general the expression does not need to be known to use trapz on a matrix of data.

Use trapz to approximate the double integral

$$I = \int_{-5}^5 \int_{-3}^3 (x^2 + y^2) dx dy .$$

To perform double or triple integrations on an array of numeric data, nest function calls to trapz.

$$I = \text{trapz}(y, \text{trapz}(x, F, 2))$$

$$I =$$

$$680.2000$$

trapz performs the integration over  $x$  first, producing a column vector. Then, the integration over  $y$  reduces the column vector to a single scalar. trapz slightly overestimates the exact answer of 680 because  $f(x,y)$  is concave up.

## Definitions

### Trapezoidal Method

trapz performs numerical integration via the trapezoidal method. This method approximates the integration over an interval by breaking the area down into trapezoids with more easily computable areas.

For an integration with  $N+1$  evenly spaced points, the approximation is

$$\begin{aligned} \int_a^b f(x) dx &\approx \frac{b-a}{2N} \sum_{n=1}^N (f(x_n) + f(x_{n+1})) \\ &= \frac{b-a}{2N} [f(x_1) + 2f(x_2) + \dots + 2f(x_N) + f(x_{N+1})], \end{aligned}$$

# trapz

---

where the spacing between each point is equal to the scalar value  $\frac{b-a}{N}$ .

If the spacing between the points is not constant, then the formula generalizes to

$$\int_a^b f(x) dx \approx \frac{1}{2} \sum_{n=1}^N (x_{n+1} - x_n) [f(x_n) + f(x_{n+1})],$$

where  $(x_{n+1} - x_n)$  is the spacing between each consecutive pair of points.

## Tips

- `trapz` reduces the size of the dimension it operates on to 1, and returns only the final integration value. `cumtrapz` also returns the intermediate integration values, preserving the size of the dimension it operates on.

## See Also

`cumsum` | `cumtrapz` | `integral` | `integral2` | `integral3`

## Concepts

- “Integration of Numeric Data”

**Purpose** Lay out tree or forest

**Syntax** `[x,y] = treelayout(parent,post)`  
`[x,y,h,s] = treelayout(parent,post)`

**Description** `[x,y] = treelayout(parent,post)` lays out a tree or a forest. `parent` is the vector of parent pointers, with 0 for a root. `post` is an optional postorder permutation on the tree nodes. If you omit `post`, `treelayout` computes it. `x` and `y` are vectors of coordinates in the unit square at which to lay out the nodes of the tree to make a nice picture.

`[x,y,h,s] = treelayout(parent,post)` also returns the height of the tree `h` and the number of vertices `s` in the top-level separator.

**See Also** `etree` | `treepplot` | `etreeplot` | `symbfact`

# treeplot

**Purpose** Plot picture of tree

**Syntax** `treeplot(p)`  
`treeplot(p,nodeSpec,edgeSpec)`

**Description** `treeplot(p)` plots a picture of a tree given a vector of parent pointers, with  $p(i) = 0$  for a root.

`treeplot(p,nodeSpec,edgeSpec)` allows optional parameters `nodeSpec` and `edgeSpec` to set the node or edge color, marker, and linestyle. Use `' '` to omit one or both.

**Examples** To plot a tree with 12 nodes, call `treeplot` with a 12-element input vector. The index of each element in the vector is shown adjacent to each node in the figure below. (These indices are shown only for the point of illustrating the example; they are not part of the `treeplot` output.)

To generate this plot, set the value of each element in the nodes vector to the index of its parent, (setting the parent of the root node to zero).

The node marked 1 in the figure is represented by `nodes(1)` in the input vector, and because this is the root node which has a parent of zero, you set its value to zero:

```
nodes(1) = 0; % Root node
```

`nodes(2)` and `nodes(8)` are children of `nodes(1)`, so set these elements of the input vector to 1:

```
nodes(2) = 1; nodes(8) = 1;
```

`nodes(5:7)` are children of `nodes(4)`, so set these elements to 4:

```
nodes(5) = 4; nodes(6) = 4; nodes(7) = 4;
```

Continue in this manner until each element of the vector identifies its parent. For the plot shown above, the `nodes` vector now looks like this:

```
nodes = [0 1 2 2 4 4 4 1 8 8 10 10];
```

Now call `treeplot` to generate the plot:

```
treeplot(nodes)
```

## See Also

`etree` | `etreeplot` | `treelayout`

# tril

**Purpose** Lower triangular part of matrix

**Syntax**  
`L = tril(X)`  
`L = tril(X,k)`

**Description** `L = tril(X)` returns the lower triangular part of `X`.  
`L = tril(X,k)` returns the elements on and below the `k`th diagonal of `X`. `k = 0` is the main diagonal, `k > 0` is above the main diagonal, and `k < 0` is below the main diagonal.

**Examples** `tril(ones(4,4), -1)`

`ans =`

```
0 0 0 0
1 0 0 0
1 1 0 0
1 1 1 0
```

**See Also** `diag` | `triu`

**Purpose**

Triangular mesh plot

**Syntax**

```
trimesh(Tri,X,Y,Z,C)
trimesh(Tri,X,Y,Z)
trimesh(Tri,X,Y)
trimesh(TR)
trimesh(... 'PropertyName',PropertyValue...)
h = trimesh(...)
```

**Description**

`trimesh(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a mesh. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the X, Y, and Z vertices. The edge color is defined by the vector `C`.

`trimesh(Tri,X,Y,Z)` uses `C = Z` so color is proportional to surface height.

`trimesh(Tri,X,Y)` displays the triangles in a 2-D plot.

`trimesh(TR)` displays the triangles in a triangulation representation.

`trimesh(... 'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trimesh(...)` returns a handle to the displayed triangles.

**Examples****Create Triangular Mesh Plot**

Create vertex vectors and a face matrix, and then create a triangular mesh plot.

```
[x,y]=meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trimesh(tri,x,y,z)
```

# trimesh

---

If the surface is already a triangulation representation, then you can pass the triangulation to `trimesh`:

```
tr = triangulation(tri,x(:),y(:),z(:));
trimesh(tr)
```

**See Also**

`patch` | `trisurf` | `delaunay` | `delaunayTriangulation` | `triangulation`

# triplequad

---

## Purpose

Numerically evaluate triple integral

`triplequad` will be removed in a future release. Use `integral3` instead.

## Syntax

```
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)
q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)
```

## Description

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax)` evaluates the triple integral  $\text{fun}(x,y,z)$  over the three dimensional rectangular region  $x_{\min} \leq x \leq x_{\max}$ ,  $y_{\min} \leq y \leq y_{\max}$ ,  $z_{\min} \leq z \leq z_{\max}$ . The first input, `fun`, is a function handle. `fun(x,y,z)` must accept a vector `x` and scalars `y` and `z`, and return a vector of values of the integrand.

“Parameterizing Functions” explains how to provide additional parameters to the function `fun`, if necessary.

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol)` uses a tolerance `tol` instead of the default, which is  $1.0e-6$ .

`q = triplequad(fun,xmin,xmax,ymin,ymax,zmin,zmax,tol,method)` uses the quadrature function specified as `method`, instead of the default `quad`. Valid values for `method` are `@quadl` or the function handle of a user-defined quadrature method that has the same calling sequence as `quad` and `quadl`.

## Examples

Pass function handle `@integrnd` to `triplequad`:P

```
Q = triplequad(@integrnd,0,pi,0,1,-1,1);
```

where the file `integrnd.m` is

```
function f = integrnd(x,y,z)
f = y*sin(x)+z*cos(x);
```

Pass anonymous function handle `F` to `triplequad`:

```
F = @(x,y,z)y*sin(x)+z*cos(x);
Q = triplequad(F,0,pi,0,1,-1,1);
```

This example integrates  $y\sin(x)+z\cos(x)$  over the region  $0 \leq x \leq \pi$ ,  $0 \leq y \leq 1$ ,  $-1 \leq z \leq 1$ . Note that the integrand can be evaluated with a vector  $x$  and scalars  $y$  and  $z$ .

## See Also

## How To

- “Anonymous Functions”

# triplot

---

**Purpose** 2-D triangular plot

**Syntax**

```
triplot(TRI,x,y)
triplot(TRI,x,y,color)
triplot(TR)
h = triplot(...)
triplot(...,'param','value','param','value'...)
```

**Description** `triplot(TRI,x,y)` displays the triangles defined in the m-by-3 matrix TRI. A row of TRI contains indices into the vectors x and y that define a single triangle. The default line color is blue.

`triplot(TRI,x,y,color)` uses the string color as the line color. color can also be a line specification. See `ColorSpec` for a list of valid color strings. See `LineStyle` for information about line specifications.

`triplot(TR)` displays the triangles in a triangulation representation.

`h = triplot(...)` returns a vector of handles to the displayed triangles.

`triplot(...,'param','value','param','value'...)` allows additional line property name/property value pairs to be used when creating the plot. See `Line Properties` for information about the available properties.

## **Examples** **Plot Delaunay Triangulation**

Plot a Delaunay triangulation for 10 randomly generated points.

```
P = gallery('uniformdata',10,2,2);
DT = delaunayTriangulation(P);
triplot(DT)
```

**See Also**

[delaunayTriangulation](#) | [triangulation](#) | [delaunay](#) | [trimesh](#)  
| [trisurf](#)

# TriRep

---

**Purpose** (Will be removed) Triangulation representation

---

**Note** TriRep will be removed in a future release. Use `triangulation` instead.

---

**Description** TriRep provides topological and geometric queries for triangulations in 2-D and 3-D space. For example, for triangular meshes you can query triangles attached to a vertex, triangles that share an edge, neighbor information, circumcenters, or other features. You can create a `TriRep` directly using existing triangulation data. Alternatively, you can create a Delaunay triangulation, via `DelaunayTri`, which provides access to the `TriRep` functionality.

**Construction** `TriRep` (Will be removed) Triangulation representation

**Methods**

<code>baryToCart</code>	(Will be removed) Convert point coordinates from barycentric to Cartesian
<code>cartToBary</code>	(Will be removed) Convert point coordinates from cartesian to barycentric
<code>circumcenters</code>	(Will be removed) Circumcenters of specified simplices
<code>edgeAttachments</code>	(Will be removed) Simplices attached to specified edges
<code>edges</code>	(Will be removed) Triangulation edges

faceNormals	(Will be removed) Unit normals to specified triangles
featureEdges	(Will be removed) Sharp edges of surface triangulation
freeBoundary	(Will be removed) Facets referenced by only one simplex
incenters	(Will be removed) Incenters of specified simplices
isEdge	(Will be removed) Test if vertices are joined by edge
neighbors	(Will be removed) Simplex neighbor information
size	(Will be removed) Size of triangulation matrix
vertexAttachments	(Will be removed) Return simplices attached to specified vertices

**Properties**

X	Coordinates of the points in the triangulation
Triangulation	Triangulation data structure

**Copy Semantics**

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

**Indexing**

TriRep objects support indexing into the triangulation using parentheses (). The syntax is the same as for arrays.

**Examples**

Load a 2-D triangulation and use the TriRep constructor to build an array of the free boundary edges:

```
load trimesh2d
```

This loads triangulation `tri` and vertex coordinates `x, y`:

```
trep = TriRep(tri, x,y);
fe = freeBoundary(trep)';
triplot(trep);
```

You can add the free edges `fe` to the plot:

```
hold on;
plot(x(fe), y(fe), 'r', 'LineWidth', 2);
hold off;
```

```
axis([-50 350 -50 350]);
axis equal;
```

**See Also**

[delaunayTriangulation](#) | [triangulation](#) | [scatteredInterpolant](#)

# TriRep

---

**Purpose** (Will be removed) Triangulation representation

---

**Note** TriRep will be removed in a future release. Use `triangulation` instead.

---

**Syntax**

```
TR = TriRep(TRI, X, Y)
TR = TriRep(TRI, X, Y, Z)
TR = TriRep(TRI, X)
```

**Description** `TR = TriRep(TRI, X, Y)` creates a 2-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y)`. `TRI` is an  $m$ -by-3 matrix that defines the triangulation in face-vertex format, where  $m$  is the number of triangles. Each row of `TRI` is a triangle defined by indices into the column vector of vertex coordinates `(X, Y)`.

`TR = TriRep(TRI, X, Y, Z)` creates a 3-D triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `(X, Y, Z)`. `TRI` is an  $m$ -by-3 or  $m$ -by-4 matrix that defines the triangulation in simplex-vertex format, where  $m$  is the number of simplices; triangles or tetrahedra in this case. Each row of `TRI` is a simplex defined by indices into the column vector of vertex coordinates `(X, Y, Z)`.

`TR = TriRep(TRI, X)` creates a triangulation representation from the triangulation matrix `TRI` and the vertex coordinates `X`. `TRI` is an  $m$ -by- $n$  matrix that defines the triangulation in simplex-vertex format, where  $m$  is the number of simplices and  $n$  is the number of vertices per simplex. Each row of `TRI` is a simplex defined by indices into the array of vertex coordinates `X`. `X` is an  $mpts$ -by- $ndim$  matrix where  $mpts$  is the number of points and  $ndim$  is the dimension of the space where the points reside, where  $2 \leq ndim \leq 3$ .

**Examples** Load a 3-D tetrahedral triangulation compute the free boundary. First, load triangulation `tet` and vertex coordinates `X`.

```
load tetmesh
```

Create the triangulation representation and compute the free boundary.

```
trep = TriRep(tet, X);
[tri, Xb] = freeBoundary(trep);
```

[scatteredInterpolant](#) | [delaunayTriangulation](#)

# TriScatteredInterp

---

**Purpose** (Will be removed) Interpolate scattered data

---

**Note** TriScatteredInterp will be removed in a future release. Use scatteredInterpolant instead.

---

**Description** TriScatteredInterp is used to perform interpolation on a scattered dataset that resides in 2-D or 3-D space. A scattered data set defined by locations  $X$  and corresponding values  $V$  can be interpolated using a Delaunay triangulation of  $X$ . This produces a surface of the form  $V = F(X)$ . The surface can be evaluated at any query location  $QX$ , using  $QV = F(QX)$ , where  $QX$  lies within the convex hull of  $X$ . The interpolant  $F$  always goes through the data points specified by the sample.

**Definitions** The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set. The *convex hull* of a set of points is the smallest convex set containing all points of the original set. These definitions extend naturally to higher dimensions.

**Construction** TriScatteredInterp (Will be removed) Interpolate scattered data

<b>Properties</b>	$X$	Defines locations of scattered data points in 2-D or 3-D space.
	$V$	Defines value associated with each data point.

Method	Defines method used to interpolate the data .	
	natural	Natural neighbor interpolation
	linear	Linear interpolation (default)
	nearest	Nearest neighbor interpolation

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Create a data set:

```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz:

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z, 'o');
```

# TriScatteredInterp

---

## See Also

[delaunayTriangulation](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

**Purpose** (Will be removed) Interpolate scattered data

---

**Note** TriScatteredInterp will be removed in a future release. Use scatteredInterpolant instead.

---

**Syntax**

```
F = TriScatteredInterp()
F = TriScatteredInterp(X, V)
F = TriScatteredInterp(X, Y, V)
F = TriScatteredInterp(X, Y, Z, V)
F = TriScatteredInterp(DT, V)
F = TriScatteredInterp(..., method)
```

**Description**

F = TriScatteredInterp() creates an empty scattered data interpolant. This can subsequently be initialized with sample data points and values (Xdata, Vdata) via F.X = Xdata and F.V = Vdata.

F = TriScatteredInterp(X, V) creates an interpolant that fits a surface of the form  $V = F(X)$  to the scattered data in (X, V). X is a matrix of size mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside (ndim is 2 or 3). The column vector V defines the values at X, where the length of V equals mpts.

F = TriScatteredInterp(X, Y, V) and F = TriScatteredInterp(X, Y, Z, V) allow the data point locations to be specified in alternative column vector format when working in 2-D and 3-D.

F = TriScatteredInterp(DT, V) uses the specified DelaunayTri object DT as a basis for computing the interpolant. DT is a Delaunay triangulation of the scattered data locations, DT.X. The matrix DT.X is of size mpts-by-ndim, where mpts is the number of points and ndim is the dimension of the space where the points reside,  $2 \leq \text{ndim} \leq 3$ . V is a column vector that defines the values at DT.X, where the length of V equals mpts.

F = TriScatteredInterp(..., method) allows selection of the technique method used to interpolate the data.

# TriScatteredInterp

---

## Input Arguments

X	Matrix of size <code>mpts-by-ndim</code> , where <code>mpts</code> is the number of points and <code>ndim</code> is the dimension of the space where the points reside. Input may also be specified as column vectors (X, Y) or (X, Y, Z)	
V	Column vector that defines the values at X, where the length of V equals <code>mpts</code> .	
DT	Delaunay triangulation of the scattered data locations	
method	natural	Natural neighbor interpolation
	linear	Linear interpolation (default)
	nearest	Nearest-neighbor interpolation

## Output Arguments

F	Creates an interpolant that fits a surface of the form $V = F(X)$ to the scattered data.
---	------------------------------------------------------------------------------------------

## Evaluation

To evaluate the interpolant, express the statement in Monge's form  $V_q = F(X_q)$ ,  $V_q = F(X_q, Y_q)$ , or  $V_q = F(X_q, Y_q, Z_q)$  where  $V_q$  is the value of the interpolant at the query location and  $X_q$ ,  $Y_q$ , and  $Z_q$  are the vectors of point locations.

## Definitions

The *Delaunay triangulation* of a set of points is a triangulation such that the unique circle circumscribed about each triangle contains no other points in the set.

## Examples

Create a data set:

```
x = rand(100,1)*4-2;
y = rand(100,1)*4-2;
z = x.*exp(-x.^2-y.^2);
```

Construct the interpolant:

```
F = TriScatteredInterp(x,y,z);
```

Evaluate the interpolant at the locations (qx, qy). The corresponding value at these locations is qz .

```
ti = -2:.25:2;
[qx,qy] = meshgrid(ti,ti);
qz = F(qx,qy);
mesh(qx,qy,qz);
hold on;
plot3(x,y,z, 'o');
```

## See Also

[delaunayTriangulation](#) | [interp1](#) | [interp2](#) | [interp3](#) | [meshgrid](#)

# trisurf

---

**Purpose** Triangular surface plot

**Syntax**

```
trisurf(Tri,X,Y,Z,C)
trisurf(Tri,X,Y,Z)
trisurf(TR)
trisurf(...'PropertyName',PropertyValue...)
h = trisurf(...)
```

**Description** `trisurf(Tri,X,Y,Z,C)` displays triangles defined in the  $m$ -by-3 face matrix `Tri` as a surface. Each row of `Tri` defines a single triangular face by indexing into the vectors or matrices that contain the  $X$ ,  $Y$ , and  $Z$  vertices. The color is defined by the vector `C`.

`trisurf(Tri,X,Y,Z)` uses `C=Z` so color is proportional to surface height.

`trisurf(TR)` displays the triangles in a triangulation representation. It uses `C = TR.Points(:,3)` to make sure the surface color is proportional to height.

`trisurf(...'PropertyName',PropertyValue...)` specifies additional patch property names and values for the patch graphics object created by the function.

`h = trisurf(...)` returns a patch handle.

## Examples **Create Triangular Surface Plot**

Create vertex vectors and a face matrix, then create a triangular surface plot.

```
[x,y] = meshgrid(1:15,1:15);
tri = delaunay(x,y);
z = peaks(15);
trisurf(tri,x,y,z)
```

If the surface is in the form of a triangulation representation, you can pass it to `trisurf` alone:

```
tr = triangulation(tri,x(:),y(:),z(:));
trisurf(tr)
```

# trisurf

---

## See Also

[patch](#) | [surf](#) | [tetramesh](#) | [trimesh](#) | [triplot](#) | [delaunay](#) | [triangulation](#) | [delaunayTriangulation](#)

**Purpose** Upper triangular part of matrix

**Syntax**  
 $U = \text{triu}(X)$   
 $U = \text{triu}(X,k)$

**Description**  $U = \text{triu}(X)$  returns the upper triangular part of  $X$ .  
 $U = \text{triu}(X,k)$  returns the element on and above the  $k$ th diagonal of  $X$ .  
 $k = 0$  is the main diagonal,  $k > 0$  is above the main diagonal, and  $k < 0$  is below the main diagonal.

**Examples** `triu(ones(4,4),-1)`

ans =

```

1 1 1 1
1 1 1 1
0 1 1 1
0 0 1 1
```

**See Also** `diag` | `tril`

# true

---

**Purpose** Logical 1 (true)

**Syntax**

```
true
T = true(n)
T = true(sz)
T = true(sz1,...,szN)
T = true(__ , 'like', p)
```

**Description** true is shorthand for logical(1).

`T = true(n)` is an n-by-n matrix of logical ones.

`T = true(sz)` is an array of logical ones where the size vector, `sz`, defines `size(T)`. For example, `true([2 3])` returns a 2-by-3 array of logical ones.

`T = true(sz1,...,szN)` is a `sz1`-by-...-by-`szN` array of logical ones where `sz1,...,szN` indicates the size of each dimension. For example, `true(2,3)` returns a 2-by-3 array of logical ones.

`T = true( __ , 'like', p)` returns an array of logical ones of the same sparsity as the logical variable `p` using any of the previous size syntaxes.

## Input Arguments

### **n - Size of square matrix**

integer

Size of square matrix, specified as an integer. `n` sets the output array size to n-by-n. For example, `true(3)` returns a 3-by-3 array of logical ones.

- If `n` is 0, then `T` is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**sz - Size vector**

row vector of integers

Size vector, specified as a row vector of integers. For example, `true([2 3])` returns a 2-by-3 array of logical ones.

- If the size of any dimension is 0, then T is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, T, does not include those dimensions.

**Data Types**

int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**sz1,...,szN - Size inputs**

comma-separated list of integers

Size inputs, specified by a comma-separated list of integers. For example, `true(2,3)` returns a 2-by-3 array of logical ones.

- If the size of any dimension is 0, then T is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, T, does not include those dimensions.

**Data Types**

int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**p - Prototype**

logical variable

Prototype, specified as a logical variable.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64

**Complex Number Support:** Yes

# true

---

## Output Arguments

### T - Output of logical ones

scalar | vector | matrix | N-D array

Output of logical ones, returned as a scalar, vector, matrix, or N-D array.

### Data Types

logical

## Examples

### Generate Square Matrix of Logical Ones

Use `true` to generate a 3-by-3 square matrix of logical ones.

```
A = true(3)
class(A)
```

```
A =
 1 1 1
 1 1 1
 1 1 1
```

```
ans =
logical
```

The result is of class `logical`.

### Generate Array of Logical Ones with Arbitrary Dimensions

Use `true` to generate a 3-by-2-by-2 matrix of logical ones.

```
true(3,2,2)
```

```
ans(:,:,1) =
 1 1
 1 1
 1 1
```

```
ans(:,:,2) =
 1 1
 1 1
 1 1
```

Alternatively, you can use a size vector to specify the size of the matrix.

```
true([3,2,2])
```

```
ans(:,:,1) =
 1 1
 1 1
 1 1
```

```
ans(:,:,2) =
 1 1
 1 1
 1 1
```

Note that specifying multiple vector inputs returns an error.

### Execute Logic Statement

true along with false can be used to execute logic statements.

Test the logical statement  $\sim(A \text{ and } B) \equiv (\sim A) \text{ or } (\sim B)$  for  $A = \text{logical true}$  and  $B = \text{logical false}$ .

```
~(true & false) == (~true) | (~false)
```

```
ans =
 1
```

The result is logical 1 (true), since the logical statements on both sides of the equation are equivalent. This logical statement is an instance of De Morgan's Law.

### Generate Logical Array of Selected Sparsity

Generate a logical array of the same sparsity as the selected array.

```
A = logical(sparse(5,3));
whos A
T = true(4,'like',A);
whos T
```

# true

---

Name	Size	Bytes	Class	Attributes
A	5x3	41	logical	sparse
Name	Size	Bytes	Class	Attributes
T	4x4	184	logical	sparse

The output array *T* has the same `sparse` attribute and data-type as the specified array *A*.

## Tips

- `true(n)` is much faster and more memory efficient than `logical(true(n))`.

## See Also

`false` | `logical`

## Concepts

- “Class Support for Array-Creation Functions”

**Purpose** Execute statements and catch resulting errors

**Syntax**

```
try
 statements
catch exception
 statements
end
```

**Description** try and catch blocks allow you to override the default error behavior for a set of program statements. If any statement in a try block generates an error, program control goes immediately to the catch block, which contains your error handling statements.

*exception* is an optional MException object input to the catch block that allows you to identify the error.

Both try and catch blocks can contain nested try/catch statements.

**Examples** Provide more information about a dimension mismatch error:

```
A = rand(3);
B = ones(5);

try
 C = [A; B];
catch err

 % Give more information for mismatch.
 if (strcmp(err.identifier, 'MATLAB:catenate:dimensionMismatch'))

 msg = ['Dimension mismatch occurred: First argument has ', ...
 num2str(size(A,2)), ' columns while second has ', ...
 num2str(size(B,2)), ' columns.'];
 error('MATLAB:myCode:dimensions', msg);

 % Display any other errors as usual.
 else
 rethrow(err);
 end
end
```

# try, catch

---

```
 end

 end % end try/catch
```

---

Catch an error when reading an image file, and try adjusting the file extension to resolve the error (.jpg and .jpeg are similar, as are .tif and .tiff):

```
function imageData = readImage(filename)
try
 imageData = imread(filename);
catch exception

 % Is the error because MATLAB could not find the file?
 if ~exist(filename, 'file')

 % Check for common typos in the extension.
 [~, ~, extension] = fileparts(filename);
 switch extension
 case '.jpg'
 altFilename = strrep(filename, '.jpg', '.jpeg');
 case '.jpeg'
 altFilename = strrep(filename, '.jpeg', '.jpg');
 case '.tif'
 altFilename = strrep(filename, '.tif', '.tiff');
 case '.tiff'
 altFilename = strrep(filename, '.tiff', '.tif');
 otherwise
 rethrow(exception);
 end

 % Try again, with modified filename.
 try
 imageData = imread(altFilename);
 catch exception2
 % Rethrow original error.
 end
 end
end
```

```
 rethrow(exception)
 end

 else
 rethrow(exception)
 end

end
```

## See Also

error | assert | MException

# tscollection

---

**Purpose** Create `tscollection` object

**Syntax**

```
tsc = tscollection(TimeSeries)
tsc = tscollection(Time)
tsc = tscollection(...,'Parameter',Value,...)
```

**Description**

`tsc = tscollection(TimeSeries)` creates a `tscollection` object `tsc` with one or more `timeseries` objects already in the MATLAB workspace. The argument `TimeSeries` can be a

- Single `timeseries` object
- Cell array of `timeseries` objects

`tsc = tscollection(Time)` creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

`tsc = tscollection(...,'Parameter',Value,...)` creates a `tscollection` object with optional parameter-value pairs you enter after specifying either a time vector or a `timeseries` object. You can specify the following parameter:

- `Name` — String that specifies the name of this `tscollection` object

## Tips

### Definition: Time Series Collection

A time series collection object is a MATLAB variable that groups several time series with a common time vector. The time series that you include in the collection are called members of this collection.

### Properties of Time Series Collection Objects

This table lists the properties of the `tscollection` object. You can specify the `Time`, `TimeSeries`, and `Name` properties as input arguments in the constructor.

Property	Description
Name	tscollection name as a string. This can differ from the tscollection name in the MATLAB workspace.
Time	<p>When TimeInfo.StartDate is empty, values are measured relative to 0 . When TimeInfo.StartDate is defined, values represent date strings measured relative to the StartDate.</p> <p>The length of Time must be the same as the first or the last dimension of Data for each collection .</p>
TimeInfo	<p>Contains fields for contextual information about Time:</p> <ul style="list-style-type: none"> <li>• <b>Units</b> — Time units with any of the following values: 'weeks', 'days', 'hours', 'minutes', 'seconds', 'milliseconds', 'microseconds', 'nanoseconds'</li> <li>• <b>Start</b> — Start time</li> <li>• <b>End</b> — End time (read only)</li> <li>• <b>Increment</b> — Interval between subsequent time values. NaN when times are not uniformly sampled.</li> <li>• <b>Length</b> — Length of the time vector (read only)</li> <li>• <b>Format</b> — String defining the date string display format. See datestr.</li> <li>• <b>StartDate</b> — Date string defining the reference date. See setabstime (tscollection).</li> <li>• <b>UserData</b> — Any additional user-defined information</li> </ul>

## Examples

The following example shows how to create a tscollection object.

1 Import the sample data.

```
load count.dat
```

# tscollection

---

- 2** Create three `timeseries` objects to store each set of data:

```
count1 = timeseries(count(:,1),1:24,'name', 'ts1');
count2 = timeseries(count(:,2),1:24,'name', 'ts2');
count3 = timeseries(count(:,3),1:24,'name', 'ts3');
```

- 3** Create a `tscollection` object named `tsc` and add to it two out of three time series already in the MATLAB workspace, by using the following syntax:

```
tsc = tscollection({count1 count2},'name','tsc')
```

## See Also

`addts` | `datestr` | `setabstime` (`tscollection`) | `timeseries`

**Purpose** Construct event object for `timeseries` object

**Syntax**

```
e = tsdata.event(Name,Time)
e = tsdata.event(Name,Time,'Datenum')
```

**Description**

`e = tsdata.event(Name,Time)` creates an event object with the specified `Name` that occurs at the time `Time`. `Time` can either be a real value or a date string.

`e = tsdata.event(Name,Time,'Datenum')` uses `'Datenum'` to indicate that the `Time` value is a serial date number generated by the `datenum` function. The `Time` value is converted to a date string after the event is created.

**Tips** You add events by using the `addevent` method.

Fields of the `tsdata.event` object include the following:

- `EventData` — MATLAB array that stores any user-defined information about the event
- `Name` — String that specifies the name of the event
- `Time` — Time value when this event occurs, specified as a real number
- `Units` — Time units
- `StartDate` — A reference date, specified in MATLAB `datestr` format. `StartDate` is empty when you have a numerical (non-date-string) time vector.

# tsearchn

---

**Purpose** N-D closest simplex search

**Syntax** `t = tsearchn(X,TRI,XI)`  
`[t,P] = tsearchn(X,TRI,XI)`

**Description** `t = tsearchn(X,TRI,XI)` returns the indices `t` of the enclosing simplex of the Delaunay triangulation `TRI` for each point in `XI`. `X` is an `m`-by-`n` matrix, representing `m` points in `N`-dimensional space. `XI` is a `p`-by-`n` matrix, representing `p` points in `N`-dimensional space. `tsearchn` returns `NaN` for all points outside the convex hull of `X`. `tsearchn` requires a triangulation `TRI` of the points `X` obtained from `delaunayn`.

`[t,P] = tsearchn(X,TRI,XI)` also returns the barycentric coordinate `P` of `XI` in the simplex `TRI`. `P` is a `p`-by-`n+1` matrix. Each row of `P` is the barycentric coordinate of the corresponding point in `XI`. It is useful for interpolation.

**See Also** `delaunayTriangulation`

**Purpose** Open Time Series Tools GUI

**Compatibility** `tstool` will be removed in a future release.

- To create a time series object, use `timeseries`.
- To create a time series collection with one or more `timeseries` objects, use `tscollection`.
- To open a time series object or collection in the Variables editor, use `openvar`.
- To plot a time series object, use `plot`.

`tstool(sldata)` and `tstool(ModelDataLogs, 'replace')` have been removed. To view logged signal data, use the Simulink Simulation Data Inspector instead.

**Syntax**

```
tstool
tstool(ts)
tstool(tsc)
```

**Description**

`tstool` starts the Time Series Tools GUI without loading any data.

`tstool(ts)` starts the Time Series Tools GUI and loads the time-series object `ts` from the MATLAB workspace.

`tstool(tsc)` starts the Time Series Tools GUI and loads the time-series collection object `tsc` from the MATLAB workspace.

**See Also** `timeseries` | `tscollection`

**How To**

- “View Logged Signal Data with the Simulation Data Inspector”

# type

---

**Purpose** Display contents of file

**Syntax** `type('filename')`  
`type filename`

**Description** `type('filename')` displays the contents of the specified file in the MATLAB Command Window. Use the full path for `filename`, or use a MATLAB relative partial path.

If you do not specify a file extension and there is no `filename` file without an extension, the `type` function adds the `.m` extension by default. The `type` function checks the folders specified in the MATLAB search path, which makes it convenient for listing the contents of files on the screen. Use `type` with `more on` to see the listing one screen at a time.

`type filename` is the command form of the syntax.

**Examples** `type('foo.bar')` lists the contents of the file `foo.bar`.

`type foo` lists the contents of the file `foo`. If `foo` does not exist, `type foo` lists the contents of the file `foo.m`.

**See Also** `cd` | `dbtype` | `delete` | `dir` | `more` | `path` | `what` | `who`

**Purpose** Convert data types without changing underlying data

**Syntax** `Y = typecast(X, type)`

**Description** `Y = typecast(X, type)` converts a numeric value in `X` to the data type specified by `type`. Input `X` must be a full, noncomplex, numeric scalar or vector. The `type` input is a string set to one of the following: 'uint8', 'int8', 'uint16', 'int16', 'uint32', 'int32', 'uint64', 'int64', 'single', or 'double'.

`typecast` is different from the MATLAB `cast` function in that it does not alter the input data. `typecast` always returns the same number of bytes in the output `Y` as were in the input `X`. For example, casting the 16-bit integer 1000 to `uint8` with `typecast` returns the full 16 bits in two 8-bit segments (3 and 232) thus keeping its original value ( $3 \times 256 + 232 = 1000$ ). The `cast` function, on the other hand, truncates the input value to 255.

The output of `typecast` can be formatted differently depending on what system you use it on. Some computer systems store data starting with its most significant byte (an ordering called *big-endian*), while others start with the least significant byte (called *little-endian*).

---

**Note** MATLAB issues an error if `X` contains fewer values than are needed to make an output value.

---

## Examples

### Example 1

This example converts between data types of the same size:

```
typecast(uint8(255), 'int8')
ans =
 -1
```

```
typecast(int16(-1), 'uint16')
ans =
```

65535

## Example 2

Set X to a 1-by-3 vector of 32-bit integers, then cast it to an 8-bit integer type:

```
X = uint32([1 255 256])
X =
 1 255 256
```

Running this on a little-endian system produces the following results. Each 32-bit value is divided up into four 8-bit segments:

```
Y = typecast(X, 'uint8')
Y =
 1 0 0 0 255 0 0 0 0 1 0 0
```

The third element of X, 256, exceeds the 8 bits that it is being converted to in Y(9) and thus overflows to Y(10):

```
Y(9:12)
ans =
 0 1 0 0
```

Note that `length(Y)` is equal to `4.*length(X)`. Also note the difference between the output of `typecast` versus that of `cast`:

```
Z = cast(X, 'uint8')
Z =
 1 255 255
```

## Example 3

This example casts a smaller data type (`uint8`) into a larger one (`uint16`). Displaying the numbers in hexadecimal format makes it easier to see just how the data is being rearranged:

```
format hex
X = uint8([44 55 66 77])
X =
```

```
2c 37 42 4d
```

The first `typecast` is done on a big-endian system. The four 8-bit segments of the input data are combined to produce two 16-bit segments:

```
Y = typecast(X, 'uint16')
Y =
 2c37 424d
```

The second is done on a little-endian system. Note the difference in byte ordering:

```
Y = typecast(X, 'uint16')
Y =
 372c 4d42
```

You can format the little-endian output into big-endian (and vice versa) using the `swapbytes` function:

```
Y = swapbytes(typecast(X, 'uint16'))
Y =
 2c37 424d
```

## Example 4

This example attempts to make a 32-bit value from a vector of three 8-bit values. MATLAB issues an error because there are an insufficient number of bytes in the input:

```
format hex
typecast(uint8([120 86 52]), 'uint32')
```

Error using `typecast`  
Too few input values to make output type.

Repeat the example, but with a vector of four 8-bit values, and it returns the expected answer:

```
typecast(uint8([120 86 52 18]), 'uint32')
ans =
```

# typecast

cast | class | swapbytes

<b>Purpose</b>	Create container object to exclusively manage radio buttons and toggle buttons
<b>Syntax</b>	<pre>uibbuttongroup('PropertyName1',Value1,'PropertyName2',Value2,...) handle = uibbuttongroup(...)</pre>
<b>Description</b>	<p>A <code>uibbuttongroup</code> groups components and manages exclusive selection behavior for radio buttons and toggle buttons that it contains. It can also contain other user interface controls, axes, <code>uipanel</code>s, and <code>uibbuttongroups</code>. It cannot contain ActiveX controls.</p> <pre>uibbuttongroup('PropertyName1',Value1,'PropertyName2',Value2,...)</pre> creates a visible container component in the current figure window. This component manages exclusive selection behavior for <code>uicontrol</code> s of style <code>radiobutton</code> and <code>togglebutton</code> .
	<pre>handle = uibbuttongroup(...)</pre> creates a <code>uibbuttongroup</code> object and returns a handle to it in <code>handle</code> .
	A <code>uibbuttongroup</code> object can have axes, <code>uicontrol</code> , <code>uipanel</code> , and <code>uibbuttongroup</code> objects as children. However, only <code>uicontrol</code> s of style <code>radiobutton</code> and <code>togglebutton</code> are managed by the component.
	When programming a button group, you do not code callbacks for the individual buttons; instead, use its <code>SelectionChangeFcn</code> callback to manage responses to selections. The following example illustrates how you use <code>uibbuttongroup</code> event data to do this.
	For the children of a <code>uibbuttongroup</code> object, the <code>Position</code> property is interpreted relative to the button group. If you move the button group, the children automatically move with it and maintain their positions in the button group.
	If you have a button group that contains a set of radio buttons and toggle buttons and you want:
	<ul style="list-style-type: none"><li>• An immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's <code>SelectionChangeFcn</code> callback function, not in the individual toggle button <code>Callback</code> functions. See the</li></ul>

# uibuttongroup

---

SelectionChangeFcn property and the example on this reference page for more information.

- Another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

Use the `Parent` property to specify the parent as a figure, `uipanel`, or `uibuttongroup`. If you do not specify a parent, `uibuttongroup` adds the button group to the current figure. If no figure exists, one is created.

See the `Uibuttongroup Properties` reference page for more information.

After creating a `uibuttongroup`, you can set and query its property values using `set` and `get`. Run `get(handle)` to see a list of properties and their current values. Run `set(handle)` to see a list of object properties you can set and their legal values.

## Tips

If you set the `Visible` property of a `uibuttongroup` object to `'off'`, any child objects it contains (buttons, button groups, etc.) become invisible along with the `uibuttongroup` panel itself. However, doing this does *not* affect the settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the button group's visibility is set to `'on'`. `uipanel` components also behave in this manner.

Do not use the `CreateFcn` of a button group to create the buttons it contains. You can toggle buttons created in the button group `CreateFcn` on and off, but clicking them does not trigger the button group `SelectionChangeCallback` and the buttons do not display the expected mutually-exclusive behavior.

## Examples

This example creates a `uibuttongroup` with three radio buttons. It manages the radio buttons with the `SelectionChangeFcn` callback, `selcbk`.

When you select a new radio button, `selcbk` displays the `uibuttongroup` handle on one line, the `EventName`, `OldValue`, and `NewValue` fields

of the event data structure on a second line, and the value of the SelectedObject property on a third line.

```
% Create the button group.
h = uibuttongroup('visible','off','Position',[0 0 .2 1]);
% Create three radio buttons in the button group.
u0 = uicontrol('Style','radiobutton','String','Option 1',...
 'pos',[10 350 100 30],'parent',h,'HandleVisibility','off');
u1 = uicontrol('Style','radiobutton','String','Option 2',...
 'pos',[10 250 100 30],'parent',h,'HandleVisibility','off');
u2 = uicontrol('Style','radiobutton','String','Option 3',...
 'pos',[10 150 100 30],'parent',h,'HandleVisibility','off');
% Initialize some button group properties.
set(h,'SelectionChangeFcn',@selcbk);
set(h,'SelectedObject',[]); % No selection
set(h,'Visible','on');
```

For the SelectionChangeFcn callback, selcbk, the source and event data structure arguments are available only if selcbk is called using a function handle. See SelectionChangeFcn for more information.

```
function selcbk(source,eventdata)
disp(source);
disp([eventdata.EventName, ' ',...
 get(eventdata.OldValue,'String'),' ', ...
 get(eventdata.NewValue,'String')]);
disp(get(get(source,'SelectedObject'),'String'));
```

# uibuttongroup

---

If you click Option 2 with no option selected, the SelectionChangeFcn callback, selcbk, displays:

```
3.0011
```

```
SelectionChanged Option 2
Option 2
```

If you then click Option 1, the SelectionChangeFcn callback, selcbk, displays:

```
3.0011
```

```
SelectionChanged Option 2 Option 1
Option 1
```

# Uibuttongroup Properties

---

## Purpose

Describe button group properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from the GUIDE Layout Editor **View** menu, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

Uibuttongroup takes its default property values from `uipanel`. To set a `uibuttongroup` default property value, set the default for the corresponding `uipanel` property. Note that you can set no default values for the `uibuttongroup` `SelectedObject` and `SelectionChangeFcn` properties.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uibuttongroup Properties

This section describes all properties useful to `uibuttongroup` objects and lists valid values. Curly braces `{ }` enclose default values.

Property Name	Description
<code>BackgroundColor</code>	Color of the button group background
<code>BeingDeleted</code>	This object is being deleted
<code>BorderType</code>	Type of border around the button group
<code>BorderWidth</code>	Width of the button group border in pixels
<code>BusyAction</code>	Interruption of other callback routines
<code>ButtonDownFcn</code>	Button-press callback routine
<code>Children</code>	All children of the button group

# Uibuttongroup Properties

Property Name	Description
Clipping	Clipping of child axes, panels, and button groups to the button group. Does not affect child user interface controls (uicontrol)
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
FontAngle	Title font angle
FontName	Title font name
FontSize	Title font size
FontUnits	Title font units
FontWeight	Title font weight
ForegroundColor	Title font color and color of 2-D border line
HandleVisibility	Handle accessibility from command line and GUIs
HighlightColor	3-D frame highlight color
Interruptible	Callback routine interruption mode
Parent	uibuttongroup object's parent
Position	Button group position relative to parent figure, panel, or button group
ResizeFcn	User-specified resize routine
SelectedObject	Currently selected uicontrol of style radiobutton or togglebutton
SelectionChangeFcn	Callback routine executed when the selected radio button or toggle button changes
ShadowColor	3-D frame shadow color
Tag	User-specified object identifier

# Uibuttongroup Properties

---

Property Name	Description
Title	Title string
TitlePosition	Location of title string in relation to the button group
Type	Object class
UIContextMenu	Associate context menu with the button group
Units	Units used to interpret the position vector
UserData	User-specified data
Visible	Button group visibility  <b>Note</b> Controls the visibility of a uibuttongroup and of its child axes, uibuttongroups, uipanel, and child uicontrols. Setting it does not change their Visible property.

BackgroundColor  
ColorSpec

*Color of the uibuttongroup background.* A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the ColorSpec reference page for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the BeingDeleted property to on when the object's delete function callback is called (see the DeleteFcn property). It remains set to on while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BorderType

`none` | `{etchedin}` | `etchedout` |  
`beveledin` | `beveledout` | `line`

*Border of the uibuttongroup area.* Used to define the button group area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders. A line border is 2-D. Use the `ForegroundColor` property to specify its color.

## BorderWidth

integer

*Width of the button group border.* The width of the button group borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

## BusyAction

`cancel` | `{queue}`

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- `'queue'` — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.

# Uibuttongroup Properties

---

- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

`ButtonDownFcn`  
string or function handle

*Button-press callback routine.* A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the `uibuttongroup`. This is useful for implementing actions to interactively modify object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

`Children`  
vector of handles

*Children of the uibuttongroup.* A vector containing the handles of all children of the `uibuttongroup`. Although a `uibuttongroup` manages only `uicontrols` of style `radiobutton` and `togglebutton`, its children can be axes, `uipanel`s, `uibuttongroup`s, and other `uicontrol`s. You can use this property to reorder the children.

`Clipping`  
{on} | off

*Clipping mode.* By default, MATLAB clips a `uibuttongroup`'s child axes, `uipanel`s, and `uibuttongroup`s to the `uibuttongroup` rectangle. If you set `Clipping` to `off`, the axis, `uipanel`, or `uibuttongroup` display outside the button group rectangle. This

property does not affect child uicontrols which, by default, can display outside the button group rectangle.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uibuttongroup` object. MATLAB sets all property values for the `uibuttongroup` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the `uibuttongroup` being created.

Setting this property on an existing `uibuttongroup` object has no effect.

To define a default `CreateFcn` callback for all new `uibuttongroups` you must define the same default for all `uipanel`s. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uibuttongroup`. For example, the code

```
set(0, 'DefaultUipanelCreateFcn', 'set(gcb0, ...
 ' 'FontName', 'arial', 'FontSize', 12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel or button group. It sets the default font name and font size of the `uipanel` or `uibuttongroup` title.

To override this default and create a button group whose `FontName` and `FontSize` properties are set to different values, call `uibuttongroup` with code similar to

```
hpt = uibuttongroup(..., 'CreateFcn', 'set(gcb0, ...
 ' 'FontName', 'times', 'FontSize', 14)')
```

# Uibuttongroup Properties

---

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uibuttongroup` call. In the example above, if instead of redefining the `CreateFcn` property for this `uibuttongroup`, you had explicitly set `FontSize` to 14, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

`DeleteFcn`  
string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uibuttongroup` object (e.g., when you issue a delete command or clear the figure containing the `uibuttongroup`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

`FontAngle`  
{normal} | italic | oblique

*Character slant used in the Title.* MATLAB uses this property to select a font from those available on your particular system.

Setting this property to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

FontName  
string

*Font family used in the Title.* The name of the font in which to display the `Title`. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set `FontName` to the string `FixedWidth`. This string value is case insensitive.

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root `FixedWidthFontName` property, which can be set to the appropriate value for a locale from `startup.m` in the end user's environment. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

FontSize  
integer

*Title font size.* A number specifying the size of the font in which to display the `Title`, in units determined by the `FontUnits` property. The default size is system dependent.

FontUnits  
inches | centimeters | normalized |  
{points} | pixels

*Title font size units.* Normalized units interpret `FontSize` as a fraction of the height of the `uibuttongroup`. When you resize the `uibuttongroup`, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).

# Uibuttongroup Properties

---

## FontWeight

light | {normal} | demi | bold

*Weight of characters in the title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to bold causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

ColorSpec

*Color used for title font and 2-D border line.* A three-element RGB vector or one of the MATLAB predefined names, specifying the font or line color. See the ColorSpec reference page for more information on specifying color.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

---

**Note** Uicontrols of style `radiobutton` and `togglebutton` that are managed by a `uibuttongroup` should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to `off` or `callback` to prevent inadvertent access.

---

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`  
`ColorSpec`

*3-D frame highlight color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`Interruptible`  
`off` | `{on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

# Uibuttongroup Properties

---

- ButtonDownFcn
- KeyPressFcn
- KeyReleaseFcn
- WindowButtonDownFcn
- WindowButtonMotionFcn
- WindowButtonUpFcn
- WindowKeyPressFcn
- WindowKeyReleaseFcn
- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

# Uibuttongroup Properties

---

Setting the `Interruptible` property to on (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uibuttongroup parent.* The handle of the `uibuttongroup`’s parent figure, `uipanel`, or `uibuttongroup`. You can move a `uibuttongroup` object to another figure, `uipanel`, or `uibuttongroup` by setting this property to the handle of the new parent.

## Position

position rectangle

# Uibuttongroup Properties

---

*Size and location of uibuttongroup relative to parent.* The rectangle defined by this property specifies the size and location of the button group within the parent figure window, uipanel, or uibuttongroup. Specify `Position` as

```
[left bottom width height]
```

`left` and `bottom` are the distance from the lower-left corner of the parent object to the lower-left corner of the `uibuttongroup` object. `width` and `height` are the dimensions of the `uibuttongroup` rectangle, including the title. All measurements are in units specified by the `Units` property.

`ResizeFcn`  
string or function handle

*Resize callback routine.* MATLAB executes this callback routine whenever a user resizes the `uibuttongroup` and the figure `Resize` property is set to `on`, or in GUIDE, the **Resize behavior** option is set to `Other`. You can query the `uibuttongroup Position` property to determine its new size and position. During execution of the callback routine, the handle to the figure being resized is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

You can use `ResizeFcn` to maintain a GUI layout that is not directly supported by the MATLAB `Position/Units` paradigm.

For example, consider a GUI layout that maintains an object at a constant height in pixels and attached to the top of the figure, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the `uicontrol` whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the `uicontrol` handle, and the `gcbo` function to retrieve the figure handle. Also note the defensive programming regarding figure `Units`, which the callback requires to be in pixels in order to work

correctly, but which the callback also restores to their previous value afterwards.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within the `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

Note that the `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

## Selected

on | off (read only)

*Is object selected?* This property indicates whether the button group is selected. When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` function to set this property, allowing users to select the object with the mouse.

## SelectedObject

scalar handle

*Currently selected radio button or toggle button uicontrol* in the managed group of components. Use this property to determine the currently selected component or to initialize selection of one of

# Uibuttongroup Properties

---

the radio buttons or toggle buttons. By default, `SelectedObject` is set to the first uicontrol radio button or toggle button that is added. Set it to `[]` if you want no selection. Note that `SelectionChangeFcn` does not execute when this property is set by the user.

`SelectionChangeFcn`  
string or function handle

Callback routine executed when the selected radio button or toggle button changes. If this routine is called as a function handle, `uibuttongroup` passes it two arguments. The first argument, `source`, is the handle of the `uibuttongroup`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table.

Event Data Structure Field	Description
<code>EventName</code>	'SelectionChanged'
<code>OldValue</code>	Handle of the object selected before this event. <code>[]</code> if none was selected.
<code>NewValue</code>	Handle of the currently selected object.

If you have a button group that contains a set of radio buttons and/or toggle buttons and you want an immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function, not in the individual toggle button `Callback` functions.

If you want another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

---

**Note** For GUIDE GUIs, `hObject` contains the handle of the selected radio button or toggle button. See “Callbacks for Specific Components” for more information.

---

**SelectionHighlight**

`{on} | off`

*Object highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

**ShadowColor**

`ColorSpec`

*3-D frame shadow color.* `ShadowColor` is a three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the `ColorSpec` reference page for more information on specifying color.

**Tag**

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

# Uibuttongroup Properties

---

## Title

string

*Title string.* The text displayed in the button group title. You can position the title using the `TitlePosition` property.

Vertical slash (`|`) characters are not interpreted as line breaks and instead show up in the text displayed in the `uibuttongroup` title.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in “Defining Default Values”. To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uibuttongroup('Title','\default');
```

## TitlePosition

{lefttop} | centertop | righttop |  
leftbottom | centerbottom | rightbottom

*Location of the title.* This property determines the location of the title string, in relation to the `uibuttongroup`.

## Type

string (read-only)

*Object class.* This property identifies the kind of graphics object. For `uibuttongroup` objects, `Type` is always the string `'uipanel'`, because its default properties derive from `uipanel`.

## UIContextMenu

handle

*Associate a context menu with a uibuttongroup.* Assign this property the handle of a `Uicontextmenu` object. MATLAB displays the context menu whenever you right-click the `uibuttongroup`. Use the `uicontextmenu` function to create the context menu.

## Units

inches | centimeters | {normalized} |  
points | pixels | characters

*Units of measurement.* MATLAB uses these units to interpret the `Position` property. For the button group itself, units are measured from the lower-left corner of its parent figure window, panel, or button group. For children of the button group, they are measured from the lower-left corner of the button group.

- Normalized units map the lower-left corner of the button group or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uibuttongroup` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

{on} | off

*Uibuttongroup visibility.* By default, a `uibuttongroup` object is visible. When set to 'off', the `uibuttongroup` is not visible, as

# Uibuttongroup Properties

---

are all child objects of the button group. When a button group is hidden in this manner, you can still query and set its properties.

---

**Note** The value of a uibuttongroup's `Visible` property determines whether its child components, such as axes, buttons, uipanel, and other uibuttongroups, are visible. However, changing the `Visible` property of a button group does *not* change the settings of the `Visible` property of its child components even though hiding the button group causes them to be hidden.

---

<b>Purpose</b>	Create context menu
<b>Syntax</b>	<code>handle = uicontextmenu('PropertyName',PropertyValue,...)</code>
<b>Description</b>	<p><code>handle = uicontextmenu('PropertyName',PropertyValue,...)</code> creates a context menu, which is a menu that appears when the user right-clicks on a graphics object. See Uicontextmenu Properties for more information.</p> <p>In its initial state, a context menu has no menu items. You create menu items within the context menu using the <code>uimenu</code> function. Menu items appear in the order in which the <code>uimenu</code> statements appear. You then associate a context menu with an object by specifying the handle of the context menu as the value for its <code>UIContextMenu</code> property.</p>

## Examples

The following statements define a context menu associated with a line on a graph. The menu items enable you to change the line style.

```
% Create axes and save handle
hax = axes;
% Plot three lines
plot(rand(20,3));
% Define a context menu; it is not attached to anything
hcmenu = uicontextmenu;
% Define callbacks for context menu
% items that change linestyle
hcb1 = ['set(gcf,'LineStyle','--')'];
hcb2 = ['set(gcf,'LineStyle',':')'];
hcb3 = ['set(gcf,'LineStyle','-')'];
% Define the context menu items and install their callbacks
item1 = uimenu(hcmenu,'Label','dashed','Callback',hcb1);
item2 = uimenu(hcmenu,'Label','dotted','Callback',hcb2);
item3 = uimenu(hcmenu,'Label','solid','Callback',hcb3);
% Locate line objects
hlines = findall(hax,'Type','line');
% Attach the context menu to each line
for line = 1:length(hlines)
```

# uicontextmenu

---

```
set(hlines(line),'uicontextmenu',hcmenu)
end
```

When you right-click on any line (or, on a Macintosh computer with a one-button mouse, press the **Ctrl** key and click), the context menu appears, as shown in the following figure.

To make context menus available immediately, attach them to lines at the time they are plotted. Therefore, when creating a GUI that uses such context menus, place code like the preceding in the callbacks that perform plotting for the GUI.

A best practice is to use function handles for callbacks. Only define callbacks as strings for simple actions. For example, you can add check marks to menu items (using the `Checked` `uimenu` property) to indicate the current style for each line. To manage the check marks, define the menu item callbacks as function handles. Place the code for the functions in the GUI code file rather than placing callback strings in the figure.

Generally, you need to attach context menus to lines at the time they are plotted in order to be sure that the menus are immediately available. Therefore, code such as the above could be placed in or called from the callbacks that perform plotting for the GUI.

# Uicontextmenu Properties

---

## Purpose

Describe context menu properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uicontextmenu Properties

This section lists all properties useful to `uicontextmenu` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

Property	Purpose
<code>BeingDeleted</code>	This object is being deleted
<code>BusyAction</code>	Callback routine interruption
<code>Callback</code>	Control action
<code>Children</code>	The <code>uimenu</code> s defined for the <code>uicontextmenu</code>
<code>CreateFcn</code>	Callback routine executed during object creation
<code>DeleteFcn</code>	Callback routine executed during object deletion
<code>HandleVisibility</code>	Whether handle is accessible from command line and GUIs
<code>Interruptible</code>	Callback routine interruption mode
<code>Parent</code>	<code>Uicontextmenu</code> object's parent

Property	Purpose
Position	Location of uicontextmenu when Visible is on
Tag	User-specified object identifier
Type	Class of graphics object
UserData	User-specified data
Visible	Uicontextmenu visibility

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the **BeingDeleted** property to **on** when the object's delete function callback is called (see the **DeleteFcn** property). It remains set to **on** while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's **BeingDeleted** property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The **BusyAction** property of the *interrupting* callback determines how MATLAB handles its execution. When the **BusyAction** property is set to:

# Uicontextmenu Properties

---

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

**Callback**  
string

*Control action.* A routine that executes whenever you right-click an object for which a context menu is defined. The routine executes immediately before the context menu is posted. Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

**Children**  
matrix

The `uimenu` items defined for the `uicontextmenu`.

**CreateFcn**  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uicontextmenu` object. MATLAB sets all property values for the `uicontextmenu` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcb0` to get the handle of the `uicontextmenu` being created.

Setting this property on an existing `uicontextmenu` object has no effect.

You can define a default `CreateFcn` callback for all new `uicontextmenus`. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontextmenu`. For example, the code

```
set(0,'DefaultUicontextmenuCreateFcn','set(gcbo,...
 'Visible','on'))
```

creates a default `CreateFcn` callback that runs whenever you create a new context menu. It sets the default `Visible` property of a context menu.

To override this default and create a context menu whose `Visible` property is set to a different value, call `uicontextmenu` with code similar to

```
hpt = uicontextmenu(...,'CreateFcn','set(gcbo,...
 'Visible','off'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontextmenu` call. In the example above, if instead of redefining the `CreateFcn` property for this `uicontextmenu`, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

# Uicontextmenu Properties

---

## DeleteFcn

string or function handle

*Delete uicontextmenu callback routine.* A callback routine that executes when you delete the `uicontextmenu` object (for example, when you issue a `delete` command or clear the figure containing the `uicontextmenu`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

For information on the syntax of callback functions, see [Function Handle Callbacks](#).

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from

command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This might be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`Interruptible`  
`off | {on}`

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

# Uicontextmenu Properties

---

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted.

For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## Parent

handle

*Uicontextmenu’s parent.* The handle of the `uicontextmenu`’s parent object, which must be a figure.

## Position

vector

*Uicontextmenu’s position.* A two-element vector that defines the location of a context menu posted by setting the `Visible` property value to `on`. Specify `Position` as

[x y]

where vector elements represent the horizontal and vertical distances in pixels from the bottom left corner of the figure window.

## Tag

string

*User-specified object label.* The `Tag` property provides a means to identify graphics objects with a user-specified label. This

# Uicontextmenu Properties

---

is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

## Type

string

*Class of graphics object.* For `uicontextmenu` objects, `Type` is always the string `'uicontextmenu'`.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uicontextmenu` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

on | {off}

*Uicontextmenu visibility.* The `Visible` property can be used in two ways:

- Its value indicates whether the context menu is currently posted. While the context menu is posted, the property value is `on`; when the context menu is not posted, its value is `off`.
- Its value can be set to `on` to force the posting of the context menu. Similarly, setting the value to `off` forces the context menu to be removed. When used in this way, the `Position` property determines the location of the posted context menu.

## See Also

`uicontextmenu`

**Purpose**

Create user interface control object

**Syntax**

```
handle = uicontrol('Name',Value,...)
handle = uicontrol(parent,'Name',Value,...)
handle = uicontrol
uicontrol(uich)
```

**Description**

`handle = uicontrol('Name',Value,...)` creates a `uicontrol` and assigns the specified properties and values to it. It assigns the default values to any properties you do not specify. The default `uicontrol` style is `pushbutton`. The default parent is the current figure. See the `Uicontrol Properties` reference page for more information.

`handle = uicontrol(parent,'Name',Value,...)` creates a `uicontrol` in the object specified by the handle, `parent`. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence. `parent` can be the handle of a figure, `uipanel`, or `uibuttongroup`.

`handle = uicontrol` creates a push button in the current figure. The `uicontrol` function assigns all properties their default values.

`uicontrol(uich)` gives focus to the `uicontrol` specified by the handle, `uich`.

`uicontrol` creates a `uicontrol` graphics objects (user interface controls), which you use to implement graphical user interfaces.

**Specifying the Uicontrol Style**

When selected, most `uicontrol` objects perform a predefined action. To create a specific type of `uicontrol`, set the `Style` property as one of the strings that follow. You can specify a partial string if it is unique among all the styles. For example, instead of `'radiobutton'`, you can specify `'radio'`.

- `'checkbox'` – A check box generates an action when you select it. Use check boxes to provide a number of independent choices. To activate a check box, click the mouse button on the object. The check box updates its appearance when its state changes.

- 'edit' – Editable text fields enable you to enter or modify text values. Use editable text when you want free text as input. To enable multiple lines of text, set `Max-Min>1`. Multiline edit boxes provide a vertical scroll bar for scrolling. The arrow keys also provide a way to scroll. Obtain the current text by getting the `String` property. The `String` property does not update as you type in an edit box. To execute the callback routine for an edit text control, type in the desired text and then do one of the following:
  - Click another component, the menu bar, or the background of the GUI.
  - For a single line editable text box, press **Enter**.
  - For a multiline editable text box, press **Ctrl+Enter**.
- 'frame'

---

**Note** MathWorks recommends you use `uipanel` or `uibuttongroup` instead of frames.

GUIDE continues to support frames in those GUIs that contain them, but the frame component does not appear in the GUIDE Layout Editor component palette.

---

- 'listbox' – List boxes display a list of items, from which you can select one or more items. Unlike pop-up menus, list boxes do not expand when clicked. The `Min` and `Max` properties control the selection mode:
  - To enable multiple selection of items, set `Max-Min > 1`.
  - To enable selection of only one item at a time, set `Max-Min <= 1`.

The `Value` property stores the row indexes of currently selected list box items, and is a vector value when you select multiple items. After any mouse button up event that changes the `Value` property, MATLAB evaluates the list box's callback routine. To delay action

when multiple items can be selected, you can associate a "Done" push button with the list box. Use the callback for that button to evaluate the list box `Value` property.

List boxes with the `Enable` property set to `on` differentiate between single and double left clicks. MATLAB sets the figure `SelectionType` property to `normal` or `open` accordingly before evaluating the list box `Callback` property. For enabled list boxes, **Ctrl**-left click and **Shift**-left click also set the figure `SelectionType` property to `normal` or `open`, respectively indicating a single or double click.

- `'popupmenu'` – Pop-up menus (also known as drop-down menus or combo boxes) display a list of choices when you open them with a button-press. When closed, a pop-up menu indicates the current choice. Pop-up menus are useful when you want to provide a number of mutually exclusive choices, but do not want to take up the amount of space that a group of radio buttons requires.
- `'pushbutton'` – Push buttons generate an action when activated. Left-click a push button to activate it. The button appears to depress until you release the mouse button. The callback activates when you release the mouse button while still pointing within the push button.
- `'radiobutton'` – Radio buttons are similar to check boxes, but are intended to be mutually exclusive within a group of related radio buttons. When used this way, you can only select one radio button at any given time). To activate a radio button, click and release the mouse button over it. The easiest way to implement mutually exclusive behavior for a set of radio buttons is to place them within a `uibuttongroup`.
- `'slider'` – Sliders accept numeric input within a specific range when you move the “thumb” button along a bar. The location of the thumb indicates a numeric value, assigned to the `Value` property when you release the mouse button. You can set the minimum, maximum, and current values, and step sizes of a slider.

Move the thumb by doing any one of the following:

- Press the mouse button on the thumb, and drag it along the bar.

- Click in the bar or on arrow buttons located at both ends of the bar.
- Click the keyboard arrow keys when the slider is in focus.
- 'text' – Static text boxes display lines of text. You typically use static text to label other controls, provide information to the user, or indicate values associated with a slider. Users cannot change static text interactively. Static text controls do not activate callback routines when clicked.
- 'togglebutton' – Toggle buttons are similar in appearance to push buttons, but they visually indicate their state, either on (pressed down) or off (up). Clicking a toggle button changes its state, and switches its Value property between Min and Max.

## Tips

- To simulate activation on static text by a mouse click, set the text *object's* Enable property to Inactive, and set its ButtonDownFcn callback to perform an action. For example, the following code displays "Text was clicked" in the Command Window when you click on the Click Me! text in the running GUI. (Without the set command, it would do nothing.)

```
h = uicontrol('Style','text','String','Click Me!');
set(h,'Enable','Inactive','ButtonDownFcn',...
 'disp(''Text was clicked'')')
```

- Adding a uicontrol to a figure removes the figure toolbar when the figure Toolbar property is 'auto' (which is the default). To prevent this from happening, set the Toolbar property to 'figure'. You can restore the toolbar by selecting **Figure Toolbar** from the **View** menu regardless of this property setting.
- The uicontrol function accepts property name/property value pairs, structures, and cell arrays as input arguments and optionally returns the handle of the created object. You can also use the set and get functions to set and query property values after creating the control.
- A uicontrol object is a child of a figure, uipanel, or uibuttongroup. Therefore, the uicontrol object does not require an axes to exist when placed in a figure window, uipanel, or uibuttongroup.

- When you pause MATLAB and a uicontrol has focus, pressing a keyboard key does not cause MATLAB to resume. Click anywhere outside a uicontrol and then press any key. For more information, see the `pause` function.

## Examples

Create a figure and an axes to contain a 3-D surface plot.

```
figure
hax = axes('Units','pixels');
surf(peaks)
```

Place a uicontrol object to let users change the colormap with a pop-up menu. Supply a function handle as the object's `Callback` property.

```
uicontrol('Style','popup',...
 'String','jet|hsv|hot|cool|gray',...
 'Position',[20 340 100 50],...
 'Callback',@setmap);
% The popup function handle callback
% is implemented as a local function
```

Add a different uicontrol. Create a push button that clears the current axes when pressed. Position the button inside the axes at the lower left. All uicontrols have default units of pixels. In this example, the axes has units of pixels, as well.

```
uicontrol('Style', 'pushbutton', 'String', 'Clear',...
 'Position', [20 20 50 20],...
 'Callback', 'cla');
% The pushbutton string callback
% calls a MATLAB function
```

Add a slider uicontrol to control the vertical scaling of the surface object. Position it at the bottom right corner of the figure. Then add a text uicontrol as a label for the slider.

```
uicontrol('Style', 'slider',...
 'Min',1,'Max',50,'Value',41,...
 'Position', [400 20 120 20],...
 'Callback', {@surfzlim,hax});
% Uses cell array function handle callback
```

# uicontrol

```
% Implemented as a local function with an argument

uicontrol('Style','text',...
 'Position',[400 45 120 20],...
 'String','Vertical Exaggeration')
```

To operate the controls, you need callback functions. The callback for the pop-up menu is a local function called `setmap` that contains the following code.

```
function setmap(hObject,event) %#ok<INUSD>
% Called when user activates popup menu
val = get(hObject,'Value');
if val ==1
 colormap(jet)
elseif val == 2
 colormap(hsv)
elseif val == 3
 colormap(hot)
elseif val == 4
 colormap(cool)
elseif val == 5
 colormap(gray)
end
end
```

The callback for the slider is also a local function in the same file, and contains the following code.

```
function surfzlim(hObject,event,ax) %#ok<INUSL>
% Called to set zlim of surface in figure axes
% when user moves the slider control
val = 51 - get(hObject,'Value');
zlim(ax,[-val val]);
end
```

To use the uicontrols in the example, you need to put all the functions in a MATLAB code file. Copy the following code and paste it into a new file. Save the file as `ex_uicontrol.m` on your search path, and then run it.

```
function ex_uicontrol
% Example code for uicontrol reference page

% Create a figure and an axes to
% contain a 3-D surface plot.
figure
hax = axes('Units','pixels');
```

```
surf(peaks)
% Create a uicontrol object to let users
% change the colormap with a pop-up menu.
% Supply a function handle as the object's
% Callback:
uicontrol('Style', 'popup',...
 'String', 'hsv|hot|cool|gray',...
 'Position', [20 340 100 50],...
 'Callback', @setmap);

% Add a different uicontrol. Create a push button
% that clears the current axes when pressed.
% Position the button inside the axes at the lower
% left. All uicontrols have default units of pixels.
% In this example, the axes does as well.
uicontrol('Style', 'pushbutton', 'String', 'Clear',...
 'Position', [20 20 50 20],...
 'Callback', 'cla');

% Add a slider uicontrol to control the vertical
% scaling of the surface object. Position it
% under the Clear button.
uicontrol('Style', 'slider',...
 'Min',1,'Max',50,'Value',41,...
 'Position', [400 20 120 20],...
 'Callback', {@surfzlim,hax});
% Slider function handle callback
% Implemented as a local function

% Add a text uicontrol to label the slider.
uicontrol('Style','text',...
 'Position',[400 45 120 20],...
 'String','Vertical Exaggeration')
end

function setmap(hObj,event) %#ok<INUSD>
```

```
% Called when user activates popup menu
val = get(hObject,'Value');
if val ==1
 colormap(jet)
elseif val == 2
 colormap(hsv)
elseif val == 3
 colormap(hot)
elseif val == 4
 colormap(cool)
elseif val == 5
 colormap(gray)
end
end

function surfzlim(hObject,event,ax) %#ok<INUSL>
% Called to set zlim of surface in figure axes
% when user moves the slider control
val = 51 - get(hObject,'Value');
zlim(ax,[-val val]);
end
```

# Uicontrol Properties

---

## Purpose

Describe user interface control (`uicontrol`) properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

To change the default value of properties see “Setting Default Property Values”. You can also set default `uicontrol` properties on the root and figure levels:

```
set(0, 'DefaultUicontrolProperty', PropertyValue...)
set(gcf, 'DefaultUicontrolProperty', PropertyValue...)
```

where *Property* is the name of the `uicontrol` property whose default value you want to set and *PropertyValue* is the value you are specifying as the default. Use `set` and `get` to access `uicontrol` properties.

For information on using these `uicontrols` within GUIDE, the MATLAB GUI development environment, see Programming GUI Components in the MATLAB Creating GUIs documentation.

## Uicontrol Properties

This section lists all properties useful to `uicontrol` objects along with valid values and descriptions of their use. Curly braces `{}` enclose default values.

Property	Purpose
<code>BackgroundColor</code>	Object background color
<code>BeingDeleted</code>	This object is being deleted
<code>BusyAction</code>	Callback routine interruption
<code>ButtonDownFcn</code>	Button-press callback routine

# Uicontrol Properties

<b>Property</b>	<b>Purpose</b>
Callback	Control action
CData	Truecolor image displayed on the control
Children	Uicontrol objects have no children
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
Enable	Enable or disable the uicontrol
Extent	position rectangle (read only)
FontAngle	Character slant
FontName	Font family
FontSize	Font size
FontUnits	Font size units
FontWeight	Weight of text characters
ForegroundColor	Color of text
HandleVisibility	Whether handle is accessible from command line and GUIs
HorizontalAlignment	Alignment of label string
Interruptible	Callback routine interruption mode
KeyPressFcn	Key press callback routine
ListboxTop	Index of top-most string displayed in list box
Max	Maximum value (depends on uicontrol object)
Min	Minimum value (depends on uicontrol object)
Parent	Uicontrol object's parent

# Uicontrol Properties

---

Property	Purpose
Position	Size and location of uicontrol object
SliderStep	Slider step size
String	Uicontrol object label, also list box and pop-up menu items
Style	Type of uicontrol object
Tag	User-specified object identifier
TooltipString	Content of object's tooltip
Type	Class of graphics object
UIContextMenu	Uicontextmenu object associated with the uicontrol
Units	Units to interpret position vector
UserData	User-specified data
Value	Current value of uicontrol object
Visible	Uicontrol visibility

BackgroundColor  
ColorSpec

*Object background color.* The color used to fill the uicontrol rectangle. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default color is determined by system settings. See `ColorSpec` for more information on specifying color.

---

**Note** Platform look and feel for a GUI element can override change requests from MATLAB. It is possible your system will not honor a request to change the background color.

---

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

# Uicontrol Properties

---

## ButtonDownFcn

string or function handle (GUIDE sets this property)

*Button-press callback routine.* A callback routine that can execute when you press a mouse button while the pointer is on or near a uicontrol. Specifically:

- If the uicontrol's `Enable` property is set to `on`, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the uicontrol or when you click the right mouse button on the control itself.
- If the uicontrol's `Enable` property is set to `inactive` or `off`, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using `selectmoveresize`, for example).

Define this routine as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the code file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets this property to the appropriate string and adds the callback to the code file.

Use the `Callback` property to specify the callback routine that executes when you activate the enabled uicontrol (e.g., click a push button).

## Callback

string or function handle (GUIDE sets this property)

*Control action.* A function that executes whenever you activate the uicontrol object (e.g., when you click on a push button or move a slider). Define this function as a string that is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

See “Callbacks for Specific Components” for examples of callback functions for each style of component.

## CData

matrix

*Truecolor image displayed on control.* A three-dimensional matrix of RGB values that defines a truecolor image displayed on a control, which must be a **push button** or **toggle button**. Each value must be between 0.0 and 1.0. Setting CData on a **radio button** or **checkbox** will replace the default CData on these controls. The control will continue to work as expected, but its state is not reflected by its appearance when clicked.

For **push buttons** and **toggle buttons**, CData overlaps the String. In the case of **radio buttons** and **checkboxes**, CData takes precedence over String and, depending on its size, it can displace the text.

Setting CData to [] restores the default CData for **radio buttons** and **checkboxes**.

## Children

matrix

The empty matrix; uicontrol objects have no children.

## Clipping

{on} | off

# Uicontrol Properties

---

This property has no effect on `uicontrol` objects.

`CreateFcn`  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uicontrol` object. MATLAB sets all property values for the `uicontrol` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the `uicontrol` being created.

Setting this property on an existing `uicontrol` object has no effect.

You can define a default `CreateFcn` callback for all new `uicontrol`s. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uicontrol`. For example, the code

```
set(0, 'DefaultUicontrolCreateFcn', 'set(gcbo, ...
 'BackgroundColor', 'white')')
```

creates a default `CreateFcn` callback that runs whenever you create a new `uicontrol`. It sets the default background color of all new `uicontrol`s.

To override this default and create a `uicontrol` whose `BackgroundColor` is set to a different value, call `uicontrol` with code similar to

```
hpt = uicontrol(..., 'CreateFcn', 'set(gcbo, ...
 'BackgroundColor', 'blue')')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uicontrol` call. In the example above, if instead of redefining the `CreateFcn` property for this `uicontrol`, you had explicitly set `BackgroundColor` to `blue`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `white`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Delete uicontrol callback routine.* A callback routine that executes when you delete the `uicontrol` object (e.g., when you issue a `delete` command or clear the figure containing the `uicontrol`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Enable

{on} | inactive | off

# Uicontrol Properties

---

*Enable or disable the uicontrol.* This property controls how uicontrols respond to mouse button clicks, including which callback routines execute.

- **on** – The uicontrol is operational (the default).
- **inactive** – The uicontrol is not operational, but looks the same as when **Enable** is on.
- **off** – The uicontrol is not operational and its image (set by the **Cdata** property) is grayed out.

When you left-click on a uicontrol whose **Enable** property is on, MATLAB performs these actions in this order:

- 1** Sets the figure **SelectionType** property.
- 2** Executes the uicontrol **Callback** routine, if any. (Static text components do not use callbacks.)
- 3** Does *not* set the figure **CurrentPoint** property and does *not* execute either the uicontrol **ButtonDownFcn** or the figure **WindowButtonDownFcn** callback.

Single-clicking or double-clicking an enabled uicontrol with the left mouse button sets the figure **SelectionType** property to **normal**, unless the uicontrol **Style** is **listbox**. For list boxes, double-clicking sets the figure **SelectionType** property to **open** on the second of the two clicks, enabling the list box callback to detect a set of multiple choices.

When you left-click on a uicontrol whose **Enable** property is **off** or **inactive**, or when you right-click a uicontrol whose **Enable** property has any value, MATLAB performs these actions in this order:

- 1** Sets the figure **SelectionType** property.
- 2** Sets the figure **CurrentPoint** property.
- 3** Executes the figure **WindowButtonDownFcn** callback, if provided.

**4** Executes the uicontrol `ButtonDownFcn` callback, if provided.

## Extent

position rectangle (read only)

*Size of uicontrol character string.* A four-element vector that defines the size and position of the character string used to label the uicontrol. It has the form:

```
[0,0,width,height]
```

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

Since the `Extent` property is defined in the same units as the uicontrol itself, you can use this property to determine proper sizing for the uicontrol with regard to its label. Do this by

- Defining the `String` property and selecting the font using the relevant properties.
- Getting the value of the `Extent` property.
- Defining the `width` and `height` of the `Position` property to be somewhat larger than the `width` and `height` of the `Extent`.

For multiline strings, the `Extent` rectangle encompasses all the lines of text. For single line strings, the `height` element of the `Extent` property returned always indicates the height of a single line, and its `width` element always indicates the width of the longest line, even if the string wraps when displayed on the control. Edit boxes are considered multiline if `Max - Min > 1`.

## FontAngle

```
{normal} | italic | oblique
```

*Character slant.* MATLAB uses this property to select a font from those available on your particular system. Setting this property

# Uicontrol Properties

---

to *italic* or *oblique* selects a slanted version of the font, when it is available on your system.

FontName  
string

*Font family.* The name of the font in which to display the String. To display and print properly, this must be a font that your system supports. The default font is system dependent.

---

**Note** MATLAB GUIs do not support the Marlett and Symbol font families.

---

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set FontName to the string FixedWidth (this string value is case sensitive):

```
set(uicontrol_handle, 'FontName', 'FixedWidth')
```

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set FontName to FixedWidth and rely on the root FixedWidthFontName property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root FixedWidthFontName property to the appropriate value for that locale from startup.m. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font.

---

**Tip** To determine what fonts exist on your system (which can differ from the GUI user's system), use the `uisetfont` GUI to select a font and return its name and other characteristics in a MATLAB structure.

---

**FontSize**  
size in `FontUnits`

*Font size.* A number specifying the size of the font in which to display the `String`, in units determined by the `FontUnits` property. The default point size is system dependent.

**FontUnits**  
{points} | normalized | inches |  
centimeters | pixels

*Font size units.* This property determines the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the uicontrol. When you resize the uicontrol, MATLAB modifies the screen `FontSize` accordingly. pixels, inches, centimeters, and points are absolute units (1 point =  $\frac{1}{72}$  inch).

**FontWeight**  
light | {normal} | demi | bold

*Weight of text characters.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

**ForegroundColor**  
`ColorSpec`

*Color of text.* This property determines the color of the text defined for the `String` property (the uicontrol label). Specify a

# Uicontrol Properties

---

color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

---

**Note** If you change the `ForegroundColor` for a uicontrol listbox, MATLAB uses that color for all listbox items *except* selected listbox items. For selected items MATLAB uses a color that ensures good contrast between the text of selected items and the color that indicates a selection.

---

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to on to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

---

**Note** Radio buttons and toggle buttons that are managed by a `uibuttongroup` should not be accessed outside the button group. Set the `HandleVisibility` of such radio buttons and toggle buttons to off to prevent inadvertent access.

---

## HitTest

{on} | off

*Selectable by mouse click.* This property has no effect on uicontrol objects.

---

**Note** Use of the uicontrol `HitTest` property is not recommended. This property might be removed in a future release.

---

## HorizontalAlignment

left | {center} | right

*Horizontal alignment of label string.* This property determines the justification of the text defined for the `String` property (the uicontrol label):

- `left` — Text is left justified with respect to the uicontrol.
- `center` — Text is centered with respect to the uicontrol.

# Uicontrol Properties

---

- `right` — Text is right justified with respect to the uicontrol.

The contents of `edit` and `text` uicontrols are always vertically aligned to the top of the rectangle.

---

**Note** On Microsoft Windows systems, although this property can be specified on all uicontrols, it affects only `edit` and `text` uicontrols.

---

## Interruptible

`off` | `{on}`

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the

*running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

# Uicontrol Properties

---

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## `KeyPressFcn`

string or function handle

*Key press callback function.* A callback routine invoked by a key press when the callback's uicontrol object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX and Microsoft Windows. If no uicontrol has focus, the figure's key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a code file, or any legal MATLAB expression.

If the specified value is the name of a code file, the callback routine can query the figure's `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

Event Data Structure Field	Description	Examples:			
		a	=	Shift	Shift/a
Character	Character interpretation of the key that was pressed.	'a'	'='	' '	'A'
Modifier	Current modifier, such as 'control', or an empty cell array if there is no modifier	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	Name of the key that was pressed.	'a'	'equal'	'shift'	'a'

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

**ListboxTop**  
scalar

*Index of top-most string displayed in list box.* This property applies only to the `listbox` style of uicontrol. It specifies which string appears in the top-most position in a list box that is not large enough to display all list entries. `ListboxTop` is an index into the array of strings defined by the `String` property and must have a value between 1 and the number of strings. Noninteger values are fixed to the next lowest integer.

**Max**  
scalar

*Maximum value.* This property specifies the largest value allowed for the `Value` property. Different styles of uicontrols interpret `Max` differently:

- Check boxes – `Max` is the setting of the `Value` property while the check box is selected.
- Editable text – The `Value` property does not apply. If `Max - Min > 1`, then editable text boxes accept multiline input. If `Max - Min`

# Uicontrol Properties

---

$\leq 1$ , then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.

- List boxes – If  $\text{Max} - \text{Min} > 1$ , then list boxes allow multiple item selection. If  $\text{Max} - \text{Min} \leq 1$ , then list boxes do not allow multiple item selection. When they do, `Value` can be a vector of indices.
- Radio buttons – `Max` is the setting of the `Value` property when the radio button is selected.
- Sliders – `Max` is the maximum slider value and must be greater than the `Min` property. The default is 1.
- Toggle buttons – `Max` is the value of the `Value` property when the toggle button is selected. The default is 1.
- Pop-up menus, push buttons, and static text do not use the `Max` property.

`Min`

scalar

*Minimum value.* This property specifies the smallest value allowed for the `Value` property. Different styles of uicontrols interpret `Min` differently:

- Check boxes – `Min` is the setting of the `Value` property while the check box is not selected.
- Editable text – The `Value` property does not apply. If  $\text{Max} - \text{Min} > 1$ , then editable text boxes accept multiline input. If  $\text{Max} - \text{Min} \leq 1$ , then editable text boxes accept only single line input. The absolute values of `Max` and `Min` have no effect on the number of lines an edit box can contain; a multiline edit box can contain any number of lines.
- List boxes – If  $\text{Max} - \text{Min} > 1$ , then list boxes allow multiple item selection. If  $\text{Max} - \text{Min} \leq 1$ , then list boxes allow only single item selection. When they do, `Value` can be a vector of indices.

- Radio buttons – Min is the setting of the Value property when the radio button is not selected.
- Sliders – Min is the minimum slider value and must be less than Max. The default is 0.
- Toggle buttons – Min is the value of the Value property when the toggle button is not selected. The default is 0.
- Pop-up menus, push buttons, and static text do not use the Min property.

## Parent

handle

*Uicontrol parent.* The handle of the uicontrol's parent object. You can move a uicontrol object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

## Position

position rectangle

*Size and location of uicontrol.* The rectangle defined by this property specifies the size and location of the control within the parent figure window, uipanel, or uibuttongroup. Specify Position as

```
[left bottom width height]
```

left and bottom are the distance from the lower-left corner of the parent object to the lower-left corner of the uicontrol object. width and height are the dimensions of the uicontrol rectangle. All measurements are in units specified by the Units property.

On Microsoft Windows systems, the height of pop-up menus is automatically determined by the size of the font. The value you specify for the height of the Position property has no effect.

# Uicontrol Properties

---

The width and height values determine the orientation of sliders. If width is greater than height, then the slider is oriented horizontally. If height is greater than width, then the slider is oriented vertically.

---

**Note** The height of a pop-up menu is determined by the font size. The height you set in the position vector is ignored. The height element of the position vector is not changed.

On Mac platforms, the height of a horizontal slider is constrained. If the height you set in the position vector exceeds this constraint, the displayed height of the slider is the maximum allowed. The height element of the position vector is not changed.

---

## Selected

on | {off}

*Is object selected.* When this property is on, MATLAB displays selection handles if the SelectionHighlight property is also on. You can, for example, define the ButtonDownFcn to set this property, allowing users to select the object with the mouse.

---

**Note** Use of the uicontrol Selected property is not recommended. This property might be removed in a future release.

---

## SelectionHighlight

{on} | off

*Object highlight when selected.* When the Selected property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When SelectionHighlight is off, MATLAB does not draw the handles.

---

**Note** Use of the uicontrol `SelectionHighlight` property is not recommended. This property might be removed in a future release.

---

## SliderStep

[minor\_step major\_step]

*Slider step size*, a two-element vector of positive values that indicates the size of the major and minor steps as a percent change in slider value. Both steps should be greater than  $1e-6$ , and `minor_step` should be less than or equal to `major_step`. The slider `Value` changes up or down by `minor_step` when you click the arrow button, and up or down by `major_step` when you click the slider trough, also called the channel.

The actual step size is a function of the specified `SliderStep` and the total slider range (`Max - Min`). The default, `[0.01 0.10]`, provides a 1 percent change for clicks on the arrow button and a 10 percent change for clicks in the trough.

For example, if you create the following slider,

```
uicontrol('Style','slider','Min',1,'Max',7,...
 'Value',2,'SliderStep',[0.1 0.6])
```

clicking an arrow button moves the thumb indicator toward it by `minor_step*(max-min)`:

```
0.1*(7-1)
ans =
 0.6000
```

Clicking the trough moves the thumb indicator toward the mouse pointer by `major_step*(max-min)`:

```
0.6*(7-1)
```

# Uicontrol Properties

---

```
ans =
 3.6000
```

If clicking moves the slider to a value outside the range, the thumb indicator moves only to the Max or Min value.

As `major_step` increases, the slider thumb indicator grows longer. When `major_step` is 1, the thumb is half as long as the trough. When `major_step` is greater than 1, the thumb continues to grow, slowly approaching the full length of the trough.

See also the `Max`, `Min`, and `Value` properties.

**String**  
string

*Uicontrol label, list box items, pop-up menu choices.*

**For check boxes, editable text, push buttons, radio buttons, static text, and toggle buttons**, the text displayed on the object. For list boxes and pop-up menus, the set of entries or items displayed in the object.

---

**Note** If you specify a numerical value for `String`, MATLAB converts it to `char` but the result may not be what you expect. If you have numerical data, you should first convert it to a string, e.g., using `num2str`, before assigning it to the `String` property.

---

**For uicontrol objects that display only one line of text** (check box, push button, radio button, toggle button), if the string value is specified as a cell array of strings or padded string matrix, only the first string of a cell array or of a padded string matrix is displayed; the rest are ignored. Vertical slash (`'\'`) characters are not interpreted as line breaks and instead show up in the text displayed in the uicontrol.

For **multiple line editable text or static text controls**, line breaks occur between each row of the string matrix, and each cell of a cell array of strings. Vertical slash (|) characters and \n characters are not interpreted as line breaks, and instead show up in the text displayed in the uicontrol. Text in edit text and static text boxes is always vertically top-aligned. For **editable text**, the String property value is set to the string entered by the user when the control loses focus. The String property for **static text** can only be set programmatically (or when authoring a GUI in GUIDE).

To place **multiple items on a list box or pop-up menu**, you can specify the items in any of the formats shown in the following table.

String Property Format	Example
Cell array of strings	{'one' 'two' 'three'}
Padded string column matrix	['one ' '; 'two ' '; 'three' ]
String vector using vertical slash ( ) as a line separator	['one two three' ]

If you specify a component width that is too small to accommodate one or more of the specified strings, MATLAB truncates those strings with an ellipsis. Use the Value property to set the index of the initial item selected.

For **check boxes, push buttons, radio buttons, toggle buttons**, and the selected item in **popup menus**, when the specified text is clipped because it is too long for the uicontrol, an ellipsis (...) is appended to the text in the active GUI to indicate that it has been clipped.

# Uicontrol Properties

---

For **push buttons** and **toggle buttons**, CData overlaps the String. In the case of **radio buttons** and **checkboxes**, CData takes precedence over String and, depending on its size, can displace the text.

---

**Reserved Words** There are three reserved words: `default`, `remove`, `factory` (case sensitive). If you want to use one of these reserved words in the String property, you must precede it with a backslash (`'\'`) character. For example,

```
h = uicontrol('Style','edit','String','\default');
```

---

## Style

{pushbutton} | togglebutton | radiobutton | checkbox |  
edit | text | slider | frame | listbox | popupmenu

*Style of uicontrol object to create.* The Style property specifies the kind of uicontrol to create. See the uicontrol Description section for information on each type.

## Tag

string (GUIDE sets this property)

*User-specified object label.* The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define Tag as any string.

## TooltipString

string

*Content of tooltip for object.* The TooltipString property specifies the text of the tooltip associated with the uicontrol. When the

user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uicontrol('Style','pushbutton');
s = sprintf('Button tooltip line 1\nButton tooltip line 2');
set(h,'TooltipString',s)
```

## Type

string (read only)

*Class of graphics object.* For `uicontrol` objects, `Type` is always the string `'uicontrol'`.

## UIContextMenu

handle

*Associate a context menu with uicontrol.* Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the `uicontrol`. Use the `uicontextmenu` function to create the context menu.

## Units

{pixels} | normalized | inches | centimeters | points | characters (GUIDE default: normalized)

*Units of measurement.* MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- Normalized units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).
- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).

# Uicontrol Properties

---

- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`  
matrix

*User-specified data.* Any data you want to associate with the uicontrol object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Value`  
scalar or vector

*Current value of uicontrol.* The uicontrol style determines the possible values this property can have:

- Check boxes set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- List boxes set `Value` to a vector of indices corresponding to the selected list entries, where 1 corresponds to the first item in the list.
- Pop-up menus set `Value` to the index of the item selected, where 1 corresponds to the first item in the menu. The Examples section shows how to use the `Value` property to determine which item has been selected.
- Radio buttons set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected).
- Sliders set `Value` to the number indicated by the slider bar.

- Toggle buttons set `Value` to `Max` when they are down (selected) and `Min` when up (not selected).
- Editable text, push buttons, and static text do not set this property.

Set the `Value` property either interactively with the mouse or through a call to the `set` function. The display reflects changes made to `Value`.

## Visible

{on} | off

*Uicontrol visibility.* By default, all uicontrols are visible. When set to `off`, the uicontrol is not visible, but still exists and you can query and set its properties.

---

**Note** Setting `Visible` to `off` for uicontrols that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

# uigetdir

---

**Purpose** Open standard dialog box for selecting directory

**Syntax**

```
folder_name = uigetdir
folder_name = uigetdir(start_path)
folder_name = uigetdir(start_path,dialog_title)
```

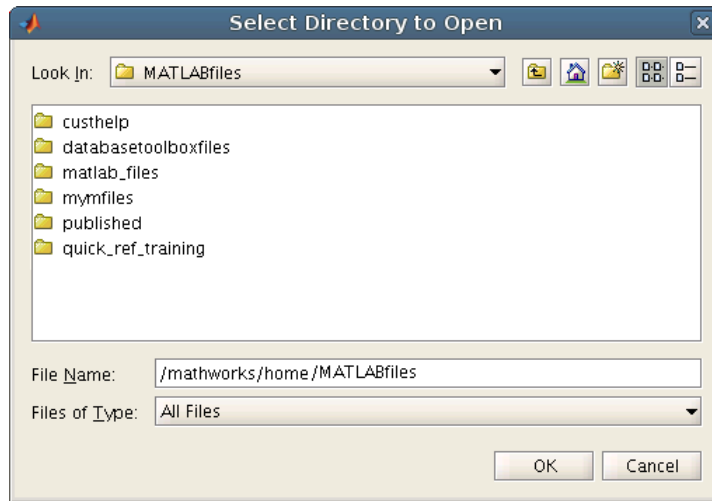

**Description** `folder_name = uigetdir` displays a modal dialog box enabling you to navigate the folder hierarchy and select a folder or type the name of a folder. If the folder exists, `uigetdir` returns the selected path when you click **OK**. If you type the name of a folder that does not exist, `uigetdir` returns the name of the current folder. If you click **Cancel**, or close the dialog box, `uigetdir` returns 0. On Microsoft Windows platforms, `uigetdir` opens a dialog box in the base folder (the Windows desktop) with the current folder selected.

`folder_name = uigetdir(start_path)` opens a dialog box with the folder specified by `start_path` selected. If `start_path` is a valid path, the dialog box opens in the specified folder. If `start_path` is an empty string ( ' ') or is not a valid path, the dialog box opens in the current folder.

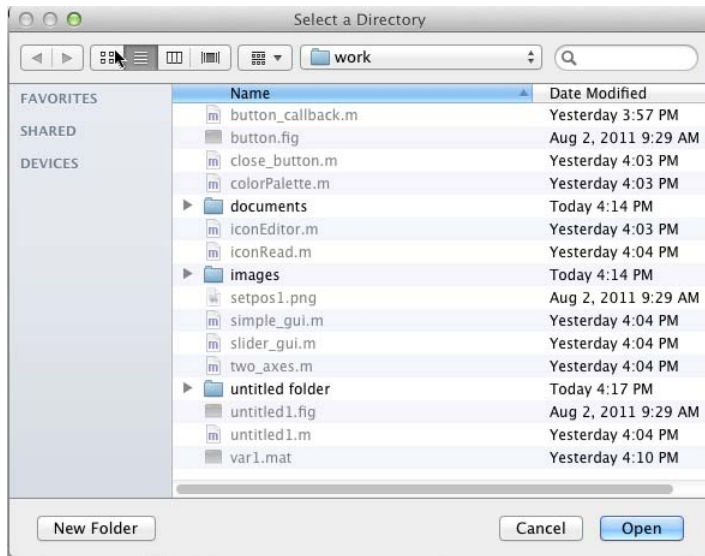

`folder_name = uigetdir(start_path,dialog_title)` opens a dialog box with the specified title. On Windows and UNIX platforms, the string replaces the default caption inside the dialog box for specifying instructions to the user. The default `dialog_title` is **Select folder to Open**.

On Windows platforms, you can click the **New Folder** button to add a new folder to the folder hierarchy displayed. You can also drag and drop existing directories into different folders.

On UNIX platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The `dialog_title` string replaces the default title of the dialog box. The dialog box looks similar to the following figure.

On Mac platforms, `uigetdir` opens a dialog box in the startup folder (the one you are in when you start MATLAB), with the current directory selected. The dialog box looks similar to the following figure.

---

**Note** A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in the MATLAB Figure Properties.

---

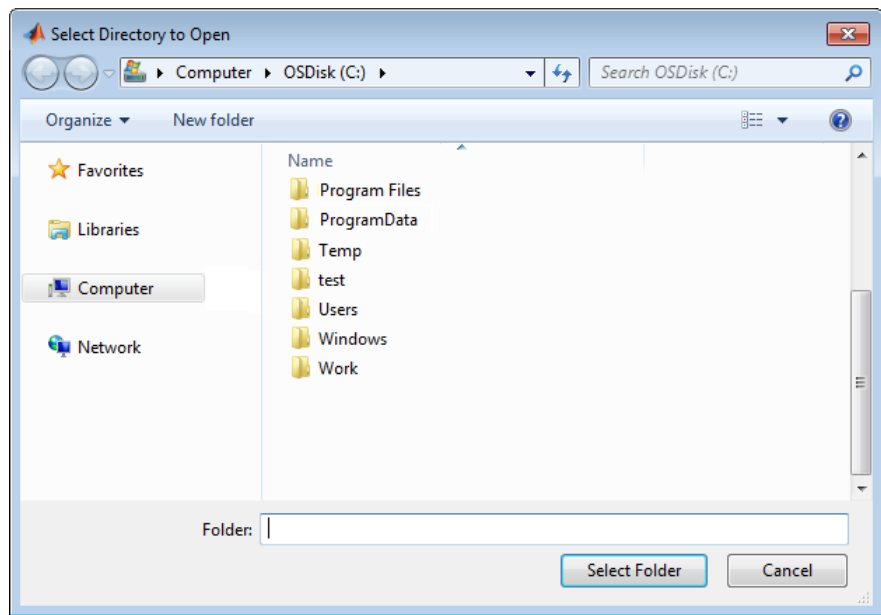

The `pwd` and `cd` functions return the name of the current folder.

## Examples

The following statement displays directories on the C: drive.

```
dname = uigetdir('C:\');
```

A dialog box such as the following displays (on Windows).

If you double-click the `Program Files` folder, and the `MATLAB` subfolder, and then click **Select Folder**, `uigetdir` returns `C:\Program Files\MATLAB` to `dname`:

The following statement uses `matlabroot` to display the MATLAB root folder in the dialog box:

```
uigetdir(matlabroot, 'MATLAB Root Directory')
```

Assuming that MATLAB is installed on drive `C:\`, selecting the folder `MATLAB\R2012b\notebook\pc` from the dialog box, returns this string:

```
C:\Program Files\MATLAB\R2012b\notebook\pc
```

## See Also

`uigetfile` | `uiputfile`

# uigetfile

---

**Purpose** Open standard dialog box for retrieving files

**Syntax**

```
filename = uigetfile
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle)
[FileName,PathName,FilterIndex] = uigetfile(FilterSpec,DialogTitle,
 DefaultName)
[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect',
 selectmode)
```

**Description** filename = uigetfile displays a modal dialog box that lists files in the current folder and enables you to select or enter the name of a file. If the file name is valid and the file exists, uigetfile returns the file name as a string when you click **Open**. Otherwise uigetfile displays an appropriate error message, after which control returns to the dialog box. You can then enter another file name or click **Cancel**. If you click **Cancel** or close the dialog window, uigetfile returns 0.

---

**Note** Successful execution of uigetfile does not open a file; it only returns the name of an existing file that you identify.

---

[FileName,PathName,FilterIndex] = uigetfile(FilterSpec) displays only those files with extensions that match FilterSpec. On some platforms uigetfile also displays in gray the files that do not match FilterSpec. The uigetfile function appends 'All Files' to the list of file types. FilterSpec can be a string or a cell array of strings, and can include the \* wildcard.

- If FilterSpec is a file name, that file name displays, selected in the **File name** field. The extension of the file is the default filter.
- FilterSpec can include a path. That path can contain '.', '..', \, '/', or '~'. For example, '../\*.\*m' lists all code files in the folder above the current folder.

- If `FilterSpec` is a folder name, `uigetfile` displays the contents of that folder, the **File name** field is empty, and no filter applies. To specify a folder name, make the last character of `FilterSpec` either `'\'` or `'/'`.
- If `FilterSpec` is a cell array of strings, it can include two columns. The first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace standard descriptions in the **Files of type** field. A description cannot be an empty string. The second and third examples illustrate use of a cell array as `FilterSpec`.

If `FilterSpec` is missing or empty, `uigetfile` uses the default list of file types (for example, all MATLAB files).

After you click **Open** and if the file name exists, `uigetfile` returns the name of the file in `FileName` and its path in `PathName`. If you click **Cancel** or close the dialog window, the function sets `FileName` and `PathName` to 0.

`FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click **Cancel** or close the dialog window, the function sets `FilterIndex` to 0.

```
[FileName,PathName,FilterIndex] =
uigetfile(FilterSpec,DialogTitle) displays a dialog box that has
the title DialogTitle. To use the default file types and specify a
dialog title, enter
```

```
uigetfile(' ',DialogTitle)
```

```
[FileName,PathName,FilterIndex] =
uigetfile(FilterSpec,DialogTitle, DefaultName) displays a dialog
box in which the file name specified by DefaultName appears in the
File name field. DefaultName can also be a path or a path/filename. In
this case, uigetfile opens the dialog box in the folder specified by the
path. You can use '.', '..', '\', or '/' in the DefaultName argument.
To specify a folder name, make the last character of DefaultName either
'\ ' or '/ '. If the specified path does not exist, uigetfile opens the
dialog box in the current folder.
```

# uigetfile

---

`[FileName,PathName,FilterIndex] = uigetfile(...,'MultiSelect', selectmode)` opens the dialog box in *multiselect* mode. Valid values for *selectmode* are 'on' and 'off' (the default, which allows single selection only). If 'MultiSelect' is 'on' and you select more than one file in the dialog box, then `FileName` is a cell array of strings. Each array element contains the name of a selected file. File names in the cell array are sorted in the order your platform uses. If you select multiple files, they must be in the same folder, otherwise MATLAB displays a warning dialog box. Be aware that Microsoft Windows libraries can span multiple folders. `PathName` is a string identifying the folder containing the files.

If you include either of the wildcard characters, '\*' or '?', in a file name, `uigetfile` does not respond to clicking **Open**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

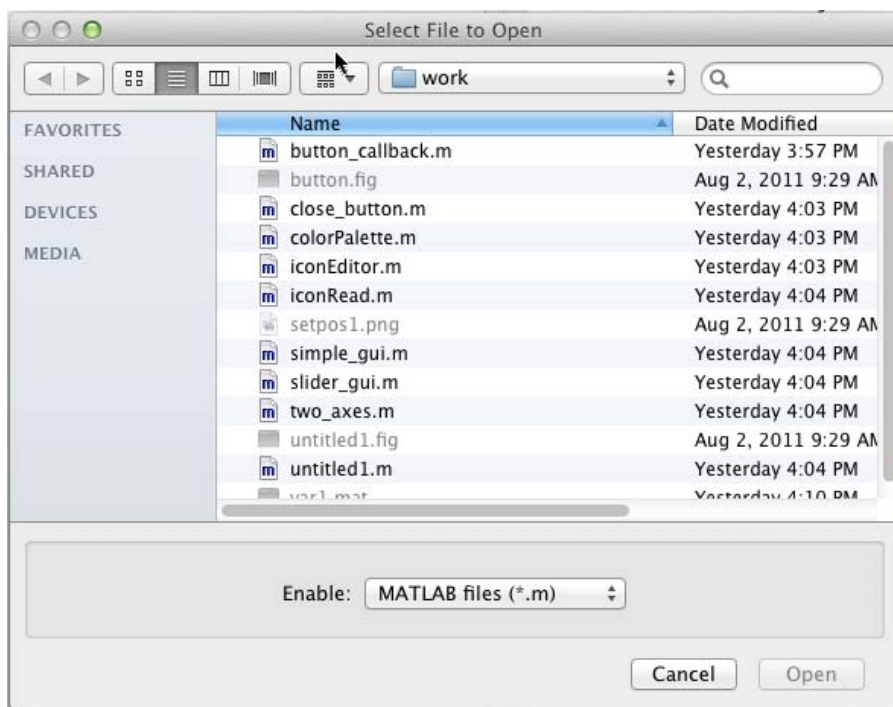

For Windows platforms, the dialog box is the Windows dialog box native to your platform. Depending on your version of Windows, dialogs you see can differ from the figures shown in following examples.

For UNIX platforms, the dialog box is like the one shown in the following figure.

For Mac platforms, the dialog box is like the one shown in the following figure.

# uigetfile

---

**Note** A modal dialog box prevents you from interacting with other windows before responding. To block MATLAB program execution, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in the MATLAB Figure Properties.

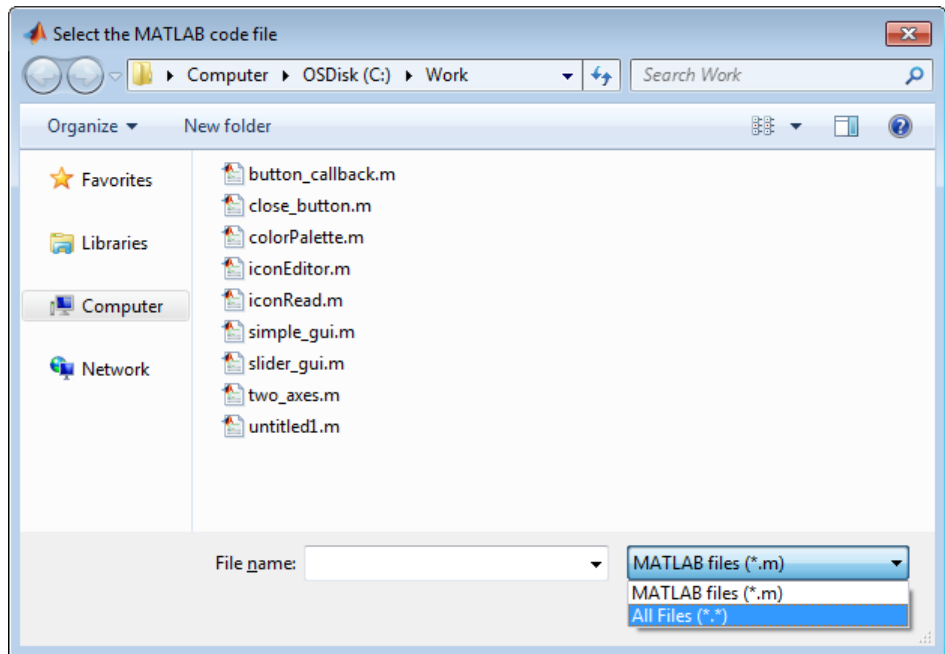

---

## Examples

The following statement displays a dialog box for retrieving a file. The dialog box lists all MATLAB code files within a selected directory. `uigetfile` returns the name and path of the selected file in `FileName` and `PathName`. `uigetfile` appends `All Files (*.*)` to the file types when `FilterSpec` is a string.

```
[FileName,PathName] = uigetfile('*.m','Select the MATLAB code file');
```

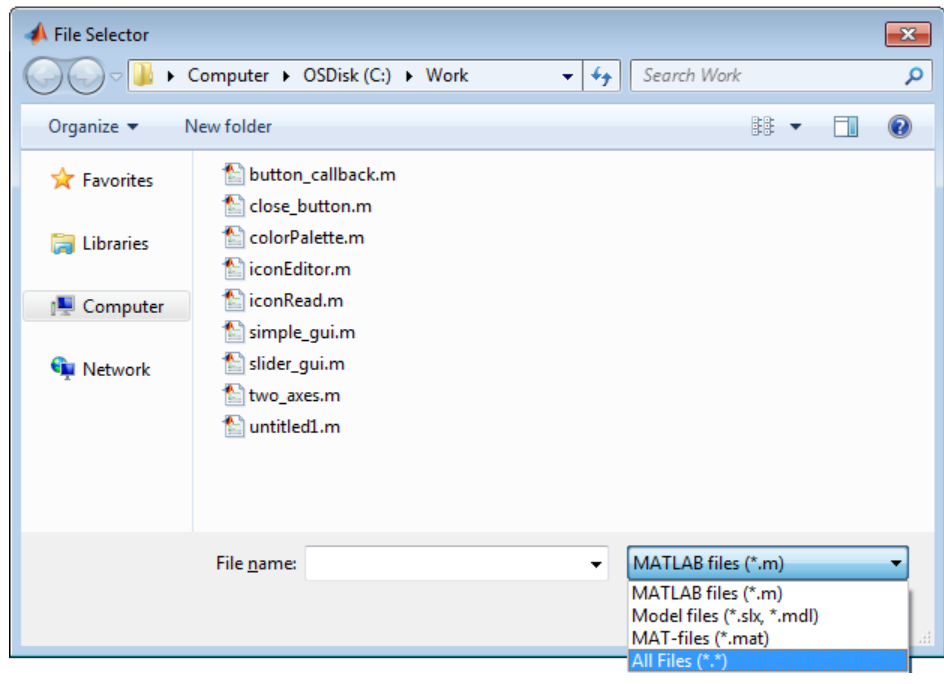

The following figure shows the dialog box with the file type drop-down list open.

To create a list of file types that appears in the file type drop-down list, separate the file extensions with semicolons, as in the following code. `uigetfile` displays a default description for each known file type, such as "Model files" for Simulink `.slx` and `.mdl` files.

```
[filename, pathname] = ...
 uigetfile({'*.m'; '*.slx'; '*.mat'; '*.*'}, 'File Selector');
```

# uigetfile

If you want to create a list of file types and give them descriptions that are different from the defaults, use a cell array, as in the following code. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname] = uigetfile(...
{'*.m;*.fig;*.mat;*.slx;*.mdl',...
'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
 '*.m', 'Code files (*.m)'; ...
 '*.fig', 'Figures (*.fig)'; ...
 '*.mat', 'MAT-files (*.mat)'; ...
 '*.mdl;*.slx', 'Models (*.slx, *.mdl)'; ...
 '*.*', 'All Files (*.*)'}, ...
'Pick a file');
```

The first column of the cell array contains the file extensions, while the second contains your descriptions of the file types. In this example, the first entry of column one contains several extensions, separated by semicolons, which are all associated with the description 'MATLAB Files (\*.m;\*.fig;\*.mat;\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code lets you select a file and then displays a message in the Command Window that summarizes the result.

```
[filename, pathname] = uigetfile('*.*', 'Select a MATLAB code file');
if isequal(filename,0)
 disp('User selected Cancel')
```

# uigetfile

---

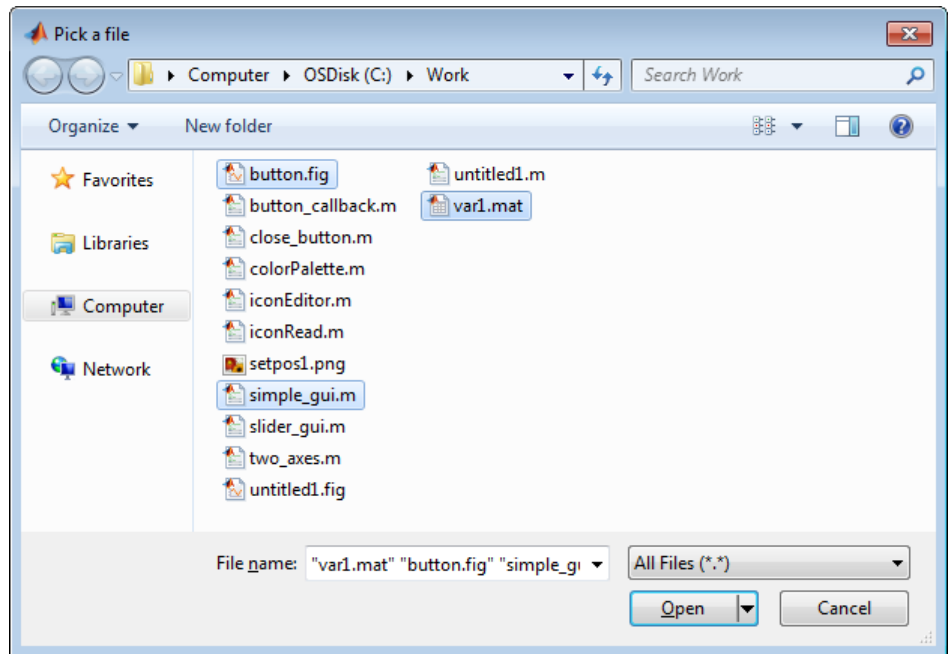

```
else
 disp(['User selected ', fullfile(pathname, filename)])
end
```

---

This code creates a list of file types and gives them descriptions that are different from the defaults. It also enables multiple-file selection. Select multiple files by holding down the **Shift** or **Ctrl** key and clicking on additional file names.

```
[filename, pathname, filterindex] = uigetfile(...
{ '*.mat', 'MAT-files (*.mat)'; ...
 '*.slx;*.mdl', 'Models (*.slx, *.mdl)'; ...
 .', 'All Files (*.*)'}, ...
'Pick a file', ...
'MultiSelect', 'on');
```

As mentioned previously, `uigetfile` does not open the file or files you select.

You can use the `DefaultName` argument to specify a start path and a default file name for the dialog box.

```
uigetfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
 '*.*', 'All Files' }, 'mytitle', ...
 'C:\myfiles\my_examples\gbtools\setpos1.png')
```

# uigetfile

---

## Alternatives

Use the `dir` function to return a filtered or unfiltered list of files in your current folder or a folder you specify. `dir` also can return file attributes.

## See Also

`uigetdir` | `uiopen` | `uiputfile`

**Purpose** Specify and conditionally open dialog box according to user preference

**Syntax**

```
pref_value =
uigetpref(group,pref,title,question,pref_choices)
[pref_value,dlgshown] = uigetpref(...)
[...] = uigetpref(... 'Name',value)
```

**Description**

`pref_value = uigetpref(group,pref,title,question,pref_choices)` returns one of the strings in `pref_choices` in either of two ways:

- Displays a multiple-choice dialog box that prompts you to answer a question. The dialog box includes a check box with the label **Do not show this dialog again**.
- Retrieves a previous answer from the preferences data base and returns it without displaying a dialog. No dialog is displayed if you previously selected the check box **Do not show this dialog again**.

`[pref_value,dlgshown] = uigetpref(...)` also returns in `dlgshown` whether or not the dialog displayed.

`[...] = uigetpref(... 'Name',value)` specify optional name-value pairs to control how dialogs display.

- Tips**
- You must supply all input arguments up to and including `pref_choices`.
  - `uigetpref` creates specified groups and preferences, if they do not currently exist. To delete a preference group you no longer need, use `rmpref`.
  - The string returned in `pref_value` is a preference name (as specified in `pref`), not its button label (as specified in `pref_choices`).
  - After you select the check box **Do not show this dialog again** and close the dialog box, the dialog box does not display again for the same preference. To reenable dialogs that are being suppressed by preferences, use the command:

# uigetpref

---

```
uigetpref('clearall')
```

Executing `uigetpref` with this command re-enables *all* preference dialogs you have defined with `uigetpref`, not just the most recent one.

## Input Arguments

### **group**

String specifying the name of the preference group that preference `pref` belongs to. If the group does not already exist, `uigetpref` creates it.

**Default:** None

### **pref**

String specifying the name of the preference that controls whether the dialog displays. If the preference does not already exist, `uigetpref` creates it.

**Default:** None

### **title**

String to display in the dialog box title bar

### **question**

String or cell array of strings specifying a descriptive paragraph for the dialog to display. Use `question` to define what you are asking the user to decide. Clearly state the alternatives and the consequences of choosing among them. The dialog box that `uigetpref` generates inserts line breaks between rows of the string array, between elements of the cell array of strings, and between `'|'` or newline characters within a string vector.

**Default:** None

### **pref\_choices**

String, cell array of strings, or ' | '-separated strings specifying the labels for the dialog box push buttons. The string on the selected push button is returned.

If the internal preference values are different from the strings displayed on the push buttons, provide a 2-by-n cell array of strings. The first row contains the preference strings, and the second row contains the associated push button strings. When `pref_choices` is not a 2-by-n cell array, MATLAB constructs lowercase versions of the button labels and returns them in `pref_value`. If your code tests returned values, make sure it compares them against the appropriate strings.

**Default:** None

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

#### **'CheckboxState'**

State of check box when dialog box opens:

- `false` or `0`: Check box is not initially selected.
- `true` or `1`: Check box is initially selected.

**Default:** 0

#### **'CheckboxString'**

String specifying the label for the check box.

**Default:** 'Do not show this dialog again'

#### **'HelpString'**

String specifying the label for **Help** button.

**Default:** No **Help** button displays.

## **'HelpFcn'**

String or function handle specifying the callback that executes when you click the **Help** button. Also, to have a button to trigger the callback, you must specify the **HelpString** option.

**Default:** doc('uigetpref')

## **'ExtraOptions'**

String or cell array of strings specifying extra buttons. The additional buttons are not mapped to any preference settings. If you click any of these buttons, the dialog closes and **uigetpref** returns the string in value.

**Default:** {}

## **'DefaultButton'**

String specifying the value that **uigetpref** returns if you close the dialog without clicking a button. This string does not have to correspond to any preference or **ExtraOption**.

**Default:** The first button specified in **pref\_choices**

## **Output Arguments**

### **pref\_value**

String containing the preference corresponding to the button you press. If you cancel the dialog by clicking its close box, **uigetpref** returns the label of the first button specified in **pref\_choices** or the value for **DefaultButton**, if specified. After you select the **Do not show this dialog again** check box, **uigetpref** does not display a dialog box when you call it with the same **group** and **pref** arguments. Instead, it returns the last choice you made (your registered preference) in **pref\_value** immediately.

### **dlgshown**

Logical value that specifies the state of the check box when the dialog box closed. The value is 1 if selected, 0 if not selected. After you select the **Do not show this dialog again** check box, `uigetpref` does not display a dialog box when you call it with the same `group` and `pref` arguments. Instead, it returns 0 in `dlgshown` immediately.

## Definitions

### Preferences

Preferences provide the ability to specify how applications behave and how users interact with them. For example, you can set a preference for which products display their documentation in the Help browser, or which messages the Code Analyzer displays. In MathWorks software products, preferences persist across sessions and are stored in a preference data base, the location of which is system-dependent. Use the **Preferences** option on the **File** menu to access all built-in preferences.

`uigetpref` uses the same preference data base as `addpref`, `getpref`, `ispref`, `rmpref`, and `setpref`. However, `uigetpref` registers the preferences it sets as a separate list, so that it and `uisetpref` can manage those preferences.

To modify preferences registered with `uigetpref`, you can use `setpref` and `uisetpref` to explicitly change preference values to 'ask'. If you specify a preference that does not already exist in the preference data base, `uigetpref` creates it.

## Examples

Create a preference dialog for the 'savefigurebeforeclosing' preference in the 'mygraphics' group of preferences.

Call `uigetpref` to display the dialog (or not) from a figure window `CloseRequestFcn` callback. The callback code takes action via a switch statement. The action (to delete or not to delete the figure) depends on whether the answer returned by `uigetpref` was `'always'` or `'never'`:

```
function save_figure_perhaps
% Closes figure conditionally, asking whether to save it first.
% User can suppress the dialog from UIGETPREF permanently by selecting
% "Do not show this dialog again".

fig = gcf;
[selectedButton dlgshown] = uigetpref(...
 'mygraphics',... % Group
 'savefigurebeforeclosing',... % Preference
 'Closing Figure',... % Window title
 {'Do you want to save your figure before closing?'
 ''
 'You can save your figure manually by typing ''hgsave(gcf)'''},...
 {'always','never';'Yes','No'},... % Values and button strings
 'ExtraOptions','Cancel',... % Additional button
 'DefaultButton','Cancel',... % Default choice
 'HelpString','Help',... % String for Help button
 'HelpFcn','doc(''closereq'');'); % Callback for Help button
switch selectedButton
case 'always' % Open a Save dialog (without testing if saved before)
 [fileName,pathName,filterIndex] = uinputfile('fig', ...
 'Save current figure', ...
```

```
 'untitled.fig');
if filterIndex == 0 % User cancelled save or named no file
 delete(fig);
else % Use filename returned from UIPUTFILE
 saveas(fig,[pathName fileName])
 delete(fig);
end
case 'never' % Close the figure without saving it
 delete(fig);
case 'cancel' % Do not close the figure
 return
end
```

To execute the example, copy it and paste the code into a new program file. Name the file `save_figure_perhaps.m` and place it on your search path. To use the function as a `CloseRequestFcn`, create a figure as follows:

```
figure('CloseRequestFcn','save_figure_perhaps');
```

Clicking the figure close box or selecting **File > Close** displays the dialog box until you select **Do not show this dialog again**.

# uiimport

---

**Purpose** Import data interactively

**Syntax**

```
uiimport
uiimport(filename)
uiimport('-file')
uiimport('-pastespecial')
S = uiimport(__)
```

**Description** `uiimport` opens a dialog to interactively load data from a file or the clipboard. MATLAB displays a preview of the data in the file.

`uiimport(filename)` opens the file specified in `filename`.

`uiimport('-file')` presents the file selection dialog first.

`uiimport('-pastespecial')` presents the clipboard contents first.

`S = uiimport( __ )` stores the resulting variables as fields in the struct `S`.

**See Also** `load` | `importdata` | `clipboard`

**How To**

---

<b>Purpose</b>	Create menus and menu items on figure windows
<b>Syntax</b>	<pre>handle = uimenu('PropertyName',PropertyValue,...) handle = uimenu(parent,'PropertyName',PropertyValue,...)</pre>
<b>Description</b>	<p><code>handle = uimenu('PropertyName',PropertyValue,...)</code> creates a menu in the current figure's menu bar using the values of the specified properties and assigns the menu handle to <code>handle</code>.</p> <p><code>handle = uimenu(parent,'PropertyName',PropertyValue,...)</code> creates a submenu of a parent menu or a menu item on a context menu specified by <code>parent</code> and assigns the menu handle to <code>handle</code>. If <code>parent</code> refers to a figure instead of another <code>uimenu</code> object or a <code>uicontextmenu</code>, MATLAB software creates a new menu on the referenced figure's menu bar.</p>
<b>Tips</b>	<p>MATLAB adds the new menu to the existing menu bar. If the figure does not have a menu bar, MATLAB creates one. Each menu choice can itself be a menu that displays its items when you select it. <code>uimenu</code> accepts property name/property value pairs as well as structures and cell arrays of properties as input arguments.</p> <p>Use the <code>uimenu</code> <code>Callback</code> property to define the action taken when you activate the created menu item.</p> <p>Uimenu only appear in figures whose <code>Window Style</code> is <code>normal</code>. If a figure containing <code>uimenu</code> children is changed to <code>modal</code>, the <code>uimenu</code> children still exist and are contained in the <code>Children</code> list of the figure, but are not displayed until the <code>WindowStyle</code> is changed to <code>normal</code>.</p> <p>The value of the figure <code>MenuBar</code> property affects the content of the figure menu bar. When <code>MenuBar</code> is <code>figure</code>, a set of built-in menus precedes any user-created <code>uimenu</code>s on the menu bar (MATLAB controls the built-in menus and their handles are not available to the user). When <code>MenuBar</code> is <code>none</code>, <code>uimenu</code>s are the only items on the menu bar (that is, the built-in menus do not appear).</p>

# uimenu

See the Uimenu Properties reference page for more information. You can set and query property values after creating a menu with the `set` and `get` functions.

## Examples

This example creates a menu labeled **Workspace** with menu options for creating a new figure window, saving workspace variables, and exiting MATLAB. In addition, it defines an accelerator key for the Quit option.

```
f = uimenu('Label','Workspace');
 uimenu(f,'Label','New Figure','Callback','figure');
 uimenu(f,'Label','Save','Callback','save');
 uimenu(f,'Label','Quit','Callback','exit',...
 'Separator','on','Accelerator','Q');
```

This example creates a new figure with a menu bar that excludes the built-in menus. It creates a **Find** menu with options **Find & Replace**, and **Variable**. For the Variable option, it creates a submenu with options of **Name** and **Value**.

```
f=figure('MenuBar','None');
mh = uimenu(f,'Label','Find');
frh = uimenu(mh,'Label','Find and Replace ...',...
 'Callback','goto');
frh = uimenu(mh,'Label','Variable');
uimenu(frh,'Label','Name...', ...
 'Callback','variable');
```

```
uimenu(frh,'Label','Value...', ...
 'Callback','value');
```

This example creates a context menu, **Font**, on a figure with menu options **Helvetica** and **Monospace**. When you run the code and then right-click anywhere within the figure window, the context menu displays.

```
% Create the UICONTEXTMENU
cmenu = uicontextmenu;

% Create the parent menu
fontmenu = uimenu(cmenu,'label','Font');

% Create the submenus
font1 = uimenu(fontmenu,'label','Helvetica',...
 'Callback','HelvFont');
font2 = uimenu(fontmenu,'label',...
 'Monospace','Callback','MonoFont');
set(gcf,'uicontextmenu',cmenu);
```

# uimenu

---

## Purpose

Describe menu properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` commands enable you to set and query the values of properties

You can set default Uimenu properties on the root, figure and menu levels:

```
set(0, 'DefaultUimenuPropertyName', PropertyValue...)
set(gcf, 'DefaultUimenuPropertyName', PropertyValue...)
set(menu_handle, 'DefaultUimenuPropertyName', PropertyValue...)
```

Where *PropertyName* is the name of the Uimenu property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of property see “Setting Default Property Values”

## Uimenu Properties

This section lists all properties useful to `uimenu` objects along with valid values and instructions for their use. Curly braces `{ }` enclose default values.

Property Name	Property Description
Accelerator	Keyboard equivalent
BeingDeleted	This object is being deleted
BusyAction	Callback routine interruption
Callback	Control action
Checked	Menu check indicator
Children	Handles of submenus

# Uimenu Properties

---

Property Name	Property Description
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
Enable	Enable or disable the uimenu
ForegroundColor	Color of text
HandleVisibility	Whether handle is accessible from command line and GUIs
Interruptible	Callback routine interruption mode
Label	Menu label
Parent	Uimenu object's parent
Position	Relative uimenu position
Separator	Separator line mode
Tag	User-specified object identifier
Type	Class of graphics object
UserData	User-specified data
Visible	Uimenu visibility

Accelerator  
character

*Keyboard equivalent.* An alphabetic character specifying the keyboard equivalent for the menu item. This allows users to select a particular menu choice by pressing the specified character in conjunction with another key, instead of selecting the menu item with the mouse. The key sequence is platform specific:

- For Microsoft Windows systems, the sequence is **Ctrl+Accelerator**. Windows reserves these keys for default

menu items: **c**, **v**, and **x**. For more information, see Keyboard shortcuts for Windows on the Microsoft support Web site.

- For Macintosh systems, the sequence is **Cmd**+Accelerator. Apple reserves these keys for default menu items: **a**, **c**, **v**, and **x**. For more information, see Mac OS X keyboard shortcuts on the Apple Computer support Web site.
- For UNIX systems, the sequence is **Ctrl**+Accelerator. These keys are reserved for default menu items: **o**, **p**, **s**, and **w**. Many UNIX applications also use **a**, **c**, **v**, and **x** in the same manner as the other platforms.

Accelerated menu items do not have to be displayed for the accelerator key to work (you can accelerate a submenu). However, some restrictions apply:

- You can define an accelerator only for menu items that do not have children menus.
- Accelerators work only for menu items that directly execute a callback routine.
- The figure must be in focus when entering the accelerator key sequence.

To remove an accelerator, set `Accelerator` to an empty string, `''`.

For a cross-platform comparison of accelerators, see the article [Table of Keyboard Shortcuts](#).

`BeingDeleted`  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

# Uimenu Properties

---

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

*Callback routine interruption.* If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, the callback associated with the new event uses the value of `BusyAction` to decide whether or not to attempt to interrupt the executing callback.

- If the value is `cancel`, the event is discarded and the second callback does not execute.
- If the value is `queue`, and the `Interruptible` property of the first callback is `on`, the second callback is added to the event queue and executes in its turn after the first callback finishes execution.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. See the `Interruptible` property for information about controlling a callback's interruptibility.

---

## Callback

string or function handle

*Menu action.* A callback routine that executes whenever you activate the menu or its submenu (if one exists). Activation is platform dependent. Typically, it is clicking the menu or, if the menu has one, its submenu. Define this routine as a string that

is a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB base workspace.

---

**Caution** Do not use a uimenu callback to dynamically change menu items. Deleting, adding, and replacing menu items in a callback can result in a blank menu on some platforms. You can hide, show, and disable menu items in a callback to achieve the same effect. To fully repopulate menu items, delete and create them outside the callback.

---

Checked

on | {off}

*Menu check indicator.* Setting this property to `on` places a check mark next to the corresponding menu item. Setting it to `off` removes the check mark. You can use this feature to create menus that indicate the state of a particular option. For example, suppose you have a menu item called **Show axes** that toggles the visibility of an axes between visible and invisible each time the user selects the menu item. If you want a check to appear next to the menu item when the axes are visible, add the following code to the callback for the **Show axes** menu item:

```
if strcmp(get(gcbo, 'Checked'), 'on')
 set(gcbo, 'Checked', 'off');
else
 set(gcbo, 'Checked', 'on');
end
```

This changes the value of the `Checked` property of the menu item from `on` to `off` or vice versa each time a user selects the menu item.

Note that there is no formal mechanism for indicating that an unchecked menu item will become checked when selected.

# Uimenu Properties

---

---

**Note** This property is ignored for top level and parent menus.

---

## Children

vector of handles

*Handles of submenus.* A vector containing the handles of all children of the uimenu object. The children objects of uimenu are other uimenu objects, which function as submenus. You can use this property to reorder the menus.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uimenu object. MATLAB sets all property values for the uimenu before executing the CreateFcn callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uimenu being created.

Setting this property on an existing uimenu object has no effect.

You can define a default CreateFcn callback for all new uimenu objects. This default applies unless you override it by specifying a different CreateFcn callback when you call `uimenu`. For example, the code

```
set(0, 'DefaultUimenuCreateFcn', 'set(gcbo, ...
 'Visible','on')')
```

creates a default CreateFcn callback that runs whenever you create a new menu. It sets the default Visible property of a uimenu object.

To override this default and create a menu whose Visible property is set to a different value, call `uimenu` with code similar to

```
hpt = uimenu(...,'CreateFcn','set(gcbo,...
'Visible','off'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uimenu` call. In the example above, if instead of redefining the `CreateFcn` property for this `uimenu`, you had explicitly set `Visible` to `off`, the default `CreateFcn` callback would have set `Visible` back to the default, i.e., `on`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Delete uimenu callback routine.* A callback routine that executes when you delete the `uimenu` object (e.g., when you issue a `delete` command or cause the figure containing the `uimenu` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which is more simply queried using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

# Uimenu Properties

---

## Enable

{on} | off

*Enable or disable the uimenu.* This property controls whether a menu item can be selected. When not enabled (set to `off`), the menu `Label` appears dimmed, indicating the user cannot select it.

## ForegroundColor

ColorSpec X-Windows only

*Color of menu label string.* This property determines color of the text defined for the `Label` property. Specify a color using a three-element RGB vector or one of the MATLAB predefined names. The default text color is black. See `ColorSpec` for more information on specifying color.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.

- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

## Interruptible

`{on} | off`

*Callback routine interruption mode.* If a callback is executing and the user triggers an event (such as a mouse click) on an object for which a callback is defined, that callback attempts to interrupt the first callback. MATLAB processes the callbacks according to these factors:

- The `Interruptible` property of the object whose callback is executing
- Whether the executing callback contains `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statements
- The `BusyAction` property of the object whose callback is waiting to execute

If the `Interruptible` property of the object whose callback is executing is `on` (the default), the callback can be interrupted. Whenever the callback calls one of the `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` functions, the function processes any events in the event queue, including the waiting callback, before performing its defined task.

If the `Interruptible` property of the object whose callback is executing is `off`, the callback cannot be interrupted (except by certain callbacks; see the note below). The `BusyAction` property

# Uimenu Properties

---

of the object whose callback is waiting to execute determines what happens to the callback.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. A figure's `WindowButtonDownFcn` callback routine, or an object's `ButtonDownFcn` or `Callback` routine are processed according to the rules described above.

---

## Label

string

*Menu label.* A string specifying the text label on the menu item. You can specify a mnemonic for the label using the '&' character. Except as noted below, the character that follows the '&' in the string appears underlined and selects the menu item when you type **Alt+** followed by that character while the menu is visible. The '&' character is not displayed. To display the '&' character in a label, use two '&' characters in the string:

'O&pen selection' yields **Open selection**

'Save && Go' yields **Save & Go**

'Save&&Go' yields **Save & Go**

'Save& Go' yields **Save& Go** (the space is not a mnemonic)

---

**Tip** Avoid specifying mnemonics for applications designed to run on Macintosh computers. Accessing menus with mnemonics violates the principles of Apple Human Interface Guidelines. However, you can set the `Accelerator` property to access individual menu items with key sequences on a Mac.

---

Avoid including the reserved words, `default`, `remove`, and `factory`, in menu labels unless you escape them. They are case sensitive. To use one of these words in the `Label` property, escape it by preceding it with a backslash (`'\'`) character. For example:

`'\remove'` yields **remove**

`'\default'` yields **default**

`'\factory'` yields **factory**

## Parent

handle

*Uimenu's parent.* The handle of the `uimenu`'s parent object. The parent of a `uimenu` object is the figure on whose menu bar it displays, or the `uimenu` of which it is a submenu. You can move a `uimenu` object to another figure by setting this property to the handle of the new parent.

## Position

scalar

*Relative menu position.* The value of `Position` indicates placement on the menu bar or within a menu. Top-level menus are placed from left to right on the menu bar according to the value of their `Position` property, with 1 representing the left-most position. The individual items within a given menu are placed from top to bottom according to the value of their `Position` property, with 1 representing the top-most position.

# Uimenu Properties

---

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line above the menu item.

## Tag

string

*User-specified object label.* The Tag property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define Tag as any string.

## Type

string (read only)

*Class of graphics object.* For uimenu objects, Type is always the string 'uimenu'.

## UserData

matrix

*User-specified data.* Any matrix you want to associate with the uimenu object. MATLAB does not use this data, but you can access it using the set and get commands.

## Visible

{on} | off

*Uimenu visibility.* By default, all uimenus are visible. When set to off, the uimenu is not visible, but still exists and you can query and set its properties.

<b>Purpose</b>	Convert to 8-bit unsigned integer
<b>Syntax</b>	<code>intArray = uint8(array)</code>
<b>Description</b>	<code>intArray = uint8(array)</code> converts the elements of an array into unsigned 8-bit (1-byte) integers of class <code>uint8</code> .
<b>Input Arguments</b>	<b>array</b> Array of any numeric class, such as <code>single</code> or <code>double</code> . If <code>array</code> is already of class <code>uint8</code> , the <code>uint8</code> function has no effect.
<b>Output Arguments</b>	<b>intArray</b> Array of class <code>uint8</code> . Values range from 0 to $2^8 - 1$ . The <code>uint8</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example, <pre>uint8(2^8)    % 2^8 = 256</pre> returns <pre>ans =     255</pre>
<b>Examples</b>	Convert a double array to <code>uint8</code> : <pre>mydata = uint8(magic(10));</pre>
<b>Alternatives</b>	When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as <code>zeros</code> , <code>ones</code> or <code>eye</code> ), rather than calling an integer conversion function. For example, <pre>I = uint8(zeros(100));    % Creates an intermediate array</pre> is not as efficient as <pre>I = zeros(100, 'uint8'); % Preferred</pre>

## Tutorials

- [“Integers”](#)
- [“Arithmetic Operations on Integer Classes”](#)

<b>Purpose</b>	Convert to 64-bit unsigned integer
<b>Syntax</b>	<code>intArray = uint64(array)</code>
<b>Description</b>	<code>uint64(array)</code> converts the elements of an array into unsigned 64-bit (8-byte) integers of class <code>uint64</code> .
<b>Tips</b>	<p>Double-precision floating-point numbers have only 52 bits in the mantissa. Therefore, <code>double</code> values cannot represent all integers greater than <math>2^{53}</math> correctly. Before performing arithmetic operations on values larger than <math>2^{53}</math> in magnitude, convert the values to 64-bit integers. For example,</p> <pre>x = uint64(2^53+1);    % Floating-point arithmetic, loses precision</pre> <p>is not as accurate as the 64-bit integer arithmetic operation:</p> <pre>x = uint64(2^53) + 1; % Preferred</pre>
<b>Input Arguments</b>	<p><b>array</b></p> <p>Array of any numeric class, such as <code>single</code> or <code>double</code>. If <code>array</code> is already of class <code>uint64</code>, the <code>uint64</code> function has no effect.</p>
<b>Output Arguments</b>	<p><b>intArray</b></p> <p>Array of class <code>uint64</code>. Values range from 0 to <math>2^{64} - 1</math>.</p> <p>The <code>uint64</code> function maps any values in <code>array</code> that are outside the limit to the nearest endpoint. For example,</p> <pre>uint64(2^64)    % 2^64 = 18446744073709551616</pre> <p>returns</p> <pre>ans =     18446744073709551615</pre>

# uint64

---

## Examples

Convert a literal value to uint64:

```
x = uint64(9007199254740993);
```

## Alternatives

When preallocating integer arrays, specify the class in the call to functions that support a class name input (such as `zeros`, `ones` or `eye`), rather than calling an integer conversion function. For example,

```
I = uint64(zeros(100)); % Creates an intermediate array
```

is not as efficient as

```
I = zeros(100, 'uint64'); % Preferred
```

**Purpose** Interactively select file to open and load data

**Syntax**

```
uiopen
uiopen(type)
uiopen(filename)
uiopen(filename, TF)
```

**Description**

uiopen displays the dialog box with the file filter set to all MATLAB files (with file extensions \*.m, \*.mat, \*.fig, \*.mdl, and \*.slx).

uiopen(type) sets the file filter according to the type.

uiopen(filename) displays filename as the default value for **File name** in the dialog box and lists only files having the same extension.

uiopen(filename, TF) directly opens file filename without displaying a dialog box if TF is true, and displays the dialog box if TF is false.

**Tips** When you select a file and click **open**, uiopen does the following:

- Gets the file using uigetfile.
- Opens the file using the open command.
  - Files with a file extension of .m open in the Editor.
  - Variables stored in files with a file extension of .mat appear in the caller's workspace.
  - Files with a file extension of .fig open as figure windows.
  - Files with a file extension of .mdl or .slx open as models in Simulink.
- uiopen('load') is the only the form of uiopen that you can compile into a standalone application. You can create a file selection dialog box that you can compile using uigetfile.
- The uiopen dialog box is modal. A modal dialog box prevents you from interacting with other windows until you respond to the modal one.

- uiopen displays the same dialog box that opens when you use the MATLAB desktop toolstrip to open a file. (On the **Home** tab, in the **File** section, click **Open** )

## Input Arguments

### type

String that specifies the kind of file to show in the dialog box (the file filter). Acceptable values for type are the following.

Type string	Files Displayed
matlab	All MATLAB files (with file extensions *.m, *.mat, *.fig, *.mdl, and *.slx.)
load	All MAT-files (*.mat)
figure	All figure files (*.fig)
simulink	All Simulink model files (*.mdl and *.slx)
editor	All MATLAB files except for .mat, .fig, and .slx files.

### filename

A string, including the file extension, naming a file to open. The filename can be a wildcard character plus extension. For example, \*.txt displays a list of all files with the file extension .txt.

### TF

A MATLAB expression that evaluates to true or false. If true, filename opens directly, without displaying the dialog.

## Definitions

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see WindowStyle in the MATLAB Figure Properties.

## Examples

Filter to display only FIG-files by setting the **Files of type** field to Figures (\*.fig):

```
uiopen('figure')
```

## Alternatives

In MATLAB code or in a command:

- To open a file appropriately based on its file extension, use the `open` function.
- To open a file in the Editor, use the `edit` function.
- To open a MAT-file and load its contents into the workspace, use the `load` function.
- To open a FIG-file, use the `openfig` function.
- To open a file in an application in Microsoft Windows, use the `winopen` function.

# uiopen

`uigetfile` | `uiputfile` | `uisave`

<b>Purpose</b>	Create panel container object
<b>Syntax</b>	<pre>h = uipanel('PropertyName1',value1,'PropertyName2',value2,...) h = uipanel(parent,'PropertyName1',value1,'PropertyName2',value2, ...)</pre>
<b>Description</b>	<p>A <code>uipanel</code> groups components. It can contain user interface controls with which the end user interacts directly. It can also contain axes, other <code>uipanel</code>s, and <code>uibuttongroups</code>. It cannot contain ActiveX controls.</p> <pre>h = uipanel('PropertyName1',value1,'PropertyName2',value2,...)</pre> <p>creates a <code>uipanel</code> container object in a figure, <code>uipanel</code>, or <code>uibuttongroup</code>. Use the <code>Parent</code> property to specify the parent figure, <code>uipanel</code>, or <code>uibuttongroup</code>. If you do not specify a parent, <code>uipanel</code> adds the panel to the current figure. If no figure exists, MATLAB creates one. See the <code>Uipanel Properties</code> reference page for more information.</p> <pre>h = uipanel(parent,'PropertyName1',value1,'PropertyName2',value2, ...)</pre> <p>creates a <code>uipanel</code> in the object specified by the handle, <code>parent</code>. If you also specify a different value for the <code>Parent</code> property, the value of the <code>Parent</code> property takes precedence. <code>parent</code> must be a figure, <code>uipanel</code>, or <code>uibuttongroup</code>.</p> <p>A <code>uipanel</code> object can have axes, <code>uicontrol</code>, <code>uipanel</code>, and <code>uibuttongroup</code> objects as children. For the children of a <code>uipanel</code>, the <code>Position</code> property is interpreted relative to the <code>uipanel</code>. If you move the panel, the children automatically move with it and maintain their positions relative to the panel.</p> <p>After creating a <code>uipanel</code> object, you can set and query its property values using <code>set</code> and <code>get</code>.</p>
<b>Tips</b>	If you set the <code>Visible</code> property of a <code>uipanel</code> object to <code>'off'</code> , any child objects it contains (buttons, button groups, axes, etc.) become invisible

along with the panel itself. However, doing this does *not* affect the settings of the `Visible` property of any of its child objects, even though all of them remain invisible until the `uipanel`'s visibility is set to `'on'`.

## Examples

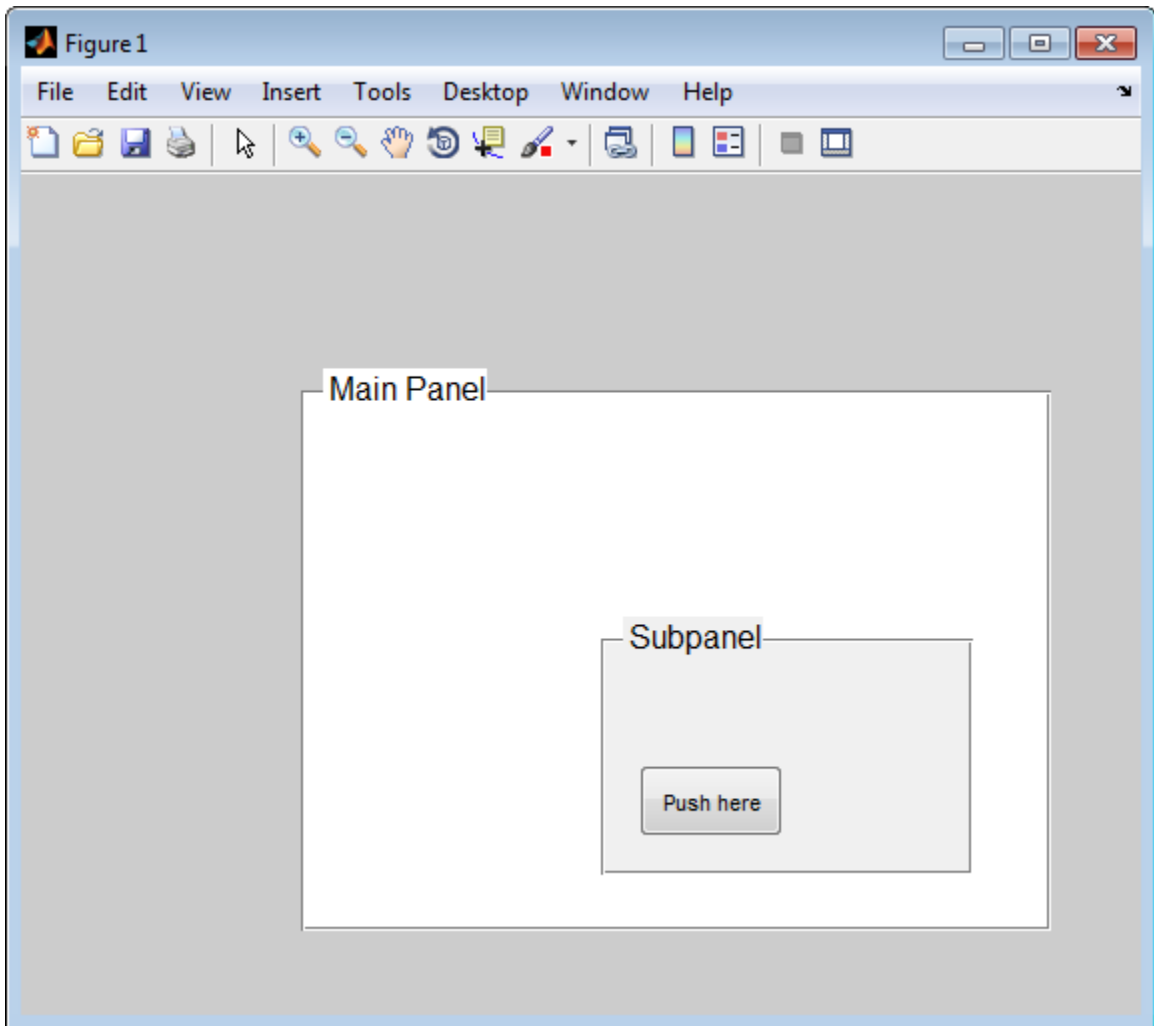

### Create uipanel with children

Create a `uipanel`, a subpanel in the first panel, and a `pushbutton` in the subpanel.

Both panels use the default `Units` property value, normalized. (Whereas the default `Units` for the `uicontrol` push button is pixels.)

```
h = figure;
hp = uipanel('Title','Main Panel','FontSize',12,...
 'BackgroundColor','white',...
 'Position',[.25 .1 .67 .67]);
hsp = uipanel('Parent',hp,'Title','Subpanel','FontSize',12,...
 'Position',[.4 .1 .5 .5]);
hbsp = uicontrol('Parent',hsp,'String','Push here',...
 'Position',[18 18 72 36]);
```

### Uipanel that always matches figure window width

Create a uipanel that always matches the width of the figure, but maintains a constant height. The `ResizeFcn` keeps the uipanel whose

`Tag` is `StatusBar` 20 pixels high, as wide as the figure, and attached to the top of the figure.

Create a file named `match_width.m` on your MATLAB path containing the code that follows. This code uses the `Tag` property to retrieve the `uipanel` handle, and the `gcbo` function to retrieve the figure handle. By default, the figure `Units` property is set to `pixels`. The code sets the panel `Units` to `match`, but restores them to their original setting before the function ends.

```
function match_width(hObject,eventdata)
 u = findobj(gcbo, 'Type','uipanel','Tag','StatusBar');
 fig = gcbo;
 panelunits = get(u,'Units');
 set(u,'Units','pixels');
 % derive the new position for the panel
 figpos = get(fig,'Position');
 upos = [1, figpos(4) - 20, figpos(3), 20];
 set(u,'Position',upos);
 % restore units for the panel
 set(u,'Units',panelunits);
end
```

Run this code in the Command Window to create a figure that specifies the `match_width` function as the `ResizeFcn` callback. (If you do not set the figure `Visible` property set to `off` initially, the `uipanel` does not display until the first time you resize the window. )

```
f = figure('Visible','off');
u = uipanel('Units','Pixels', 'Tag','StatusBar');
set(f,'ResizeFcn', @match_width);
set(f,'Visible','on');
```

Resize the figure window to observe the effect of the `ResizeFcn` callback.

## Purpose

Describe panel properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from the GUIDE Layout Editor **View** menu, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uipanel properties by typing:

```
set(h, 'DefaultUipanelPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uipanel handle. `PropertyName` is the name of the uipanel property and `PropertyValue` is the value you specify as the default for that property.

---

**Note** Default properties you set for uipanel also apply to `uibuttongroups`.

---

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uipanel Properties

This section lists all properties useful to `uipanel` objects along with valid values and a descriptions of their use. Curly braces `{ }` enclose default values.

Property Name	Description
<code>BackgroundColor</code>	Color of the uipanel background
<code>BeingDeleted</code>	This object is being deleted
<code>BorderType</code>	Type of border around the uipanel area.

# Uipanel Properties

---

Property Name	Description
BorderWidth	Width of the panel border.
BusyAction	Interruption of other callback routines
ButtonDownFcn	Button-press callback routine
Children	All children of the uipanel
Clipping	Clipping of child axes, uipanel, and uibuttongroups to the uipanel. Does not affect child uicontrols.
CreateFcn	Callback routine executed during object creation
DeleteFcn	Callback routine executed during object deletion
FontAngle	Title font angle
FontName	Title font name
FontSize	Title font size
FontUnits	Title font units
FontWeight	Title font weight
ForegroundColor	Title font color
HandleVisibility	Handle accessibility from command line and GUIs
HighlightColor	3-D frame highlight color
Interruptible	Callback routine interruption mode
Parent	Uipanel object's parent
Position	Panel position relative to parent figure or uipanel
ResizeFcn	User-specified resize routine
ShadowColor	3-D frame shadow color

Property Name	Description
Tag	User-specified object identifier
Title	Title string
TitlePosition	Location of title string in relation to the panel
Type	Object class
UIContextMenu	Associates uicontextmenu with the uipanel
Units	Units used to interpret the position vector
UserData	User-specified data
Visible	Uipanel visibility. <hr/> <b>Note</b> Controls the visibility of a uipanel and of its child axes, uibuttongroups, uipanels, and child uicontrols. Setting it does not change their Visible property. <hr/>

BackgroundColor  
ColorSpec

*Color of the uipanel background.* A three-element RGB vector or one of the MATLAB predefined names, specifying the background color. See the ColorSpec reference page for more information on specifying color.

BeingDeleted  
on | {off} (read-only)

*This object is being deleted.* Mechanism to determine if objects are in the process of being deleted. MATLAB sets the BeingDeleted property to on when the object's delete function callback is called (see the DeleteFcn property). It remains set to on while the delete function executes, after which the object no longer exists.

# Uipanel Properties

---

For example, an object's delete function calls other functions that act on a number of different objects. If a function does not need to perform an action on an about-be-deleted object, it can check the object's `BeingDeleted` property before acting.

## BorderType

`none` | `{etchedin}` | `etchedout` | `beveledin` | `beveledout`  
| `line`

*Border of the uipanel area.* Used to define the panel area graphically. Etched and beveled borders provide a 3-D look. Use the `HighlightColor` and `ShadowColor` properties to specify the border color of etched and beveled borders.

A line border is 2-D. Use the `HighlightColor` property to specify its color.

## BorderWidth

`integer`

*Width of the panel border.* The width of the panel borders in pixels. The default border width is 1 pixel. 3-D borders wider than 3 may not appear correctly at the corners.

## BusyAction

`cancel` | `{queue}`

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `ButtonDownFcn`

string or function handle

*Button-press callback routine.* A callback routine that executes when you press a mouse button while the pointer is in a 5-pixel wide border around the uipanel. This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on (using the `selectmoveresize` function, for example).

If you define this routine as a string, the string can be a valid MATLAB expression or the name of a code file. The expression executes in the MATLAB workspace.

## `Children`

vector of handles

*Children of the uipanel.* A vector containing the handles of all children of the uipanel. A `uipanel` object's children are axes, uipanels, uibuttongroups, and uicontrols. You can use this property to reorder the children.

## `Clipping`

{on} | off

*Clipping mode.* By default, MATLAB clips a uipanel's child axes, uipanels, and uibuttongroups to the uipanel rectangle. If you set `Clipping` to `off`, the axis, uipanel, or uibuttongroup is displayed outside the panel rectangle. This property does not

# Uipanel Properties

---

affect child uicontrols which, by default, can display outside the panel rectangle.

**CreateFcn**  
string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uipanel` object. MATLAB sets all property values for the `uipanel` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the `uipanel` being created.

Setting this property on an existing `uipanel` object has no effect.

You can define a default `CreateFcn` callback for all new `uipanel`s. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uipanel`. For example, the code

```
set(0, 'DefaultUipanelCreateFcn', 'set(gcbo, ...
 'FontName', 'arial', 'FontSize', 12)')
```

creates a default `CreateFcn` callback that runs whenever you create a new panel. It sets the default font name and font size of the `uipanel` title.

---

**Note** `Uibuttongroup` takes its default property values from `uipanel`. Defining a default property for all `uipanel`s defines the same default property for all `uibuttongroups`.

---

To override this default and create a panel whose `FontName` and `FontSize` properties are set to different values, call `uipanel` with code similar to

```
hpt = uipanel(..., 'CreateFcn', 'set(gcbo, ...
 'FontName', 'times', 'FontSize', 14)')
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this uipanel, you had explicitly set `FontSize` to 14, the default `CreateFcn` callback would have set `FontSize` back to the system dependent default.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the uipanel object (e.g., when you issue a delete command or clear the figure containing the uipanel). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine. The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

## FontAngle

{normal} | italic | oblique

*Character slant used in the Title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

# Uipanel Properties

---

FontName  
string

*Font family used in the Title.* The name of the font in which to display the Title. To display and print properly, this must be a font that your system supports. The default font is system dependent. To eliminate the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan), set FontName to the string FixedWidth (this string value is case insensitive).

```
set(uicontrol_handle,'FontName','FixedWidth')
```

This then uses the value of the root FixedWidthFontName property which can be set to the appropriate value for a locale from startup.m in the end user's environment. Setting the root FixedWidthFontName property causes an immediate update of the display to use the new font

FontSize  
integer

*Title font size.* A number specifying the size of the font in which to display the Title, in units determined by the FontUnits property. The default size is system dependent.

FontUnits  
inches | centimeters | normalized | {points} | pixels

*Title font size units.* Normalized units interpret FontSize as a fraction of the height of the uipanel. When you resize the uipanel, MATLAB modifies the screen FontSize accordingly. pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).

FontWeight  
light | {normal} | demi | bold

*Weight of characters in the title.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to bold causes MATLAB to use a bold version of the font, when it is available on your system.

ForegroundColor  
ColorSpec

*Color used for title.* A three-element RGB vector or one of the MATLAB predefined names, specifying the title color. See the ColorSpec reference page for more information on specifying color.

HandleVisibility  
{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

# Uipanel Properties

---

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HighlightColor`  
`ColorSpec`

*3-D frame highlight color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the highlight color. See the `ColorSpec` reference page for more information on specifying color.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* `HitTest` determines if the `uipanel` can become the current object (as returned by the `gco` command and the figure `CurrentObject` property) as a result of a mouse click on the panel. If `HitTest` is `off`, clicking the panel sets the `CurrentObject` to the closest ancestor of the panel that registers `HitTest`. The `uipanel` property `HandleVisibility` must be `'on'` for it to become the `CurrentObject`. If the `uipanel` `HandleVisibility` is `'off'` or `'callback'`, or if the panel and all its ancestors have `HitTest` set to `'off'`, the figure `CurrentObject` is the empty matrix.

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

# Uipanel Properties

---

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent  
handle

*Uipanel parent.* The handle of the uipanel’s parent figure, uipanel, or uibuttongroup. You can move a uipanel object to

another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

## Position

position rectangle

*Size and location of uipanel relative to parent.* The rectangle defined by this property specifies the size and location of the panel within the parent figure window, uipanel, or uibuttongroup. Specify Position as

[left bottom width height]

left and bottom are the distance from the lower-left corner of the parent object to the lower-left corner of the uipanel object. width and height are the dimensions of the uipanel rectangle, including the title. All measurements are in units specified by the Units property.

## ResizeFcn

function handle or string

*Resize callback routine.* MATLAB executes this callback routine whenever a user manually or programmatically resizes the uipanel, or in GUIDE, the Resize behavior option is set to other. You can query the uipanel Position property to determine its new size and position. During execution of the callback routine, the handle to the uipanel being resized is accessible only through the root CallbackObject property, which you can query using gcbo.

All axes, uipanel, uitable and uicontrol objects that have their Units set to normalized automatically resize proportionally to the figure. You can define individual resize functions for any such object as needed. For example, you can use ResizeFcn to maintain a GUI layout that is not directly supported by the MATLAB Position-and-Units paradigm.

# Uipanel Properties

---

For example, consider a GUI layout that maintains an object attached to the top of the figure at a constant height in pixels, but always matches the width of the figure. The following `ResizeFcn` accomplishes this; it keeps the uicontrol whose `Tag` is `'StatusBar'` 20 pixels high, as wide as the figure, and attached to the top of the figure. Note the use of the `Tag` property to retrieve the uicontrol handle, and the `gcbo` function to retrieve the figure handle. The code also does “defensive programming” to save and restores figure `Units`. The callback requires `Units` in pixels in order to work correctly, but takes care not to permanently alter that property.

```
u = findobj('Tag','StatusBar');
fig = gcbo;
old_units = get(fig,'Units');
set(fig,'Units','pixels');
figpos = get(fig,'Position');
upos = [0, figpos(4) - 20, figpos(3), 20];
set(u,'Position',upos);
set(fig,'Units',old_units);
```

You can change the figure `Position` from within a uipanel `ResizeFcn` callback; however, the `ResizeFcn` is not called again as a result.

A figure’s uipanel resize before the figure itself does. Nested uipanel resize from inner to outer, with child `ResizeFcns` being called before parent `ResizeFcns`.

The `print` command can cause the `ResizeFcn` to be called if the `PaperPositionMode` property is set to `manual` and you have defined a resize function. If you do not want your resize function called by `print`, set the `PaperPositionMode` to `auto`.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

See [Resize Behavior](#) for information on creating resize functions using [GUIDE](#).

## Selected

on | off (read only)

*Is object selected?* This property indicates whether the panel is selected. When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

## SelectionHighlight

{on} | off

*Object highlighted when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

## ShadowColor

ColorSpec

*3-D frame shadow color.* A three-element RGB vector or one of the MATLAB predefined names, specifying the shadow color. See the [ColorSpec](#) reference page for more information on specifying color.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the

# Uipanel Properties

---

handles of all children (of the specified figures) that have the Tag value 'FormatTb'.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

## Title

string

*Title string.* The text displayed in the panel title. Vertical slash ('|') characters are not interpreted as line breaks and instead show up in the text displayed in the uipanel title. You can position the title using the `TitlePosition` property.

Setting a property value to `default`, `remove`, or `factory` produces the effect described in “Defining Default Values”. To set `Title` to one of these words, you must precede the word with the backslash character. For example,

```
hp = uipanel(...,'Title','\default');
```

## TitlePosition

{lefttop} | centertop | righttop | leftbottom |  
centerbottom | rightbottom

*Location of the title.* This property determines the location of the title string, in relation to the uipanel.

## Type

string (read-only)

*Object class.* This property identifies the kind of graphics object. For uipanel objects, `Type` is always the string 'uipanel'.

## UIContextMenu

handle

*Associate a context menu with a uipanel.* Assign this property the handle of a `Uicontextmenu` object. MATLAB displays the

context menu whenever you right-click the `uipanel`. Use the `uicontextmenu` function to create the context menu.

## Units

`inches` | `centimeters` | `{normalized}` | `points` | `pixels`  
| `characters`

*Units of measurement.* MATLAB uses these units to interpret the `Position` property. For the panel itself, units are measured from the lower-left corner of the figure window. For children of the panel, they are measured from the lower-left corner of the panel.

- Normalized units map the lower-left corner of the panel or figure window to (0,0) and the upper-right corner to (1.0,1.0).
- `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point = 1/72 inch).
- `Character` units are characters using the default system font; the width of one character is the width of the letter `x`, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

## UserData

matrix

*User-specified data.* Any data you want to associate with the `uipanel` object. MATLAB does not use this data, but you can access it using `set` and `get`.

## Visible

`{on}` | `off`

*Uipanel visibility.* By default, a `uipanel` object is visible. When set to `'off'`, the `uipanel` is not visible, as are all child objects of

# Uipanel Properties

---

the panel. When a panel is hidden in this manner, you can still query and set its properties.

---

**Note** The value of a uipanel's `Visible` property determines whether its child components, such as axes, buttons, `uibuttongroups`, and other uipanel, are visible. However, changing the `Visible` property of a panel does *not* change the settings of the `Visible` property of its child components even though hiding the panel causes them to be hidden.

---

<b>Purpose</b>	Create push button on toolbar
<b>Syntax</b>	<pre>hpt = uipushtool hpt = uipushtool('PropertyName1',value1,'PropertyName2',value2,...) hpt = uipushtool(ht,...)</pre>
<b>Description</b>	<p><code>hpt = uipushtool</code> creates a push button on the <code>uitoolbar</code> at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no <code>uitoolbar</code> exists, one is created. The <code>uitoolbar</code> is the parent of the <code>uipushtool</code>. Use the returned handle <code>hpt</code> to set properties of the tool. The <code>ClickedCallback</code> passes the handle as its first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting <code>CData</code> for the tool.</p> <pre>hpt = uipushtool('PropertyName1',value1,'PropertyName2',value2,...) , creates a uipushtool and returns a handle to it. uipushtool assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the <code>set</code> function. You can specify properties as parameter name/value pairs, cell arrays containing parameter names and values, or structures with fields containing parameter names and values as input arguments. For a complete list, see <code>Uipushtool Properties</code>. Type <code>get(hpt)</code> to see a list of <code>uipushtool</code> object properties and their current values. Type <code>set(hpt)</code> to see a list of <code>uipushtool</code> object properties that you can set and their legal property values.</pre> <p><code>hpt = uipushtool(ht,...)</code> creates a button with <code>ht</code> as a parent. <code>ht</code> must be a <code>uitoolbar</code> handle.</p> <p><code>Uipushtools</code> appear in figures whose <code>Window Style</code> is <code>'normal'</code> or <code>'docked'</code>. Push tools do not appear in figures with <code>'modal'</code> <code>WindowStyle</code>. If you change the <code>WindowStyle</code> of a figure containing a <code>uitoolbar</code> and its <code>uipushtool</code> children to <code>'modal'</code>, the <code>uipushtools</code> continue to exist as <code>Children</code> of the <code>uitoolbar</code>. However, they do</p>

not display until you change the figure `WindowStyle` to `'normal'` or `'docked'`.

Unlike push buttons, uipushtools have no way to indicate that you have double-clicked them. That is, a double click does not set the figure `SelectionType` property to `'open'`. Double-clicking a uipushtool simply executes its `ClickedCallback` twice in succession. Also, uipushtools cannot have context menus.

## Examples

### Toolbar with push button

Create a `uitoolbar` object and place a `uipushtool` object on it.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
% Use a MATLAB icon for the tool
[X map] = imread(fullfile(...
 matlabroot,'toolbox','matlab','icons','matlabicon.gif'));
% Convert indexed image and colormap to truecolor
icon = ind2rgb(X,map);
% Create a uipushtool in the toolbar
hpt = uipushtool(ht,'CData',icon,...
 'TooltipString','Toolbar push button',...
 'ClickedCallback',...
 'disp(''Thank you for clicking a uipushtool.'')')
```

**Alternatives**

You can also create toolbars with push tools using GUIDE.

# Uipushtool Properties

---

## Purpose

Describe push tool properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uipushtool properties by typing:

```
set(h, 'DefaultUipushtoolPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, a uicontrol handle, or a uipushtool handle. *PropertyName* is the name of the Uipushtool property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see [Setting Default Property Values](#).

## Uipushtool Properties

This section lists all properties useful to uipushtool objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption.
CData	Truecolor image displayed on the control.
ClickedCallback	Control action.
CreateFcn	Callback routine executed during object creation.
DeleteFcn	Delete uipushtool callback routine.

Property	Purpose
Enable	Enable or disable the uipushtool.
HandleVisibility	Control access to object's handle.
Interruptible	Callback routine interruption mode.
Parent	Handle of uipushtool's parent.
Separator	Separator line mode
Tag	User-specified object label.
TooltipString	Content of object's tooltip.
Type	Object class.
UIContextMenu	Uicontextmenu object associated with the uipushtool
UserData	User specified data.
Visible	Uipushtool visibility.

## BeingDeleted

on | {off} (read only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to `on` when the object's delete function callback is called (see the `DeleteFcn` property). It remains set to `on` while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

# Uipushtool Properties

---

## *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## `CData`

3-dimensional array

*Truecolor image displayed on control.* An  $n$ -by- $m$ -by-3 array of RGB values that defines a truecolor image displayed on either a push button or toggle button. Each value must be between 0.0 and 1.0. If your `CData` array is larger than 16 in the first or second dimension, it may be clipped or cause other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

## `ClickedCallback`

string or function handle

*Control action.* A routine that executes when the uipushtool's `Enable` property is set to on, and you press a mouse button while the pointer is on the push tool itself or in a 5-pixel wide border around it.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uipushtool object. MATLAB sets all property values for the uipushtool before executing the CreateFcn callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the push tool being created.

Setting this property on an existing uipushtool object has no effect.

You can define a default CreateFcn callback for all new uipushtools. This default applies unless you override it by specifying a different CreateFcn callback when you call `uipushtool`. For example, the code

```
imga(:, :, 1) = rand(20);
imga(:, :, 2) = rand(20);
imga(:, :, 3) = rand(20);
set(0, 'DefaultUipushtoolCreateFcn', ...
 'set(gcbo, 'Cdata', imga)')
```

creates a default CreateFcn callback that runs whenever you create a new push tool. It sets the default image `imga` on the push tool.

To override this default and create a push tool whose `Cdata` property is set to a different image, call `uipushtool` with code similar to

```
a = [.05:.05:0.95];
imgb(:, :, 1) = repmat(a, 19, 1)';
imgb(:, :, 2) = repmat(a, 19, 1);
imgb(:, :, 3) = repmat(flip(a, 2), 19, 1);
hpt = uipushtool(..., 'CreateFcn', ...
 'set(gcbo, 'CData', imgb)', ...)
```

# Uipushtool Properties

---

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uipushtool` call. In the example above, if instead of redefining the `CreateFcn` property for this push tool, you had explicitly set `CData` to `imgb`, the default `CreateFcn` callback would have set `CData` back to `imga`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

`DeleteFcn`  
string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uipushtool` object (e.g., when you call the `delete` function or cause the figure containing the `uipushtool` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

`Enable`  
{on} | off

*Enable or disable the uipushtool.* This property controls how uipushtools respond to mouse button clicks, including which callback routines execute.

- **on** – The uipushtool is operational (the default).
- **off** – The uipushtool is not operational and its image (set by the `Cdata` property) is grayed out.

When you left-click a uipushtool whose `Enable` property is **on**, MATLAB performs these actions in this order:

- 1** Executes the push tool's `ClickedCallback` routine.
- 2** Does *not* set the figure `CurrentPoint` property and does not execute the figure's `WindowButtonDownFcn` callback.
- 3** Does *not* set the figure `SelectionType` property.

When you left-click a uipushtool whose `Enable` property is **off**, or when you right-click a uipushtool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

`HandleVisibility`  
{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is **on**.

# Uipushtool Properties

---

- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
{on} | off

*Selectable by mouse click.* This property has no effect on uipushtool objects.

---

**Note** Use of the uipushtool `HitTest` property is not recommended. This property might be removed in a future release.

---

`Interruptible`  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

# Uipushtool Properties

---

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent  
handle

*Uipushtool parent.* The handle of the uipushtool’s parent toolbar. You can move a uipushtool object to another toolbar by setting this property to the handle of the new parent.

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line to the left of the uipushtool.

## Tag

string

*User-specified object identifier.* The Tag property provides a means to identify graphics objects with a user-specified label. You can define Tag as any string.

With the `findobj` function, you can locate an object with a given Tag property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the Tag value 'Copy'.

```
h = findobj(uitoolbarhandles, 'Tag', 'Copy')
```

## TooltipString

string

*Content of tooltip for object.* The TooltipString property specifies the text of the tooltip associated with the uipushtool. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the TooltipString to that value. For example:

```
h = uipushtool;
s = sprintf('Pushtool tooltip line 1\nPushtool tooltip line 2');
set(h, 'TooltipString', s)
```

# Uipushtool Properties

---

## Type

string (read-only)

Object class. This property identifies the kind of graphics object. For uipushtool objects, Type is always the string 'uipushtool'.

## UINavigationController

handle

*Associate a context menu with uicontrol.* This property has no effect on uipushtool objects.

## UserData

array

*User specified data.* You can specify UserData as any array you want to associate with the uipushtool object. The object does not use this data, but you can access it using the `set` and `get` functions.

## Visible

{on} | off

*Uipushtool visibility.* By default, all uipushtools are visible. When set to off, the uipushtool is not visible, but still exists and you can query and set its properties.

**Purpose** Open standard dialog box for saving files

**Syntax**

```
FileName = uiputfile
[FileName,PathName] = uiputfile
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle)
[FileName,PathName,FilterIndex] = uiputfile(FilterSpec,DialogTitle,
 DefaultName)
```

## Description

---

**Note** Successful execution of `uiputfile` does not create a file; it only returns the name of a new or existing file that you designate.

---

`FileName = uiputfile` displays a modal dialog box for selecting or specifying a file you want to create or save. The dialog box lists the files and folders in the current folder. If the selected or specified file name is valid, `uiputfile` returns it in `FileName`.

`[FileName,PathName] = uiputfile` also returns the path to `FileName` in `PathName`, or if you cancel the dialog, returns 0 for both arguments. If you do not provide any output arguments, the file name alone is returned in `ans`.

`[FileName,PathName,FilterIndex] = uiputfile(FilterSpec)` displays only those files with extensions that match `FilterSpec`. On some platforms `uiputfile` also displays in gray any files that do not match `FilterSpec`. The `uiputfile` function appends 'All Files' to the list of file types. `FilterSpec` can be a string or a cell array of strings, and can include the \* and ? wildcard characters. For example, '\*.m' lists all MATLAB program files in a folder.

`FilterSpec` can be a string that contains a file name. `uiputfile` displays the file name selected in the **File name** field and uses the file extension as the default filter. The `FilterSpec` string can include a path, or consist of a path only. To specify a folder only, make the last character in `DefaultName` '\ ' or '/ '. A path can contain special

path characters, such as '.', '..', '/', '\', or '~'. For example, '../\*.\*m' lists all program files in the folder above the current folder. If `FilterSpec` is a cell array of strings, the first column contains a list of file extensions. The optional second column contains a corresponding list of descriptions. These descriptions replace the default descriptions in the **Save as type** pop-up menu. A description cannot be an empty string. See the “Examples” on page 1-7396 for illustration of using cell arrays as `FilterSpec`. If you do not specify `FilterSpec`, `uiputfile` uses the default list of file types (all MATLAB files). `FilterIndex` is the index of the filter selected in the dialog box. Indexing starts at 1. If you click the **Cancel** button, close the dialog window, or if the file does not exist, `uiputfile` returns `FilterIndex` as 0.

```
[FileName,PathName,FilterIndex] =
uiputfile(FilterSpec,DialogTitle)displays a dialog box that has
the title DialogTitle. To use the default file types and to specify a
dialog title, enter uiputfile(' ', 'DialogTitle')
```

```
[FileName,PathName,FilterIndex] =
uiputfile(FilterSpec,DialogTitle, DefaultName)displays a dialog
box in which the file name specified by DefaultName appears in the
File name field. DefaultName can also be a path or a path+filename.
To specify a folder only, make the last character in DefaultName '\\' or
'/'. In this case, uiputfile opens the dialog box in the folder specified
by the path. If you specify a path in DefaultName that does not exist,
uiputfile opens the dialog box in the current folder. You can use
'.', '..', '\', '/', or ~ in the DefaultName argument.
```

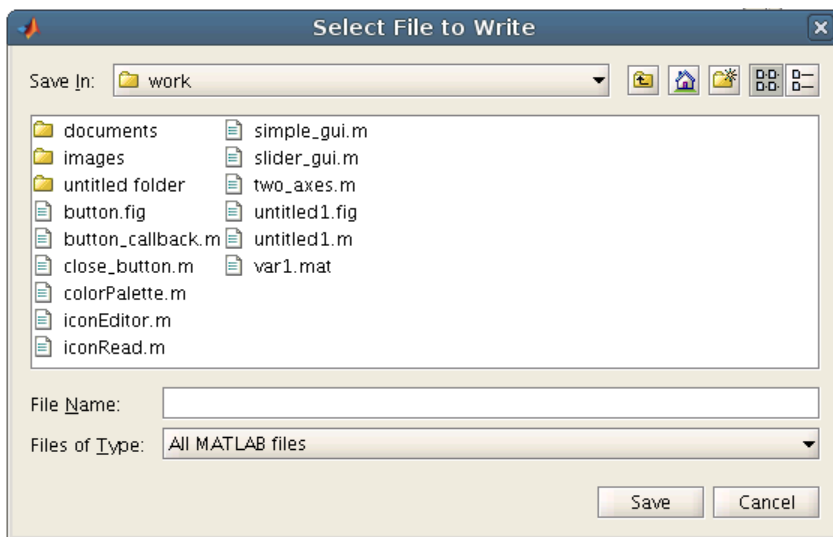

When typing into the dialog box, if you include either of the wildcard characters '\*' or '?' in a file name, `uiputfile` does not respond to clicking **Save**. The dialog box remains open until you cancel it or remove the wildcard characters. This restriction applies to all platforms, even to file systems that permit these characters in file names.

If you select or specify an existing file name, a warning dialog box opens stating that the file already exists and asks if you want to replace it.

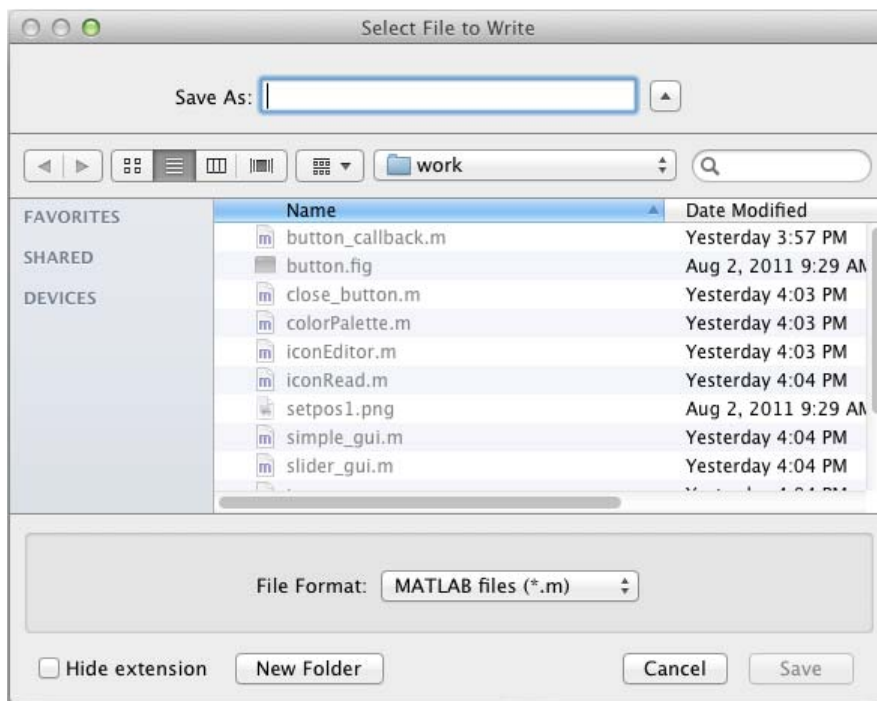

Select **Yes** to replace the existing file or **No** to return to the dialog to select another file name. Selecting **Yes** returns the name of the file. Selecting **No** returns 0.

For Microsoft Windows platforms, the dialog box is the Windows dialog box native to your platform, and thus can differ from what you see in the examples that follow.

For UNIX platforms, the dialog box is like the one shown in the following figure.

For Mac platforms, the dialog box is like the one shown in the following figure.

---

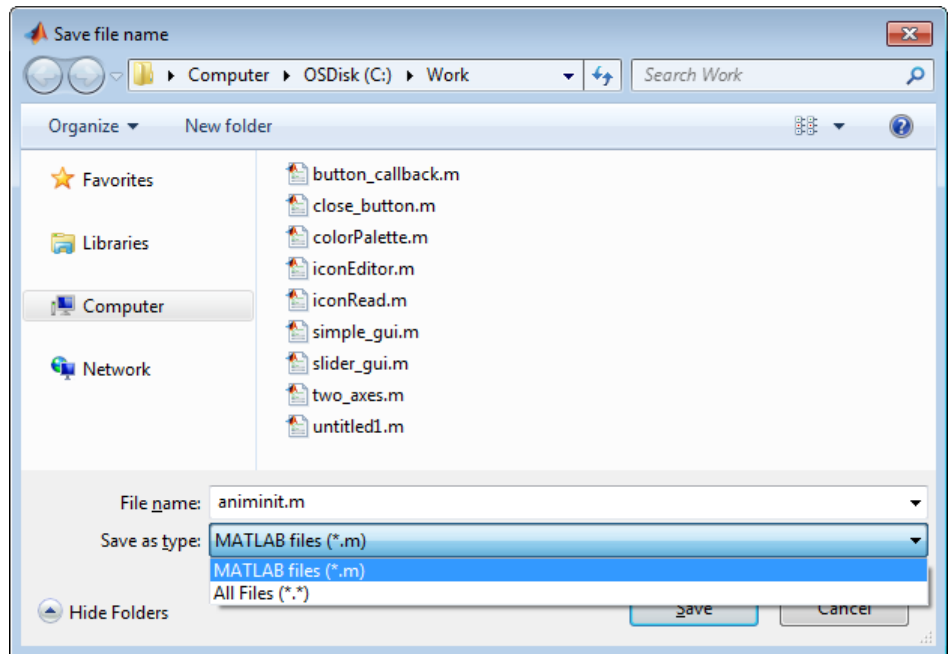

**Note** A modal dialog box prevents you from interacting with other MATLAB windows before responding. To block MATLAB program execution as well, use the `uiwait` function. For more information about modal dialog boxes, see `WindowState` in MATLAB Figure Properties.

---

## Examples

The following statement displays a dialog box entitled 'Save file name', setting the **File name** field to `animinit.m` and the filter to program files (`*.m`). Because `FilterSpec` is a string, the filter also includes All Files (`*.*`)

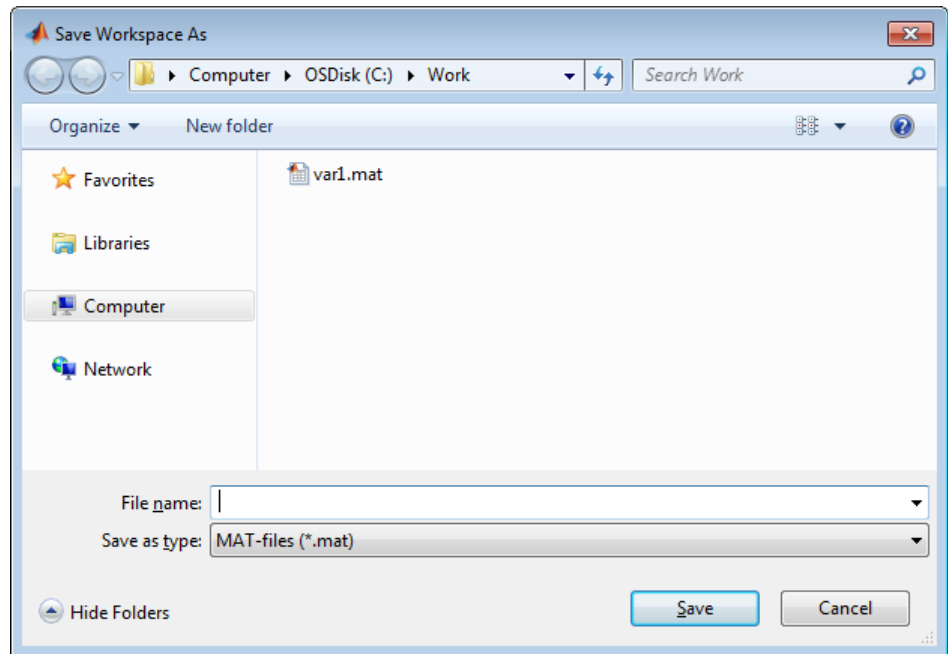

```
[file,path] = uiputfile('animinit.m','Save file name');
```

The following statement displays a dialog box entitled 'Save Workspace As' with the filter set to MAT-files.

```
[file,path] = uiputfile('*.mat','Save Workspace As');
```

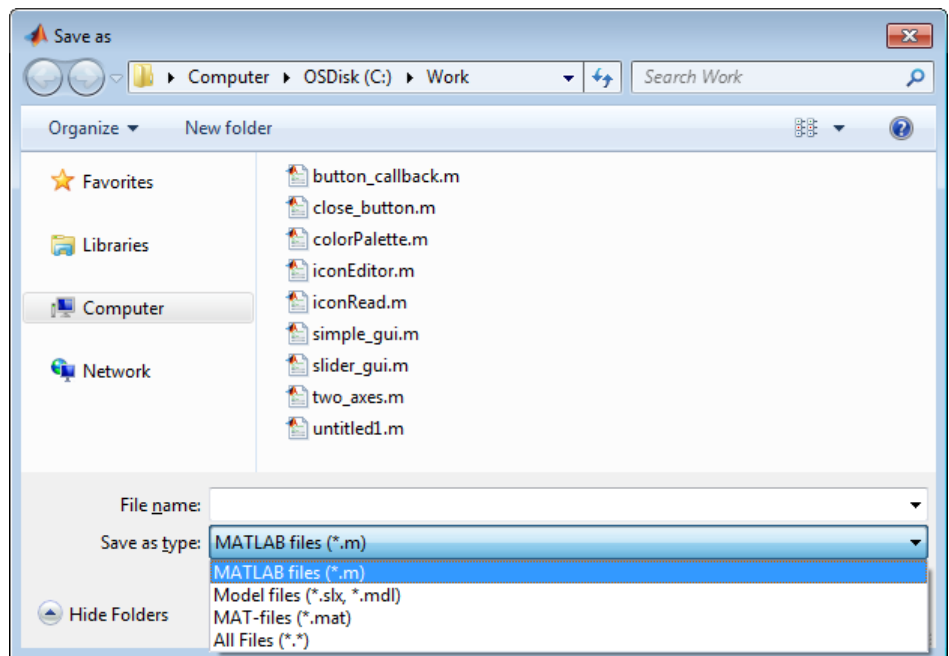

# uiputfile

To display several file types in the **Save as type** list box, separate each file extension with a semicolon, as in the following code. `uiputfile` displays a default description for each known file type, such as "Model files" for Simulink `.mdl` and `.slx` files.

```
[filename, pathname] = uiputfile(...
 {'*.m'; '*.slx'; '*.mat'; '*.*'}, ...
 'Save as');
```

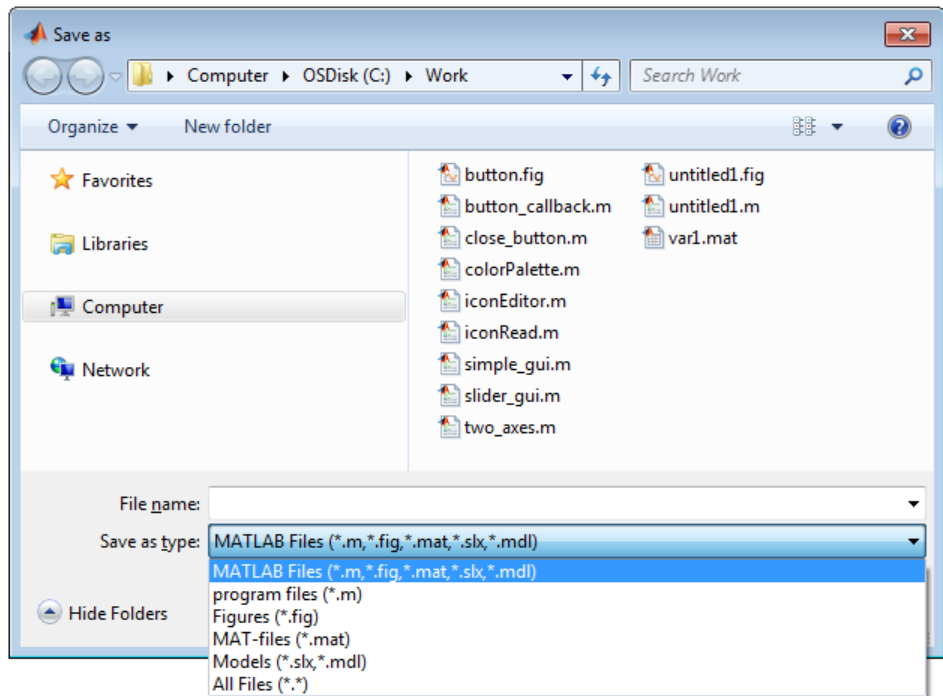

To create a list of file types and give them descriptions that are different from the defaults, use a cell array. This example also associates multiple file types with the 'MATLAB Files' and 'Models' descriptions.

```
[filename, pathname, filterindex] = uiputfile(...
{'*.m;*.fig;*.mat;*.slx;*.mdl',...
'MATLAB Files (*.m,*.fig,*.mat,*.slx,*.mdl)';
 '*.m', 'program files (*.m)';...
 '*.fig', 'Figures (*.fig)';...
 '*.mat', 'MAT-files (*.mat)';...
 '*.slx;*.mdl', 'Models (*.slx,*.mdl)';...
 '.*', 'All Files (*.*)'},...
'Save as');
```

# uiputfile

The first column of the cell array contains the file extensions, while the second contains the descriptions you want to provide for the file types. The first entry of column one contains several extensions separated by semicolons. These file types all associate with the description 'MATLAB Files (\*.m;\*.fig;\*.mat;\*.slx;\*.mdl)'. The code produces the dialog box shown in the following figure.

The following code checks for the existence of the file and displays a message about the result of the file selection operation.

```
[filename, pathname] = uiputfile('*.m',...
 'Pick a MATLAB program file');
if isequal(filename,0) || isequal(pathname,0)
 disp('User selected Cancel')
```

```

else
 disp(['User selected ',fullfile(pathname,filename)])
end

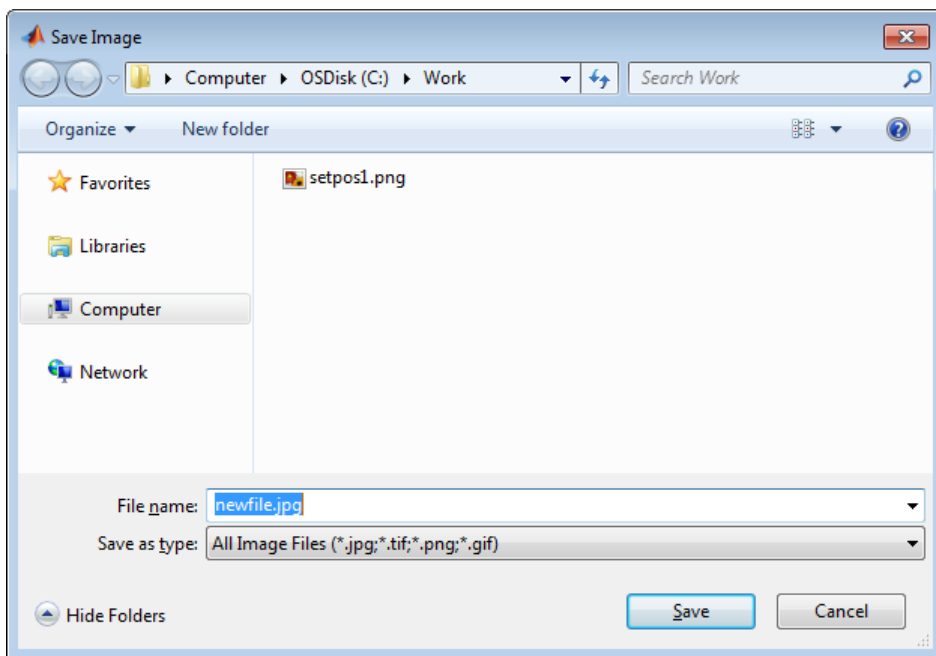

```

Select or enter a file name for saving a figure as an image in one of four formats, described in a cell array.

```

uiputfile({'*.jpg;*.tif;*.png;*.gif','All Image Files';...
 '*.','All Files' },'Save Image',...
 'C:\Work\newfile.jpg')

```

# uiresume

---

<b>Purpose</b>	Resume execution of blocked program
<b>Syntax</b>	<code>uiresume(h)</code>
<b>Description</b>	<code>uiresume(h)</code> resumes the program execution that <code>uiwait</code> suspended.

**Tips**

The `uiwait` and `uiresume` functions block and resume MATLAB program execution. When creating a dialog box, you should have a `uicontrol` component with a callback that calls `uiresume` or a callback that destroys the dialog box. These are the only methods that resume program execution after the `uiwait` function blocks execution.

When used in conjunction with a modal dialog box, `uiresume` can resume the execution of the program that `uiwait` suspended while presenting a dialog box.

**Examples**

This example creates a GUI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
 'Callback','uiresume(gcf)');
disp('This will print immediately');
uiwait(gcf);
disp('This will print after you click Continue');
close(f);
```

`gcbf` is the handle of the figure that contains the object whose callback is executing.

“Modal Dialog Box in a GUIDE GUI” is a more complex example for a GUIDE GUI.

---

<b>Purpose</b>	Interactively save workspace variables to MAT-file
<b>Syntax</b>	<pre>uisave uisave(variables) uisave(variables,filename)</pre>
<b>Description</b>	<p>uisave, with no arguments, prompts you for a file name, and then saves all variables from your workspace to that file.</p> <p>uisave(variables) saves one or more workspace variables listed in variables.</p> <p>uisave(variables,filename) uses the specified filename as the default <b>File name</b> in the Save Workspace Variables dialog box, instead of the default matlab.mat.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• If you type a name in the <b>File name</b> field, such as my_vars, and click <b>Save</b>, the dialog saves all workspace variables to the file my_vars.mat. The default filename is matlab.mat.</li><li>• uisave calls uiputfile to choose a filename.</li><li>• If the filename you specify exists in that folder, uisave informs you and gives you a chance to cancel the operation.</li><li>• The uisave dialog box is modal.</li><li>• The uisave dialog is modal. A modal dialog box prevents you from interacting with other windows until you respond to it.</li></ul>
<b>Input Arguments</b>	<p><b>variable</b></p> <p>String containing the name of a variable in the current workspace or cell array of strings when specifying more than one variable.</p> <p><b>Default:</b> All variables in the current workspace are saved to a MAT-file.</p> <p><b>filename</b></p>

String naming a file to appear in the dialog **File name** field when the dialog opens. You can omit a file extension, or specify the file extension as `.mat`.

**Default:** `matlab.mat`

## Definitions

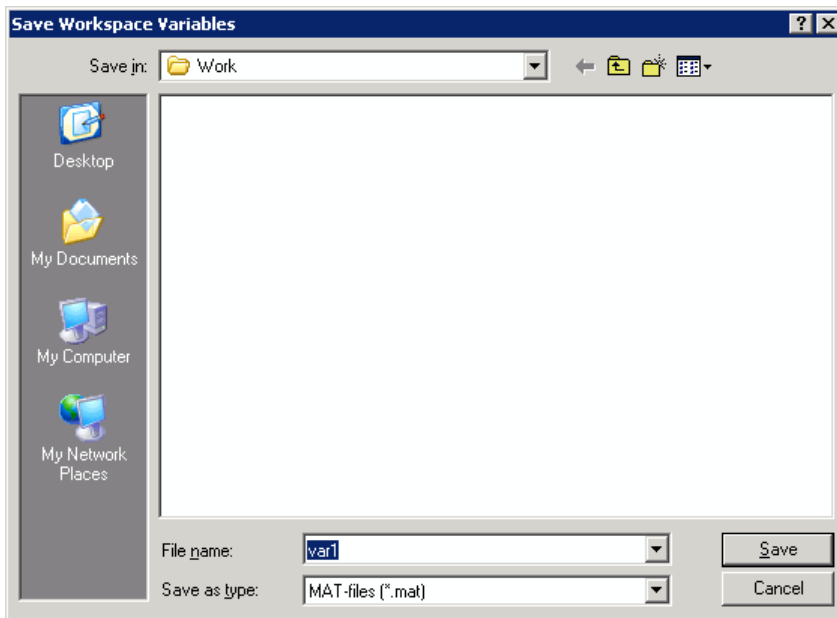

### Modal Dialog

A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

## Examples

Create workspace variables `h` and `g`, and then display the Save Workspace Variables dialog box in the current folder with the default **File name** set to `var1`.

```
h = 365;
g = 52;
uisave({'h', 'g'}, 'var1');
```

Clicking **Save** stores the workspace variables `h` and `g` in the file `var1.mat` in the displayed folder.

## Alternatives

Use any of the following GUI options to save workspace variables:

- Use **File > Save** to save workspace variables.
- Click the Save icon  in the Workspace Browser.
- Select one or more variables in the Workspace Browser, right-click, and choose **Save as** from the context menu.

# uicolor

---

**Purpose** Open standard dialog box for setting object's color specification (ColorSpec)

**Syntax**

```
c = uicolor
c = uicolor([r g b])
c = uicolor(h)
c = uicolor(..., 'dialogTitle')
```

**Description**

`c = uicolor` displays a modal color selection dialog appropriate to the platform, and returns the color selected by the user. The dialog box is initialized to white.

`c = uicolor([r g b])` displays a dialog box initialized to the specified color, and returns the color selected by the user. `r`, `g`, and `b` must be values between 0 and 1.

`c = uicolor(h)` displays a dialog box initialized to the color of the object specified by handle `h`, returns the color selected by the user, and applies it to the object. `h` must be the handle to an object containing a color property.

`c = uicolor(..., 'dialogTitle')` displays a dialog box with the specified title.

If the user presses **Cancel** from the dialog box, or if any error occurs, the output value is set to the input RGB triple, if provided; otherwise, it is set to 0.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

**See Also** ColorSpec

**Purpose** Open standard dialog box for setting object's font characteristics

**Syntax**

```
uifont
uifont(h)
uifont(S)
uifont(..., 'DialogTitle')
S = uifont(...)
```

**Description** `uifont` enables you to change font properties (`FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle`) for a `text`, `axes`, or `uicontrol` object. The function returns a structure consisting of font properties and values. You can specify an alternate title for the dialog box.

`uifont` displays a modal dialog box and returns the selected font properties.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. For more information, see `WindowState` in the MATLAB Figure Properties.

---

`uifont(h)` displays a modal dialog box, initializing the font property values with the values of those properties for the object whose handle is `h`. Selected font property values are applied to the current object. If a second argument is supplied, it specifies a name for the dialog box.

`uifont(S)` displays a modal dialog box, initializing the font property values with the values defined for the specified structure (`S`). `S` must define legal values for one or more of these properties: `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` and the field names must match the property names exactly. If other properties are defined, they are ignored. If a second argument is supplied, it specifies a name for the dialog box.

`uifont(..., 'DialogTitle')` displays a modal dialog box with the title `DialogTitle` and returns the values of the font properties selected in the dialog box.

`S = uifont(...)` returns the properties `FontName`, `FontUnits`, `FontSize`, `FontWeight`, and `FontAngle` as fields in a structure. If the user presses **Cancel** from the dialog box or if an error occurs, the output value is set to 0.

## Examples

These statements create a text object, then display a dialog box (labeled Update Font) that enables you to change the font characteristics:

```
h = text(.5,.5,'Figure Annotation');
uifont(h, 'Update Font')
```

These statements create two push buttons, then set the font properties of one based on the values set for the other:

```
% Create push button with string ABC
c1 = uicontrol('Style', 'pushbutton', ...
 'Position', [10 10 100 20], 'String', 'ABC');
% Create push button with string XYZ
c2 = uicontrol('Style', 'pushbutton', ...
 'Position', [10 50 100 20], 'String', 'XYZ');
% Display set font dialog box for c1, make selections,
& and save to d
d = uifont(c1);
% Apply those settings to c2
set(c2, d)
```

## See Also

[axes](#) | [text](#) | [uicontrol](#)

**Purpose** Manage preferences used in `uisetpref`

**Syntax** `uisetpref('clearall')`

**Description** `uisetpref('clearall')` resets the value of all preferences registered through `uisetpref` to 'ask'. This causes the dialog box to display when you call `uisetpref`.

---

**Note** Use `setpref` to set the value of a particular preference to 'ask'.

---

**See Also** `setpref` | `uisetpref`

# uistack

---

**Purpose** Reorder visual stacking order of objects

**Syntax**  
`uistack(h)`  
`uistack(h,stackopt)`  
`uistack(h,stackopt,step)`

**Description** `uistack(h)` raises the visual stacking order of the objects specified by the handles in `h` by one level (step of 1). All handles in `h` must have the same parent.

`uistack(h,stackopt)` moves the objects specified by `h` in the stacking order, where `stackopt` is one of the following:

- 'up' – moves `h` up one position in the stacking order
- 'down' – moves `h` down one position in the stacking order
- 'top' – moves `h` to the top of the current stack
- 'bottom' – moves `h` to the bottom of the current stack

`uistack(h,stackopt,step)` moves the objects specified by `h` up or down the number of levels specified by `step`.

---

**Note** In a GUI, axes objects are always at a lower level than `uicontrol` objects. You cannot stack an axes object on top of a `uicontrol` object.

---

See “Set Tab Order in a Programmatic GUI” in the MATLAB documentation for information about changing the tab order.

**Examples** Create three stacked push buttons, and then use `uistack` to change the stacking order. Initially, the Ready push button appears on top.

```
fh=figure;
pb1 = uicontrol('Parent', fh,'String','Go');
pb2 = uicontrol('Parent', fh,'String','Set');
pb3 = uicontrol('Parent', fh,'String','Ready');
```

Use `uistack` to move the push button that is first in the stacking order of the figure handle `fh` down two positions.

```
v = allchild(fh);
uistack(v(1), 'down', 2);
```

The Ready push button moves to the bottom of the stack.

# uitable

---

**Purpose** Create 2-D graphic table GUI component

**Syntax**

```
uitable
uitable('PropertyName1', value1, 'PropertyName2', value2, ...)
uitable(parent, ...)
handle = uitable(...)
```

**Description** `uitable` creates an empty `uitable` object in the current figure window, using default property values. If no figure exists, a new figure window opens.

`uitable('PropertyName1', value1, 'PropertyName2', value2, ...)` creates a `uitable` object with specified property values. Properties that you do not specify assume the default property values. See the `Uitable Properties` reference page for information about the available properties.

`uitable(parent, ...)` creates a `uitable` object as a child of the specified parent handle `parent`. The parent can be a figure or `uipanel` handle. If you also specify a different value for the `Parent` property, the value of the `Parent` property takes precedence.

`handle = uitable(...)` creates a `uitable` object and returns its handle.

**Tips** After creating a `uitable` object, you can set and query its property values using the `set` and `get` functions.

If the `ColumnEditable` property is `true` for columns you edit, you can change values in a displayed table. By default, this property is `false` for all columns. If a noneditable column contains pop-up choices, only the current choice is visible (and not the pop-up menu control).

If you attempt to create a `uitable` object when running MATLAB on a UNIX system without a Java virtual machine (`matlab -nojvm`) or without a display (`matlab nodisplay`), no table generates and you receive an error.

The **`CellEditCallback`** executes after you edit a value and do any of the following:

- Type **Enter**.
- Click another table cell.
- Click anywhere else within the table.
- Click another control or area within the same figure window.
- Click another window, click again on the GUI containing the table (or use **Alt+Tab** to switch windows), and then perform any of the above four actions.

When the `CellEditCallback` callback executes, `uitable` updates the underlying data matrix (the table `Data` property) to contain the value that the cell now displays.

The `CellSelectionCallback` executes when you select a table cell or remove one from the current selection by **Ctrl**+clicking it. Clicking a cell without pressing any key selects it and deselects all currently selected cells. You can define a range of table cells by **Shift**+clicking an unselected cell after selecting one or more cells. The callback provides event data that identifies the rows and columns of all cells in the current selection.

You cannot select table cells programmatically. Directly clicking cells is the only method of selection.

## Examples

Create a table, provide magic-square data, set column widths uniformly, and specify the `uitable` `ColumnWidth` property as a cell array:

- 1 Create a table in the current figure. If no figure exists, one opens:

```
t = uitable;
```

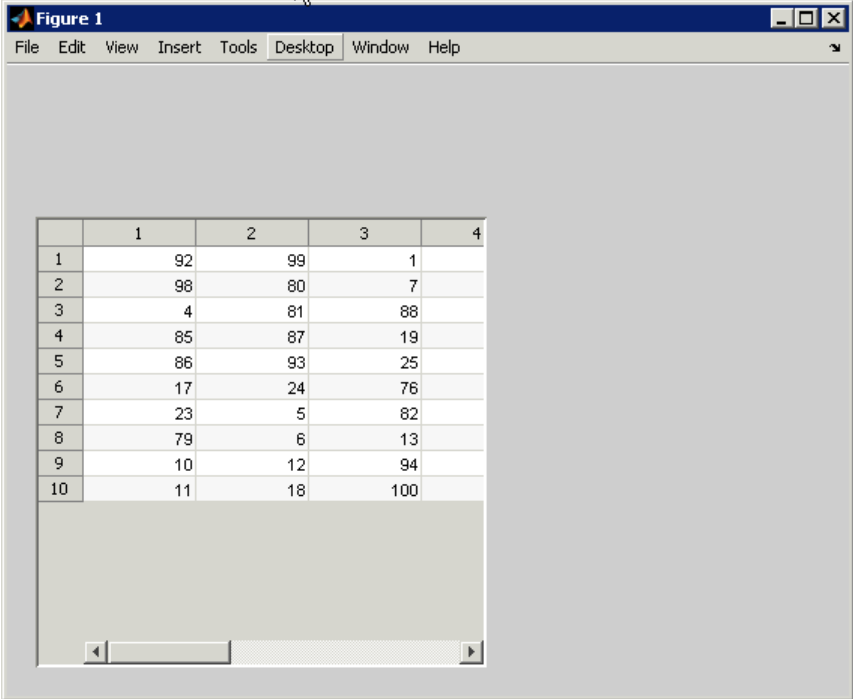

# uitable

- 2** As the table has no content (its Data property is empty), it initially displays no rows or columns. Provide data (a magic square)

```
set(t,'Data',magic(10))
```

	1	2	3	4
1	92	99	1	
2	98	80	7	
3	4	81	88	
4	85	87	19	
5	86	93	25	
6	17	24	76	
7	23	5	82	
8	79	6	13	
9	10	12	94	
10	11	18	100	

- 3** Make the entire table contents visible. Set column widths to 25 pixels uniformly. Specify the `ColumnWidth` property of the table as a cell array.

```
set(t, 'ColumnWidth', {25})
```

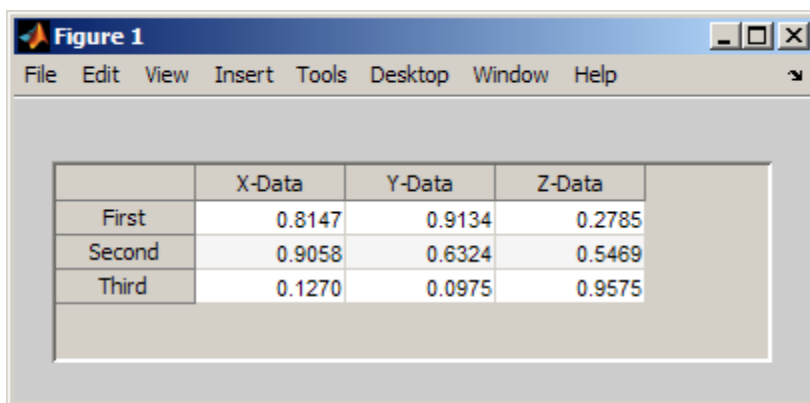

Cell arrays that specify `ColumnWidth` can contain:

- One number (a width measured in pixels, as shown here) or the string 'auto'.
- A cell array containing a list of pixel sizes having up to as many entries as the table has columns .

If a list of column widths has  $n$  entries, where  $n$  is smaller than the number of columns, it sets the first  $n$  column widths only. You can substitute 'auto' for any value in the cell array to have the width of that column calculated automatically.

Create a figure and add a table to contain a 3-by-3 data matrix. The code specifies the column names, row names, parent, and position of the table:

```
f = figure('Position',[200 200 400 150]);
dat = rand(3);
cnames = {'X-Data','Y-Data','Z-Data'};
rnames = {'First','Second','Third'};
t = uitable('Parent',f,'Data',dat,'ColumnName',cnames,...
 'RowName',rnames,'Position',[20 20 360 100]);
```

Create a table to contain a 3-by-4 array that contains numeric, logical, and string data, as follows:

- First column (**Rate**): Numeric, with three decimals (not editable)
- Second column (**Amount**): Currency (not editable)
- Third column (**Available**): Check box (editable)
- Fourth column (**Fixed/Adj**): Pop-up menu with two choices: Fixed and Adjustable (editable)
- Specify the RowName property as empty to remove row names from the table.

```
f = figure('Position',[100 100 400 150]);
```

# uitable

```
dat = {6.125, 456.3457, true, 'Fixed';...
 6.75, 510.2342, false, 'Adjustable';...
 7, 658.2, false, 'Fixed'}};
columnname = {'Rate', 'Amount', 'Available', 'Fixed/Adj'};
columnformat = {'numeric', 'bank', 'logical', {'Fixed' 'Adjustable'}};
columneditable = [false false true true];
t = uitable('Units','normalized','Position',...
 [0.1 0.1 0.9 0.9], 'Data', dat,...
 'ColumnName', columnname,...
 'ColumnFormat', columnformat,...
 'ColumnEditable', columneditable,...
 'RowName', []);
```

## Alternatives

You can add tables to GUIs you create with “Table”.

## How To

- “Table”

## Purpose

Describe table properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from the GUIDE Layout Editor **View** menu, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default uitable properties by typing:

```
set(h, 'DefaultUitablePropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uitable handle. *PropertyName* is the name of the uitable property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”. For an example, see the `CreateFcn` property.

## Uitable Properties

This section lists all properties useful to uitable objects along with valid values and descriptions of their use. In the property descriptions, curly braces { } enclose default values.

Property Name	Description
<code>BackgroundColor</code>	Background color of cells.
<code>BeingDeleted</code>	This object is being deleted.
<code>BusyAction</code>	Callback routine interruption
<code>ButtonDownFcn</code>	Button-press callback routine
<code>CellEditCallback</code>	Callback when data in a cell is changed.

# Uitable Properties

---

Property Name	Description
CellSelectionCallback	Callback when cell is selected
Children	uitable objects have no children
Clipping	Does not apply to uitable objects
ColumnEditable	Determines data in a column as editable
ColumnFormat	Determines display and editability of columns
ColumnName	Column header label
ColumnWidth	Width of each column in pixels
CreateFcn	Callback routine during object creation
Data	Table data
DeleteFcn	Callback routine during object deletion
Enable	Enable or disable the uitable
Extent	Size of uitable rectangle
FontAngle	Character slant of cell content
FontName	Font family for cell content
FontSize	Font size of cell content
FontUnits	Font size units for cell content
FontWeight	Weight of cell text characters
ForegroundColor	Color of text in cells
HandleVisibility	Control access to object's handle
Interruptible	Callback routine interruption mode
KeyPressFcn	Key press callback function
Parent	uitable parent

Property Name	Description
Position	Size and location of uitable
RearrangeableColumns	Location of the column
RowName	Row header label names
RowStriping	Color striping of label rows
Tag	Use-specified object label
TooltipString	Content of tooltip for object
Type	Class of graphics object
UIContextMenu	Associate context menu with uitable
Units	Units of measurement
UserData	User-specified data
Visible	uitable visibility

## BackgroundColor

1-by-3 or 2-by-3 matrix of RGB triples

*Cell background color.* Color used to fill the uitable cells. Specify as an 1-by-3 or 2-by-3 matrix of RGB triples, such as [ .8 .9 .8] or [1 1 .9; .9 1 1]. Each row is an RGB triplet of real numbers between 0.0 and 1.0 that defines one color. (Color names are not allowed.) The default is a 1-by-3 matrix of platform-dependent colors. See ColorSpec for information about RGB colors.

Row 2 of the matrix is used only if the RowStriping property is on. The table background is not striped unless both RowStriping is on and the BackgroundColor color matrix has two rows.

# Uitable Properties

---

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the `BeingDeleted` property to on when the object's delete function callback is called (see the `DeleteFcn` property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's `BeingDeleted` property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## ButtonDownFcn

string or function handle (GUIDE sets this property)

*Button-press callback routine.* A callback routine that can execute when you press a mouse button while the pointer is on or near a `uitable`. Specifically:

- If the `uitable` `Enable` property is set to on, the `ButtonDownFcn` callback executes when you click the right or left mouse button in a 5-pixel border around the `uitable` or when you click the right mouse button on the control itself.
- If the `uitable` `Enable` property is set to inactive or off, the `ButtonDownFcn` executes when you click the right or left mouse button in the 5-pixel border or on the control itself.

This is useful for implementing actions to interactively modify control object properties, such as size and position, when they are clicked on.

Define this routine as a string that is a valid MATLAB expression or the name of a MATLAB function file. The expression executes in the MATLAB workspace.

To add a `ButtonDownFcn` callback in GUIDE, select **View Callbacks** from the Layout Editor **View** menu, then select `ButtonDownFcn`. GUIDE sets this property to the appropriate string and adds the callback to the program file the next time you save the GUI. Alternatively, you can set this property to the string `%automatic`. The next time you save the GUI, GUIDE sets this property to the appropriate string and adds the callback to the program file.

## CellEditCallback

function handle, cell array containing function handle and additional arguments, or string (not recommended)

*Callback to edit user-entered data*

# Uitable Properties

---

Callback function executed when the user modifies a table cell. It can perform evaluations, validations, or other customizations. If this function is called as a function handle, `uitable` passes it two arguments. The first argument, `source`, is the handle of the `uitable`. The second argument, `eventdata`, is an event data structure that contains the fields shown in the following table. All fields in the event data structure are read only.

Event Data Structure Field	Type	Description
Indices	1-by-2 matrix	Row index and column index of the cell the user edited.
PreviousData	1-by-1 matrix or cell array	Previous data for the changed cell. The default is an empty matrix, <code>[]</code> .
EditData	String	User-entered string.
NewData	1-by-1 matrix or cell array	Value that <code>uitable</code> wrote to <code>Data</code> . It is either the same as <code>EditData</code> or a converted value, for example, <code>2</code> where <code>EditData</code> is <code>'2'</code> and the cell is numeric.  Empty if <code>uitable</code> detected an error in the user-entered data and did not write it to <code>Data</code> .
Error	String	Error that occurred when <code>uitable</code> tried to convert the <code>EditData</code> string into a value appropriate for <code>Data</code> . For example, <code>uitable</code> could not convert the <code>EditData</code> string consistent with the <code>Column Format</code> property, if any, or the data type for the changed cell.  Empty if <code>uitable</code> wrote the value to <code>Data</code> .

Event Data Structure Field	Type	Description
		If Error is not empty, the <code>CellEditCallback</code> can pass the error string to the user or can attempt to manipulate the data. For example, the string 'pi' would raise an error in a numeric cell but the <code>CellEditCallback</code> could convert it to its numerical equivalent and store it in <code>Data</code> without passing the error to the user.

When a user edits a cell, `uitable` first attempts to store the user-entered value in `Data`, converting the value if necessary. It then calls the `CellEditCallback` and passes it the event data structure. If there is no `CellEditCallback` and the user-entered data results in an error, the contents of the cell reverts to its previous value and no error is displayed. The `CellEditCallback` is issued when the user has modified a table cell and presses **Enter** or clicks anywhere outside the cell.

#### `CellSelectionCallback`

function handle, cell array containing function handle and additional arguments, or string (not recommended)

*Callback that executes when cell is selected.* Callback function that executes when the user highlights a cell by navigating to it or clicking it. For multiple selection, this callback executes when new cells are added to the selection. The callback includes event data, a structure with one member

# Uitable Properties

---

Event Data Structure Field	Type	Description
Indices	n-by-2 matrix	Row index and column index of the cells the user currently has selected

Once a cell selection has been made, cells within it can be removed one at a time by **Ctrl**-clicking them.

Children  
matrix

The empty matrix; `uitable` objects have no children.

Clipping  
{on} | off

This property has no effect on `uitable` objects.

ColumnEditable  
logical 1-by-n matrix | scalar logical value | {empty matrix ([ ])}

*Determines if column is user-editable.*

Determines if the data can be edited by the end user. Each value in the cell array corresponds to a column. `false` is default because the developer needs to have control over changes users potentially might make to data.

Specify elements of a logical matrix as `true` if the data in a column is editable by the user or `false` if it is not. An empty matrix indicates that no columns are editable.

Columns that contain check boxes or pop-up menus must be editable for the user to manipulate these controls. If a column that contains pop-up menus is not editable, the currently selected choice appears without displaying the pop-up control. The

Elements of the `ColumnEditable` matrix must be in the same order as columns in the `Data` property. If you do not specify `ColumnEditable`, the default is an empty matrix (`[]`).

## `ColumnFormat`

cell array of strings

*Cell display formatting.* Determines how the data in each column displays and is edited. Elements of the cell array must be in the same order as table columns in the `Data` property. If you do not want to specify a display format for a particular column, enter `[]` as a placeholder. If no format is specified for a column, the default display is determined by the data type of the data in the cell. Default `ColumnFormat` is an empty cell array (`{}`). In most cases, the default is similar to the command window.

Elements of the cell array must be one of the strings described in the following table.

Cell Format	Description
'char'	Displays a left-aligned string. To edit, the user types a string that replaces the existing string.
'logical'	Displays a check box. To edit, the user checks or unchecks the check box. <code>uitable</code> sets the corresponding <code>Data</code> value to <code>true</code> or <code>false</code> accordingly. Initially, the check box is checked if the corresponding <code>Data</code> value would produce <code>true</code> if passed to the <code>logical</code> function, and unchecked otherwise.

# Uitable Properties

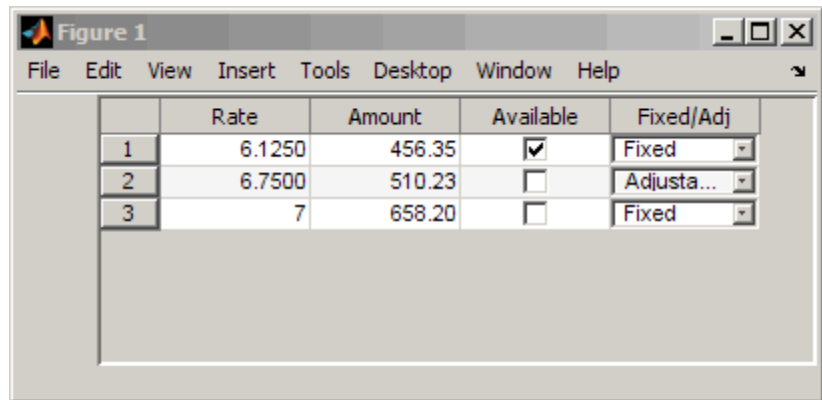

---

Cell Format	Description
'numeric'	<p>Displays a right-aligned string equivalent to the command window, for numeric data. If the cell Data value is boolean, then 1 or 0 is displayed. If the cell Data value is not numeric and not boolean, then NaN is displayed.</p> <p>To edit, the user can enter any string. This enables a user to enter a value such as 'pi' that can be converted to its numeric equivalent by a <code>CellEditCallback</code>. The <code>uitable</code> function first attempts to convert the user-entered string to a numeric value and store it in <code>Data</code>. It then calls the <code>CellEditCallback</code>. See <code>CellEditCallback</code> for more information.</p>
1-by-n cell array of strings that define a pop-up menu, e.g., {'one' 'two' 'three'}	<p>Displays a pop-up menu.</p> <p>To edit, the user makes a selection from the pop-up menu. <code>uitable</code> sets the corresponding <code>Data</code> value to the selected menu item.</p> <p>The initial values for the pop-up menus in the column are the corresponding strings in <code>Data</code>. These initial values do not have to be items in the pop-up menu. See Example 3 on the <code>uitable</code> reference page.</p>
Valid string accepted by the format function, e.g., 'short' or 'bank'	<p>Displays the <code>Data</code> value using the specified format. For example, for a two-column table, <code>set(htable, 'ColumnFormat', {'short', 'bank'})</code>.</p>

In some cases, you may need to insert an appropriate column in Data. If Data is a numerical or logical matrix, you must first convert it to a cell array using the `mat2cell` function.

## Data and ColumnFormat

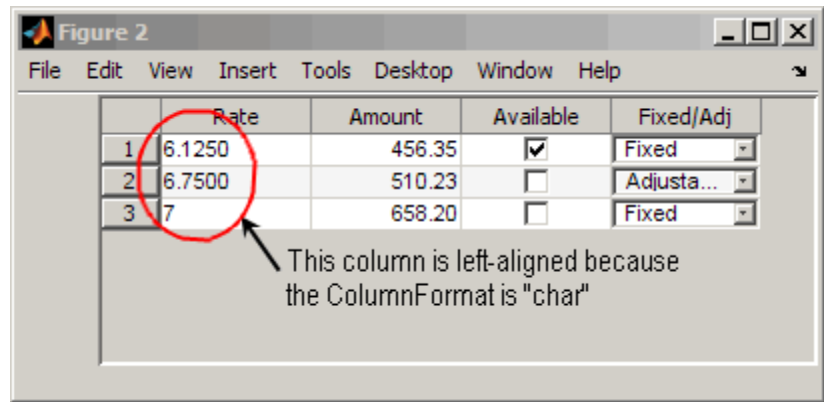

When you create a table, you must specify value of Data. The Data property dictates what type of data can exist in any given cell. By default, the value of the Data also dictates the display of the cell to the end user, unless you specify a different format using the ColumnFormat property.

	Rate	Amount	Available	Fixed/Adj
1	6.1250	456.35	<input checked="" type="checkbox"/>	Fixed
2	6.7500	510.23	<input type="checkbox"/>	Adjusta...
3	7	658.20	<input type="checkbox"/>	Fixed

ColumnFormat controls the presentation of the Data to the end user. Therefore, if you specify a ColumnFormat of `char` (or pick **Text** from the Table Property Editor), you are asking the table to display the Data associated with that column as a string. For example, if the Data for a particular column is numeric, and you specify the ColumnFormat as `char`, then the display of the numeric data will be left-aligned

# Uitable Properties

If your column is editable and the user enters a number, the number will be left-aligned. However, if the user enters a text string, the table displays a NaN.

Another possible scenario is that the value Data is char and you set the ColumnFormat to be a pop-up menu. Here, if the value of the Data in the cell matches one of the pop-up menu choices you define in ColumnFormat, then the Data is shown in the cell. If it does not match, then the cell defaults to display the first option from the choices you specify in ColumnFormat. Similarly, if Data

is numeric or logical with the ColumnFormat as pop-up menu, if the Data value in the cell does not match any of the choices you specify in ColumnFormat, the cell defaults to display the first option in the pop-menu choice.

This table describes how Data values correspond with your ColumnFormat when the columns are editable.

		ColumnFormat Selections		
		numeric	char	logical
Data Type	numeric	Values match. MATLAB displays numbers as is.	MATLAB converts the text string entered to a double. See <code>str2double</code> for more information. If string cannot be converted, <code>NaN</code> is displayed.	Does not work: warning is thrown. <hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown
	char	MATLAB converts the entered number to a text string.	Values match. MATLAB displays the string as is.	Does not work: warning is thrown. <hr/> <b>Note</b> If you have defined <code>CellEditCallback</code> , this warning will not be thrown
	logical	Does not work: warning is thrown.	If text string entered is true	Values match. MATLAB displays

# Uitable Properties

		<hr/> <p><b>Note</b> If you have defined <code>CellEditCallback</code>, this warning will not be thrown</p> <hr/>	<p>or <code>false</code>, MATLAB converts string to the corresponding logical value and displays it. For all others, it Does not work: warning is thrown.</p> <hr/> <p><b>Note</b> If you have defined <code>CellEditCallback</code>, this warning will not be thrown</p> <hr/>	<p>logical value as a check box as is.</p>
--	--	-------------------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------

If you get a mismatch error, you have the following options:

- Change the `ColumnFormat` or value of `Data` to match.
- Implement the `CellEditCallback` to handle custom data conversion.

## ColumnName

*n*-by-1 cell array of strings | 1-by-*n* cell array of strings | {'numbered'} | empty matrix ([])

*Column heading names.* Each element of the cell array is the name of a column. Multiline column names can be expressed as a string vector separated by vertical slash (|) characters, e.g., 'Standard|Deviation'

For sequentially numbered column headings starting with 1, specify `ColumnName` as 'numbered'. This is the default.

To remove the column headings, specify `ColumnName` as the empty matrix ( []).

The number of columns in the table is the larger of `ColumnName` and the number of columns in the `Data` property matrix or cell array.

If you specify the `ColumnName` value as a 1-by- $n$  cell array of strings, MATLAB stores and returns the value as a  $n$ -by-1 cell array of strings.

## ColumnWidth

1-by- $n$  cell array | 'auto'

*Column widths.* The width of each column in units of pixels. Column widths are always specified in pixels; they do not obey the `Units` property. Each column in the cell array corresponds to a column in the uitable. By default, the width of the column name, as specified in `ColumnName`, along with some other factors, is used to determine the width of a column. If `ColumnWidth` is a cell array and the width of a column is set to 'auto' or if **auto** is selected for that column in the Property Inspector GUI for columns, the column width defaults to a size determined by the table. The table decides the default size using a number of factors, including the `ColumnName` and the minimum column size.

To default all column widths in an existing table, use

```
set(uitable_handle, 'ColumnWidth', 'auto')
```

To default some column widths but not others, use a cell array containing a mixture of pixel values and 'auto'. For example,

```
set(uitable_handle, 'ColumnWidth', {64 'auto' 40 40 'auto' 72})
```

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uitable object. MATLAB sets all property values for the uitable before executing

# Uitable Properties

---

the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the uitable being created.

Setting this property on an existing uitable object has no effect.

You can define a default `CreateFcn` callback for all new uitables. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitable`. For example, the code

```
set(0,'DefaultUitableCreateFcn','set(gcbo,...
 'BackgroundColor','blue'))
```

creates a default `CreateFcn` callback that runs whenever you create a new uitable. It sets the default background color of all new uitables.

To override this default and create a uitable whose `BackgroundColor` is set to a different value, call `uitable` with code similar to

```
hpt = uitable(...,'CreateFcn','set(gcbo,...
 'BackgroundColor','white'))
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitable` call. In the example above, if instead of redefining the `CreateFcn` property for this uitable, you had explicitly set `BackgroundColor` to `white`, the default `CreateFcn` callback would have set `BackgroundColor` back to the default, i.e., `blue`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the

CreateFcn repeatedly, which raises a series of error messages after exceeding the root object's RecursionLimit property.

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

## Data

matrix or cell array of numeric, logical, or character data

*Data content of uitable.* The matrix or cell array must be 2-dimensional. A cell array can mix data types.

Use `get` and `set` to modify Data. For example,

```
data = get(tablehandle, 'Data')
data(event.indices(1), event.indices(2)) = pi();
set(tablehandle, 'Data', data);
```

See `CellEditCallback` for information about the event data structure. See `ColumnFormat` for information about specifying the data display format.

The number of rows in the table is the larger of `RowName` and the number of rows in `Data`. The number of columns in the table is the larger of `ColumnName` and the number of columns in `Data`.

## DeleteFcn

string or function handle

*Delete uitable callback routine.* A callback routine that executes when you delete the `uitable` object (e.g., when you issue a `delete` command or `clear` the figure containing the `uitable`). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

# Uitable Properties

---

See “Function Handle Callbacks” for information on how to use function handles to define a callback function.

**Enable**

{on} | inactive | off

*Enable or disable the uitable.* This property determines how uitables respond to mouse button clicks, including which callback routines execute.

- **on** – The uitable is operational (the default).
- **inactive** – The uitable is not operational, but looks the same as when **Enable** is on.
- **off** – The uitable is not operational and its image is grayed out.

When you left-click on a uitable whose **Enable** property is on, MATLAB performs these actions in this order:

- 1** Sets the figure’s **SelectionType** property.
- 2** Executes the uitable’s **CellSelectionCallback** routine (but only for table cells, not header cells). Row and column indices of the cells the user selects continuously update the **Indices** field in the **eventdata** passed to the callback.
- 3** Does not set the figure’s **CurrentPoint** property and does not execute either the table’s **ButtonDownFcn** or the figure’s **WindowButtonDownFcn** callback.

When you left-click on a uitable whose **Enable** property is **off**, or when you right-click a uitable whose **Enable** property has any value, MATLAB performs these actions in this order:

- 1** Sets the figure’s **SelectionType** property.
- 2** Sets the figure’s **CurrentPoint** property.
- 3** Executes the figure’s **WindowButtonDownFcn** callback.

## Extent

position rectangle (read only)

*Size of uitable rectangle.* A four-element vector of the form `[0,0,width,height]` that contains the calculated values of the largest extent of the table based on the current `Data`, `RowName` and `ColumnName` property values. Calculation depends on column and row widths, when they are available. The calculated extent can be larger than the figure.

The first two elements are always zero. `width` and `height` are the dimensions of the rectangle. All measurements are in units specified by the `Units` property.

When the uitable's `Units` property is set to `'Normalized'`, its `Extent` is measured relative to the figure, regardless of whether the table is contained in (parented to) a `uipanel` or not.

You can use this property to determine proper sizing for the uitable with respect to its content. Do this by setting the `width` and `height` of the uitable `Position` property to the `width` and `height` of the `Extent` property. However, doing this can cause the table to extend beyond the right or top edge of the figure and/or its `uipanel` parent, if any, for tables with large extents.

## FontAngle

{normal} | italic | oblique

*Character slant of cell content.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `italic` or `oblique` selects a slanted version of the font, when it is available on your system.

## FontName

string

*Font family for cell content.* The name of the font in which to display cell content. To display and print properly, this must

# Uitable Properties

---

be a font that your system supports. The default font is system dependent.

To use a fixed-width font that looks good in any locale (and displays properly in Japan, where multibyte character sets are used), set `FontName` to the string `FixedWidth` (this string value is case sensitive):

```
set(uitable_handle, 'FontName', 'FixedWidth')
```

This parameter value eliminates the need to hard code the name of a fixed-width font, which may not display text properly on systems that do not use ASCII character encoding (such as in Japan). A properly written MATLAB application that needs to use a fixed-width font should set `FontName` to `FixedWidth` and rely on the root `FixedWidthFontName` property to be set correctly in the end user's environment.

End users can adapt a MATLAB application to different locales or personal environments by setting the root `FixedWidthFontName` property to the appropriate value for that locale from `startup.m`. Setting the root `FixedWidthFontName` property causes an immediate update of the display to use the new font.

## FontSize

size in `FontUnits`

*Font size for cell contents.* A number specifying the size of the font in which to display cell contents, in units determined by the `FontUnits` property. The default point size is system dependent. If `FontUnits` is set to `normalized`, `FontSize` is a number between 0 and 1.

## FontUnits

{points} | normalized | inches |  
centimeters | pixels

*Font size units for cell contents.* This property determines the units used by the `FontSize` property. Normalized units interpret `FontSize` as a fraction of the height of the uitable. When you resize the uitable, MATLAB modifies the screen `FontSize` accordingly. `pixels`, `inches`, `centimeters`, and `points` are absolute units (1 point =  $1/72$  inch).

## FontWeight

`light` | `{normal}` | `demi` | `bold`

*Weight of cell text characters.* MATLAB uses this property to select a font from those available on your particular system. Setting this property to `bold` causes MATLAB to use a bold version of the font, when it is available on your system.

## ForegroundColor

1-by-3 matrix of RGB triples or a color name

*Color of text in cells.* Determines the color of the text defined for cell contents. Text in all cells share the current color. Specify as a 1-by-3 matrix of RGB triples, such as `[0 0 .8]` or as a color name. The default is a 1-by-3 matrix of platform-dependent colors. See `ColorSpec` for information about specifying RGB colors.

## HandleVisibility

`{on}` | `callback` | `off`

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is on.

# Uitable Properties

---

- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
{on} | off

*Selectable by mouse click.* When `HitTest` is `off`, the `ButtonDownFcn` callback does not execute.

---

**Note** Use of the uitable `Hittest` property is not recommended. This property may be removed in a future release.

---

`Interruptible`  
off | {on}

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

# Uitable Properties

---

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

`KeyPressFcn`  
string or function handle

*Key press callback function.* A callback routine invoked by a key press when the callback’s `uitable` object has focus. Focus is denoted by a border or a dotted border, respectively, in UNIX

and Microsoft Windows. If no uitable has focus, the figure's key press callback function, if any, is invoked. `KeyPressFcn` can be a function handle, the name of a MATLAB function file, or any legal MATLAB expression.

If the specified value is the name of a function code file, the callback routine can query the figure's `CurrentCharacter` property to determine what particular key was pressed and thereby limit the callback execution to specific keys.

If the specified value is a function handle, the callback routine can retrieve information about the key that was pressed from its event data structure argument.

Event Data Structure Field	Description	Examples:			
		a	=	Shift	Shift/a
Character	Character interpretation of the key that was pressed.	'a'	'='	' '	'A'
Modifier	Current modifier, such as 'control', or an empty cell array if there is no modifier	{1x0 cell}	{1x0 cell}	{'shift'}	{'shift'}
Key	Name of the key that was pressed.	'a'	'equal'	'shift'	'a'

The uitable `KeyPressFcn` callback executes for all keystrokes, including arrow keys or when a user edits cell content.

See “Function Handle Callbacks” for information on how to use function handles to define the callback function.

Parent  
handle

# Uitable Properties

---

*Uitable parent.* The handle of the uitable's parent object. You can move a uitable object to another figure, uipanel, or uibuttongroup by setting this property to the handle of the new parent.

## Position

position rectangle

*Size and location of uitable.* The rectangle defined by this property specifies the size and location of the table within the parent figure window, ui, or uibuttongroup. Specify **Position** as a 4-element vector:

[left bottom width height]

**left** and **bottom** are the distance from the lower-left corner of the parent object to the lower-left corner of the uitable object. **width** and **height** are the dimensions of the uitable rectangle. All measurements are in units specified by the **Units** property.

---

**Note** If you are specifying both **Units** and **Position** in the same call to `uitable`, specify **Units** first if you want **Position** to be interpreted using those units.

---

## RearrangeableColumns

on | {off}

*This object can be rearranged.* The **RearrangeableColumns** property provides a mechanism that you can use to reorder the columns in the table. All columns are rearrangeable when this property is turned on. MATLAB software sets the **RearrangeableColumns** property to `off` by default.

When this property is on, the user of a table can move any column of data (but not the row labels) at a time left or right to reorder it by clicking and dragging its header. Rearranging columns does

not affect the ordering of columns in the table's Data, only the user's view of it.

## RowName

*n*-by-1 cell array of strings | 1-by-*n* cell array of strings |  
{'numbered'} | empty matrix ([])

*Row heading names.* Each element of the cell array is the name of a row. Row names are restricted to one line of text.

For sequentially numbered row headings starting with 1, specify RowName as 'numbered'. This is the default.

To remove the row headings, specify RowName as the empty matrix ( []).

The number of rows in the table is the larger of RowName and the number of rows in the Data property matrix or cell array.

If you specify the RowName value as a 1-by-*n* cell array of strings, MATLAB stores and returns the value as a *n*-by-1 cell array of strings.

## RowStriping

{on} | off

*Color striping of table rows.* When RowStriping is on, the background of consecutive rows of the table display in the pair of colors that the BackgroundColor color matrix specifies. The first color matrix row applies to odd-numbered rows, and the second to even-numbered rows. If the BackgroundColor matrix has only one row, it is applied to all rows (that is, no striping occurs).

When RowStriping is off, the first color specified for BackgroundColor is applied to all rows.

## Selected

on | {off}

# Uitable Properties

---

*Is object selected.* When this property is on, MATLAB displays selection handles if the `SelectionHighlight` property is also on. You can, for example, define the `ButtonDownFcn` to set this property, allowing users to select the object with the mouse.

---

**Note** Use of the uitable `Selected` property is not recommended. This property may be removed in a future release.

---

`SelectionHighlight`  
{on} | off

*Object highlight when selected.* When the `Selected` property is on, MATLAB indicates the selected state by drawing four edge handles and four corner handles. When `SelectionHighlight` is off, MATLAB does not draw the handles.

---

**Note** Use of the uitable `SelectionHighlight` property is not recommended. This property may be removed in a future release.

---

`Tag`  
string (GUIDE sets this property)

*User-specified object label.* The `Tag` property provides a means to identify graphics objects with a user-specified label. This is particularly useful when constructing interactive graphics programs that would otherwise need to define object handles as global variables or pass them as arguments between callback routines. You can define `Tag` as any string.

`TooltipString`  
string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the uitable. When the user moves the mouse pointer over the table and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitable;
s = sprintf('UITable tooltip line 1\nUITable tooltip line 2');
set(h,'TooltipString',s)
```

## Type

string (read only)

*Class of graphics object.* For uitable objects, `Type` is always the string `'uitable'`.

## UIContextMenu

handle

*Associate a context menu with uitable.* Assign this property the handle of a `uicontextmenu` object. MATLAB displays the context menu whenever you right-click over the uitable. Use the `uicontextmenu` function to create the context menu.

## Units

{pixels} | normalized | inches | centimeters | points | characters (GUIDE default: normalized)

*Units of measurement.* MATLAB uses these units to interpret the `Extent` and `Position` properties. All units are measured from the lower-left corner of the parent object.

- Normalized units map the lower-left corner of the parent object to (0,0) and the upper-right corner to (1.0,1.0).

# Uitable Properties

---

- pixels, inches, centimeters, and points are absolute units (1 point = 1/72 inch).
- Character units are characters using the default system font; the width of one character is the width of the letter x, the height of one character is the distance between the baselines of two lines of text.

If you change the value of `Units`, it is good practice to return it to its default value after completing your computation so as not to affect other functions that assume `Units` is set to the default value.

`UserData`  
matrix

*User-specified data.* Any data you want to associate with the uitable object. MATLAB does not use this data, but you can access it using `set` and `get`.

`Visible`  
{on} | off

*Uitable visibility.* By default, all uitables are visible. When set to `off`, the uitable is not visible, but still exists and you can query and set its properties.

---

**Note** Setting `Visible` to `off` for uitables that are not displayed initially in the GUI, can result in faster startup time for the GUI.

---

**Purpose** Create toggle button on toolbar

**Syntax**

```
htt = uitoggletool
htt =
uitoggletool('PropertyName1',value1,'PropertyName2',value2,
...)
htt = uitoggletool(ht,...)
```

**Description** `htt = uitoggletool` creates a toggle button on the uitoolbar at the top of the current figure window, sets all its properties to default values, and returns a handle to the tool. If no uitoolbar exists, one is created. The uitoolbar is the parent of the uitoggletool. Use the returned handle `htt` to set properties of the uitoggletool. The `OnCallback`, `OffCallback` and `ClickedCallback` use the handle as their first argument. The button has no icon, but its border highlights when you hover over it with the mouse cursor. Add an icon by setting `CData` for the tool. Type `get(htt)` to see a list of uitoggletool object properties and their current values. Type `set(htt)` to see a list of uitoggletool object properties you can set and legal property values.

```
htt =
uitoggletool('PropertyName1',value1,'PropertyName2',value2,
...)
```

assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the `set` function. You can specify properties as parameter name/value pairs, cell arrays containing parameter names and values, or structures with fields containing parameter names and values as input arguments. For a complete list, see `Uitoggletool Properties`. Type `get(htt)` to see a list of uipushtool object properties and their current values. Type `set(htt)` to see a list of uipushtool object properties that you can set and their legal property values.

`htt = uitoggletool(ht,...)` creates a button with `ht` as a parent. `ht` must be a uitoolbar handle.

Toggle tools appear in figures whose `Window Style` is `normal` or `docked`. They do not appear in figures with a `'modal'` `WindowStyle`. If the `WindowStyle` property of a figure containing a tool bar and its

# uitoggletool

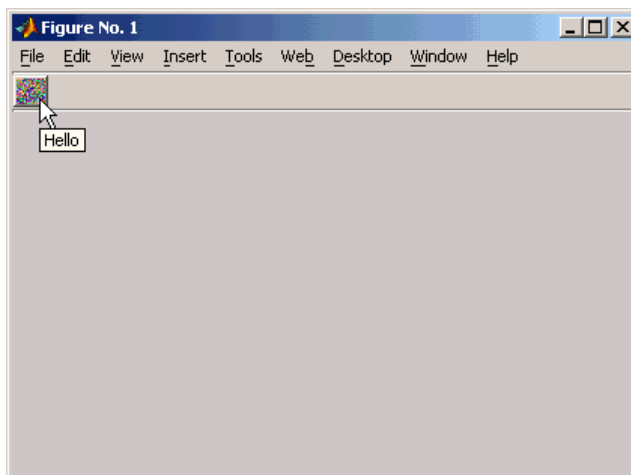

---

toggle tool children changes to `modal`, the toggle tools continue to exist as Children of the tool bar. The toggle tools do not display until you change the `WindowState` to `normal` or `docked`.

## Examples

Create a `uitoolbar` object and places a `uitoggletool` object on it by specifying the toolbar handle as the toggle tool parent. Generate a random set of colors for the tool icon and specify a tool tip.

```
h = figure('ToolBar','none');
ht = uitoolbar(h);
a = rand(16,16,3);
htt = uitoggletool(ht,'CData',a,'TooltipString','Hello');
```

## Alternatives

You can create toolbars with toggle tools using `GUIDE`.

# Uitoggletool Properties

---

## Purpose

Describe toggle tool properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoggletool properties by typing:

```
set(h, 'DefaultUitoggletoolPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, a uitoolbar handle, or a uitoggletool handle. *PropertyName* is the name of the Uitoggletool property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see “Setting Default Property Values”.

## Properties

This section lists all properties useful to uitoggletool objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption.
CData	Truecolor image displayed on the toggle tool.
ClickedCallback	Control action independent of the toggle tool position.

# Uitoggletool Properties

Property	Purpose
CreateFcn	Callback routine executed during object creation.
DeleteFcn	Callback routine executed during object deletion.
Enable	Enable or disable the uitoggletool.
HandleVisibility	Control access to object's handle.
Interruptible	Callback routine interruption mode.
OffCallback	Control action when toggle tool is set to the off position.
OnCallback	Control action when toggle tool is set to the on position.
Parent	Handle of uitoggletool's parent toolbar.
Separator	Separator line mode.
State	Uitoggletool state.
Tag	User-specified object label.
TooltipString	Content of object's tooltip.
Type	Object class.
UIContextMenu	Uicontextmenu object associated with the uitoggletool
UserData	User specified data.
Visible	Uitoggletool visibility.

## BeingDeleted

on | {off} (read only)

*This object is being deleted.* The `BeingDeleted` property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the

# Uitoggletool Properties

---

BeingDeleted property to on when the object's delete function callback is called (see the DeleteFcn property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's BeingDeleted property before acting.

## BusyAction

cancel | {queue}

### *Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The BusyAction property of the *interrupting* callback determines how MATLAB handles its execution. When the BusyAction property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the Interruptible property of the callback controls whether other callbacks can interrupt the *running* callback, see the Interruptible property description.

## CData

3-dimensional array

*Truecolor image displayed on control as its icon.* An  $n$ -by- $m$ -by-3 array of RGB values that defines a truecolor image displayed on either a push button or toggle button. Each value must be

between 0.0 and 1.0. If your CData array is larger than 16 in the first or second dimension, it can be clipped or result in other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

## ClickedCallback

string or function handle

*Control action independent of the toggle tool position.* A routine that executes after either the OnCallback routine or OffCallback routine runs to completion. The uitoggletool Enable property must be set to on.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a uitoggletool object. MATLAB sets all property values for the uitoggletool before executing the CreateFcn callback so these values are available to the callback. Within the function, use gcbo to get the handle of the toggle tool being created.

Setting this property on an existing uitoggletool object has no effect.

You can define a default CreateFcn callback for all new uitoggletools. This default applies unless you override it by specifying a different CreateFcn callback when you call uitoggletool. For example, the statement,

```
set(0, 'DefaultUitoggletoolCreateFcn', ...
 'set(gcbo, 'Enable', 'off')')
```

creates a default CreateFcn callback that runs whenever you create a new toggle tool. It sets the toggle tool Enable property to off.

# Uitoggletool Properties

---

To override this default and create a toggle tool whose `Enable` property is set to `on`, you could call `uitoggletool` with code similar to

```
htt = uitoggletool(...,'CreateFcn',...
 'set(gcbo,'Enable','on')',...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoggletool` call. In the example above, if instead of redefining the `CreateFcn` property for this toggle tool, you had explicitly set `Enable` to `on`, the default `CreateFcn` callback would have set `CData` back to `off`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the `uicontrol` object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

`DeleteFcn`  
string or function handle

*Callback routine executed during object deletion.* A callback routine that executes when you delete the `uitoggletool` object (e.g., when you call the `delete` function or cause the figure containing the `uitoggletool` to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

The handle of the object whose `DeleteFcn` is being executed is accessible only through the root `CallbackObject` property, which you can query using `gcbo`.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

## Enable

{on} | off

*Enable or disable the uitoggletool.* This property controls how uitoggletools respond to mouse button clicks, including which callback routines execute.

- **on** – The uitoggletool is operational (the default).
- **off** – The uitoggletool is not operational and its icon (set by the `Cdata` property) is grayed out.

When you left-click on a uitoggletool whose `Enable` property is `on`, MATLAB performs these actions in this order:

- 1** Executes the toggle tool `OnCallback` or `OffCallback` routine, depending on its current state, and its `ClickedCallback` routine.
- 2** Does *not* set the figure `CurrentPoint` property and does *not* execute the figure's `WindowButtonDownFcn` callback.
- 3** Does *not* set the figure `SelectionType` property.

When you left-click a uitoggletool whose `Enable` property is `off`, or when you right-click a uitoggletool whose `Enable` property has any value, no action is reported, no callback executes, and neither the `SelectionType` nor `CurrentPoint` figure properties are modified.

## HandleVisibility

{on} | callback | off

# Uitoggletool Properties

---

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI (such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
{`on`} | `off`

*Selectable by mouse click.* This property has no effect on `uitoggletool` objects.

---

**Note** Use of the `uitoggletool HitTest` property is not recommended. This property might be removed in a future release.

---

## Interruptible

off | {on}

### *Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`
- `WindowButtonMotionFcn`
- `WindowButtonUpFcn`
- `WindowKeyPressFcn`
- `WindowKeyReleaseFcn`
- `WindowScrollWheelFcn`

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

# Uitoggletool Properties

---

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object's `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object's `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

## OffCallback

string or function handle

*Control action.* A routine that executes if the `uitoggletool`'s `Enable` property is set to `on`, and either

- The toggle tool `State` is set to `off`.
- The toggle tool is set to the `off` position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

The `ClickedCallback` routine, if there is one, runs after the `OffCallback` routine runs to completion.

## OnCallback

string or function handle

*Control action.* A routine that executes if the `uitoggletool`'s `Enable` property is set to `on`, and either

- The toggle tool `State` is set to `on`.
- The toggle tool is set to the `on` position by pressing a mouse button while the pointer is on the toggle tool itself or in a 5-pixel wide border around it.

# Uitoggletool Properties

---

The `ClickedCallback` routine, if there is one, runs after the `OffCallback` routine runs to completion.

## Parent

handle

*Uitoggletool parent.* The handle of the uitoggletool's parent toolbar. You can move a uitoggletool object to another toolbar by setting this property to the handle of the new parent.

## Separator

on | {off}

*Separator line mode.* Setting this property to on draws a dividing line to left of the uitoggletool.

## State

on | {off}

*Uitoggletool state.* When the state is on, the toggle tool appears in the down, or pressed, position. When the state is off, it appears in the up position. Changing the state causes the appropriate `OnCallback` or `OffCallback` routine to run.

## Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified toolbars) that have the `Tag` value 'Bold'.

```
h = findobj(uitoolbarhandles, 'Tag', 'Bold')
```

**TooltipString**  
string

*Content of tooltip for object.* The `TooltipString` property specifies the text of the tooltip associated with the `uitoggletool`. When the user moves the mouse pointer over the control and leaves it there, the tooltip is displayed.

To create a tooltip that has more than one line of text, use `sprintf` to generate a string containing newline (`\n`) characters and then set the `TooltipString` to that value. For example:

```
h = uitoggletool;
s = sprintf('Toggletool tooltip line 1\nToggletool tooltip line 2');
set(h,'TooltipString',s)
```

**Type**  
string (read-only)

Object class. This property identifies the kind of graphics object. For `uitoggletool` objects, `Type` is always the string `'uitoggletool'`.

**UIContextMenu**  
handle

*Associate a context menu with uicontrol.* This property has no effect on `uitoggletool` objects.

**UserData**  
array

*User specified data.* You can specify `UserData` as any array you want to associate with the `uitoggletool` object. The object does not use this data, but you can access it using the `set` and `get` functions.

**Visible**  
{on} | off

# Uitoggletool Properties

---

*Uitoggletool visibility.* By default, all uitoggletools are visible. When set to `off`, the uitoggletool is not visible, but still exists and you can query and set its properties.

<b>Purpose</b>	Create toolbar on figure
<b>Syntax</b>	<pre>ht = uitoolbar('PropertyName1',value1,'PropertyName2',value2,...) ht = uitoolbar(h,...)</pre>
<b>Description</b>	<p>ht = uitoolbar('PropertyName1',value1,'PropertyName2',value2,...) creates an empty toolbar at the top of the current figure window, and returns a handle to it. <code>uitoolbar</code> assigns the specified property values, and assigns default values to the remaining properties. You can change the property values at a later time using the <code>set</code> function.</p> <p>Type <code>get(ht)</code> to see a list of <code>uitoolbar</code> object properties and their current values. Type <code>set(ht)</code> to see a list of <code>uitoolbar</code> object properties that you can set and legal property values. See the <a href="#">Uitoolbar Properties</a> reference page for more information.</p> <p><code>ht = uitoolbar(h,...)</code> creates a toolbar with <code>h</code> as a parent. <code>h</code> must be a figure handle.</p>
<b>Tips</b>	<p><code>uitoolbar</code> accepts property name/property value pairs, as well as structures and cell arrays of properties as input arguments.</p> <p>Uitoolbars appear in figures whose <code>Window Style</code> is <code>normal</code> or <code>docked</code>. They do not appear in figures whose <code>WindowStyle</code> is <code>modal</code>. If the <code>WindowStyle</code> property of a figure containing a <code>uitoolbar</code> is changed to <code>modal</code>, the <code>uitoolbar</code> still exists and is contained in the <code>Children</code> list of the figure, but is not displayed until the <code>WindowStyle</code> is changed to <code>normal</code> or <code>docked</code>.</p>
<b>Examples</b>	<p>This example creates a figure with no toolbar, then adds a toolbar to it.</p> <pre>h = figure('ToolBar','none') ht = uitoolbar(h)</pre>

# uitoolbar

## Purpose

Describe toolbar properties

## Modifying Properties

You can set and query graphics object properties in two ways:

- The Property Inspector is an interactive tool that enables you to see and change object property values. The Property inspector is available from GUIDE, or use the `inspect` function at the command line.
- The `set` and `get` functions enable you to set and query the values of properties.

You can set default Uitoolbar properties by typing:

```
set(h, 'DefaultUitoolbarPropertyName', PropertyValue...)
```

Where `h` can be the root handle (0), a figure handle, or a uitoolbar handle. *PropertyName* is the name of the Uitoolbar property and *PropertyValue* is the value you specify as the default for that property.

For more information about changing the default value of a property see [Setting Default Property Values](#).

## Uitoolbar Properties

This section lists all properties useful to uitoolbar objects along with valid values and a descriptions of their use. Curly braces { } enclose default values.

Property	Purpose
BeingDeleted	This object is being deleted.
BusyAction	Callback routine interruption.
Children	Handles of uitoolbar's children.
CreateFcn	Callback routine executed during object creation.
DeleteFcn	Callback routine executed during object deletion.
HandleVisibility	Control access to object's handle.

# Uitoolbar Properties

---

Property	Purpose
Interruptible	Callback routine interruption mode.
Parent	Handle of uitoolbar's parent.
Tag	User-specified object identifier.
Type	Object class.
UIContextMenu	Uicontextmenu object associated with the uitoolbar
UserData	User specified data.
Visible	Uitoolbar visibility.

## BeingDeleted

on | {off} (read-only)

*This object is being deleted.* The **BeingDeleted** property provides a mechanism that you can use to determine if objects are in the process of being deleted. MATLAB software sets the **BeingDeleted** property to on when the object's delete function callback is called (see the **DeleteFcn** property) It remains set to on while the delete function executes, after which the object no longer exists.

For example, some functions may not need to perform actions on objects that are being deleted, and therefore, can check the object's **BeingDeleted** property before acting.

## BusyAction

cancel | {queue}

*Callback queuing*

Determines how MATLAB handles the execution of interrupting callbacks.

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. The `BusyAction` property of the *interrupting* callback determines how MATLAB handles its execution. When the `BusyAction` property is set to:

- 'queue' — Puts the *interrupting* callback in a queue to be processed after the *running* callback finishes execution.
- 'cancel' — Discards the *interrupting* callback as MATLAB finishes execution.

For information about how the `Interruptible` property of the callback controls whether other callbacks can interrupt the *running* callback, see the `Interruptible` property description.

## Children

vector of handles

*Handles of tools on the toolbar.* A vector containing the handles of all children of the `uitoolbar` object, in the order in which they appear on the toolbar. The children objects of `uitoolbars` are `uipushtools` and `uitoggletools`. You can use this property to reorder the children.

## CreateFcn

string or function handle

*Callback routine executed during object creation.* The specified function executes when MATLAB creates a `uitoolbar` object. MATLAB sets all property values for the `uitoolbar` before executing the `CreateFcn` callback so these values are available to the callback. Within the function, use `gcbo` to get the handle of the toolbar being created.

Setting this property on an existing `uitoolbar` object has no effect.

# Uitoolbar Properties

---

You can define a default `CreateFcn` callback for all new uitoolbars. This default applies unless you override it by specifying a different `CreateFcn` callback when you call `uitoolbar`. For example, the statement,

```
set(0,'DefaultUitoolbarCreateFcn',...
 'set(gcbo,'Visibility','off')')
```

creates a default `CreateFcn` callback that runs whenever you create a new toolbar. It sets the toolbar visibility to `off`.

To override this default and create a toolbar whose `Visibility` property is set to `on`, you could call `uitoolbar` with a call similar to

```
ht = uitoolbar(...,'CreateFcn',...
 'set(gcbo,'Visibility','on')',...)
```

---

**Note** To override a default `CreateFcn` callback you must provide a new callback and not just provide different values for the specified properties. This is because the `CreateFcn` callback runs after the property values are set, and can override property values you have set explicitly in the `uitoolbar` call. In the example above, if instead of redefining the `CreateFcn` property for this toolbar, you had explicitly set `Visibility` to `on`, the default `CreateFcn` callback would have set `Visibility` back to `off`.

---

Do not call `copyobj` or `textwrap` (which calls `copyobj`) inside a `CreateFcn`. The act of copying the uicontrol object fires the `CreateFcn` repeatedly, which raises a series of error messages after exceeding the root object's `RecursionLimit` property.

See [Function Handle Callbacks](#) for information on how to use function handles to define a callback function.

## DeleteFcn

string or function handle

*Callback routine executed during object deletion.* A callback function that executes when the uitoolbar object is deleted (e.g., when you call the `delete` function or cause the figure containing the uitoolbar to reset). MATLAB executes the routine before destroying the object's properties so these values are available to the callback routine.

Within the function, use `gcbo` to get the handle of the toolbar being deleted.

## HandleVisibility

{on} | callback | off

*Control access to object's handle.* This property determines when an object's handle is visible in its parent's list of children. When a handle is not visible in its parent's list of children, it is not returned by functions that obtain handles by searching the object hierarchy or querying handle properties. This includes `get`, `findobj`, `gca`, `gcf`, `gco`, `newplot`, `cla`, `clf`, and `close`. Neither is the handle visible in the parent figure's `CurrentObject` property. Handles that are hidden are still valid. If you know an object's handle, you can `set` and `get` its properties, and pass it to any function that operates on handles.

- Handles are always visible when `HandleVisibility` is `on`.
- Setting `HandleVisibility` to `callback` causes handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This provides a means to protect GUIs from command-line users, while allowing callback routines to have complete access to object handles.
- Setting `HandleVisibility` to `off` makes handles invisible at all times. This may be necessary when a callback routine invokes a function that might potentially damage the GUI

# Uitoolbar Properties

---

(such as evaluating a user-typed string), and so temporarily hides its own handles during the execution of that function.

You can set the root `ShowHiddenHandles` property to `on` to make all handles visible, regardless of their `HandleVisibility` settings. This does not affect the values of the `HandleVisibility` properties.

`HitTest`  
`{on} | off`

*Selectable by mouse click.* This property has no effect on uitoolbar objects.

---

**Note** Use of the uitoolbar `HitTest` property is not recommended. This property might be removed in a future release.

---

`Interruptible`  
`off | {on}`

*Callback routine interruption*

Controls whether MATLAB can interrupt an object's callback function when subsequent callbacks attempt to interrupt it.

For user interface objects, the `Interruptible` property affects the callbacks for these properties only:

- `ButtonDownFcn`
- `KeyPressFcn`
- `KeyReleaseFcn`
- `WindowButtonDownFcn`

- WindowButtonMotionFcn
- WindowButtonUpFcn
- WindowKeyPressFcn
- WindowKeyReleaseFcn
- WindowScrollWheelFcn

A *running* callback is the currently executing callback. The *interrupting* callback is the callback that tries to interrupt the *running* callback. MATLAB handles both callbacks based on the `Interruptible` property of the object of the *running* callback.

When the `Interruptible` property is set to:

- 'off', MATLAB finishes execution of the *running* callback without any interruptions
- 'on', these conditions apply:
  - If there is a `drawnow`, `figure`, `getframe`, `waitfor`, or `pause` command in the *running* callback, then MATLAB executes the *interrupting* callbacks which are already in the queue and returns to finish execution of the current callback.
  - If one of the above functions is not in the *running* callback, then MATLAB finishes execution of the current callback without any interruption.

The `BusyAction` property of the object of interrupting callback determines whether the callback should be ignored or should be put in the queue.

Setting the `Interruptible` property to `on` (default), allows a callback from other user interface objects to interrupt callback functions originating from this object.

# Uitoolbar Properties

---

---

**Note** MATLAB does not save the state of properties or the display when an interruption occurs. For example, the handle returned by the `gca` or `gcf` command may be changed as another callback is executed.

---

After the function that interrupts a callback completes, the callback resumes execution where it halted when interrupted. For more information, see “Control Callback Execution and Interruption”.

---

**Note** If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback, or a figure’s `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of that object’s `Interruptible` property. The interrupting callback starts execution at the next `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` statement. An object’s `ButtonDownFcn` or `Callback` routine is processed according to the rules described previously in this section.

---

Parent

handle

*Uitoolbar parent.* The handle of the uitoolbar’s parent figure. You can move a uitoolbar object to another figure by setting this property to the handle of the new parent.

Tag

string

*User-specified object identifier.* The `Tag` property provides a means to identify graphics objects with a user-specified label. You can define `Tag` as any string.

With the `findobj` function, you can locate an object with a given `Tag` property value. This saves you from defining object handles as global variables. For example, this function call returns the handles of all children (of the specified figures) that have the `Tag` value `'FormatTb'`.

```
h = findobj(figurehandles,'Tag','FormatTb')
```

## Type

string (read-only)

Object class. This property identifies the kind of graphics object. For uitoolbar objects, `Type` is always the string `'uitoolbar'`.

## UIContextMenu

handle

*Associate a context menu with uicontrol.* This property has no effect on uitoolbar objects.

## UserData

array

*User specified data.* You can specify `UserData` as any array you want to associate with the uitoolbar object. The object does not use this data, but you can access it using the `set` and `get` functions.

## Visible

{on} | off

*Uitoolbar visibility.* By default, all uitoolbars are visible. When set to `off`, the uitoolbar is not visible, but still exists and you can query and set its properties.

# uiwait

---

**Purpose** Block program execution and wait to resume

**Syntax**

```
uiwait
uiwait(h)
uiwait(h,timeout)
```

**Description** `uiwait` blocks execution until `uiresume` is called or the current figure is deleted. This syntax is the same as `uiwait(gcf)`.

`uiwait(h)` blocks execution until `uiresume` is called or the figure `h` is deleted.

`uiwait(h,timeout)` blocks execution until `uiresume` is called, the figure `h` is deleted, or `timeout` seconds elapse. The minimum value of `timeout` is 1. If `uiwait` receives a smaller value, it issues a warning and uses a 1 second `timeout`.

**Tips** The `uiwait` and `uiresume` functions block and resume MATLAB and Simulink program execution. `uiwait` also blocks the execution of Simulink models. The functions `pause` (with no argument) and `waitfor` also block execution in this manner. `uiwait` is a convenient way to use the `waitfor` command. You typically use it in conjunction with a dialog box. It provides a way to block the execution of the MATLAB program that created the dialog, until the user responds to the dialog box. When used in conjunction with a modal dialog, `uiwait` can block the execution of the program file *and* restrict user interaction to the dialog only.

**Examples** This example creates a GUI with a **Continue** push button. The example calls `uiwait` to block MATLAB execution until `uiresume` is called. This happens when the user clicks the **Continue** push button because the push button's `Callback`, which responds to the click, calls `uiresume`.

```
f = figure;
h = uicontrol('Position',[20 20 200 40],'String','Continue',...
 'Callback','uiresume(gcf)');
disp('This will print immediately');
uiwait(gcf);
```

```
disp('This will print after you click Continue');
close(f);
```

gcbf is the handle of the figure that contains the object whose callback is executing.

# uminus, -

---

**Purpose**           Unary minus

**Syntax**            C = -A  
                  C = uminus(A)

**Description**       C = -A negates the elements of A and stores the result in C.

C = uminus(A) is an alternative way to execute -A, but is rarely used. It enables operator overloading for classes.

**Input Arguments**

**A - Input array**

scalar | vector | matrix | multidimensional array

Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | logical | char

**Complex Number Support:** Yes

**Examples**

**Negate Elements of Matrix**

Create a 2-by-2 matrix, A.

```
A = [1 -3; -2 4]
```

```
A =
```

```
 1 -3
 -2 4
```

Negate the elements of A.

```
C = -A
```

```
C =
```

-1 3  
2 -4

**See Also**    minus | uplus

# undocheckout

---

**Purpose** Undo previous checkout from source control system (UNIX platforms)

**Syntax** `undocheckout('filename')`  
`undocheckout({'filename1', 'filename2', ..., 'filenamen'})`

**Description** `undocheckout('filename')` makes the file `filename` available for checkout, where `filename` does not reflect any of the changes you made after you last checked it out. Use the full path for `filename` and include the file extension.

`undocheckout({'filename1', 'filename2', ..., 'filenamen'})` makes `filename1` through `filenamen` available for checkout, where the files do not reflect any of the changes you made after you last checked them out. Use the full paths for the file names and include the file extensions.

**Examples** Undo the checkouts of `/myserver/myfiles/clock.m` and `/myserver/myfiles/calendar.m` from the source control system:

```
undocheckout({'/myserver/myfiles/clock.m', ...
 '/myserver/myfiles/calendar.m'})
```

**See Also** `checkin` | `checkout` | `verctrl`

**How To** • “Undo the Checkout (UNIX Platforms)”

<b>Purpose</b>	Convert Unicode character representation to numeric bytes
<b>Syntax</b>	<pre>bytes = unicode2native(unicodestr) bytes = unicode2native(unicodestr,encoding)</pre>
<b>Description</b>	<p><code>bytes = unicode2native(unicodestr)</code> converts a char vector of Unicode character representations, <code>unicodestr</code>, to the user default encoding, and returns the bytes as a <code>uint8</code> vector, <code>bytes</code>. Output vector <code>bytes</code> has the same general array shape as the <code>unicodestr</code> input. You can save the output of <code>unicode2native</code> to a file using the <code>fwrite</code> function.</p> <p><code>bytes = unicode2native(unicodestr,encoding)</code> converts <code>unicodestr</code> to the character encoding scheme specified by the string <code>encoding</code>. <code>encoding</code> must be the empty string ('') or a name or alias for an encoding scheme. Some examples are 'UTF-8', 'latin1', 'US-ASCII', and 'Shift_JIS'. If <code>encoding</code> is unspecified or is the empty string (''), the default encoding scheme is used.</p>
<b>Examples</b>	<p>This example begins with two strings containing Unicode character representations. It assumes that string <code>str1</code> contains text in a Western European language and string <code>str2</code> contains Japanese text. The example writes both strings into the same file, using the ISO-8859-1 character encoding scheme for the first string and the Shift-JIS encoding scheme for the second string. The example uses <code>unicode2native</code> to convert the two strings to the appropriate encoding schemes.</p> <pre>fid = fopen('mixed.txt', 'w'); bytes1 = unicode2native(str1, 'ISO-8859-1'); fwrite(fid, bytes1, 'uint8'); bytes2 = unicode2native(str2, 'Shift_JIS'); fwrite(fid, bytes2, 'uint8'); fclose(fid);</pre>
<b>See Also</b>	<code>native2unicode</code>

# union

---

**Purpose** Set union of two arrays

**Syntax**

```
C = union(A,B)
C = union(A,B, 'rows')
[C,ia,ib] = union(A,B)
[C,ia,ib] = union(A,B, 'rows')

[C,ia,ib] = union(__ ,setOrder)

[C,ia,ib] = union(A,B, 'legacy')

[C,ia,ib] = union(A,B, 'rows', 'legacy')
```

**Description** `C = union(A,B)` returns the combined data from A and B with no repetitions.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then `union` returns the combined values from A and B. The values of C are in sorted order.
- If A and B are tables, then `union` returns the combined set of rows from both tables. The rows of table C are in sorted order.

`C = union(A,B, 'rows')` treats each row of A and each row of B as single entities and returns the combined rows from A and B with no repetitions. The rows of C are in sorted order.

The 'rows' option does not support cell arrays.

`[C,ia,ib] = union(A,B)` also returns index vectors `ia` and `ib`.

- If A and B are numeric arrays, logical arrays, character arrays, categorical arrays, or cell arrays of strings, then the values in C are a sorted combination of the values of A(`ia`) and B(`ib`).
- If A and B are tables, then C is a sorted combination of the rows of A(`ia,:`) and B(`ib,:`).

`[C,ia,ib] = union(A,B,'rows')` also returns index vectors `ia` and `ib`, such that the rows of `C` are a sorted combination of the rows of `A(ia,:)` and `B(ib,:)`.

`[C,ia,ib] = union(___,setOrder)` returns `C` in a specific order using any of the input arguments in the previous syntaxes. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`, and then `B`. If no value is specified, the default is `'sorted'`.

`[C,ia,ib] = union(A,B,'legacy')` and `[C,ia,ib] = union(A,B,'rows','legacy')` preserve the behavior of the `union` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Input Arguments

### A,B - Input arrays

numeric arrays | logical arrays | character arrays | categorical arrays  
| cell arrays of strings | tables

Input arrays, specified as numeric arrays, logical arrays, character arrays, categorical arrays, cell arrays of strings, or tables.

`A` and `B` must be of the same class with the following exceptions:

- `logical`, `char`, and all numeric classes can combine with `double` arrays.
- Cell arrays of strings can combine with `char` arrays.
- Categorical arrays can combine with cell arrays of strings or single strings.

If `A` and `B` are both ordinal categorical arrays, they must have the same sets of categories, including their order. If neither `A` nor `B` are ordinal, they need not have the same sets of categories, and the comparison is performed using the category names. In this case, the categories of `C` are the sorted union of the categories from `A` and `B`.

# union

If you specify the 'rows' option, A and B must have the same number of columns.

If A and B are tables, they must have the same variable names. Conversely, the row names do not matter. Two rows that have the same values, but different names, are considered equal.

Furthermore, A and B can be objects with the following class methods:

- sort (or sortrows for the 'rows' option)
- ne

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

## setOrder - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = union([5 5 3],[1 2], 'sorted') returns C = [1 2 3 5].
'stable'	The values (or rows) in C return in the same order as they appear in A and B. For example: C = union([5 5 3],[1 2], 'stable') returns C = [5 3 1 2].

## Output Arguments

### C - Combined data of A and B

vector | matrix | table

Combined data of A and B, returned as a vector, matrix, or table. If the inputs A and B are tables, the order of the variables in the resulting table, C, is the same as the order of the variables in A.

The following describes the shape of **C** when the inputs are vector or matrices and when the 'legacy' flag is not specified:

- If the 'rows' flag is not specified, then **C** is a column vector unless both **A** and **B** are row vectors.
- If the 'rows' flag is not specified and both **A** and **B** are row vectors, then **C** is a row vector.
- If the 'rows' flag is specified, then **C** is a matrix containing the combined rows of **A** and **B**.

The class of the inputs **A** and **B** determines the class of **C**:

- If the class of **A** and **B** are the same, then **C** is the same class.
- If you combine a `char` or nondouble numeric class with `double`, then **C** is the same class as the nondouble input.
- If you combine a `logical` class with `double`, then **C** is `double`.
- If you combine a cell array of strings with `char`, then **C** is a cell array of strings.
- If you combine a categorical array with a cell array of strings or single string, then **C** is a categorical array.

### **ia - Index to A**

column vector

Index to **A**, returned as a column vector when the 'legacy' flag is not specified. **ia** indicates the values (or rows) in **A** that contribute to the union. If a value (or row) appears multiple times in **A**, then **ia** contains the index to the first occurrence of the value (or row). If a value appears in both **A** and **B**, then **ia** contains the index to the first occurrence in **A**.

### **ib - Index to B**

column vector

Index to **B**, returned as a column vector when the 'legacy' flag is not specified. **ib** indicates the values (or rows) in **B** that contribute to the union. If there is a repeated value (or row) appearing exclusively in **B**,

then `ib` contains the index to the first occurrence of the value. If a value (or row) appears in both A and B, then `ib` does not contain an index to the value (or row).

## Examples

### Union of Two Vectors

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors A and B.

```
C = union(A,B)
```

```
C =
```

```
 1 3 5 7
```

### Union of Two Tables

Define two tables with rows in common.

```
A = table([1:5]', ['A'; 'B'; 'C'; 'D'; 'E'], logical([0;1;0;1;0]))
```

```
B = table([1:2:10]', ['A'; 'C'; 'E'; 'G'; 'I'], logical(zeros(5,1)))
```

```
A =
```

Var1	Var2	Var3
1	A	false
2	B	true
3	C	false
4	D	true
5	E	false

```
B =
```

Var1	Var2	Var3
------	------	------

```

1 A false
3 C false
5 E false
7 G false
9 I false

```

Find the union of tables A and B.

```
C = union(A,B)
```

```
C =
```

```

Var1 Var2 Var3

1 A false
2 B true
3 C false
4 D true
5 E false
7 G false
9 I false

```

### Union of Two Vectors and Their Indices

Define two vectors with a value in common.

```
A = [5 7 1]; B = [3 1 1];
```

Find the union of vectors A and B, as well as the index vectors, ia and ib.

```
[C,ia,ib] = union(A,B)
```

```
C =
```

```
1 3 5 7
```

# union

---

```
ia =
```

```
 3
 1
 2
```

```
ib =
```

```
 1
```

The values in C are the combined values of A(ia) and B(ib).

## Union of Two Tables and Their Indices

Define a table, A, of gender, age, and height for three people.

```
A = table(['M';'M';'F'],[27;52;31],[74;68;64],...
'VariableNames',{'Gender' 'Age' 'Height'},...
'RowNames',{'Ted' 'Fred' 'Betty'})
```

```
A =
```

	Gender	Age	Height
	-----	---	-----
Ted	M	27	74
Fred	M	52	68
Betty	F	31	64

Define a table, B with the same variables as A.

```
B = table(['F';'M'],[64;68],[31;47],...
'VariableNames',{'Gender' 'Height' 'Age'},...
'RowNames',{'Meg' 'Joe'})
```

```
B =
```

	Gender	Height	Age
--	--------	--------	-----

	-----	-----	---
Meg	F	64	31
Joe	M	68	47

Find the union of tables A and B, as well as the index vectors, `ia` and `ib`.

```
[C,ia,ib] = union(A,B)
```

C =

	Gender	Age	Height
	-----	---	-----
Betty	F	31	64
Ted	M	27	74
Joe	M	47	68
Fred	M	52	68

ia =

```
3
1
2
```

ib =

```
2
```

The data for Meg and Betty are the same. `union` only returns the index from A, which corresponds to Betty.

### Union of Rows in Two Matrices

Define two matrices with a row in common.

```
A = [2 2 2; 0 0 1];
B = [1 2 3; 2 2 2; 2 2 2];
```

# union

---

Find the combined rows of A and B, with no repetition, as well as the index vectors ia and ib.

```
[C,ia,ib] = union(A,B,'rows')
```

```
C =
```

```
 0 0 1
 1 2 3
 2 2 2
```

```
ia =
```

```
 2
 1
```

```
ib =
```

```
 1
```

The rows of C are the combined rows of A(ia,:) and B(ib,:).

## **Union of Two Vectors with Specified Output Order**

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A and B.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'stable')
```

```
C =
```

```
 5 7 1 3
```

```
ia =
```

```
1
2
3
```

```
ib =
```

```
1
```

Alternatively, you can specify 'sorted' order.

```
A = [5 7 1]; B = [3 1 1];
[C,ia,ib] = union(A,B,'sorted')
```

```
C =
```

```
1 3 5 7
```

```
ia =
```

```
3
1
2
```

```
ib =
```

```
1
```

### **Union of Vectors Containing NaNs**

Define two vectors containing NaN.

```
A = [5 NaN 1]; B = [4 NaN NaN];
```

Find the union of vectors A and B.

# union

---

```
C = union(A,B)
C =
 1 4 5 NaN NaN NaN
```

union treats NaN values as distinct.

## Cell Array of Strings with Trailing White Space

Create a cell array of strings, A.

```
A = {'dog', 'cat', 'fish', 'horse'};
```

Create a cell array of strings, B, where some of the strings have trailing white space.

```
B = {'dog ', 'cat', 'fish ', 'horse'};
```

Combine the elements of A and B.

```
[C,ia,ib] = union(A,B)
C =
 'cat' 'dog' 'dog ' 'fish' 'fish ' 'horse'

ia =
 2
 1
 3
 4

ib =
 1
```

3

union treats trailing white space in cell arrays of strings as distinct characters.

### **Union of Vectors of Different Classes and Shapes**

Create a column vector character array.

```
A = ['A'; 'B'; 'C'], class(A)
```

```
A =
```

```
A
```

```
B
```

```
C
```

```
ans =
```

```
char
```

Create a row vector containing elements of numeric type double.

```
B = [68 69 70], class(B)
```

```
B =
```

```
68 69 70
```

```
ans =
```

```
double
```

The union of A and B returns a column vector character array.

# union

---

```
C = union(A,B), class(C)
```

```
C =
```

```
A
```

```
B
```

```
C
```

```
D
```

```
E
```

```
F
```

```
ans =
```

```
char
```

## **Union of Char and Cell Array of Strings**

Create a character array containing the letters a , b, and c.

```
A = ['a'; 'b'; 'c'];
class(A)
```

```
ans =
```

```
char
```

Create a cell array of strings containing the letters c, d, and e.

```
B = {'c', 'd', 'e'};
class(B)
```

```
ans =
```

```
cell
```

Combine the elements of A and B.

```
C = union(A,B)
```

```
C =
```

```
 'a'
 'b'
 'c'
 'd'
 'e'
```

The result, C, is a cell array of strings.

```
class(C)
```

```
ans =
```

```
cell
```

### Preserve Legacy Behavior of union

Use the 'legacy' flag to preserve the behavior of union from R2012b and prior releases in your code.

Find the union of A and B with the current behavior.

```
A = [5 7 1]; B = [3 1 1];
[C1,ia1,ib1] = union(A,B)
```

```
C1 =
```

```
 1 3 5 7
```

```
ia1 =
```

```
 3
```

# union

---

```
1
2
```

```
ib1 =

1
```

Find the union of A and B, and preserve the legacy behavior.

```
A = [5 7 1]; B = [3 1 1];
[C2,ia2,ib2] = union(A,B,'legacy')
```

```
C2 =

1 3 5 7
```

```
ia2 =

1 2
```

```
ib2 =

3 1
```

## Tips

- To find the union with respect to a subset of variables from a table, you can use column subscripting. For example, you can use `union(A(:,vars),B(:,vars))`, where `vars` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

## See Also

`unique` | `intersect` | `ismember` | `issorted` | `setdiff` | `setxor` | `sort`

## Concepts

- “Combine Categorical Arrays”

**Purpose**

Unique values in array

**Syntax**

```
C = unique(A)
C = unique(A,'rows')
[C,ia,ic] = unique(A)
[C,ia,ic] = unique(A,'rows')

[C,ia,ic] = unique(A,setOrder)

[C,ia,ic] = unique(A,'rows',setOrder)

[C,ia,ic] = unique(A,'legacy')

[C,ia,ic] = unique(A,'rows','legacy')

[C,ia,ic] = unique(A,occurrence,'legacy')

[C,ia,ic] = unique(A,'rows',occurrence,'legacy')
```

**Description**

`C = unique(A)` returns the same data as in `A`, but with no repetitions.

- If `A` is a numeric array, logical array, character array, categorical array, or a cell array of strings, then `unique` returns the unique values in `A`. The values of `C` are in sorted order.
- If `A` is a table, then `unique` returns the unique rows in `A`. The rows of table `C` are in sorted order.

`C = unique(A,'rows')` treats each row of `A` as a single entity and returns the unique rows of `A`. The rows of the array `C` are in sorted order.

The `'rows'` option does not support cell arrays.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic`.

- If `A` is a numeric array, logical array, character array, categorical array, or a cell array of strings, then `C = A(ia)` and `A = C(ic)`.

# unique

---

- If `A` is a table, then `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,'rows')` also returns index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

`[C,ia,ic] = unique(A,setOrder)` and `[C,ia,ic] = unique(A,'rows',setOrder)` return `C` in a specific order. `setOrder='sorted'` returns the values (or rows) of `C` in sorted order. `setOrder='stable'` returns the values (or rows) of `C` in the same order as `A`. If no value is specified, the default is `'sorted'`.

`[C,ia,ic] = unique(A,'legacy')`, `[C,ia,ic] = unique(A,'rows','legacy')`, `[C,ia,ic] = unique(A,occurrence,'legacy')`, and `[C,ia,ic] = unique(A,'rows',occurrence,'legacy')` preserve the behavior of the `unique` function from R2012b and prior releases.

The `'legacy'` option does not support categorical arrays or tables.

## Input Arguments

### **A** - Input array

numeric array | logical array | character array | categorical array | cell array of strings | table

Input array, specified as a numeric array, logical array, character array, categorical array, cell array of strings, or table.

If `A` is a table, `unique` does not take row names into account. Two rows that have the same values, but different names, are considered equal.

Furthermore, `A` can be an object with the following class methods:

- `sort` (or `sortrows` for the `'rows'` option)
- `ne`

The object class methods must be consistent with each other. These objects include heterogeneous arrays derived from the same root class.

### **setOrder** - Order flag

'sorted' (default) | 'stable'

Order flag, specified as 'sorted' or 'stable', indicates the order of the values (or rows) in C.

Order Flag	Meaning
'sorted'	The values (or rows) in C return in sorted order. For example: C = unique([5 5 3 4], 'sorted') returns C = [3 4 5].
'stable'	The values (or rows) in C return in the same order as in A. For example: C = unique([5 5 3 4], 'stable') returns C = [5 3 4].

**occurrence - Occurrence flag for legacy behavior**

'last' (default) | 'first'

Occurrence flag for legacy behavior, specified as 'first' or 'last', indicates whether ia should contain the first or last indices to repeated values found in A.

Occurrence Flag	Meaning
'last'	If there are repeated values (or rows) in A, then ia contains the index to the last occurrence of the repeated value. For example: [C,ia,ic] = unique([9 9 9], 'last', 'legacy') returns ia = 3.
'first'	If there are repeated values (or rows) in A, then ia contains the index to the first occurrence of the repeated value. For example: [C,ia,ic] = unique([9 9 9], 'first', 'legacy') returns ia = 1.

# unique

---

## Output Arguments

### **C** - Unique data of A

vector | matrix | table

Unique data of A, returned as a vector, matrix, or table. The following describes the shape of C when the input, A, is a vector or a matrix:

- If the 'rows' flag is not specified and A is a row vector, then C is a row vector.
- If the 'rows' flag is not specified and A is not a row vector, then C is a column vector.
- If the 'rows' flag is specified, then C is a matrix containing the unique rows of A.

The class of C is the same as the class of the input A.

### **ia** - Index to A

column vector

Index to A, returned as a column vector of indices to the first occurrence of repeated elements. When the 'legacy' flag is specified, ia is a row vector that contains indices to the last occurrence of repeated elements.

The indices satisfy  $C = A(ia)$  (or  $C = A(ia, :)$  for the 'rows' option).

### **ic** - Index to C

column vector

Index to C, returned as a column vector when the 'legacy' flag is not specified. ic contains indices, such that  $A = C(ic)$  (or  $A = C(ic, :)$  for the 'rows' option).

## Examples

### Unique Values in Vector

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =
```

```
 2 5 9
```

### Unique Rows in Table

Define a table with repeated data.

```
Name = {'Fred'; 'Betty'; 'Bob'; 'George'; 'Jane'};
```

```
Age = [38; 43; 38; 40; 38];
```

```
Height = [71; 69; 64; 67; 64];
```

```
Weight = [176; 163; 131; 185; 131];
```

```
A = table(Age, Height, Weight, 'RowNames', Name)
```

```
A =
```

	Age	Height	Weight
	---	-----	-----
Fred	38	71	176
Betty	43	69	163
Bob	38	64	131
George	40	67	185
Jane	38	64	131

Find the unique rows of A.

```
C = unique(A)
```

```
C =
```

	Age	Height	Weight
	---	-----	-----
Bob	38	64	131
Fred	38	71	176
George	40	67	185
Betty	43	69	163

# unique

---

`unique` returns the rows of `A` in sorted order by the first variable, `Age` and then by the second variable, `Height`.

## Unique Values and Their Indices

Define a vector with a repeated value.

```
A = [9 2 9 5];
```

Find the unique values of `A` and the index vectors `ia` and `ic`, such that `C = A(ia)` and `A = C(ic)`.

```
[C, ia, ic] = unique(A)
```

```
C =
```

```
 2 5 9
```

```
ia =
```

```
 2
 4
 1
```

```
ic =
```

```
 3
 1
 3
 2
```

## Unique Rows in Matrix

Define a matrix with a repeated row.

```
A = [9 2 9 5; 9 2 9 0; 9 2 9 5];
```

Find the unique rows of A and the index vectors `ia` and `ic`, such that `C = A(ia,:)` and `A = C(ic,:)`.

```
[C, ia, ic] = unique(A, 'rows')
```

```
C =
```

```
 9 2 9 0
 9 2 9 5
```

```
ia =
```

```
 2
 1
```

```
ic =
```

```
 2
 1
 2
```

Notice that the second row in A is identified as unique even though the elements 9, 2, and 9 are repeated in the other rows.

### Unique Values in Vector with Specified Order

Use the `setOrder` argument to specify the ordering of the values in C.

Specify `'stable'` if you want the values in C to have the same order as in A.

```
A = [9 2 9 5];
[C, ia, ic] = unique(A, 'stable')
```

```
C =
```

```
 9 2 5
```

# unique

---

```
ia =
```

```
1
2
4
```

```
ic =
```

```
1
2
1
3
```

Alternatively, you can specify 'sorted' order.

```
[C, ia, ic] = unique(A, 'sorted')
```

```
C =
```

```
2 5 9
```

```
ia =
```

```
2
4
1
```

```
ic =
```

```
3
1
3
```

2

### Unique Values in Array Containing NaNs

Define a vector containing NaN.

```
A = [5 5 NaN NaN];
```

Find the unique values of A.

```
C = unique(A)
```

```
C =
```

```
 5 NaN NaN
```

unique treats NaN values as distinct.

### Unique Entries in Cell Array of Strings

Define a cell array of strings.

```
A = {'one', 'two', 'twenty-two', 'One', 'two'};
```

Find the unique strings contained in A.

```
C = unique(A)
```

```
C =
```

```
 'One' 'one' 'twenty-two' 'two'
```

### Cell Array of Strings with Trailing White Space

Define a cell array of strings, A, where some of the strings have trailing white space.

```
A = {'dog', 'cat', 'fish', 'horse', 'dog ', 'fish '};
```

Find the unique strings contained in A.

# unique

---

```
C = unique(A)
```

```
C =
```

```
 'cat' 'dog' 'dog ' 'fish' 'fish ' 'horse'
```

`unique` treats trailing white space in cell arrays of strings as distinct characters.

## Preserve Legacy Behavior of `unique`

Use the `'legacy'` flag to preserve the behavior of `unique` from R2012b and prior releases in your code.

Find the unique elements of `A` with the current behavior.

```
A = [9 2 9 5];
```

```
[C1, ia1, ic1] = unique(A)
```

```
C1 =
```

```
 2 5 9
```

```
ia1 =
```

```
 2
 4
 1
```

```
ic1 =
```

```
 3
 1
 3
 2
```

Find the unique elements of `A`, and preserve the legacy behavior.

```
[C2, ia2, ic2] = unique(A, 'legacy')
```

```
C2 =
```

```
 2 5 9
```

```
ia2 =
```

```
 2 4 3
```

```
ic2 =
```

```
 3 1 3 2
```

## Tips

- To find unique rows in table A with respect to a subset of variables, you can use column subscripting. For example, you can use `unique(A(:,vars))`, where *vars* is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

# matlab.unittest

---

**Purpose** Summary of packages and classes in MATLAB Unit Test Framework

**Description** The matlab.unittest package consists of the following classes and packages:

matlab.unittest.constraints	Summary of classes in MATLAB Constraints Interface
matlab.unittest.diagnostics	Summary of classes in MATLAB Diagnostics Interface
matlab.unittest.fixtures	Summary of classes in MATLAB Fixtures Interface
matlab.unittest.parameters	Summary of classes associated with MATLAB Unit Test parameters
matlab.unittest.plugins	Summary of classes in MATLAB Plugins Interface
matlab.unittest.plugins.plugindata	Summary of classes in MATLAB Plugin Data Interface
matlab.unittest.qualifications	Summary of classes in MATLAB Qualifications Interface
matlab.unittest.selectors	Summary of classes in MATLAB Selectors Interface
matlab.unittest.Test	Specification of a single test method
matlab.unittest.TestCase	Superclass of all <code>matlab.unittest</code> test classes
matlab.unittest.TestResult	Result of running test suite
matlab.unittest.TestRunner	Class for running tests in <code>matlab.unittest</code> framework
matlab.unittest.TestSuite	Class for grouping tests to run

**Purpose**

Execute UNIX command and return output

**Syntax**

```
status = unix(command)
[status,cmdout] = unix(command)
[status,cmdout] = unix(command,'-echo')
```

**Description**

`status = unix(command)` calls the UNIX operating system to execute the specified command. The operation waits for the command to finish execution before returning the exit status of the command to the `status` variable.

`[status,cmdout] = unix(command)` additionally returns the standard output of the command to `cmdout`. This syntax is most useful for commands that do not require user input.

`[status,cmdout] = unix(command,'-echo')` additionally displays (echoes) the command output in the MATLAB Command Window. This syntax is most useful for commands that require user input and that run correctly in the MATLAB Command Window.

**Input Arguments**

**command - UNIX command**

string

UNIX command, specified as a string. The command executes in a UNIX shell, which might not be the shell from which you launched MATLAB.

**Example:** 'ls'

**Output Arguments**

**status - Command exit status**

0 | nonzero integer

Command exit status, returned as either 0 or a nonzero integer. When the command is successful, `status` is 0. Otherwise, `status` is a nonzero integer.

- If `command` includes the ampersand character (&), then `status` is the exit status upon command launch.

- If `command` does not include the ampersand character (&), then `status` is the exit status upon command completion.

## **cmdout - Output of operating system command**

string

Output of the operating system command, returned as a string.

## **Examples**

### **Save UNIX Command Exit Status and Output**

List all users who are currently logged in, and save the command exit status and output. Then, view the status.

```
command = 'who';
[status,cmdout] = unix(command);
status
```

```
status =
```

```
0
```

A `status` of zero indicates that the command completed successfully. MATLAB returns a string containing the list of users in `cmdout`.

## **Tips**

- To execute the operating system command in the background, include the trailing character, &, in the `command` argument (for example, `'emacs &'`). The exit status is immediately returned to the `status` variable. This syntax is useful for console programs that require interactive user command input while they run, and that do not run correctly in the MATLAB Command Window.

---

**Note** If `command` includes the trailing & character, `cmdout` is empty.

---

- The `unix` function redirects `stdin` to the invoked command, `command`, by default. This redirection also forwards MATLAB script commands and the keyboard type-ahead buffer to the invoked command while

the `unix` function executes. This can lead to corrupted output when `unix` does not complete execution immediately. To disable `stdin` and type-ahead redirection, include the formatted string `< /dev/null` in the call to the invoked command.

## Algorithms

MATLAB uses a shell program to execute the given command. It determines which shell program to use by checking environment variables on your system. MATLAB first checks the `MATLAB_SHELL` variable, and if either empty or not defined, then checks `SHELL`. If `SHELL` is also empty or not defined, MATLAB uses `/bin/sh`.

# unloadlibrary

---

<b>Purpose</b>	Unload shared library from memory
<b>Syntax</b>	<code>unloadlibrary libname</code>
<b>Description</b>	<code>unloadlibrary libname</code> unloads library <code>libname</code> from memory.
<b>Limitations</b>	<ul style="list-style-type: none"><li>• Use with libraries that are loaded using the <code>loadlibrary</code> function.</li></ul>
<b>Input Arguments</b>	<p><b>libname</b> - Name of shared library</p> <p>string</p> <p>Name of shared library, specified as a string. If you call <code>loadlibrary</code> using the <code>alias</code> option, then you must use the alias name for the <code>libname</code> argument.</p> <p><b>Data Types</b></p> <p>char</p>
<b>Examples</b>	<p><b>Unload Library</b></p> <p>Add path to examples folder.</p> <pre>addpath(fullfile(matlabroot,'extern','examples','shrlib'))</pre> <p>Load the library, if it is not already loaded.</p> <pre>if ~libisloaded('shrlibsample')     loadlibrary('shrlibsample') end</pre> <p>Clean up.</p> <pre>unloadlibrary shrlibsample</pre>
<b>Tips</b>	<ul style="list-style-type: none"><li>• To unload a MEX-file, use the <code>clear</code> function.</li></ul>
<b>See Also</b>	<code>loadlibrary</code>   <code>libisloaded</code>   <code>clear</code>

---

<b>Purpose</b>	Convert edge matrix to coordinate and Laplacian matrices	
<b>Syntax</b>	$[L,XY] = \text{unmesh}(E)$	
<b>Description</b>	$[L,XY] = \text{unmesh}(E)$ returns the Laplacian matrix $L$ and mesh vertex coordinate matrix $XY$ for the $M$ -by-4 edge matrix $E$ . Each row of the edge matrix must contain the coordinates $[x1\ y1\ x2\ y2]$ of the edge endpoints.	
<b>Input Arguments</b>	$E$	$M$ -by-4 edge matrix $E$ .
<b>Output Arguments</b>	$L$	Laplacian matrix representation of the graph.
	$XY$	Mesh vertex coordinate matrix.
<b>Examples</b>	Take a simple example of a square with vertices at $(1,1)$ , $(1,-1)$ , $(-1,-1)$ , and $(-1,1)$ , where the connections between vertices are the four perpendicular edges of the square plus one diagonal connection between $(-1, -1)$ and $(1,1)$ .	

The edge matrix E for this graph is:

```
E=[1 1 1 -1; % edge from 1 to 2
1 -1 -1 -1; % edge from 2 to 3
-1 -1 -1 1; % edge from 3 to 4
-1 -1 1 1; % edge from 4 to 1
-1 1 1 1] % edge from 3 to 1
```

Use unmesh to create the output matrices,

```
[A,XY]=unmesh(E);
4 vertices:
4/4
```

The Laplacian matrix is defined as

$$L_{ij} = \begin{cases} \deg(v_i) & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and } v_i \text{ is adjacent to } v_j \\ 0 & \text{otherwise} \end{cases}$$

unmesh returns the Laplacian matrix L in sparse notation.

L

L =

(1,1)	3
(2,1)	-1
(3,1)	-1
(4,1)	-1
(1,2)	-1
(2,2)	2
(4,2)	-1
(1,3)	-1
(3,3)	2
(4,3)	-1
(1,4)	-1
(2,4)	-1
(3,4)	-1

To see L in regular matrix notation, use the full command.

full(L)

ans =

3	-1	-1	-1
-1	2	0	-1
-1	0	2	-1
-1	-1	-1	3

The mesh coordinate matrix XY returns the coordinates of the corners of the square.

# unmesh

---

XY

XY =

```
-1 -1
-1 1
 1 -1
 1 1
```

## See Also

[gplot](#) | [treepplot](#)

**Purpose** Piecewise polynomial details

**Syntax** `[breaks,coefs,l,k,d] = unmkpp(pp)`

**Description** `[breaks,coefs,l,k,d] = unmkpp(pp)` extracts, from the piecewise polynomial `pp`, its breaks `breaks`, coefficients `coefs`, number of pieces `l`, order `k`, and dimension `d` of its target. Create `pp` using `spline` or the spline utility `mkpp`.

**Examples** This example creates a description of the quadratic polynomial

$$\frac{-x^2}{4} + x$$

as a piecewise polynomial `pp`, then extracts the details of that description.

```
pp = mkpp([-8 -4],[-1/4 1 0]);
[breaks,coefs,l,k,d] = unmkpp(pp)
```

```
breaks =
 -8 -4
```

```
coefs =
 -0.2500 1.0000 0
```

```
l =
 1
```

```
k =
 3
```

```
d =
 1
```

**See Also** `mkpp` | `ppval` | `spline`

# unregisterallevents

---

**Purpose** Unregister all event handlers associated with COM object events at run time

**Syntax** `h.unregisterallevents`  
`unregisterallevents(h)`

**Description** `h.unregisterallevents` unregisters all events previously registered with COM object `h`. After calling `unregisterallevents`, the object no longer responds to any events until you register them again using the `registerevent` function.

`unregisterallevents(h)` is an alternate syntax.

COM functions are available on Microsoft Windows systems only.

**Examples** Register and unregister events for an instance of the `mwsamp` control, using the `eventlisteners` function to see the event handler associated with each event:

**1** Register three events and their respective handler routines.

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
 [0 0 200 200], f, ...
 {'Click' 'myclick'; 'Db1Click' 'my2click'; ...
 'MouseDown' 'mymoused'});
h.eventlisteners
```

```
ans =
 'click' 'myclick'
 'dblclick' 'my2click'
 'mousedown' 'mymoused'
```

**2** Unregister all events simultaneously with `unregisterallevents`. `eventlisteners` returns an empty cell array, indicating that there are no longer any events registered with the control:

```
h.unregisterallevents;
```

```
h.eventlisteners
```

```
ans =
 {}
```

## See Also

```
events (COM) | eventlisteners | registerevent | unregisterevent
| isevent
```

# unregisterevent

---

**Purpose** Unregister event handler associated with COM object event at run time

**Syntax** `h.unregisterevent(eventhandler)`  
`unregisterevent(h, eventhandler)`

**Description** `h.unregisterevent(eventhandler)` unregisters specific event handler routines from their corresponding events. Once you unregister an event, the object no longer responds to the event.

`unregisterevent(h, eventhandler)` is an alternate syntax.

You can unregister events at any time after creating a control. The `eventhandler` argument, which is a cell array, specifies both events and event handlers.

```
h.unregisterevent({'event_name', @event_handler});
```

Specify events in the `eventhandler` argument using the names of the events. Strings used in the `eventhandler` argument are not case sensitive. `unregisterevent` does not accept numeric event identifiers.

COM functions are available on Microsoft Windows systems only.

**Examples** Unregister events for a control:

- 1 Create an `mwsamp` control and register all events with the same handler routine, `sampev`. Use `eventlisteners` to see the event handler used by each event. In this case, each event, when fired, calls `sampev.m`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
 [0 0 200 200], f, ...
 'sampev');
h.eventlisteners
```

```
ans =
```

```
'Click' 'sampev'
'DbClick' 'sampev'
'MouseDown' 'sampev'
'Event_Args' 'sampev'
```

- 2** Unregister just the `dblclick` event. Now, when you list the registered events using `eventlisteners`, `dblclick` is no longer registered and the control does not respond when you double-click the mouse over it:

```
h.unregisterevent({'dblclick' 'sampev'});
h.eventlisteners
```

```
ans =
 'Click' 'sampev'
 'MouseDown' 'sampev'
 'Event_Args' 'sampev'
```

- 3** Now, register the `click` and `dblclick` events with a different event handler for `myclick` and `my2click`, respectively:

```
h.unregisterallevents;
h.registerevent({'click' 'myclick'; ...
 'dblclick' 'my2click'});
h.eventlisteners
```

```
ans =
 'click' 'myclick'
 'dblclick' 'my2click'
```

- 4** Unregister these same events by specifying event names and their handler routines in a cell array. `eventlisteners` now returns an empty cell array, meaning that no events are registered for the `mwsamp` control:

```
h.unregisterevent({'click' 'myclick'; ...
 'dblclick' 'my2click'});
h.eventlisteners
```

# unregisterevent

---

```
ans =
 {}
```

---

Unregister Microsoft Excel workbook events:

- 1 Create a Workbook object and register two events with the event handler routines, `EvtActivateHndlr` and `EvtDeactivateHndlr`:

```
myApp = actxserver('Excel.Application');
wbs = myApp.Workbooks;
wb = wbs.Add;wb.registerevent({'Activate' 'EvtActivateHndlr'; ...
 'Deactivate' 'EvtDeactivateHndlr'})
wb.eventlisteners
```

```
ans =
 'Activate' 'EvtActivateHndlr'
 'Deactivate' 'EvtDeactivateHndlr'
```

MATLAB shows the events with the corresponding event handlers.

- 2 Next, unregister the `Deactivate` event handler:

```
wb.unregisterevent({'Deactivate' 'EvtDeactivateHndlr'})
wb.eventlisteners
```

```
ans =
 'Activate' 'EvtActivateHndlr'
```

MATLAB shows the remaining registered event (`Activate`) with its corresponding event handler.

## How To

- “Writing Event Handlers”

**Purpose**

Unstack data from single variable into multiple variables

**Syntax**

```
W = unstack(T,vars,ivar)
W = unstack(T,vars,ivar,Name,Value)
[W,it] = stack(___)
```

**Description**

`W = unstack(T,vars,ivar)` converts the tall table, `T`, to an equivalent table, `W`, that is in wide format. `unstack` unstacks a single variable in `T`, specified by `vars`, into multiple variables in `W`. In general, `W` contains more variables, but fewer rows, than `T`.

An indicator variable in `T`, specified by `ivar`, determines which variable in `W` contains each value in `var` after it is unstacked. `unstack` treats the remaining variables in `T` as grouping variables. Each unique combination of values in the grouping variables identifies a group of rows in `T` that will be unstacked into a single row of `W`.

`W = unstack(T,vars,ivar,Name,Value)` converts the table `T` to wide format with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify how `unstack` converts variables from `T` to variables in `W`.

`[W,it] = stack( ___ )` also returns an index vector, `it`, indicating the correspondence between rows in `W` and rows in `T`. You can use any of the previous input arguments.

**Input Arguments****T - Tall table**

table

Tall table, specified as a table. `T` must contain data variables to unstack, `vars`, and an indicator variable, `ivars`. The remaining variables in `T` are either grouping variables or constant variables.

**vars - Variables in T to unstack**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables in  $T$  to unstack, specified as a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

### **ivar - Indicator variable in T**

positive integer | variable name

Indicator variable in  $T$ , specified as a positive integer or a variable name. The variable specified by `ivar` indicates which variable in  $W$  each value in `var` is unstacked into.

`ivar` can be a numeric vector, logical vector, character array, cell array of strings, or categorical vector.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'AggregationFunction', @mean` applies the aggregation function `@mean` to the values in `vars`.

### **'GroupingVariables' - Grouping variables in T that define groups of rows**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Grouping variables in  $T$  that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. Each group of rows in  $T$  becomes one row in  $W$ .

The default is all the variables in  $T$  not listed in `vars` or `ivar`.

**'ConstantVariables' - Variables constant within a group**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

Variables constant within a group, specified as the comma-separated pair consisting of 'ConstantVariables' and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector. The default is no variables.

The values for these variables in W are taken from the first row in each group in T.

**'NewDataVariableNames' - Names for new data variables in W**

cell array of strings

Names for new data variables in W, specified as the comma-separated pair consisting of 'NewDataVariableNames' and a cell array of strings. The default is strings based on the values of the grouping variable specified in `ivar`.

**'AggregationFunction' - Aggregation function from values in vars to single value**

function handle

Aggregation function from values in `vars` to single value, specified as the comma-separated pair consisting of 'AggregationFunction' and a function handle. `unstack` applies this function to rows from the same group that have the same value in `ivar`. The function must aggregate the data values into a single value.

For a numeric data variable, the default is `@sum`. For nonnumeric variables, there is no default function, and you must specify the 'AggregationFunction' name-value pair argument if multiple rows in the same group have the same value in `ivar`.

## Output Arguments

### **W - Wide table**

table

Wide table, returned as a table. *W* contains the unstacked data variables, the grouping variables, and the first value of each group from any constant variables.

The order of the data in *W* is based on the order of the unique values in the grouping variables.

You can store additional metadata such as descriptions, variable units, variable names, and row names in the table. For more information, see [Table Properties](#).

### **it - Index to T**

column vector

Index to *T*, returned as a column vector. For each row in *W*, the index vector, *it*, identifies the index of the first value in the corresponding group of rows in *T*.

## Examples

### **Separate One Variable into Three Variables**

Create a table indicating the amount of snowfall in various towns for various storms.

```
Storm = [3;3;1;3;1;1;4;2;4;2;4;2];
Town = {'T1';'T3';'T1';'T2';'T2';'T3';...
 'T2';'T1';'T3';'T3';'T1';'T2'};
Snowfall = [0;3;5;5;9;10;12;13;15;16;17;21];
```

```
T = table(Storm,Town,Snowfall)
```

```
T =
```

Storm	Town	Snowfall
3	'T1'	0

3	'T3'	3
1	'T1'	5
3	'T2'	5
1	'T2'	9
1	'T3'	10
4	'T2'	12
2	'T1'	13
4	'T3'	15
2	'T3'	16
4	'T1'	17
2	'T2'	21

T contains three snowfall entries for each storm, one for each town.

Separate the variable `Snowfall` into three variables, one for each town specified in the variable, `Town`.

```
W = unstack(T, 'Snowfall', 'Town')
```

W =

Storm	T1	T2	T3
3	0	5	3
1	5	9	10
4	17	12	15
2	13	21	16

Each row in `W` contains data from rows in `T` that have the same value in the grouping variable, `Storm`. The order of the unique values in `Storm` determines the order of the data in `W`.

### Apply Aggregation Function to Each Group

Unstack data and apply an aggregation function to multiple rows in the same group that have the same values in the indicator variable.

Create a table containing data on the price of two stocks over 2 days.

# unstack

---

```
Date = [repmat({'4/12/2008'},6,1);...
 repmat({'4/13/2008'},5,1)];
Stock = {'Stock1','Stock2','Stock1','Stock2';...
 'Stock2','Stock2','Stock1','Stock2';...
 'Stock2','Stock1','Stock2'};
Price = [60.35;27.68;64.19;25.47;28.11;27.98;...
 63.85;27.55;26.43;65.73;25.94];
```

```
T = table(Date,Stock,Price)
```

```
T =
```

Date	Stock	Price
'4/12/2008'	'Stock1'	60.35
'4/12/2008'	'Stock2'	27.68
'4/12/2008'	'Stock1'	64.19
'4/12/2008'	'Stock2'	25.47
'4/12/2008'	'Stock2'	28.11
'4/12/2008'	'Stock2'	27.98
'4/13/2008'	'Stock1'	63.85
'4/13/2008'	'Stock2'	27.55
'4/13/2008'	'Stock2'	26.43
'4/13/2008'	'Stock1'	65.73
'4/13/2008'	'Stock2'	25.94

T contains two prices for STOCK1 during the first day and four prices for STOCK2 during the first day.

Create a table containing separate variables for each stock and one row for each day. Use Date as the grouping variable and apply the aggregation function, @mean, to the numeric values from the variable, Price, for each group.

```
[W,it] = unstack(T,'Price','Stock',...
 'AggregationFunction',@mean)
```

W =

Date	Stock1	Stock2
'4/12/2008'	62.27	27.31
'4/13/2008'	64.79	26.64

it =

1  
7

W contains the average price for each stock grouped by date.

it identifies the index of the first value for each group of rows in T. The first value for the group '4/13/2008' is in the seventh row of T.

## Tips

- You can specify more than one data variable in T, and each variable becomes a set of unstacked data variables in W. Use a vector of positive integers, a cell array containing multiple variable names, or a logical vector to specify vars. The one indicator variable, specified by the input argument, ivar, applies to all data variables specified by vars.

## Definitions

### Grouping Variables

Grouping variables are utility variables used to group, or categorize, data. Grouping variables are useful for summarizing or visualizing data by group. You can define groups in your table by specifying one or more grouping variables.

A grouping variable can be any of the following:

- Categorical vector
- Cell array of strings
- Character array

# unstack

---

- Numeric vector, typically containing positive integers
- Logical vector

Rows that have the same grouping variable value belong to the same group. If you use multiple grouping variables, rows that have the same combination of grouping variable values belong to the same group.

## See Also

`stack` | `join`

**Purpose**

Extract contents of tar file

**Syntax**

```
untar(tarfilename)
untar(tarfilename,outputdir)
untar(url, ___)
filenames = untar(___)
```

**Description**

`untar(tarfilename)` extracts the archived contents of `tarfilename` into the current directory and sets the files' attributes. It overwrites any existing files with the same names as those in the archive if the existing files' attributes and ownerships permit it. For example, if you rerun `untar` on the same `tarfilename`, MATLAB software does not overwrite files with a read-only attribute; instead, `untar` displays a warning for such files. On Microsoft Windows platforms, the hidden, system, and archive attributes are not set.

`tarfilename` is a string specifying the name of the tar file. `tarfilename` is gunzipped to a temporary directory and deleted if its extension ends in `.tgz` or `.gz`. If an extension is omitted, `untar` searches for `tarfilename` appended with `.tgz`, `.tar.gz`, or `.tar`. `tarfilename` can include the directory name; otherwise, the file must be in the current directory or in a directory on the MATLAB path.

`untar(tarfilename,outputdir)` uncompresses the archive `tarfilename` into the directory `outputdir`. If `outputdir` does not exist, MATLAB creates it.

`untar(url, ___)` extracts the tar archive from an Internet URL. The URL must include the protocol type (for example, `'http://'` or `'ftp://'`). MATLAB downloads the URL to a temporary directory, and then deletes it.

`filenames = untar( ___)` extracts the tar archive and returns the names of the extracted files in the string cell array `filenames`. If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

## Examples

### Using tar and untar to Copy Files

Copy all .m files in the current directory to the directory backup.

```
tar('myfiles.tar.gz','*.m');
untar('myfiles','backup');
```

### Using untar with URL

Run untar to list Cleve Moler's "Numerical Computing with MATLAB" examples to the output directory ncm.

```
url = 'http://www.mathworks.com/moler/ncm.tar.gz';
ncmFiles = untar(url,'ncm')
```

## See Also

gzip | gunzip | tar | unzip | zip

**Purpose** Correct phase angles to produce smoother phase plots

**Syntax**

```
Q = unwrap(P)
Q = unwrap(P,tol)
Q = unwrap(P,[],dim)
Q = unwrap(P,tol,dim)
```

**Description** `Q = unwrap(P)` corrects the radian phase angles in a vector `P` by adding multiples of  $\pm 2\pi$  when absolute jumps between consecutive elements of `P` are greater than or equal to the default jump tolerance of  $\pi$  radians. If `P` is a matrix, `unwrap` operates columnwise. If `P` is a multidimensional array, `unwrap` operates on the first nonsingleton dimension.

`Q = unwrap(P,tol)` uses a jump tolerance `tol` instead of the default value,  $\pi$ .

`Q = unwrap(P,[],dim)` unwraps along `dim` using the default tolerance.

`Q = unwrap(P,tol,dim)` uses a jump tolerance of `tol`.

---

**Note** A jump tolerance less than  $\pi$  has the same effect as a tolerance of  $\pi$ . For a tolerance less than  $\pi$ , if a jump is greater than the tolerance but less than  $\pi$ , adding  $\pm 2\pi$  would result in a jump larger than the existing one, so `unwrap` chooses the current point. If you want to eliminate jumps that are less than  $\pi$ , try using a finer grid in the domain.

---

## Examples

### Example 1

The following phase data comes from the frequency response of a third-order transfer function. The phase curve jumps 3.5873 radians between  $w = 3.0$  and  $w = 3.5$ , from -1.8621 to 1.7252.

```
w = [0:.2:3,3.5:1:10];
p = [0
 -1.5728
 -1.5747
 -1.5772
```

```
-1.5790
-1.5816
-1.5852
-1.5877
-1.5922
-1.5976
-1.6044
-1.6129
-1.6269
-1.6512
-1.6998
-1.8621
1.7252
1.6124
1.5930
1.5916
1.5708
1.5708
1.5708];
semilogx(w,p,'b*-'), hold
```

Using `unwrap` to correct the phase angle, the resulting jump is 2.6959, which is less than the default jump tolerance  $\pi$ . This figure plots the new curve over the original curve.

```
semilogx(w,unwrap(p),'r*-')
```

# unwrap

## Example 2

Array P features smoothly increasing phase angles except for discontinuities at elements (3,1) and (1,2).

```
P = [0 7.0686 1.5708 2.3562
 0.1963 0.9817 1.7671 2.5525
 6.6759 1.1781 1.9635 2.7489
 0.5890 1.3744 2.1598 2.9452]
```

The function  $Q = \text{unwrap}(P)$  eliminates these discontinuities.

```
Q =
 0 7.0686 1.5708 2.3562
 0.1963 7.2649 1.7671 2.5525
 0.3927 7.4613 1.9635 2.7489
 0.5890 7.6576 2.1598 2.9452
```

**See Also**

abs | angle

# unzip

---

## Purpose

Extract contents of zip file

## Syntax

```
unzip(zipfilename)
unzip(zipfilename,outputdir)
filenames = unzip(zipfilename,outputdir)
```

## Description

`unzip(zipfilename)` extracts the archived contents of `zipfilename` into the current folder, preserving the files' attributes and timestamps. The `unzip` function can extract files from your local system or files from an Internet URL.

`unzip(zipfilename,outputdir)` extracts the contents of `zipfilename` into the folder `outputdir`.

`filenames = unzip(zipfilename,outputdir)` returns the names of the extracted files in the string cell array `filenames`. Specifying `outputdir` is optional.

## Tips

- `unzip` does not support password-protected or encrypted zip archives.
- If any files in the target folder have the same name as files in the zip file, and you have write permission to the files, `unzip` overwrites the existing files with the archived versions. If you do not have write permission, `unzip` issues a warning.
- Extract files that contain non-7-bit ASCII characters on a machine that has the appropriate language/encoding settings.

## Input Arguments

### **zipfilename**

String that specifies the name of the zip file.

If `zipfilename` does not include the full path, `unzip` searches for the file in the current folder and along the MATLAB path. If you do not specify the file extension, `unzip` appends `.zip`.

If you are downloading a URL, `zipfilename` must include the protocol type (for example, `http://`). The `unzip` function downloads the URL to the temporary folder on your system, and deletes the URL on cleanup.

**outputdir**

String that specifies the target folder for the extracted files.

**Default:** current folder ('.')

**Output Arguments****entrynames**

Cell array of strings that contain the paths of the extracted files.

If `outputdir` specifies a relative path, `filenames` contains the relative path. If `outputdir` specifies an absolute path, `filenames` contains the absolute path.

**Examples**

Copy the example MAT-files to the folder archive:

```
% Zip the example MAT-files to examples.zip
zip('examples.zip','*.mat',...
 fullfile(matlabroot,'toolbox','matlab','demos'))
```

```
% Unzip examples.zip to the folder 'archive'
unzip('examples','archive')
```

---

Download Cleve Moler's "Numerical Computing with MATLAB" examples to the output folder ncm:

```
url = 'http://www.mathworks.com/moler/ncm.zip';
ncmFiles = unzip(url,'ncm')
```

**Alternatives**

To extract files from a zip file using the Current Folder browser, select the zip file, right-click to open the context menu, and then select **Extract**.

**See Also**

`fileattrib` | `gzip` | `gunzip` | `tar` | `untar` | `zip`

# uplus, +

---

**Purpose** Unary plus

**Syntax**  
C = +A  
C = uplus(A)

**Description** C = +A returns array A and stores it in C.

C = uplus(A) is an alternate way to execute +A, but is rarely used. It enables operator overloading for classes.

**Input Arguments** **A - Input array**  
scalar | vector | matrix | multidimensional array  
Input array, specified as a scalar, vector, matrix, or multidimensional array.

**Data Types**  
single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char  
**Complex Number Support:** Yes

**Examples** **Unary Plus of Matrix**

Create a 2-by-2 matrix, A.

```
A = [1 -3; -2 4]
```

```
A =
```

```
 1 -3
 -2 4
```

Use unary plus on A.

```
C = +A
```

```
C =
```

1 -3  
-2 4

C and A are the same.

**See Also**

uminus | plus

# upper

---

**Purpose** Convert string to uppercase

**Syntax** `t = upper('str')`  
`B = upper(A)`

**Description** `t = upper('str')` converts any lowercase characters in the string `str` to the corresponding uppercase characters and leaves all other characters unchanged.

`B = upper(A)` when `A` is a cell array of strings, returns a cell array the same size as `A` containing the result of applying `upper` to each string within `A`.

**Examples** `upper('attention!')` is ATTENTION!.

**Tips** Character sets supported:

- PC: Windows Latin-1
- Other: ISO Latin-1 (ISO 8859-1)

**See Also** `lower`

**Purpose** Download URL content to MATLAB string

**Syntax**

```
str = urlread(URL)
str = urlread(URL,Name,Value)
[str,status] = urlread(___)
```

**Description** `str = urlread(URL)` downloads the HTML Web content from the specified URL into the string `str`. `urlread` does not retrieve hyperlink targets and images.

`str = urlread(URL,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[str,status] = urlread( ___ )` suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0

## Input Arguments

### URL - Content location

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

**Example:** `'http://www.mathworks.com/matlabcentral'`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

### 'Get' - Data to send to the Web form using the GET method

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of 'get' and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Get' includes the data in the URL, separated by ? and & characters.

**Example:** 'Get', {'term', 'urlread'}

## **'Post' - Data to send to the Web form using the POST method**

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of 'post' and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

'Post' submits the data as part of the request headers, not explicitly in the URL.

## **'Charset' - Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of 'Charset' and a string. If you do not specify Charset, the function attempts to determine the character encoding from the headers of the file. If the character encoding cannot be determined, Charset defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

**Example:** 'Charset', 'ISO-8859-1'

## **'Timeout' - Timeout duration**

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of 'Timeout' and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

**Example:** 'Timeout',10

### **'UserAgent' - Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

**Example:** 'UserAgent', 'MATLAB R2012b'

### **'Authentication' - HTTP authentication mechanism**

'Basic'

HTTP authentication mechanism, specified as the comma-separated pair consisting of 'Authentication' and a string. Currently, only the value 'Basic' is supported. 'Authentication', 'Basic' specifies basic authentication.

If you include the Authentication argument, you must also include the Username and Password arguments.

### **'Username' - User identifier**

string

User identifier, specified as the comma-separated pair consisting of 'Username' and a string. If you include the Username argument, you must also include the Password and Authentication arguments.

**Example:** 'Username', 'myName'

### **'Password' - User authentication password**

string

User authentication password, specified as the comma-separated pair consisting of 'Password' and a string. If you include the Password argument, you must also include the Username and Authentication arguments.

**Example:** 'Password', 'myPassword123'

# urlread

---

## Output Arguments

### **str - Contents of the file at the specified URL**

string

Contents of the file at the specified URL, returned as a string. For example, if the URL corresponds to an HTML page, `str` contains the text and markup in the HTML file. If the URL corresponds to a binary file, `str` is not readable.

### **status - Download status**

1 | 0

Download status, returned as either 1 or 0. When the download is successful, `status` is 1. Otherwise, `status` is 0.

## Examples

### **Download Web Content by Specifying Complete URL**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlread'];
str = urlread(fullURL);
```

`urlread` reads from the specified URL and downloads the HTML content to the string `str`.

### **Download Web Content Related to a Term**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlread`.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
str = urlread(URL, 'Get', {'term', 'urlread'});
```

`urlread` reads from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlread` and downloads the HTML content to the string `str`.

### Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlread'];
str = urlread(fullURL,'Timeout',5);
```

### Tips

- urlread saves Web content to a string. To save content to a file, use urlwrite.
- urlread and urlwrite can download content from FTP sites. Alternatively, use the ftp function to connect to an FTP server and the mget function to download a file.

### See Also

urlwrite | ftp | web | mget

### Concepts

- “Specify Proxy Server Settings for Connecting to the Internet”

# urlwrite

---

**Purpose** Download URL content and save to file

**Syntax** `urlwrite(URL,filename)`  
`urlwrite(URL,filename,Name,Value)`  
  
`[filestr,status] = urlwrite( __ )`

**Description** `urlwrite(URL,filename)` reads Web content at the specified URL and saves it to the file specified by `filename`.

`urlwrite(URL,filename,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[filestr,status] = urlwrite( __ )` stores the file path in variable `filestr`, and suppresses the display of error messages, using any of the input arguments in the previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0.

## Input Arguments

### **URL - Content location**

string

Content location, specified as a string. Include the transfer protocol, such as `http`, `ftp`, or `file`.

**Example:** `'http://www.mathworks.com/matlabcentral'`

### **filename - Name of file to store Web content**

string

Name of the file to store the Web content, specified as a string. If you do not specify the path for `filename`, `urlwrite` saves the file in the current folder.

**Example:** `'myfile.html'`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Timeout',10,'Charset','UTF-8'` specifies that `urlread` should time out after 10 seconds, and the character encoding of the file is UTF-8.

## **'Get' - Data to send to the Web form using the GET method**

cell array

Parameters of the data to send to the Web form using the GET method, specified as the comma-separated pair consisting of `'get'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Get'` includes the data in the URL, separated by `?` and `&` characters.

**Example:** `'Get',{'term','urlread'}`

## **'Post' - Data to send to the Web form using the POST method**

cell array

Parameters of the data to send to the Web form using the POST method, specified as the comma-separated pair consisting of `'post'` and a cell array of paired parameter names and values. The supported parameters depend upon the URL.

`'Post'` submits the data as part of the request headers, not explicitly in the URL.

## **'Charset' - Character encoding**

string

Character encoding, specified as the comma-separated pair consisting of `'Charset'` and a string. If you do not specify `Charset`, the function attempts to determine the character encoding from the headers of the

file. If the character encoding cannot be determined, Charset defaults to the native encoding for the file protocol, and UTF-8 for all other protocols.

**Example:** 'Charset', 'ISO-8859-1'

## **'Timeout' - Timeout duration**

scalar

Timeout duration in seconds, specified as the comma-separated pair consisting of 'Timeout' and a scalar. The timeout duration determines when the function errors rather than continues to wait for the server to respond or send data.

**Example:** 'Timeout', 10

## **'UserAgent' - Client user agent identification**

string

Client user agent identification, specified as the comma-separated pair consisting of 'UserAgent' and a string.

**Example:** 'UserAgent', 'MATLAB R2012b'

## **'Authentication' - HTTP authentication mechanism**

'Basic'

HTTP authentication mechanism, specified as the comma-separated pair consisting of 'Authentication' and a string. Currently, only the value 'Basic' is supported. 'Authentication', 'Basic' specifies basic authentication.

If you include the Authentication argument, you must also include the Username and Password arguments.

## **'Username' - User identifier**

string

User identifier, specified as the comma-separated pair consisting of 'Username' and a string. If you include the Username argument, you must also include the Password and Authentication arguments.

**Example:** 'Username', 'myName'

### **'Password' - User authentication password**

string

User authentication password, specified as the comma-separated pair consisting of 'Password' and a string. If you include the Password argument, you must also include the Username and Authentication arguments.

**Example:** 'Password', 'myPassword123'

## **Output Arguments**

### **filestr - Path of the file**

string

Path of the file specified by filename, returned as a string.

### **status - Download status**

1 | 0

Download status, returned as either 1 or 0. When the download is successful, status is 1. Otherwise, status is 0.

## **Examples**

### **Download Web Content by Specifying Complete URL**

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to urlwrite. Save the results to samples.html in the current directory.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename);
```

View the file.

```
web(filename)
```

## Download Web Content Related to a Term

Download the HTML for the page on the MATLAB Central File Exchange that lists submissions related to `urlwrite`. Save the results to `samples.html` in the current directory.

```
URL = 'http://www.mathworks.com/matlabcentral/fileexchange';
filename = 'samples.html';
urlwrite(URL,filename,'get',{'term','urlwrite'});
```

`urlwrite` downloads the HTML content from `http://www.mathworks.com/matlabcentral/fileexchange/?term=urlwrite` and writes it to `samples.html`.

## Specify Timeout Duration

Download content from a page on the MATLAB Central File Exchange as in the first example, and specify a timeout duration of 5 seconds.

```
fullURL = ['http://www.mathworks.com/matlabcentral/fileexchange' ...
 '?term=urlwrite'];
filename = 'samples.html';
urlwrite(fullURL,filename,'Timeout',5);
```

### Tips

- `urlread` and `urlwrite` can download content from FTP sites. Alternatively, use the `ftp` function to connect to an FTP server and the `mget` function to download a file.

`urlread` | `mget` | `web` | `ftp`

### Concepts

- “Specify Proxy Server Settings for Connecting to the Internet”

<b>Purpose</b>	Determine if Java feature is available								
<b>Syntax</b>	<code>tf = usejava(feature)</code>								
<b>Description</b>	<code>tf = usejava(feature)</code> returns logical 1 (true) if the specified feature is supported. Otherwise, it returns logical 0 (false). Use for error handling if Java feature is unavailable.								
<b>Input Arguments</b>	<p><b>feature - Java feature</b> 'awt'   'desktop'   'jvm'   'swing'</p> <p>Java feature, specified as one of these values:</p> <table><tr><td>'awt'</td><td>Java GUI components in the Abstract Window Toolkit (AWT) components are available.</td></tr><tr><td>'desktop'</td><td>MATLAB interactive desktop is running.</td></tr><tr><td>'jvm'</td><td>Java Virtual Machine software (JVM) is running.</td></tr><tr><td>'swing'</td><td>Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.</td></tr></table>	'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.	'desktop'	MATLAB interactive desktop is running.	'jvm'	Java Virtual Machine software (JVM) is running.	'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.
'awt'	Java GUI components in the Abstract Window Toolkit (AWT) components are available.								
'desktop'	MATLAB interactive desktop is running.								
'jvm'	Java Virtual Machine software (JVM) is running.								
'swing'	Swing components (Java lightweight GUI components in the Java Foundation Classes) are available.								
<b>Examples</b>	<p><b>Display Error Message</b></p> <p>Use the following code snippet to test that the AWT GUI components are available before attempting to display a Java Frame.</p> <pre>if usejava('awt')     myFrame = java.awt.Frame; else     disp('Unable to open a Java Frame'); end</pre>								

If the AWT is not available on your system, MATLAB displays the message.

## Call error Function

Use the following code snippet to terminate a script if MATLAB does not have access to JVM software.

The variable, `filename`, is a function that contains Java code.

```
if ~usejava('jvm')
 error([filename ' requires Java to run.']);
end
```

## See Also

`javachk` | `error`

## Concepts

- “Bringing Java Classes into MATLAB Workspace”

**Purpose** View or change user portion of search path

**Syntax** `userpath`

```
userpath(newpath)
userpath('reset')
userpath('clear')
```

**Description** `userpath` returns a string specifying the first folder on the search path. MATLAB adds the *userpath* to the search path upon startup.

`userpath(newpath)` sets the primary *userpath* folder to `newpath`. The `newpath` folder appears at the top of the search path immediately and at startup in future sessions. MATLAB removes the folder previously specified by *userpath* from the search path.

`userpath('reset')` sets the primary *userpath* folder to the default for that platform, creating the Documents/MATLAB (or My Documents/MATLAB) folder, if it does not exist. MATLAB immediately adds the default folder to the top of the search path, and also adds it to the search path at startup in future sessions. On Linux, the MATLAB directory is not created if the Documents directory does not exist.

`userpath('clear')` clears the value for the primary *userpath* immediately, and for future MATLAB sessions. MATLAB removes the folder previously specified by *userpath* from the search path.

## Input Arguments

### **newpath - New userpath value**

string

New userpath value, specified as a string. `newpath` must be an absolute path.

**Example:** 'C:\myFolder'

## Examples

### View userpath Folder

This example assumes *userpath* is set to the default value on the Windows XP platform, My Documents\MATLAB. Start MATLAB and display the current folder:

```
pwd
```

```
H:\My Documents\MATLAB
```

In this example, H is the drive at which My Documents is located.

Confirm that the current folder is the *userpath*.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Display the search path.

```
path
```

```
MATLABPATH
```

```
H:\My Documents\MATLAB
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB returns the search path. The *userpath* portion is at the top.

### Set New Value for userpath

Assume *userpath* is set to the default value on the Windows XP platform, My Documents\MATLAB. Change the value from the default for *userpath* to C:\Research\_Project.

```
newpath = 'C:\Research_Project';
userpath(newpath)
```

View the effect of the change on the search path.

```
path
```

```
MATLABPATH
```

```
C:\Research_Project
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

MATLAB displays the search path, with the new value for *userpath* portion at the top. Note that MATLAB automatically removed the previous value of *userpath*, H:\My Documents\MATLAB, from the search path when you assigned a new value to *userpath*.

### **Clear the Value for userpath**

Assume *userpath* is set to the default value and you do not want any folders to be added to the search path upon startup. Confirm the default is currently set.

```
userpath
```

```
H:\My Documents\MATLAB;
```

Verify that the *userpath* folder is at the top of the search path.

```
path
```

```
MATLABPATH
```

```
H:\My Documents\MATLAB
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

Clear the value.

```
userpath('clear')
```

# userpath

---

Verify the result.

```
userpath
```

```
ans =
 ''
```

Confirm the *userpath* folder was removed from the search path.

```
path
```

```
MATLABPATH
```

```
C:\Program Files\MATLAB\R2009a\toolbox\matlab\general
C:\Program Files\MATLAB\R2009a\toolbox\matlab\ops
...
```

---

**Note** By default, the startup folder is the *userpath* folder when you start MATLAB by double-clicking the shortcut on Windows platforms, or by double-clicking the application on Macintosh platforms. If you clear the value for *userpath*, the startup folder will not necessarily be on the search path. Removing the *userpath* folder from the search path *and* saving the changes to the path has the same effect.

---

## Tips

- On Macintosh and UNIX platforms, you can automatically add subfolders to the top of the search path upon startup by specifying the path for the subfolders via the MATLABPATH environment variable.

## See Also

[addpath](#) | [path](#) | [rmpath](#) | [savepath](#) | [startup](#)

## Concepts

- “What Is the MATLAB Search Path?”
- “MATLAB Startup Folder”

## Purpose

Check validity of array

## Syntax

```
validateattributes(A,classes,attributes)
validateattributes(A,classes,attributes,argIndex)
validateattributes(A,classes,attributes,funcName)
validateattributes(A,classes,attributes,funcName,varName)
validateattributes(A,classes,attributes,funcName,varName,argIndex)
```

## Description

`validateattributes(A,classes,attributes)` validates that array `A` belongs to at least one of the specified classes (or its subclass) and has all of the specified attributes. If `A` does not meet the criteria, MATLAB throws an error and displays a formatted error message. Otherwise, `validateattributes` completes without displaying any output.

`validateattributes(A,classes,attributes,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validateattributes(A,classes,attributes,funcName)` includes the specified function name in generated error identifiers.

`validateattributes(A,classes,attributes,funcName,varName)` includes the specified variable name in generated error messages.

`validateattributes(A,classes,attributes,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

## Input Arguments

### **A** - Input

any type of array

Input, specified as any type of array.

# validateattributes

---

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64 | logical | char | struct | cell  
| function\_handle

**Complex Number Support:** Yes

## classes - Valid data types

cell array of strings

Valid data types, specified as a cell array of strings. Each string can be the name of any built-in or custom class, including:

'single'	Single-precision number
'double'	Double-precision number
'int8'	Signed 8-bit integer
'int16'	Signed 16-bit integer
'int32'	Signed 32-bit integer
'int64'	Signed 64-bit integer
'uint8'	Unsigned 8-bit integer
'uint16'	Unsigned 16-bit integer
'uint32'	Unsigned 32-bit integer
'uint64'	Unsigned 64-bit integer
'logical'	Logical true or false
'char'	Character or string
'struct'	Structure array
'cell'	Cell array
'function_handle'	function handle

'numeric'	Any data type for which the <code>isa(A, 'numeric')</code> function returns true, including <code>int8</code> , <code>int16</code> , <code>int32</code> , <code>int64</code> , <code>uint8</code> , <code>uint16</code> , <code>uint32</code> , <code>uint64</code> , <code>single</code> , or <code>double</code>
'<class_name>'	Any other class name

## Data Types

`cell`

### attributes - Valid attributes

`cell` array of strings

Valid attributes, specified as a `cell` array of strings.

Some attributes also require numeric values, such as attributes that specify the size or number of elements of `A`. For these attributes, the numeric value or vector must immediately follow the attribute name string in the `cell` array.

Attributes that describe the size and shape of array `A`:

'2d'	Two-dimensional array, including scalars, vectors, matrices, and empty arrays
'3d'	Array with three or fewer dimensions
'column'	Column vector, N-by-1
'row'	Row vector, 1-by-N
'scalar'	Scalar value, 1-by-1
'vector'	Row or column vector, or a scalar value
'size', [d1,...,dN]	Array with dimensions d1-by-...-by-dN. To skip checking a particular dimension, specify NaN for that dimension, such as [3,4,NaN,2].
'numel', N	Array with N elements
'ncols', N	Array with N columns

# validateattributes

---

'nrows', N	Array with N rows
'ndims', N	N-dimensional array
'square'	Square matrix; in other words, a two-dimensional array with equal number of rows and columns
'diag'	Diagonal matrix
'nonempty'	No dimensions that equal zero
'nonsparse'	Array that is not sparse

Attributes that specify valid ranges for values in A:

'>', N	All values greater than N
'>=', N	All values greater than or equal to N
'<', N	All values less than N
'<=', N	All values less than or equal to N

Attributes that check types of values in a numeric or logical array, A:

'binary'	Array of ones and zeros
'even'	Array of even integers (includes zero)
'odd'	Array of odd integers
'integer'	Array of integer values
'real'	Array of real values
'finite'	Array of finite values
'nonnan'	No NaN (Not a Number) elements
'nonnegative'	No elements less than zero
'nonzero'	No elements equal to zero

'positive'	No elements less than or equal to zero
'decreasing'	Each element of a column is less than the previous element and no element is NaN
'increasing'	Each element of a column is greater than the previous element and no element is NaN
'nondecreasing'	Each element of a column is greater than or equal to the previous element and no element is NaN
'nonincreasing'	Each element of a column is less than or equal to the previous element and no element is NaN

## Data Types

cell

### **funcName - Name of function whose input you are validating**

string

Name of function whose input you are validating, specified as a string. If you specify an empty string, '', the validateattribute function ignores the funcName input.

## Data Types

char

### **varName - Name of input variable**

string

Name of input variable, specified as a string. If you specify an empty string, '', the validateattribute function ignores the varName input.

## Data Types

char

### **argIndex - Position of input argument**

positive integer

Position of input argument, specified as a positive integer.

# validateattributes

---

## Data Types

double

## Examples

### Validate the Size of an Array

```
classes = {'numeric'};
attributes = {'size',[4,6,2]};
```

```
A = rand(3,5,2);
validateattributes(A,classes,attributes)
```

Expected input to be of size 4x6x2 when it is actually size 3x5x2.

Because A did not match the specified attributes, MATLAB throws an error message.

### Validate Array Monotonicity

Determine if an array is increasing or nondecreasing.

```
A = [1 5 8 2;
 9 6 9 4]
validateattributes(A, {'double'},{'nondecreasing'})
validateattributes(A, {'double'},{'increasing'})
```

A =

```
 1 5 8 2
 9 6 9 4
```

Since A is both increasing and nondecreasing, `validateattributes` does not throw an error for either attribute check.

Setting `A(2,3)` equal to `A(1,3)` results in a column that is no longer strictly increasing, so `validateattributes` throws an error.

```
A(2,3) = 8
validateattributes(A, {'double'},{'increasing'})
```

A =

```
 1 5 8 2
 9 6 8 4
```

Expected input to be increasing valued.

However, the columns remain nondecreasing since each column element is equal to or greater than the next. The following code does not throw an error.

```
validateattributes(A, {'double'}, {'nondecreasing'})
```

## Check the Attributes of a Complex Number

Assuming that `a` is to be the second input argument to a function, check that it is nonnegative.

```
a = complex(1,1);
validateattributes(a, {'numeric'}, {'nonnegative'}, 2);
```

Expected input number 2 to be nonnegative.

Because complex numbers lack a well-defined ordering in the complex plane, `validateattributes` does not recognize them as positive or negative.

## Ensure Array Values Are Within a Specified Range

Check that the values in an array are 8-bit integers between 0 and 10.

Assume that this code occurs in a function called `Rankings`.

```
classes = {'uint8', 'int8'};
attributes = {'>', 0, '<', 10};
funcName = 'Rankings';
A = int8(magic(4));
```

```
validateattributes(A, classes, attributes, funcName)
```

# validateattributes

---

Error using Rankings

Expected input to be an array with all of the values < 10.

## Validate Function Input Parameters Using inputParser

Create a custom function that checks input parameters with `inputParser`, and use `validateattributes` as the validating function for the `addRequired` and `addOptional` methods.

Define the function.

```
function a = findArea(shape,dim1,varargin)
 p = inputParser;
 charchk = {'char'};
 numchk = {'numeric'};
 nempty = {'nonempty'};

 addRequired(p,'shape',@(x)validateattributes(x,charchk,nempty));
 addRequired(p,'dim1',@(x)validateattributes(x,numchk,nempty));
 addOptional(p,'dim2',1,@(x)validateattributes(x,numchk,nempty));
 parse(p,shape,dim1,varargin{:});

 switch shape
 case 'circle'
 a = pi * dim1.^2;
 case 'rectangle'
 a = dim1 .* p.Results.dim2;
 end
end
```

Call the function with a nonnumeric third input.

```
myarea = findArea('rectangle',3,'x')
```

Error using findArea (line 10)

Argument 'dim2' failed validation with error:

Expected input to be one of these types:

double, single, uint8, uint16, uint32, uint64, int8, int16, int32, int64

Instead its type was char.

## Validate Arguments of a Function

Check the inputs of a function and include information about the input name and position in generated error.

Define the function.

```
function v = findVolume(shape,ht,wd,ln)
 validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
 validateattributes(ht,{'numeric'},{'nonempty'},mfilename,'Height',2)
 validateattributes(wd,{'numeric'},{'nonempty'},mfilename,'Width',3)
 validateattributes(ln,{'numeric'},{'nonempty'},mfilename,'Length',4)
```

Call the function without the shape input string.

```
vol = findVolume(10,7,4)
```

```
Error using findVolume
Expected input number 1, Shape, to be one of these types:
```

```
char
```

Instead its type was double.

```
Error in findVolume (line 2)
validateattributes(shape,{'char'},{'nonempty'},mfilename,'Shape',1)
```

The function name becomes part of the error identifier.

```
MException.last.identifier
```

```
ans =
```

```
MATLAB:findVolume:invalidType
```

## See Also

[validatestring](#) | [is\\*](#) | [isa](#) | [isnumeric](#) | [inputParser](#)

# validatestring

---

**Purpose** Check validity of text string

**Syntax**

```
validStr = validatestring(str,validStrings)
validStr = validatestring(str,validStrings,argIndex)
validStr = validatestring(str,validStrings,funcName)
validStr =
validatestring(str,validStrings,funcName,varName)
validStr =
validatestring(str,validStrings,funcName,varName,argIndex)
```

**Description** `validStr = validatestring(str,validStrings)` checks the validity of text string `str`. If `str` is an unambiguous, case-insensitive match to a string in cell array `validStrings`, the `validatestring` function returns the matching string in `validStr`. Otherwise, MATLAB throws an error and issues a formatted error message.

`validStr = validatestring(str,validStrings,argIndex)` includes the position of the input in your function argument list as part of any generated error messages.

`validStr = validatestring(str,validStrings,funcName)` includes the specified function name in generated error identifiers.

`validStr = validatestring(str,validStrings,funcName,varName)` includes the specified variable name in generated error messages.

`validStr = validatestring(str,validStrings,funcName,varName,argIndex)` includes the specified information in generated error messages or identifiers.

**Input Arguments**

**str**  
String to validate, of type `char`.

**validStrings**  
Cell array of allowed strings.

## funcName

String that specifies the name of the function whose input you are validating. If you specify an empty string, '', the validatestring function ignores the funcname input.

## varName

String that specifies the name of the input variable. If you specify an empty string, '', the validatestring function ignores the varName input.

## argIndex

Positive integer that specifies the position of the input argument.

## Output Arguments

### validStr

String that contains the element of validStrings that is an unambiguous, case-insensitive match to str.

Example – Match 'ball' with . . .	Return Value	Type of Match
ball, barn, bell	ball	Exact match
balloon, barn	balloon	Partial match (leading characters)
ballo, balloo, balloon	ballo (shortest match)	Multiple partial matches where each string is a subset of another
balloon, ballet	Error	Multiple partial matches to unique strings
barn, bell	Error	No match

## Examples

Check whether a string is in a set of valid values.

```
str = 'won';
```

# validatestring

---

```
validStrings = {'wind', 'wonder', 'when'};
```

```
validStr = validatestring(str, validStrings)
```

Because `str` is a partial match to a unique string, this code returns

```
validStr =
 wonder
```

However, if `str` is a partial match to multiple strings, and the strings are not subsets of each other, `validatestring` throws an error and displays a formatted message.

```
str = 'won';
validStrings = {'wonder', 'wondrous', 'wonderful'};
```

```
validStr = validatestring(str, validStrings)
```

The error message is

Expected argument to match one of these strings:

```
wonder, wondrous, wonderful
```

The input, `'won'`, matched more than one valid string.

---

Check inputs to a custom function, and include information about the input name and position in generated errors.

```
function a = findArea(shape, ht, wd, units)
```

```
 a = 0;
 expectedShapes = {'square', 'rectangle', 'triangle'};
 expectedUnits = {'cm', 'm', 'in', 'ft', 'yds'};
```

```
 shapeName = validatestring(shape, expectedShapes, mfilename, 'Shape', 1)
 unitAbbrev = validatestring(units, expectedUnits, mfilename, 'Units', 4)
```

When you call the function with valid input strings,

```
myarea = findArea('rect',10,3,'cm')
```

the function stores the inputs in local variables `shapeName` and `unitAbbrev`:

```
shapeName =
 rectangle
```

```
unitAbbrev =
 cm
```

However, if the inputs are not valid, such as

```
myarea = findArea('circle',10,3,'cm')
```

MATLAB displays

```
Error using findArea
Expected argument 1, Shape, to match one of these strings:
```

```
 square, rectangle, triangle
```

The input, 'circle', did not match any of the valid strings.

The function name is part of the error identifier, so

```
MException.last.identifier
```

```
returns
```

```
MATLAB:findArea:unrecognizedStringChoice
```

## See Also

[validateattributes](#) | [is\\*](#) | [isa](#) | [inputParser](#)

# containers.Map.values

---

**Purpose** Identify values in containers.Map object

**Syntax**  
`valueSet = values(mapObj)`  
`valueSet = values(mapObj, keySet)`

**Description** `valueSet = values(mapObj)` returns all of the values in `mapObj`.  
`valueSet = values(mapObj, keySet)` returns values that correspond to the specified keys.

**Input Arguments**  
**mapObj**  
Object of class `containers.Map`.

**keySet**  
Cell array that specifies keys in `mapObj`.

**Output Arguments**  
**valueSet**  
Cell array containing values from `mapObj`. If you specify `keySet`, the `valueSet` array has the same size and dimensions as `keySet`.

## Examples **Get All Values in a Map**

Create a map, and view all values in the map:

```
myKeys = {'a', 'b', 'c'};
myValues = [1, 2, 3];
mapObj = containers.Map(myKeys, myValues);
```

```
valueSet = values(mapObj)
```

This code returns 1-by-3 cell array `valueSet`:

```
valueSet =
 [1] [2] [3]
```

## Get Selected Values in a Map

View the values corresponding to keys a and c in `mapObj`, created in the previous example:

```
keySet = {'a', 'c'};
valueSet = values(mapObj, keySet)
```

This code returns 1-by-2 cell array `valueSet`:

```
valueSet =
 [1] [3]
```

## See Also

`containers.Map` | `keys` | `isKey`

# vander

---

**Purpose** Vandermonde matrix

**Syntax** `A = vander(v)`

**Description** `A = vander(v)` returns the Vandermonde matrix whose columns are powers of the vector `v`, that is,  $A(i, j) = v(i)^{(n-j)}$ , where  $n = \text{length}(v)$ .

**Examples** `vander(1:.5:3)`

ans =

1.0000	1.0000	1.0000	1.0000	1.0000
5.0625	3.3750	2.2500	1.5000	1.0000
16.0000	8.0000	4.0000	2.0000	1.0000
39.0625	15.6250	6.2500	2.5000	1.0000
81.0000	27.0000	9.0000	3.0000	1.0000

**See Also** `gallery`

**Purpose**

Variance

**Syntax**

```
V = var(X)
V = var(X,1)
V = var(X,w)
V = var(X,w,dim)
```

**Description**

`V = var(X)` returns the variance of `X` for vectors. For matrices, `var(X)` is a row vector containing the variance of each column of `X`. For `N`-dimensional arrays, `var` operates along the first nonsingleton dimension of `X`. The result `V` is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples.

`var` normalizes `V` by  $N - 1$  if  $N > 1$ , where  $N$  is the sample size. This is an unbiased estimator of the variance of the population from which `X` is drawn, as long as `X` consists of independent, identically distributed samples. For  $N = 1$ , `V` is normalized by 1.

`V = var(X,1)` normalizes by  $N$  and produces the second moment of the sample about its mean. `var(X,0)` is equivalent to `var(X)`.

`V = var(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `var` operates, and its elements must be nonnegative. If `X(i)` is assumed to have variance proportional to  $1/w(i)$ , then  $V * \text{mean}(w)/w(i)$  is an estimate of the variance of `X(i)`. In other words,  $V * \text{mean}(w)$  is an estimate of variance for an observation given weight 1.

`V = var(X,w,dim)` takes the variance along the dimension `dim` of `X`. Pass in 0 for `w` to use the default normalization by  $N - 1$ , or 1 to use  $N$ .

The variance is the square of the standard deviation (STD).

**Examples**

Create a matrix and find the variance along the dimensions.

```
X = [4 -2 1; 9 5 7]
var(X,0,1)
ans =
```

## var

---

```
12.5000 24.5000 18.0000
```

```
var(X,0,2)
```

```
ans =
```

```
9
```

```
4
```

**Purpose** Variable-length input argument list

**Syntax** varargin

**Description** varargin is an input variable in a function definition statement that allows the function to accept any number of input arguments. Specify varargin using lowercase characters, and include it as the last input argument after any explicitly declared inputs. When the function executes, varargin is a 1-by- $N$  cell array, where  $N$  is the number of inputs that the function receives after the explicitly declared inputs.

## Examples **Variable Number of Function Inputs**

Define a function in a file named varlist.m that accepts a variable number of inputs and displays the values of each input.

```
function varlist(varargin)
 fprintf('Number of arguments: %d\n',nargin);
 celldisp(varargin)
```

Call varlist with several inputs.

```
varlist(ones(3),'some text',pi)
```

```
Number of arguments: 3
```

```
varargin{1} =
 1 1 1
 1 1 1
 1 1 1
```

```
varargin{2} =
some text
```

```
varargin{3} =
3.1416
```

# varargin

---

## varargin and Declared Inputs

Define a function in a file named `varlist2.m` that expects inputs `X` and `Y`, and accepts a variable number of additional inputs.

```
function varlist2(X,Y,varargin)
 fprintf('Total number of inputs = %d\n',nargin);

 nVarargs = length(varargin);
 fprintf('Inputs in varargin(%d):\n',nVarargs)
 for k = 1:nVarargs
 fprintf(' %d\n', varargin{k})
 end
```

Call `varlist2` with more than two inputs.

```
varlist2(10,20,30,40,50)
```

```
Total number of inputs = 5
Inputs in varargin(3):
 30
 40
 50
```

## Related Examples

- “Support Variable Number of Inputs”

## Concepts

- “Argument Checking in Nested Functions”

**Purpose** Variable-length output argument list

**Syntax** varargout

**Description** varargout is an output variable in a function definition statement that allows the function to return any number of output arguments. Specify varargout using lowercase characters, and include it as the last output argument after any explicitly declared outputs. When the function executes, varargout is a 1-by- $N$  cell array, where  $N$  is the number of outputs requested after the explicitly declared outputs.

## **Examples** Variable Number of Function Outputs

Define a function in a file named `sizeout.m` that returns an output size vector `s` and a variable number of additional scalar values.

```
function [s,varargout] = sizeout(x)
nout = max(nargout,1) - 1;
s = size(x);
for k=1:nout
 varargout{k} = s(k);
end
```

Output `s` contains the dimensions of the input array `x`. Additional outputs correspond to the individual dimensions within `s`.

Call `sizeout` on a three-dimensional array and request three outputs.

```
[s,rows,cols] = sizeout(rand(4,5,2))
```

```
s =
 4 5 2
```

```
rows =
 4
```

```
cols =
 5
```

# varargout

---

<b>Purpose</b>	Apply function to table variables
<b>Syntax</b>	$B = \text{varfun}(\text{func}, A)$ $B = \text{varfun}(\text{func}, A, \text{Name}, \text{Value})$
<b>Description</b>	<p><math>B = \text{varfun}(\text{func}, A)</math> applies the function <code>func</code> separately to each variable of the table <code>A</code> and returns the results in the table <code>B</code>.</p> <p>The function <code>func</code> must take one input argument and return arrays with the same number of rows each time it is called. The <math>i</math>th variable in the output table, <math>B\{:, i\}</math>, is equal to <math>\text{func}(A\{:, i\})</math>.</p> <p><math>B = \text{varfun}(\text{func}, A, \text{Name}, \text{Value})</math> applies the function <code>func</code> separately to each variable of the table <code>A</code> with additional options specified by one or more <code>Name, Value</code> pair arguments.</p> <p>For example, you can specify which variables to pass to the function.</p>
<b>Input Arguments</b>	<p><b>func - Function</b> function handle</p> <p>Function, specified as a function handle. You can define the function in a file or as an anonymous function. If <code>func</code> corresponds to more than one function file (that is, if <code>func</code> represents a set of overloaded functions), MATLAB determines which function to call based on the class of the input arguments.</p> <p>Use the <code>'OutputFormat', 'cell'</code> name-value pair argument, if the function <code>func</code> take one input argument and returns arrays with a different numbers of rows each time it is called. Otherwise, <code>func</code> must return arrays with the same number of rows.</p> <p><b>Example:</b> <code>func = @(x) x.^2;</code> computes the square of each element of an input.</p> <p><b>A - Input table</b> table</p> <p>Input table, specified as a table.</p>

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'InputVariables', 2` uses only the second variable in `A` as an input to `func`.

## **'InputVariables' - Variables of A to pass to func**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector | ...

Variables of `A` to pass to `func`, specified as the comma-separated pair consisting of `'InputVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector, or an anonymous function that returns a logical scalar. If you specify `'InputVariables'` as an anonymous function that returns a logical scalar, `varfun` only passes the variables in `A` where the specified function returns 1 (`true`).

## **'GroupingVariables' - One or more variables in A that define groups of rows**

positive integer | vector of positive integers | variable name | cell array of variable names | logical vector

One or more variables in `A` that define groups of rows, specified as the comma-separated pair consisting of `'GroupingVariables'` and a positive integer, vector of positive integers, variable name, cell array of variable names, or logical vector.

A grouping variable can be a numeric vector, logical vector, string (or character array), cell array of strings, or a categorical vector. Rows in `A` that have the same grouping variable values belong to the same group. `varfun` applies `func` to each group of rows within each of the variables of `A`, rather than to each entire variable.

The output, B, has one row for each group when you specify 'OutputFormat', 'uniform' or 'OutputFormat', 'cell'. When you specify 'OutputFormat', 'table', the sizes of the outputs from func determine how many rows of B correspond to each group. When multiple rows of B correspond to a group, varfun appends a unique identifier to the row names.

### 'OutputFormat' - Format of B

'table' (default) | 'uniform' | 'cell'

Format of B, specified as the comma-separated pair consisting of 'OutputFormat' and either the string 'uniform', 'table', or 'cell'.

'table' varfun returns a table with one variable for each variable in A (or each variable specified with 'InputVariables'). For grouped computation, B, also contains the grouping variables.

'table' allows you to use a function that returns values of different sizes or data types for the different variables in A. However, for ungrouped computation, func must return arrays with the same number of rows each time it is called. For grouped computation, func must return values with the same number of rows each time it is called for a given group.

This is the default output format.

'uniform' varfun concatenates the values into a vector. func must return a scalar with the same data type each time it is called.

'cell' varfun returns B as a cell array. 'cell' allows you to use a function that returns values of different sizes or data types.

### 'ErrorHandler' - Function to call if func fails

function handle

# varfun

---

Function to call if `func` fails, specified as the comma-separated pair consisting of 'ErrorHandler' and a function handle. Define this function so that it rethrows the error or returns valid outputs for function `func`.

MATLAB calls the specified error-handling function with two input arguments:

- A structure with these fields:

<code>identifier</code>	Error identifier.
<code>message</code>	Error message text.
<code>index</code>	Index of the variable for which the error occurred.
<code>name</code>	Name of the variable for which the error occurred.

- The set of input arguments to function `func` at the time of the error.

For example,

```
function [A, B] = errorFunc(S, varargin)
warning(S.identifier, S.message);
A = NaN; B = NaN;
```

## Output Arguments

### **B** - Output table

table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

## Examples

### Apply Element-wise Function

Define and apply an element-wise function to the variables of a table to square all the elements.

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

```
A =
```

Var1	Var2
0.71	0.23
-2.05	0.12
-0.35	-0.18
-0.82	0.23
1.57	0.41

Define the anonymous function to find the square of an input.

```
func = @(x) x.^2;
```

Apply the function to all the variables of table A.

```
B = varfun(func,A)
```

```
B =
```

Fun_Var1	Fun_Var2
0.5041	0.0529
4.2025	0.0144
0.1225	0.0324
0.6724	0.0529
2.4649	0.1681

The variables of B have names based on the function and the variable names from A.

### **Apply Function that Returns Scalar From Vector**

Compute the mean of each variable in a 5-by-2 table.

# varfun

---

Define a table containing numeric variables.

```
A = table([0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

A =

Var1	Var2
0.71	0.23
-2.05	0.12
-0.35	-0.18
-0.82	0.23
1.57	0.41

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

func uses an existing MATLAB function to define the operation.

Apply the function to all the variables of table A.

```
B = varfun(func,A)
```

B =

mean_Var1	mean_Var2
-0.188	0.162

B is a table containing the average value from each variable.

To return a numeric vector instead of a table, you can use `B = varfun(func,A,'OutputFormat','uniform')`.

## Apply Function to Groups Within Variables

Compute the group-wise means of variables in a table, A, and return them as rows in a table, B.

Create a table where one variable defines groups.

```
A = table({'test2';'test1';'test2';'test3';'test1'},...
 [0.71;-2.05;-0.35;-0.82;1.57],[0.23;0.12;-0.18;0.23;0.41])
```

A =

Var1	Var2	Var3
'test2'	0.71	0.23
'test1'	-2.05	0.12
'test2'	-0.35	-0.18
'test3'	-0.82	0.23
'test1'	1.57	0.41

Define the anonymous function to find the mean of an input.

```
func = @mean;
```

func uses an existing MATLAB function to define the operation.

Apply the function to each group of data defined by Var1.

```
B = varfun(func,A,'GroupingVariables','Var1')
```

B =

	Var1	GroupCount	mean_Var2	mean_Var3
test1	'test1'	2	-0.24	0.265
test2	'test2'	2	0.18	0.025
test3	'test3'	1	-0.82	0.23

B contains row names based on the grouping variables and a variable called GroupCount to indicate the number of entries from table A in that group.

# varfun

---

## Concepts

- “Anonymous Functions”

**Purpose** Vectorize expression

**Syntax** `vectorize(s)`  
`vectorize(f)`

**Description** `vectorize(s)` where `s` is a string expression, inserts a `.` before any `^`, `*` or `/` in `s`. The result is a character string.

---

**Note** `vectorize` will not accept inline function objects (`f`) in a future release.

---

`vectorize(f)` where `f` is an inline function object, vectorizes the formula for `f`. The result is the vectorized version of the function.

**See Also** `inline` | `cd` | `dbtype` | `delete` | `dir` | `path` | `what` | `who`

**Purpose** Version information for MathWorks products

**Syntax**

```
ver
ver product

product_info = ver(product)
```

**Description** `ver` displays:

- A header containing the current MATLAB product family version number, license number, operating system, and version of Java software for the MATLAB product.
- The version numbers for MATLAB and all other installed MathWorks products.

`ver product` displays, in addition to the header information:

- The current version number for `product`, where `product` is the name of the folder that contains the `Contents.m` file for the product you are inquiring about.

`product_info = ver(product)` returns product information to the structure array, `product_info`.

## Input Arguments

**product - product-specific information**  
string

The product or toolbox for which you want to view version information, specified as a string.

To determine the string to use, run the following code, substituting the name of a product function for *toolboxfcn*:

```
n = 'toolboxfcn';
pat = '(?<=^[\\/]toolbox[\\/])[^\\/]+';
regexp(which(n), pat, 'match', 'once')
```

## Output Arguments

### **product\_info - product name, version, release, and date**

structure array

Product name, version, release, and date, returned as a structure array with these fields: Name, Version, Release, and Date. If a license is a trial version, the value in the Version field is preceded by the letter T

## Examples

### **Version for All Installed Products**

Display version information for all installed products. The output shown here is representative. Your results may differ.

```
ver
```

```

MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot (T

```

```
MATLAB Version 8.2
Simulink Version 8.2
Control System Toolbox Version 9.6
```

### **Version for a Particular Product**

Display version information for MATLAB and the Control System Toolbox product. The output shown here is representative. Your results may differ.

1. Determine the product name for Control System Toolbox by setting `n` to the name of a function unique to Control System Toolbox, such as `dss`:

```
n = 'dss';
pat = '(?<=^.+[\\\/]toolbox[\\\/])[^\\\/]+';
regexp(which(n), pat, 'match', 'once')
```

```
ans=
control
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
ver control
```

```

MATLAB Version: 8.2.0.29 (R2013b)
MATLAB License Number: 234567
Operating System: Microsoft Windows 7 Version 6.1 (Build 7601: Service Pa
Java Version: Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM)

Control System Toolbox Version 9.6
```

### **Structure Containing Version for the MATLAB family of products**

Create a structure containing version information, and then display the structure values. The output shown here is representative. Your results may differ.

```
v = ver;
for k = 1:length(v)
 fprintf('%s\n', v(k).Name);
 fprintf(' Version: %s\n', v(k).Version);
end
```

```
MATLAB
 Version: 8.2
```

```
MATLAB Builder JA
 Version: 2.3
```

```
MATLAB Builder NE
 Version: 4.2
```

```
MATLAB Compiler
 Version: 5.0
```

```
My Custom Toolbox
```

Version: 1.0

## Structure Containing Version for a Particular Product

Create a structure containing version information for just the Symbolic Math Toolbox™ product. The output shown here is representative. Your results may differ.

1. Determine the product name for Symbolic Math Toolbox by setting `n` to the name of a function unique to Symbolic Math Toolbox, such as `sym`:

```
n = 'sym';
pat = '(?<=^[\\/]toolbox[\\/])(^[\\/]+';
regexpi(which(n), pat, 'match', 'once')
```

```
ans =
```

```
symbolic
```

2. Specify the value returned in the previous step as an argument to `ver`:

```
v = ver('symbolic')
```

```
v =
```

```
 Name: 'Symbolic Math Toolbox'
 Version: '5.11'
 Release: '(R2013b)'
 Date: '19-May-2013'
```

## Concepts

- “Information About your Installation”
- “Create Help Summary Files (Contents.m)”

# verctrl

---

**Purpose** Source control actions (Windows platforms)

**Syntax**

```
verctrl('action',{filename1,'filename2',...},0)
result=verctrl('action',{filename1,'filename2',...},0)
verctrl('action','filename',0)
result=verctrl('isdiff','filename',0)
list = verctrl('all_systems')
```

**Description** verctrl('action',{filename1,'filename2',...},0) performs the source control operation specified by 'action' for a single file or multiple files. Enter one file as a string; specify multiple files using a cell array of strings. Use the full paths for each file name and include the extensions. Specify 0 as the last argument. Complete the resulting dialog box to execute the operation. Available values for 'action' are as follows:

<b>action Argument</b>	<b>Purpose</b>
'add'	Adds files to the source control system. Files can be open in the Editor or closed when added.
'checkin'	Checks files into the source control system, storing the changes and creating a new version.
'checkout'	Retrieves files for editing.
'get'	Retrieves files for viewing and compiling, but not editing. When you open the files, they are labeled as read-only.
'history'	Displays the history of files.
'remove'	Removes files from the source control system. It does not delete the files from disk, but only from the source control system.

<b>action Argument</b>	<b>Purpose</b>
'runsc'	Starts the source control system. The file name can be an empty string.
'uncheckout'	Cancels a previous checkout operation and restores the contents of the selected files to the precheckout version. All changes made to the files since the checkout are lost.

`result=verctrl('action',{'filename1','filename2',...},0)` performs the source control operation specified by *action* on a single file or multiple files. The action can be any one of: 'add', 'checkin', 'checkout', 'get', 'history', or 'undocheckout'. `result` is a logical 1 (true) when you complete the operation by clicking **OK** in the resulting dialog box, and is a logical 0 (false) when you abort the operation by clicking **Cancel** in the resulting dialog box.

`verctrl('action','filename',0)` performs the source control operation specified by *action* for a single file. Use the absolute path for *filename*. Specify 0 as the last argument. Complete any resulting dialog boxes to execute the operation. Available values for *action* are as follows:

<b>action Argument</b>	<b>Purpose</b>
'showdiff'	Displays the differences between a file and the latest checked in version of the file in the source control system.
'properties'	Displays the properties of a file.

`result=verctrl('isdiff','filename',0)` compares `filename` with the latest checked in version of the file in the source control system. `result` is a logical 1 (true) when the files are different, and is a logical 0

(false) when the files are identical. Use the full path for 'filename'. Specify 0 as the last argument.

`list = verctrl('all_systems')` displays in the Command Window a list of all source control systems installed on your computer.

## Examples

### Check In a File

Check in D:\file1.ext to the source control system:

```
result = verctrl('checkin','D:\file1.ext', 0)
```

This opens the Check in file(s) dialog box. Click **OK** to complete the check in. MATLAB displays

```
result = 1
```

indicating the checkin was successful.

### Add Files to the Source Control System

Add D:\file1.ext and D:\file2.ext to the source control system.

```
verctrl('add',{'D:\file1.ext','D:\file2.ext'}, 0)
```

This opens the Add to source control dialog box. Click **OK** to complete the operation.

### Display the Properties of a File

Display the properties of D:\file1.ext.

```
verctrl('properties','D:\file1.ext', 0)
```

This opens the source control properties dialog box for your source control system. The function is complete when you close the properties dialog box.

### Show Differences for a File

To show the differences between the version of file1.ext that you just edited and saved, with the last version in source control, run

```
verctrl('showdiff','D:\file1.ext',0)
```

MATLAB displays differences dialog boxes and results specific to your source control system. After checking in the file, if you run this statement again, MATLAB displays

```
??? The file is identical to latest version under source control.
```

### List All Installed Source Control Systems

To view all of the source control systems installed on your computer, type

```
list = verctrl ('all_systems')
```

MATLAB displays all the source control systems currently installed on your computer. For example:

```
list =
'Microsoft Visual SourceSafe'
'ComponentSoftware RCS'
```

### How To

- “Source Control Interface on Microsoft Windows”

# verLessThan

---

**Purpose** Compare toolbox version to specified version string

**Syntax** `verLessThan(toolbox, version)`

**Description** `verLessThan(toolbox, version)` returns logical 1 (true) if the version of the toolbox specified by the string `toolbox` is older than the version specified by the string `version`, and logical 0 (false) otherwise. Use this function when you want to write code that can run across multiple versions of the MATLAB software, when there are differences in the behavior of the code in the different versions.

The `toolbox` argument is a string enclosed within single quotation marks that contains the name of a MATLAB toolbox folder. The `version` argument is a string enclosed within single quotation marks that contains the version to compare against. This argument must be in the form `major[.minor[.revision]]`, such as 7, 7.1, or 7.0.1. If `toolbox` does not exist, MATLAB generates an error.

To specify `toolbox`, find the folder that holds the `Contents.m` file for the toolbox and use that folder name. To see a list of all toolbox folder names, enter the following statement in the MATLAB Command Window:

```
dir([matlabroot '/toolbox'])
```

## Examples

These examples illustrate usage of the `verLessThan` function.

### Example 1 – Checking For the Minimum Required Version

```
if verLessThan('simulink', '4.0')
 error('Simulink 4.0 or higher is required.');
```

```
end
```

### Example 2 – Choosing Which Code to Run

```
if verLessThan('matlab', '7.0.1')
% -- Put code to run under MATLAB 7.0.0 and earlier here --
else
% -- Put code to run under MATLAB 7.0.1 and later here --
```

```
end
```

### Example 3 – Looking Up the Folder Name

Find the name of the Data Acquisition Toolbox folder:

```
dir([matlabroot '/toolbox/d*'])
```

```
 daq database des distcomp dotnetbuilder
 dastudio datafeed dials dml dspblks
```

Use the toolbox folder name, daq, to compare the Data Acquisition Toolbox software version that MATLAB is currently running against version number 3:

```
verLessThan('daq', '3')
```

```
ans =
```

```
 1
```

### See Also

[ver](#) | [version](#) | [license](#) | [ispc](#) | [isunix](#) | [ismac](#) | [dir](#)

# version

---

**Purpose** Version number for MATLAB and libraries

**Syntax**

```
version
version -date
version -description
version -release
version -java
v = version('-versionOption')
[v d] = version
```

**Description**

`version` returns in `ans` the version and release number for the MATLAB software currently running.

`version -date` returns in `ans` the release date for the MATLAB software.

`version -description` returns in `ans` a description of the version. Usually, the description is for special versions, such as beta versions.

`version -release` returns in `ans` the release number for the MATLAB software currently running.

`version -java` returns in `ans` the version of the Oracle JVM software that MATLAB is using.

`v = version('-versionOption')`, where *versionOption* is one of the above option strings, is an alternate form of the syntax.

`[v d] = version` returns the version and release number in string `v` and the release date in string `d`. No input arguments are allowed in this syntax.

**Examples**      **Display MATLAB Version**

```
version

ans =

8.2.0.29 (R2013b)
```

## Display MATLAB Release

Display the release, prefaced by a descriptor.

```
['Release R' version('-release')]
```

```
ans =
```

```
Release R2013b
```

## Get Release Version and Date as Separate Strings

```
[v d] = version
```

```
v =
```

```
8.2.0.29 (R2013b)
```

```
d =
```

```
May 19, 2013
```

## Display Java Version

```
version -java
```

```
ans =
```

```
Java 1.7.0_11-b21 with Oracle Corporation Java HotSpot(TM) 64-Bit Ser
```

## See Also

## How To

- “Check for Software Updates”

# vertcat

---

**Purpose** Concatenate arrays vertically

**Syntax** `C = vertcat(A1,...,AN)`

**Description** `C = vertcat(A1,...,AN)` vertically concatenates arrays `A1,...,AN`. All arrays in the argument list must have the same number of columns.

- If the inputs are multidimensional arrays, `vertcat` concatenates N-dimensional arrays along the first dimension. The remaining dimensions must match.
- If the inputs are tables, `vertcat` concatenates by matching variable names. Variable names for all tables must be identical, except for order. Row names, when present, must be unique across tables.

`vertcat` fills in default row names when some of the inputs have names and some do not. `vertcat` assigns values for each table property (except for `RowNames`) using the first nonempty value for the corresponding property in the tables `A1,...,AN`.

`vertcat` also concatenates character strings. Each string being concatenated must have the same number of characters.

MATLAB calls `C = vertcat(A1, A2, ...)` for the syntax `C = [A1; A2; ...]` when any of the inputs are an object.

**Tips** You can concatenate categorical arrays with cell arrays of strings. For more information, see “Combine Categorical Arrays”.

If all the input arrays are ordinal categorical arrays, they must have the same sets of categories including their order. For more information, see “Ordinal Categorical Arrays”.

For information on combining unlike integer types, integers with nonintegers, cell arrays with non-cell arrays, or empty matrices with other elements, see “Valid Combinations of Unlike Classes”.

**Examples** **Vertically Concatenate Two Matrices**

Create a 5-by-3 matrix, `A`.

```
A = magic(5);
A(:, 4:5) = []
```

```
A =
```

```
 17 24 1
 23 5 7
 4 6 13
 10 12 19
 11 18 25
```

Create a 3-by-3 matrix, B.

```
B = magic(3)*100
```

```
B =
```

```
 800 100 600
 300 500 700
 400 900 200
```

Vertically concatenate A and B.

```
C = vertcat(A,B)
```

```
C =
```

```
 17 24 1
 23 5 7
 4 6 13
 10 12 19
 11 18 25
 800 100 600
 300 500 700
 400 900 200
```

### Vertically Concatenate Two Tables

Create a table, A, with three rows and five variables.

# vertcat

```
A = table([5;6;5],['M'; 'M'; 'M'],[45;41;40],[45;32;34],{'NY'; 'CA'; 'MA'},...
 'VariableNames',{'Age' 'Gender' 'Height' 'Weight' 'Birthplace'},...
 'RowNames',{'Thomas' 'Gordon' 'Percy'})
```

A =

	Age	Gender	Height	Weight	Birthplace
Thomas	5	M	45	45	'NY'
Gordon	6	M	41	32	'CA'
Percy	5	M	40	34	'MA'

Create a table, B, with the same variables as A except for order.

```
B = table(['F'; 'M'; 'F'],[6;6;5],{'AZ'; 'NH'; 'CO'},[31;42;33],[39;43;40],...
 'VariableNames',{'Gender' 'Age' 'Birthplace' 'Weight' 'Height'})
```

B =

	Gender	Age	Birthplace	Weight	Height
F		6	'AZ'	31	39
M		6	'NH'	42	43
F		5	'CO'	33	40

Vertically concatenate tables A and B.

```
C = vertcat(A,B)
```

C =

	Age	Gender	Height	Weight	Birthplace
Thomas	5	M	45	45	'NY'
Gordon	6	M	41	32	'CA'
Percy	5	M	40	34	'MA'
Row4	6	F	39	31	'AZ'
Row5	6	M	43	42	'NH'

```
Row6 5 F 40 33 'C0'
```

The variables of **C** are in the same order as the variables of **A** and default row names are used for the rows from **B**.

**See Also**

`horzcat` | `cat`

**How To**

- “Redefining Concatenation for Your Class”

# vertcat (tscollection)

---

**Purpose** Vertical concatenation for tscollection objects

**Syntax** `tsc = vertcat(tsc1,tsc2,...)`

**Description** `tsc = vertcat(tsc1,tsc2,...)` performs  
`tsc = [tsc1;tsc2;...]`

This operation appends tscollection objects. The time vectors must not overlap. The last time in tsc1 must be earlier than the first time in tsc2. All tscollection objects to be concatenated must have the same timeseries members.

**See Also** `horzcat (tscollection) | tscollection`

**Purpose** (Will be removed) Return simplices attached to specified vertices

---

**Note** `vertexAttachments(TriRep)` will be removed in a future release. Use `vertexAttachments(triangulation)` instead.

---

`TriRep` will be removed in a future release. Use `triangulation` instead.

---

**Syntax** `SI = vertexAttachments(TR, VI)`

**Description** `SI = vertexAttachments(TR, VI)` returns the vertex-to-simplex information for the specified vertices `VI`. For 2-D triangulations in MATLAB, the triangles `SI` are arranged in counter-clockwise order around the attached vertex `VI`.

**Input Arguments**

<code>TR</code>	Triangulation representation
<code>VI</code>	<code>VI</code> is a column vector of indices into the array of points representing the vertex coordinates, <code>TR.X</code> . The simplices associated with vertex <code>i</code> are the <code>i</code> 'th entry in the cell array. If <code>VI</code> is not specified the vertex-simplex information for the entire triangulation is returned.

**Output Arguments**

<code>SI</code>	Cell array of indices of the simplices attached to a vertex. A cell array is used to store the information because the number of simplices associated with each vertex can vary. The simplices associated with vertex <code>i</code> are in the <code>i</code> 'th entry in the cell array <code>SI</code> .
-----------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Definitions** A simplex is a triangle/tetrahedron or higher dimensional equivalent.

# TriRep.vertexAttachments

---

## Examples

### Example 1

Load a 2-D triangulation and use TriRep to compute the vertex-to-triangle relations.

```
load trimesh2d
trep = TriRep(tri, x, y);
```

Find the indices of the tetrahedra attached to the first vertex:

```
Tv = vertexAttachments(trep, 1)
Tv{:}
```

### Example 2

Perform a direct query of a 2-D triangulation created using DelaunayTri.

```
x = rand(20,1);
y = rand(20,1);
dt = DelaunayTri(x,y);
```

Find the triangles attached to vertex 5:

```
t = vertexAttachments(dt,5);
```

Plot the triangulation:

```
triplot(dt);
hold on;
```

Plot the triangles attached to vertex 5 (in red):

```
triplot(dt(t{:},:),x,y,'Color','r');
hold off;
```

**See Also** [delaunayTriangulation](#) | [triangulation](#)

# VideoReader

---

**Purpose** Read video files

**Description** Use the `VideoReader` function with the `read` method to read video data from a file into the MATLAB workspace.

The file formats that `VideoReader` supports vary by platform, as follows (with no restrictions on file extensions):

All Platforms	AVI, including uncompressed, indexed, grayscale, and Motion JPEG-encoded video (.avi) Motion JPEG 2000 (.mj2)
All Windows	MPEG-1 (.mpg) Windows Media Video (.wmv, .asf, .asx) Any format supported by Microsoft DirectShow®
Windows 7 or later	MPEG-4, including H.264 encoded video (.mp4, .m4v) Apple QuickTime Movie (.mov) Any format supported by Microsoft Media Foundation
Macintosh	Most formats supported by QuickTime Player, including: MPEG-1 (.mpg) MPEG-4, including H.264 encoded video (.mp4, .m4v) Apple QuickTime Movie (.mov) 3GPP 3GPP2 AVCHD DV
Linux	Any format supported by your installed plug-ins for GStreamer 0.10 or above, as listed on <a href="http://gstreamer.freedesktop.org/documentation/plugins.html">http://gstreamer.freedesktop.org/documentation/plugins.html</a> , including Ogg Theora (.ogg).

**Construction** `obj = VideoReader(filename)` constructs `obj` to read video data from the file named `filename`. If it cannot construct the object for any reason, `VideoReader` generates an error.

`obj = VideoReader(filename,Name,Value)` constructs the object with additional options specified by one or more **Name,Value** pair arguments. **Name** is 'Tag' or 'UserData' and **Value** is the corresponding value. You can specify two name and value pair arguments in any order as `Name1,Value1,Name2,Value2`.

## Input Arguments

### filename

String in single quotation marks that specifies the video file to read. The `VideoReader` constructor searches for the file on the MATLAB path.

### Name-Value Pair Arguments

Optional comma-separated pairs of **Name,Value** arguments, where **Name** is 'Tag' or 'UserData' and **Value** is the corresponding value. You can specify two name and value pair arguments in any order as `Name1,Value1,Name2,Value2`.

### Tag

String that identifies the object.

**Default:** ''

### UserData

Generic field for data of any class that you want to add to the object.

**Default:** []

## Properties

All properties are read-only except `Tag` and `UserData`.

### BitsPerPixel

Bits per pixel of the video data.

# VideoReader

---

## **Duration**

Total length of the file in seconds.

## **FrameRate**

Frame rate of the video in frames per second.

## **Height**

Height of the video frame in pixels.

## **Name**

Name of the file associated with the object.

## **NumberOfFrames**

Total number of frames in the video stream.

Some files store video at a variable frame rate, including many Windows Media Video files. For these files, `VideoReader` cannot determine the number of frames until you read the last frame. When you construct the object, `VideoReader` returns a warning and does not set the `NumberOfFrames` property.

To count the number of frames in a variable frame rate file, use the `read` method to read the last frame of the file. For example:

```
vidObj = VideoReader('varFrameRateFile.wmv');
lastFrame = read(vidObj, inf);
numFrames = vidObj.NumberOfFrames;
```

For more information, see “Read Variable Frame Rate Video” in the MATLAB Data Import and Export documentation..

## **Path**

String containing the full path to the file associated with the reader.

## **Tag**

String that identifies the object.

**Default:** ''

## Type

Class name of the object: 'VideoReader'.

## UserData

Generic field for data of any class that you want to add to the object.

**Default:** []

## VideoFormat

String indicating the MATLAB representation of the video format.

Video Format	Value of VideoFormat
AVI or MPEG-4 files with RGB24 video	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, VideoFormat is one of the following.

Format of Image Data	Value of VideoFormat
Single-band uint8	'Mono8'
Single-band int8	'Mono8 Signed'
Single-band uint16	'Mono16'
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'
Three-banded uint16	'RGB48'
Three-banded int16	'RGB48 Signed'

# VideoReader

---

## Width

Width of the video frame in pixels.

## Methods

<code>get</code>	Query property values for video reader object
<code>getFileFormats</code>	File formats that <code>VideoReader</code> supports
<code>read</code>	Read video frame data from file
<code>set</code>	Set property values for video reader object

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Construct VideoReader Object

Construct a `VideoReader` object for the example movie file `xylophone.mp4` and view its properties.

```
xyloObj = VideoReader('xylophone.mp4','Tag','My reader object');
get(xyloObj)
```

General Settings:

```
Duration = 4.7000
Name = xylophone.mp4
Path = matlabroot\toolbox\matlab\audiovideo
Tag = My reader object
Type = VideoReader
UserData = []
```

Video Settings:

```
BitsPerPixel = 24
FrameRate = 30
Height = 240
```

```
NumberOfFrames = 141
VideoFormat = RGB24
Width = 320
```

## Read and Play Back Movie File

Read and play back the movie file `xylophone.mp4`.

```
xyloObj = VideoReader('xylophone.mp4');
```

```
nFrames = xyloObj.NumberOfFrames;
vidHeight = xyloObj.Height;
vidWidth = xyloObj.Width;
```

Preallocate the movie structure.

```
mov(1:nFrames) = ...
 struct('cdata',zeros(vidHeight,vidWidth, 3,'uint8'),...
 'colormap',[]);
```

Read one frame at a time.

```
for k = 1 : nFrames
 mov(k).cdata = read(xyloObj,k);
end
```

Size a figure based on the video's width and height.

```
hf = figure;
set(hf, 'position', [150 150 vidWidth vidHeight])
```

Play back the movie once at the video's frame rate.

```
movie(hf, mov, 1, xyloObj.FrameRate);
```

## See Also

## How To

- “Read Video Files”

# VideoWriter

---

**Purpose** Write video files

**Description** Use the `VideoWriter` object with the `open`, `writeVideo`, and `close` methods to create video files from figures, still images, or MATLAB movies. `VideoWriter` can create uncompressed AVI and Motion JPEG 2000 compressed AVI files on all platforms, and MPEG-4 files on Windows 7 or later and Mac OS X 10.7 and higher. `VideoWriter` supports files larger than 2 GB, which is the limit for `avifile`.

To set video properties, `VideoWriter` includes predefined *profiles* such as 'Uncompressed AVI' or 'MPEG-4'.

**Construction** `writerObj = VideoWriter(filename)` constructs a `VideoWriter` object to write video data to an AVI file with Motion JPEG compression.

`writerObj = VideoWriter(filename,profile)` applies a set of properties tailored to a specific file format (such as 'MPEG-4' or 'Uncompressed AVI') to a `VideoWriter` object.

## Input Arguments

### **filename**

String enclosed in single quotation marks that specifies the name of the file to create.

`VideoWriter` supports these file extensions:

<code>.avi</code>	AVI file
<code>.mj2</code>	Motion JPEG 2000 file
<code>.mp4</code> or <code>.m4v</code>	MPEG-4 file (systems with Windows 7 or later, or Mac OS X 10.7 and later)

If you do not specify a valid file extension, `VideoWriter` appends the extension `.avi`, `.mj2` or `.mp4`, depending on the `profile`. If you do not specify a value for `profile`, then `VideoWriter` creates a Motion JPEG compressed AVI file with the extension `.avi`.

## profile

String enclosed in single quotation marks that describes the type of file to create. Specifying a profile sets default values for video properties such as `VideoCompressionMethod`. Possible values:

'Archival'	Motion JPEG 2000 file with lossless compression
'Motion JPEG AVI'	Compressed AVI file using Motion JPEG codec
'Motion JPEG 2000'	Compressed Motion JPEG 2000 file
'MPEG-4'	Compressed MPEG-4 file with H.264 encoding (systems with Windows 7 or later, or Mac OS X 10.7 and later)
'Uncompressed AVI'	Uncompressed AVI file with RGB24 video
'Indexed AVI'	Uncompressed AVI file with indexed video
'Grayscale AVI'	Uncompressed AVI file with grayscale video

**Default:** 'Motion JPEG AVI'

## Properties

### ColorChannels

Number of color channels in each output video frame. (Read-only)

AVI and MPEG-4 files with RGB24 data have three color channels. Indexed and Grayscale AVI files have one color channel. The number of channels for Motion JPEG 2000 files depends on the input data to the `writeVideo` method: one for monochrome image data, three for color data.

### Colormap

P-by-3 numeric matrix that contains color information about the video file. The colormap can have a maximum of 256 entries of type `uint8` or `double`. The entries of the colormap must be integers. Each row of `Colormap` specifies the red, green, and blue components of a single color. The colormap can be set explicitly before the call to `open`, or using the `colormap` field of a movie frame structure at the time of writing the first frame.

Only applies to objects associated with Indexed AVI files.

After you call `open`, you cannot change the `Colormap` value.

**Default:** none

## **CompressionRatio**

Number greater than 1 that specifies the target ratio between the number of bytes in the input image and the number of bytes in the compressed image. The data is compressed as much as possible, up to the specified target.

Only available for objects associated with Motion JPEG 2000 files. After you call `open`, you cannot change the `CompressionRatio` value. If you previously set `LosslessCompression` to `true`, setting `CompressionRatio` generates an error.

**Default:** 10

## **Duration**

Scalar value specifying the duration of the file in seconds.  
(Read-only)

## **FileFormat**

String specifying the type of file to write: `'avi'`, `'mp4'`, or `'mj2'`.  
(Read-only)

## **Filename**

String specifying the name of the file. (Read-only)

## **FrameCount**

Number of frames written to the video file. (Read-only)

## **FrameRate**

Rate of playback for the video in frames per second. After you call `open`, you cannot change the `FrameRate` value.

**Default:** 30

## **Height**

Height of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame height for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a row of black pixels at the bottom.

## **LosslessCompression**

Boolean value (logical `true` or `false`) only available for objects associated with Motion JPEG 2000 files. If `true`:

- The `writeVideo` method uses reversible mode so that the decompressed data is identical to the input data.
- `VideoWriter` ignores any specified value for `CompressionRatio`.

After you call `open`, you cannot change the `LosslessCompression` value.

**Default:** `false` for the 'Motion JPEG 2000' profile, `true` for the 'Archival' profile

## **MJ2BitDepth**

# VideoWriter

---

Number of least significant bits in the input image data, from 1 to 16.

Only available for objects associated with Motion JPEG 2000 files. If you do not specify a value before calling the `open` method, VideoWriter sets the bit depth based on the input data type. For example, if the input data to `writeVideo` is an array of `uint8` or `int8` values, `MJ2BitDepth` is 8.

## **Path**

String specifying the fully qualified path. (Read-only)

## **Quality**

Integer from 0 through 100. Higher quality numbers result in higher video quality and larger file sizes. Lower quality numbers result in lower video quality and smaller file sizes.

Only available for objects associated with the MPEG-4 or Motion JPEG AVI profile. After you call `open`, you cannot change the Quality value.

**Default:** 75

## **VideoBitsPerPixel**

Number of bits per pixel in each output video frame. (Read-only)

AVI and MPEG-4 files have 24 bits per pixel (8 bits for each of three color bands).

For Motion JPEG 2000 files, the number of bits per pixel depends on the value of `MJ2BitDepth` and the number of bands of image data. For example, if the input data to `writeVideo` is a three-dimensional array of `uint16` or `int16` values, the default value of `MJ2BitDepth` is 16, and `VideoBitsPerPixel` is 48 (three times the bit depth).

## **VideoCompressionMethod**

String indicating the type of video compression: 'None', 'H.264', 'Motion JPEG', or 'Motion JPEG 2000'. (Read-only)

## VideoFormat

String indicating the MATLAB representation of the video format. (Read-only)

Video Format	Value of VideoFormat
AVI or MPEG-4 files with RGB24 video	'RGB24'
AVI files with indexed video	'Indexed'
AVI files with grayscale video	'Grayscale'

For Motion JPEG 2000 files, VideoFormat depends on the value of MJ2BitDepth and the format of the input image data to the writeVideo method. For example, if you do not specify the MJ2BitDepth property, VideoWriter sets the format as shown in this table.

Format of Image Data	Value of VideoFormat
Single-band uint8	'Mono8'
Single-band int8	'Mono8 Signed'
Single-band uint16	'Mono16'
Single-band int16	'Mono16 Signed'
Three-banded uint8	'RGB24'
Three-banded int8	'RGB24 Signed'
Three-banded uint16	'RGB48'
Three-banded int16	'RGB48 Signed'

## Width

# VideoWriter

---

Width of each video frame in pixels. The `writeVideo` method sets values for `Height` and `Width` based on the dimensions of the first frame. (Read-only)

MPEG-4 files require frame dimensions that are divisible by two. If the input frame width for an MPEG-4 file is not an even number, `VideoWriter` pads the frame with a column of black pixels along the right side.

## Methods

<code>close</code>	Close file after writing video data
<code>getProfiles</code>	List profiles and file formats supported by <code>VideoWriter</code>
<code>open</code>	Open file for writing video data
<code>writeVideo</code>	Write video data to file

## Copy Semantics

Handle. To learn how handle classes affect copy operations, see [Copying Objects in the MATLAB documentation](#).

## Examples

### View and Set Object Properties

Construct a `VideoWriter` object and view its properties.

```
writerObj = VideoWriter('newfile.avi')
```

Set the frame rate to 60 frames per second, using the `FrameRate` property.

```
writerObj.FrameRate = 60;
```

### AVI File from Animation

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
```

```
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca, 'nextplot', 'replacechildren');
set(gcf, 'Renderer', 'zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
 surf(sin(2*pi*k/20)*Z,Z)
 frame = getframe;
 writeVideo(writerObj, frame);
end

close(writerObj);
```

## See Also

[VideoReader](#) | [mmfileinfo](#)

# view

---

**Purpose** Viewpoint specification

**Syntax**

```
view(az,e1)
view([az,e1])
view([x,y,z])
view(2)
view(3)
view(ax,...)
[az,e1] = view
```

**Description** The position of the viewer (the viewpoint) determines the orientation of the axes. You specify the viewpoint in terms of azimuth and elevation, or by a point in three-dimensional space.

`view(az,e1)` and `view([az,e1])` set the viewing angle for a three-dimensional plot. The azimuth, `az`, is the horizontal rotation about the  $z$ -axis as measured in degrees from the negative  $y$ -axis. Positive values indicate counterclockwise rotation of the viewpoint. `e1` is the vertical elevation of the viewpoint in degrees. Positive values of elevation correspond to moving above the object; negative values correspond to moving below the object.

`view([x,y,z])` sets the view direction to the Cartesian coordinates  $x$ ,  $y$ , and  $z$ . The magnitude of  $(x,y,z)$  is ignored.

`view(2)` sets the default two-dimensional view, `az = 0`, `e1 = 90`.

`view(3)` sets the default three-dimensional view, `az = 37.5`, `e1 = 30`.

`view(ax,...)` uses axes `ax` instead of the current axes.

`[az,e1] = view` returns the current azimuth and elevation.

**Tips** Azimuth is a polar angle in the  $x$ - $y$  plane, with positive angles indicating counterclockwise rotation of the viewpoint. Elevation is the angle above (positive angle) or below (negative angle) the  $x$ - $y$  plane.

This diagram illustrates the coordinate system. The arrows indicate positive directions.

## Examples

View the object from directly overhead.

```
az = 0;
el = 90;
view(az, el);
```

Set the view along the  $y$ -axis, with the  $x$ -axis extending horizontally and the  $z$ -axis extending vertically in the figure.

```
view([0 0]);
```

Rotate the view about the  $z$ -axis by  $180^\circ$ .

```
az = 180;
el = 90;
view(az, el);
```

# view

---

## See Also

[hgtransform](#) | [rotate3d](#) | [CameraPosition](#) | [CameraTarget](#) | [CameraViewAngle](#) | [Projection](#)

## How To

- “View Overview”

**Purpose** View transformation matrices

**Syntax**

```
viewmtx
T = viewmtx(az,e1)
T = viewmtx(az,e1,phi)
T = viewmtx(az,e1,phi,xc)
```

**Description** `viewmtx` computes a 4-by-4 orthographic or perspective transformation matrix that projects four-dimensional homogeneous vectors onto a two-dimensional view surface (e.g., your computer screen).

`T = viewmtx(az,e1)` returns an *orthographic* transformation matrix corresponding to azimuth `az` and elevation `e1`. `az` is the azimuth (i.e., horizontal rotation) of the viewpoint in degrees. `e1` is the elevation of the viewpoint in degrees. This returns the same matrix as the commands

```
view(az,e1)
T = view
```

but does not change the current view.

`T = viewmtx(az,e1,phi)` returns a *perspective* transformation matrix. `phi` is the perspective viewing angle in degrees. `phi` is the subtended view angle of the normalized plot cube (in degrees) and controls the amount of perspective distortion.

Phi	Description
0 degrees	Orthographic projection
10 degrees	Similar to telephoto lens
25 degrees	Similar to normal lens
60 degrees	Similar to wide-angle lens

`T = viewmtx(az,e1,phi,xc)` returns the perspective transformation matrix using `xc` as the target point within the normalized plot cube (i.e., the camera is looking at the point `xc`). `xc` is the target point that is the

center of the view. You specify the point as a three-element vector,  $x_c = [x_c, y_c, z_c]$ , in the interval  $[0,1]$ . The default value is  $x_c = [0,0,0]$ .

A four-dimensional homogenous vector is formed by appending a 1 to the corresponding three-dimensional vector. For example,  $[x, y, z, 1]$  is the four-dimensional vector corresponding to the three-dimensional point  $[x, y, z]$ .

## Examples

Determine the projected two-dimensional vector corresponding to the three-dimensional point  $(0.5, 0.0, -3.0)$  using the default view direction. Note that the point is a column vector.

```
A = viewmtx(-37.5,30);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)
x2d =
 0.3967
 -2.4459
```

These vectors trace the edges of a unit cube:

```
x = [0 1 1 0 0 0 1 1 0 0 1 1 1 1 0 0];
y = [0 0 1 1 0 0 0 1 1 0 0 0 1 1 1 1];
z = [0 0 0 0 0 1 1 1 1 1 1 0 0 1 1 0];
```

Transform the points in these vectors to the screen, then plot the object.

```
A = viewmtx(-37.5,30);
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:);
y2(:) = x2d(2,:);
figure
plot(x2,y2)
```

Use a perspective transformation with a 25 degree viewing angle:

```
A = viewmtx(-37.5,30,25);
x4d = [.5 0 -3 1]';
x2d = A*x4d;
x2d = x2d(1:2)/x2d(4) % Normalize
x2d =
 0.1777
 -1.8858
```

Transform the cube vectors to the screen and plot the object:

```
figure
A = viewmtx(-37.5,30,25);
```

```
[m,n] = size(x);
x4d = [x(:),y(:),z(:),ones(m*n,1)]';
x2d = A*x4d;
x2 = zeros(m,n); y2 = zeros(m,n);
x2(:) = x2d(1,:)./x2d(4,:);
y2(:) = x2d(2,:)./x2d(4,:);
plot(x2,y2)
```

## Tutorials

- “Camera Graphics Terminology”

**Purpose** Compare two text files, MAT-Files, binary files, Zip files, or folders

**Syntax**

```
visdiff('fname1', 'fname2')
visdiff('filename1', 'filename2', 'type')
```

**Description** `visdiff('fname1', 'fname2')` opens the Comparison Tool and presents the differences between the two files or folders. Either ensure that the two files or folders appear on the MATLAB path, or provide the full path for each file or folder. You can compare files or any combination of folders, zip files, or Simulink manifests.

If you have Simulink Report Generator™ software, you can select a pair of Simulink models to compare XML text files generated from them.

`visdiff('filename1', 'filename2', 'type')` opens the Comparison Tool and presents the differences between the two files using the specified comparison type. *type* can be 'text' or 'binary'. If you do not specify *type*, `visdiff` creates the default comparison type for your selected files. The *type* option does not apply when comparing folders.

If there are multiple comparison types available for your selections (e.g., text, binary, file list, or XML comparison), you can create a new comparison and choose a different comparison type.

**1** In the Comparison Tool, click the New comparison button.

The dialog box Select Files or Folders for Comparison opens and shows your previous comparison selections in the drop-down lists.

**2** Change the comparison type and click **Compare**.

## Examples

### Specifying Files or Folders to Compare

The `visdiff` function accepts fully qualified file names, relative file names, or names of files on the MATLAB path.

If the files you want to compare appear on the MATLAB path or in the current folder, you can specify the file names without the full path, for example:

```
visdiff('lengthofline.m', 'lengthofline2.m')
```

or

```
visdiff('lengthofline', 'lengthofline2')
```

If the files you want to compare are not on the path, either specify the full path to each file, or add the folders to the path.

For example, to specify the fully qualified file names to compare two example files:

```
visdiff(fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'gatlin.mat'), ...
fullfile(matlabroot, 'toolbox', 'matlab', 'demos', 'gatlin2.mat'))
```

Specify the full path to files as follows:

```
visdiff('C:\Work\comp\lengthofline.m', 'C:\Work\comp\lengthofline2.m')
```

You can specify paths to files relative to the current folder. For the preceding example, if the current folder is `Work`, then the relative paths are:

```
visdiff('comp\lengthofline.m', 'comp\lengthofline2.m')
```

### Compare Two Text Files

To view a comparison of the two example files, `lengthofline.m` and `lengthofline2.m`:

```
visdiff(fullfile(matlabroot, 'help', 'techdoc', 'matlab_env', ...
'examples', 'lengthofline.m'), fullfile(matlabroot, 'help', ...
```

```
'techdoc','matlab_env','examples','lengthofline2.m'))
```

For information about using the report features, see “Comparing Text Files”.

---

**Note** If the text files you compare are XML files, you see different results if you have MATLAB Report Generator installed. For details, see “Comparing Files and Folders”.

---

### Compare Two MAT-Files

To compare two example files:

```
visdiff(fullfile(matlabroot,'toolbox','matlab','demos','gatlin.mat'), ...
fullfile(matlabroot,'toolbox','matlab','demos','gatlin2.mat'))
```

For information about the report features, see “Comparing MAT-Files”.

### Compare Two Binary Files

The following example code adds a folder containing two MEX-files to the MATLAB path, and then compares the files:

```
addpath([matlabroot '\extern\examples\shrlib'])
visdiff('shrlibsample.mexw32', 'yprime.mexw32')
```

The Comparison Tool opens and indicates that the files are different, but does not provide details about the differences.

For more information on binary comparisons, see “Comparing Binary Files”.

### Compare Two Folders or Zip Files

You can perform file list comparisons for any combinations of folders and zip files. To view an example folder comparison and instructions for using the report features, see “Comparing Folders and Zip Files”.

## Compare Files and Specify Type

To compare two example text files and specify comparison type as binary:

```
visdiff(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline.m'), fullfile(matlabroot,'help',...
'techdoc','matlab_env','examples','lengthofline2.m'), 'binary')
```

If you do not specify type, `visdiff` creates the default comparison type for your selected files, in this case, text comparison. By changing to the binary comparison type you could examine differences such as end-of-line characters.

Similarly, when you compare XML files without specifying type, you get a hierarchical XML comparison report. If instead you want a text or binary comparison, you can specify "text" or "binary" comparison types to see more details. When you compare zip files, the default comparison type is a file list comparison, and you might want to specify a binary comparison instead.

## Alternatives

As an alternative to the `visdiff` function, compare files and folders using any of these GUI methods:

- From the Current Folder browser:
  - Select a file or folder. Right-click the file or folder, and select **Compare Against**.
  - For two files or subfolders in the same folder, select the files or folders. Then, right-click, and select **Compare Selected Files/Folders**.
- From the MATLAB desktop, on the **Home** tab, in the **File** section, click **Compare** and then select the files or folders to compare.
- If you have a file open in the Editor, on the **Editor** tab, in the **File** section, click **Compare**. Alternatively, under **Compare**, you can choose a file to compare against, or compare with the autosave

version or the version on disk. See “Comparing Files with Autosave Version or Version on Disk”.

**How To**

- “Comparing Files and Folders”

# volumebounds

---

**Purpose** Coordinate and color limits for volume data

**Syntax**

```
lims = volumebounds(X,Y,Z,V)
lims = volumebounds(X,Y,Z,U,V,W)
lims = volumebounds(V)
lims = volumebounds(U,V,W)
```

**Description** `lims = volumebounds(X,Y,Z,V)` returns the x, y, z, and color limits of the current axes for scalar volume data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax cmin cmax]
```

You can pass this vector to the `axis` command.

`lims = volumebounds(X,Y,Z,U,V,W)` returns the x, y, and z limits of the current axes for vector volume data. `lims` is returned as a vector:

```
[xmin xmax ymin ymax zmin zmax]
```

`lims = volumebounds(V)` and `lims = volumebounds(U,V,W)` assumes X, Y, and Z are determined by the expression

```
[X Y Z] = meshgrid(1:n,1:m,1:p)
```

where `[m n p] = size(V)`.

**Examples** This example uses `volumebounds` to set the axis and color limits for an isosurface generated by the flow function.

```
[x y z v] = flow;
p = patch(isosurface(x,y,z,v,-3));
isonormals(x,y,z,v,p)
daspect([1 1 1])
isocolors(x,y,z,flipplr(v),p)
shading interp
axis(volumebounds(x,y,z,v))
```

**See Also** [isosurface](#) | [streamslice](#)

**Purpose** Voronoi diagram

---

**Note** Qhull-specific options are no longer supported. Remove the `OPTIONS` argument from all instances in your code that pass it to `voronoi`.

---

**Syntax**

```
voronoi(x,y)
voronoi(x,y,TRI)
voronoi(dt)
voronoi(AX,...)
voronoi(...,'LineStyle')
h = voronoi(...)
[vx,vy] = voronoi(...)
```

**Description**

`voronoi(x,y)` plots the bounded cells of the Voronoi diagram for the points `x,y`. Lines-to-infinity are approximated with an arbitrarily distant endpoint.

`voronoi(x,y,TRI)` uses the triangulation `TRI` instead of computing internally.

`voronoi(dt)` uses the Delaunay triangulation `dt` instead of computing it.

`voronoi(AX,...)` plots into `AX` instead of `gca`.

`voronoi(...,'LineStyle')` plots the diagram with color and line style specified.

`h = voronoi(...)` returns, in `h`, handles to the line objects created.

`[vx,vy] = voronoi(...)` returns the finite vertices of the Voronoi edges in `vx` and `vy`.

---

**Note** For the topology of the Voronoi diagram, i.e., the vertices for each Voronoi cell, use `voronoin`.

```
[v,c] = voronoin([x(:) y(:)])
```

---

## Definitions

Consider a set of coplanar points  $P$ . For each point  $P_x$  in the set  $P$ , you can draw a boundary enclosing all the intermediate points lying closer to  $P_x$  than to other points in the set  $P$ . Such a boundary is called a *Voronoi polygon*, and the set of all Voronoi polygons for a given point set is called a *Voronoi diagram*.

## Visualization

Use one of these methods to plot a Voronoi diagram:

- If you provide no output argument, `voronoi` plots the diagram.
- To gain more control over color, line style, and other figure properties, use the syntax `[vx,vy] = voronoi(...)`. This syntax returns the vertices of the finite Voronoi edges, which you can then plot with the `plot` function.
- To fill the cells with color, use `voronoin` with `n = 2` to get the indices of each cell, and then use `patch` and other plot functions to generate the figure. Note that `patch` does not fill unbounded cells with color.

## Examples

### Voronoi Diagram Based on Points

This code uses the `voronoi` function to plot the Voronoi diagram for 10 randomly generated points.

```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
voronoi(x,y)
```

### Voronoi Diagram Based on Vertices of Veronoi Edges

This code uses the vertices of the finite Voronoi edges to plot the Voronoi diagram for the same 10 points used in the previous example.

```
x = gallery('uniformdata',[1 10],0);
y = gallery('uniformdata',[1 10],1);
[vx, vy] = voronoi(x,y);
plot(x,y,'r+',vx,vy,'b-'); axis equal
```

# voronoi

---

Note that you can add the following code to get the figure shown in the previous example.

```
xlim([min(x) max(x)])
ylim([min(y) max(y)])
```

### Voronoi Diagram with Color

This code uses `voronoin` and `patch` to fill the bounded cells of the same Voronoi diagram with color.

```
x = gallery('uniformdata',[10 2],5);
[v,c]=voronoin(x);
for i = 1:length(c)
 if all(c{i}~=1) % If at least one of the indices is 1,
 % then it is an open region and we can't
```

# voronoi

---

```
 % patch that.
patch(v(c{i},1),v(c{i},2),i); % use color i.
end
end
```

| [voronoin](#)

**Purpose** (Will be removed) Voronoi diagram

---

**Note** `voronoiDiagram(DelaunayTri)` will be removed in a future release. Use `voronoiDiagram(delaunayTriangulation)` instead.

`DelaunayTri` will be removed in a future release. Use `delaunayTriangulation` instead.

---

**Syntax** `[V, R] = voronoiDiagram(DT)`

**Description** `[V, R] = voronoiDiagram(DT)` returns the vertices `V` and regions `R` of the Voronoi diagram of the points `DT.X`. The region `R{i}` is a cell array of indices into `V` that represents the Voronoi vertices bounding the region. The Voronoi region associated with the `i`'th point, `DT.X(i)` is `R{i}`. For 2-D, vertices in `R{i}` are listed in adjacent order, i.e. connecting them will generate a closed polygon (Voronoi diagram). For 3-D the vertices in `R{i}` are listed in ascending order.

The Voronoi regions associated with points that lie on the convex hull of `DT.X` are unbounded. Bounding edges of these regions radiate to infinity. The vertex at infinity is represented by the first vertex in `V`.

**Input Arguments**

<code>DT</code>	Delaunay triangulation.
-----------------	-------------------------

# DelaunayTri.voronoiDiagram

---

## Output Arguments

V	numv-by-ndim matrix representing the coordinates of the Voronoi vertices, where numv is the number of vertices and ndim is the dimension of the space where the points reside.
R	Vector cell array of length(DR.X), representing the Voronoi cell associated with each point.

## Definitions

The *Voronoi diagram* of a discrete set of points  $X$  decomposes the space around each point  $X(i)$  into a region of influence  $R\{i\}$ . Locations within the region are closer to point  $i$  than any other point. The region of influence is called the Voronoi region. The collection of all the Voronoi regions is the Voronoi diagram.

The *convex hull* of a set of points  $X$  is the smallest convex polygon (or polyhedron in higher dimensions) containing all of the points of  $X$ .

## Examples

Compute the Voronoi Diagram of a set of points:

```
X = [0.5 0
 0 0.5
 -0.5 -0.5
 -0.2 -0.1
 -0.1 0.1
 0.1 -0.1
 0.1 0.1]
dt = DelaunayTri(X)
[V,R] = voronoiDiagram(dt)
```

## See Also

[voronoi](#) | [voronoin](#) | [triangulation](#) | [delaunayTriangulation](#)

**Purpose**

N-D Voronoi diagram

**Syntax**

[V,C] = voronoin(X)  
 [V,C] = voronoin(X,options)

**Description**

[V,C] = voronoin(X) returns Voronoi vertices V and the Voronoi cells C of the Voronoi diagram of X. V is a numv-by-n array of the numv Voronoi vertices in n-dimensional space, each row corresponds to a Voronoi vertex. C is a vector cell array where each element contains the indices into V of the vertices of the corresponding Voronoi cell. X is an m-by-n array, representing m n-dimensional points, where n > 1 and m >= n+1.

The first row of V is a point at infinity. If any index in a cell of the cell array is 1, then the corresponding Voronoi cell contains the first point in V, a point at infinity. This means the Voronoi cell is unbounded.

voronoin uses Qhull.

[V,C] = voronoin(X,options) specifies a cell array of strings options to be used in Qhull. The default options are

- {'Qbb'} for 2- and 3-dimensional input
- {'Qbb','Qx'} for 4 and higher-dimensional input

If options is [], the default options are used. If code is {''}, no options are used, not even the default. For more information on Qhull and its options, see <http://www.qhull.org>.

**Visualization**

You can plot individual bounded cells of an n-dimensional Voronoi diagram. To do this, use convhulln to compute the vertices of the facets that make up the Voronoi cell. Then use patch and other plot functions to generate the figure.

**Examples**

**Example 1**

Let

```
x = [0.5 0
 0 0.5
```

# voronoin

---

```
-0.5 -0.5
-0.2 -0.1
-0.1 0.1
 0.1 -0.1
 0.1 0.1]
```

then

```
[V,C] = voronoin(x)
```

V =

```
 Inf Inf
 0.3833 0.3833
 0.7000 -1.6500
 0.2875 0.0000
-0.0000 0.2875
-0.0000 -0.0000
-0.0500 -0.5250
-0.0500 -0.0500
-1.7500 0.7500
-1.4500 0.6500
```

C =

```
[1x4 double]
[1x5 double]
[1x4 double]
[1x4 double]
[1x4 double]
[1x5 double]
[1x4 double]
```

Use a for loop to see the contents of the cell array C.

```
for i=1:length(C), disp(C{i}), end
```

```
 4 2 1 3
10 5 2 1 9
 9 1 3 7
```

```

10 8 7 9
10 5 6 8
 8 6 4 3 7
 6 4 2 5

```

In particular, the fifth Voronoi cell consists of 4 points:  $V(10, :)$ ,  $V(5, :)$ ,  $V(6, :)$ ,  $V(8, :)$ .

### Example 2

The following example illustrates the options input to voronoin. The commands

```

X = [-1 -1; 1 -1; 1 1; -1 1];
[V,C] = voronoin(X)

```

return an error message.

```

? qhull input error: can not scale last coordinate. Input is
cocircular
 or cospherical. Use option 'Qz' to add a point at infinity.

```

The error message indicates that you should add the option 'Qz'. The following command passes the option 'Qz', along with the default 'Qbb', to voronoin.

```

[V,C] = voronoin(X,{'Qbb','Qz'})
V =

```

```

 Inf Inf
 0 0

```

C =

```

[1x2 double]
[1x2 double]
[1x2 double]
[1x2 double]

```

# voronoin

---

## Algorithms

voronoin is based on Qhull [1]. For information about Qhull, see <http://www.qhull.org/>.

**Purpose**

Open or update wait bar dialog box

**Syntax**

```
h = waitbar(x,'message')
waitbar(x,'message','CreateCancelBtn','button_callback')
waitbar(x,'message',property_name,property_value,...)
waitbar(x)
waitbar(x,h)
waitbar(x,h,'updated message')
```

**Description**

A wait bar is a figure that displays what percentage of a calculation is complete as the calculation proceeds by progressively filling a bar with red from left to right.

`h = waitbar(x,'message')` displays a wait bar of fractional length `x`. The wait bar figure displays until the code that controls it closes it or the user clicks its Close Window button. Its (figure) handle is returned in `h`. The argument `x` must be between 0 and 1.

---

**Note** Wait bars are not modal figures (their `WindowState` is 'normal'). They often appear to be modal because the computational loops within which they are called prevent interaction with the Command Window until they terminate. For more information, see `WindowState` in the MATLAB Figure Properties documentation.

---

`waitbar(x,'message','CreateCancelBtn','button_callback')` specifying `CreateCancelBtn` adds a **Cancel** button to the figure that executes the MATLAB commands specified in `button_callback` when the user clicks the **Cancel** button or the **Close Figure** button. `waitbar` sets both the **Cancel** button callback and the figure `CloseRequestFcn` to the string specified in `button_callback`.

`waitbar(x,'message',property_name,property_value,...)` optional arguments `property_name` and `property_value` enable you to set figure properties for the waitbar.

# waitbar

---

`waitbar(x)` subsequent calls to `waitbar(x)` extend the length of the bar to the new position `x`. Successive values of `x` normally increase. If they decrease, the wait bar runs in reverse.

`waitbar(x,h)` extends the length of the bar in the wait bar `h` to the new position `x`.

`waitbar(x,h,'updated message')` updates the message text in the waitbar figure, in addition to setting the fractional length to `x`.

## Examples

### Example 1 – Basic Wait Bar

Typically, you call `waitbar` repeatedly inside a `for` loop that performs a lengthy computation. For example:

```
h = waitbar(0,'Please wait...');
steps = 1000;
for step = 1:steps
 % computations take place here
 waitbar(step / steps)
end
close(h)
```

### Example 2 – Wait Bar with Dynamic Text and Cancel Button

Adding a **Cancel** button allows user to abort the computation. Clicking it sets a logical flag in the figure's application data (`appdata`). The function tests for that value within the main loop and exits the loop as soon as the flag has been set. The example iteratively approximates the value of  $\pi$ . At each step, the current value is encoded as a string and displayed in the wait bar's message field. When the function finishes,

it destroys the wait bar and returns the current estimate of  $\pi$  and the number of steps it ran.

Copy the following function to a code file and save it as `approxpi.m`. Execute it as follows, allowing it to run for 10,000 iterations.

```
[estimated_pi steps] = approxpi(10000)
```

You can click **Cancel** or close the window to abort the computation and return the current estimate of  $\pi$ .

```
function [valueofpi step] = approxpi(steps)
% Converge on pi in steps iterations, displaying waitbar.
% User can click Cancel or close button to exit the loop.
% Ten thousand steps yields error of about 0.001 percent.

h = waitbar(0,'1','Name','Approximating pi...',...
 'CreateCancelBtn',...
 'setappdata(gcf,'canceling',1)');
setappdata(h,'canceling',0)
% Approximate as $\pi^2/8 = 1 + 1/9 + 1/25 + 1/49 + \dots$
pisqover8 = 1;
denom = 3;
valueofpi = sqrt(8 * pisqover8);
for step = 1:steps
 % Check for Cancel button press
 if getappdata(h,'canceling')
 break
 end
 % Report current estimate in the waitbar's message field
 waitbar(step/steps,h,sprintf('%12.9f',valueofpi))
 % Update the estimate
 pisqover8 = pisqover8 + 1 / (denom * denom);
 denom = denom + 2;
 valueofpi = sqrt(8 * pisqover8);
end
delete(h) % DELETE the waitbar; don't try to CLOSE it.
```

# waitbar

---

The function sets the figure Name property to describe what is being computed. In the for loop, calling waitbar sets the fractional progress indicator and displays intermediate results. the code `waitbar(i/steps,h,sprintf('%12.9f',valueofpi))` sets the wait bar's message variable to a string representation of the current estimate of  $\pi$ . Naturally, the extra computation involved makes iterations last longer than they need to, but such feedback can be helpful to users.

---

**Note** You should call `delete` to remove a wait bar when you give it a `CloseRequestFcn`, as in the preceding code; calling `close` does not close it, and makes its Cancel and Close Window buttons unresponsive. This happens because the figure's `CloseRequestFcn` recursively calls itself. In such a situation you must forcibly remove the wait bar, for example like this:

```
set(0,'ShowHiddenHandles','on')
delete(get(0,'Children'))
```

However, as issuing these commands will delete all open figures—not just the wait bar—it is best never to use `close` in a `CloseRequestFcn` to close a window.

---

## See Also

`close` | `delete` | `dialog` | `msgbox` | `getappdata` | `setappdata`

**Purpose**

Block execution and wait for event or condition

**Syntax**

```
waitfor(h)
waitfor(h, 'PropertyName')
waitfor(h, 'PropertyName', PropertyValue)
```

**Description**

`waitfor(h)` blocks the caller from executing statements until the graphics object identified by handle `h` closes (is deleted). `h` must be scalar. When object `h` no longer exists, `waitfor` returns, enabling execution to resume. If the object does not exist, `waitfor` returns immediately without processing any events.

`waitfor(h, 'PropertyName')` blocks the caller from executing until the value of `'PropertyName'` (any property of the graphics object `h`) changes or `h` closes (is deleted). If `'PropertyName'` is not a valid property for the object, `waitfor` returns immediately without processing any events.

`waitfor(h, 'PropertyName', PropertyValue)` blocks the caller from executing until the value of `'PropertyName'` for the graphics object `h` changes to the specific value `PropertyValue` or `h` closes (is deleted). If the value of `'PropertyName'` is already `PropertyValue`, `waitfor` returns immediately without processing any events.

**Definitions**

- `waitfor` blocks execution so that command-line expressions and subsequent statements in the blocked file do not execute until a specified condition occurs.
- While `waitfor` prevents its caller from continuing, callbacks that respond to various events (for example, pressing a mouse button) can still run, unaffected by `waitfor`.
- `waitfor` also blocks Simulink models from executing, but callbacks do still execute.
- `waitfor` can block nested function calls. For example, a callback invoked while `waitfor` is active can invoke `waitfor`.
- If you type **Ctrl+C** in the Command Window while `waitfor` is blocking execution, the executing program terminates. To avoid

terminating, the program can call `waitfor` within a `try/catch` block that handles the exception that typing **Ctrl+C** generates. To learn more, see the third following example.

## Examples

Create a plot and pause execution of the rest of the statements until you close the figure window:

```
f = warndlg('This is a warning.', 'A Warning Dialog');
disp('This prints immediately');
drawnow % Necessary to print the message
waitfor(f);
disp('This prints after you close the warning dialog');
```

---

Suspend execution until name of figure changes:

```
f = figure('Name', datestr(now));
h = uicontrol('String','Change Name',...
 'Position',[20 20 100 30],...
 'Callback', 'set(gcf, 'Name', datestr(now))');
disp('This prints immediately');
drawnow % Necessary to print the message
waitfor(f, 'Name');
disp('This prints after button click that changes the figure''s name');
```

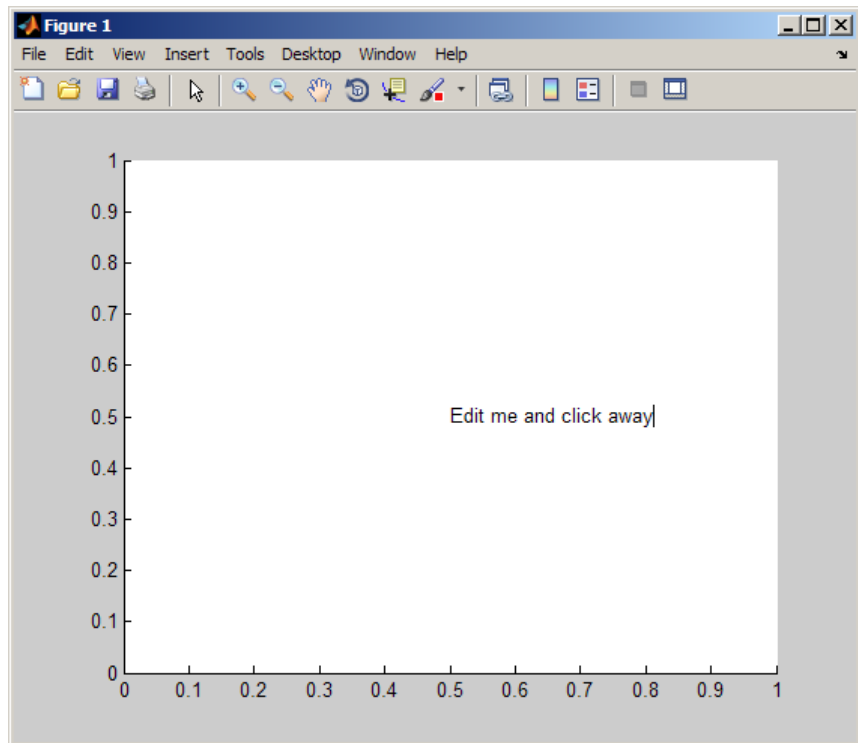

---

Display text object and wait for user to edit it:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH,'Editing','on', 'BackgroundColor',[1 1 1]);
disp('This prints immediately. ');
drawnow
waitfor(textH,'Editing','off');
set(textH,'BackgroundColor',[1 1 0]);
```

```
disp('This prints after text editing is complete.');
```

If you close the figure while `waitfor` is executing, an error occurs because the code attempts to access handles of objects that no longer exist. You can handle the error by enclosing code starting with the call to `waitfor` in a `try/catch` block, as follows:

```
figure;
textH = text(.5, .5, 'Edit me and click away');
set(textH, 'Editing', 'on', 'BackgroundColor', [1 1 1]);
disp('This prints immediately.');
```

`drawnow`  
% Use `try/catch` block to handle errors,  
% such as deleting figure

# waitfor

---

```
try
 waitfor(textH,'Editing','off');
 set(textH,'BackgroundColor',[1 1 0]);
 disp('This prints after text editing is complete.');
```

catch ME

```
 disp('This prints if figure is deleted:')
 disp(ME.message)
 % You can place other code to respond to the error here
end
```

The ME variable is a MATLAB Exception object that you can use to determine the type of error that occurred. For more information, see “Respond to an Exception”.

## How To

- “Control Callback Execution and Interruption”

<b>Purpose</b>	Wait for key press or mouse-button click
<b>Syntax</b>	<code>k = waitforbuttonpress</code>
<b>Description</b>	<p><code>k = waitforbuttonpress</code> blocks the caller's execution stream until the function detects that the user has clicked a mouse button or pressed a key while the figure window is active. The function returns</p> <ul style="list-style-type: none"><li>• 0 if it detects a mouse button click</li><li>• 1 if it detects a key press</li></ul> <p>If a <code>WindowButtonDownFcn</code> is defined for the figure, its callback is executed before <code>waitforbuttonpress</code> returns a value.</p> <p>Only keys that generate characters cause the function to return. Pressing any of the following keys by itself does nothing: <b>Ctrl</b>, <b>Shift</b>, <b>Alt</b>, <b>Caps_lock</b>, <b>Num_lock</b>, <b>Scroll_lock</b>.</p> <p>Additional information about the event that causes execution to resume is available through the figure <code>CurrentCharacter</code>, <code>SelectionType</code>, and <code>CurrentPoint</code> properties.</p> <p>You can interrupt <code>waitforbuttonpress</code> by typing <b>Ctrl+C</b>, but an error results unless the function is called from within a <code>try/catch</code> block. You also receive an error from <code>waitforbuttonpress</code> if you close the figure by clicking the <b>X</b> close box unless you call <code>waitforbuttonpress</code> within a <code>try/catch</code> block.</p>

**Examples** These statements display text in the Command Window when the user either clicks a mouse button or types a key in the figure window:

```
w = waitforbuttonpress;
if w == 0
 disp('Button click')
else
 disp('Key press')
end
```

# waitforbuttonpress

---

## See Also

`dragrect` | `ginput` | `rbbox` | `waitfor`

## Purpose

Open warning dialog box

## Syntax

```
h = warndlg
h = warndlg(warningstring)
h = warndlg(warningstring,dlgname)
h = warndlg(warningstring,dlgname,createmode)
```

## Description

`h = warndlg` displays a dialog box named Warning Dialog containing the string `This is the default warning string`. The `warndlg` function returns the handle of the dialog box in `h`. The warning dialog box disappears after the user clicks **OK**.

`h = warndlg(warningstring)` displays a dialog box with the title Warning Dialog containing the string specified by `warningstring`. The `warningstring` argument can be any valid string format – cell arrays are preferred.

To use multiple lines in your warning, define `warningstring` using either of the following:

- `sprintf` with newline characters separating the lines

```
warndlg(sprintf('Message line 1 \n Message line 2'))
```

- Cell arrays of strings

```
warndlg({'Message line 1';'Message line 2'})
```

`h = warndlg(warningstring,dlgname)` displays a dialog box with title `dlgname`.

`h = warndlg(warningstring,dlgname,createmode)` specifies whether the warning dialog box is modal or nonmodal. Optionally, it can also specify an interpreter for `warningstring` and `dlgname`. The `createmode` argument can be a string or a structure.

If `createmode` is a string, it must be one of the values shown in the following table.

createmode Value	Description
modal	Replaces the warning dialog box having the specified Title, that was last created or clicked on, with a modal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.
non-modal (default)	Creates a new nonmodal warning dialog box with the specified parameters. Existing warning dialog boxes with the same title are not deleted.
replace	Replaces the warning dialog box having the specified Title, that was last created or clicked on, with a nonmodal warning dialog box as specified. All other warning dialog boxes with the same title are deleted. The dialog box which is replaced can be either modal or nonmodal.

---

**Note** A modal dialog box prevents the user from interacting with other windows before responding. To block MATLAB program execution as well, use the `uiwait` function.

If you open a dialog with `errordlg`, `msgbox`, or `warndlg` using 'CreateMode', 'modal' and a non-modal dialog created with any of these functions is already present and *has the same name as the modal dialog*, the non-modal dialog closes when the modal one opens.

For more information about modal dialog boxes, see `WindowState` in the Figure Properties.

---

If `CreateMode` is a structure, it can have fields `WindowStyle` and `Interpreter`. `WindowStyle` must be one of the options shown in the table above. `Interpreter` is one of the strings 'tex' or 'none'. The default value for `Interpreter` is 'none'.

## Examples

The statement

```
warndlg('Pressing OK will clear memory','!! Warning !!')
```

displays this dialog box:

## See Also

[dialog](#) | [errorDlg](#) | [helpDlg](#) | [inputDlg](#) | [listDlg](#) | [msgBox](#) | [questDlg](#) | [figure](#) | [uiwait](#) | [uiresume](#) | [warning](#)

# warning

---

**Purpose** Warning message

**Syntax**

```
warning('message')
warning('message', a1, a2,...)
warning('message_id', 'message')
warning('message_id', 'message', a1, a2, ..., an)
s = warning(state, 'message_id')
s = warning(state, mode)
```

**Description**

`warning('message')` displays descriptive text message and sets the warning state that `lastwarn` returns. If `message` is an empty string (`''`), `warning` resets the warning state but does not display any text.

`warning('message', a1, a2,...)` displays a message string that contains formatting conversion characters, such as those used with the MATLAB `sprintf` function. Each conversion character in `message` is converted to one of the values `a1, a2, ...` in the argument list.

---

**Note** MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. See Example 3 below.

---

`warning('message_id', 'message')` attaches a unique identifier, or `message_id`, to the warning message. The identifier enables you to single out certain warnings during the execution of your program, controlling what happens when the warnings are encountered.

`warning('message_id', 'message', a1, a2, ..., an)` includes formatting conversion characters in `message`, and the character translations in arguments `a1, a2, ..., an`.

`s = warning(state, 'message_id')` is a warning control statement that enables you to indicate how you want MATLAB to act on certain warnings. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `message_id` argument can be a message identifier string, `'all'`, or `'last'`.

Output `s` is a structure array that indicates the previous state of the selected warnings. The structure has the fields `identifier` and `state`.

`s = warning(state, mode)` is a warning control statement that enables you to display a stack trace or display more information with each warning. The `state` argument can be `'on'`, `'off'`, or `'query'`. The `mode` argument can be `'backtrace'` or `'verbose'`.

## Examples

### Example 1

Generate a warning that displays a simple string:

```
if ~ischar(p1)
 warning('Input must be a string')
end
```

### Example 2

Generate a warning string that is defined at run-time. The first argument defines a message identifier for this warning:

```
warning('MATLAB:paramAmbiguous', ...
 'Ambiguous parameter name, "%s".', param)
```

### Example 3

MATLAB converts special characters (like `\n` and `%d`) in the warning message string only when you specify more than one input argument with `warning`. In the single argument case shown below, `\n` is taken to mean `backslash-n`. It is not converted to a newline character:

```
warning('In this case, the newline \n is not converted.')
Warning: In this case, the newline \n is not converted.
```

But, when more than one argument is specified, MATLAB does convert special characters. This is true regardless of whether the additional argument supplies conversion values or is a message identifier:

```
warning('WarnTests:convertTest', ...
 'In this case, the newline \n is converted.')
Warning: In this case, the newline
```

# warning

---

is converted.

## Example 4

Turn on one particular warning, saving the previous state of this one warning in `s`. Remember that this nonquery syntax performs an implicit query prior to setting the new state:

```
s = warning('on', 'Control:parameterNotSymmetric');
```

After doing some work that includes making changes to the state of some warnings, restore the original state of all warnings:

```
warning(s)
```

**Purpose** Waterfall plot

**Syntax**

```
waterfall(Z)
waterfall(X,Y,Z)
waterfall(...,C)
waterfall(axes_handles,...)
h = waterfall(...)
```

**Description** The `waterfall` function draws a mesh similar to the `meshz` function, but it does not generate lines from the columns of the matrices. This produces a “waterfall” effect.

`waterfall(Z)` creates a waterfall plot using  $x = 1:\text{size}(Z,2)$  and  $y = 1:\text{size}(Z,1)$ .  $Z$  determines the color, so color is proportional to surface height.

`waterfall(X,Y,Z)` creates a waterfall plot using the values specified in  $X$ ,  $Y$ , and  $Z$ .  $Z$  also determines the color, so color is proportional to the surface height. If  $X$  and  $Y$  are vectors,  $X$  corresponds to the columns of  $Z$ , and  $Y$  corresponds to the rows, where  $\text{length}(x) = n$ ,  $\text{length}(y) = m$ , and  $[m,n] = \text{size}(Z)$ .  $X$  and  $Y$  are vectors or matrices that define the  $x$ - and  $y$ -coordinates of the plot.  $Z$  is a matrix that defines the  $z$ -coordinates of the plot (i.e., height above a plane). If  $C$  is omitted, color is proportional to  $Z$ .

`waterfall(...,C)` uses scaled color values to obtain colors from the current colormap. Color scaling is determined by the range of  $C$ , which must be the same size as  $Z$ . MATLAB performs a linear transformation on  $C$  to obtain colors from the current colormap.

`waterfall(axes_handles,...)` plots into the axes with handle `axes_handle` instead of the current axes (`gca`).

`h = waterfall(...)` returns the handle of the patch graphics object used to draw the plot.

# waterfall

---

## Tips

For column-oriented data analysis, use `waterfall(Z')` or `waterfall(X',Y',Z')`.

## Examples

Produce a waterfall plot of the peaks function.

```
figure
[X,Y,Z] = peaks(30);
waterfall(X,Y,Z)
```

## Algorithms

The range of `X`, `Y`, and `Z`, or the current setting of the axes `Xlim`, `Ylim`, and `Zlim` properties, determines the range of the axes (also set by `axis`). The range of `C`, or the current setting of the axes `CLim` property, determines the color scaling (also set by `caxis`).

The `CData` property for the patch graphics objects specifies the color at every point along the edge of the patch, which determines the color of the lines.

The `waterfall` plot looks like a mesh surface; however, it is a patch graphics object. To create a surface plot similar to `waterfall`, use the `meshz` function and set the `MeshStyle` property of the surface to `'Row'`. For a discussion of parametric surfaces and related color properties, see `surf`.

# wavinfo

---

**Purpose** Information about WAVE (.wav) sound file

---

**Note** `wavinfo` will be removed in a future release. Use `audioinfo` instead.

---

**Syntax** `[m d] = wavinfo(filename)`

**Description** `[m d] = wavinfo(filename)` returns information about the contents of the WAVE sound file specified by the string *filename*. Enclose the *filename* input in single quotes.

*m* is the string 'Sound (WAV) file', if *filename* is a WAVE file. Otherwise, it contains an empty string ('').

*d* is a string that reports the number of samples in the file and the number of channels of audio data. If *filename* is not a WAVE file, it contains the string 'Not a WAVE file'.

**See Also** `audioplayer` | `audiorecorder` | `audioread` | `audiowrite`

**Purpose** Play recorded sound on PC-based audio output device

---

**Note** wavplay has been removed. Use audioplayer instead.

---

**Syntax**

```
wavplay(y,Fs)
wavplay(y,Fs,mode)
```

**Description** wavplay(y,Fs) plays the audio signal stored in the vector y on a PC-based audio output device. Fs is the integer sample rate in Hz (samples per second). The default value for Fs is 11025 Hz. wavplay supports only 1- or 2-channel (mono or stereo) audio signals. To play in stereo, y must be a two-column matrix.

wavplay(y,Fs,mode) specifies how wavplay interacts with the command line. The string mode is one of the following:

- 'sync' (default): You do not have access to the command line until the sound has finished playing (a blocking device call).
- 'async': You have immediate access to the command line as soon as the sound begins to play on the audio output device (a nonblocking device call). If you call wavplay again in async mode while the audio is playing, wavplay blocks access to the command line until the original playback completes.

The audio signal y can be one of four data types. The number of bits used to quantize and play back each sample depends on the data type.

#### Data Types for wavplay

Data Type	Quantization
Double-precision (default value)	16 bits/sample
Single-precision	16 bits/sample
16-bit signed integer	16 bits/sample
8-bit unsigned integer	8 bits/sample

# wavplay

---

## Tips

The wavplay function is for use only with 32-bit Microsoft Windows operating systems. To play audio data on other platforms, use audioplayer.

## Examples

The MAT-files gong.mat and chirp.mat both contain an audio signal y and a sampling frequency Fs. Load and play the gong and the chirp audio signals. Change the names of these signals in between load commands and play them sequentially using the 'sync' option for wavplay.

```
load chirp;
y1 = y; Fs1 = Fs;
load gong;
wavplay(y1,Fs1,'sync') % The chirp signal finishes before the
wavplay(y,Fs) % gong signal begins playing.
```

## See Also

[audioplayer](#) | [audioinfo](#) | [audioread](#) | [audiowrite](#)

**Purpose** Read WAVE (.wav) sound file

---

**Note** wavread will be removed in a future release. Use audioread instead.

---

**Syntax**

```
y = wavread(filename)
[y, Fs] = wavread(filename)
[y, Fs, nbits] = wavread(filename)
[y, Fs, nbits, opts] = wavread(filename)
[___] = wavread(filename, N)
[___] = wavread(filename, [N1 N2])
[___] = wavread(___, fmt)
siz = wavread(filename, 'size')
```

**Description** `y = wavread(filename)` loads a WAVE file specified by the string `filename`, returning the sampled data in `y`. If `filename` does not include an extension, `wavread` appends `.wav`.

`[y, Fs] = wavread(filename)` returns the sample rate (`Fs`) in Hertz used to encode the data in the file.

`[y, Fs, nbits] = wavread(filename)` returns the number of bits per sample (`nbits`).

`[y, Fs, nbits, opts] = wavread(filename)` returns a structure `opts` of additional information contained in the WAV file. The content of this structure differs from file to file. Typical structure fields include `opts.fmt` (audio format information) and `opts.info` (text that describes the title, author, etc.).

`[ ___ ] = wavread(filename, N)` returns only the first `N` samples from each channel in the file.

`[ ___ ] = wavread(filename, [N1 N2])` returns only samples `N1` through `N2` from each channel in the file.

[ \_\_\_ ] = wavread( \_\_\_, *fmt*) specifies the data format of *y* used to represent samples read from the file. *fmt* can be either of the following values, or a partial match (case-insensitive):

- 'double'      Double-precision normalized samples (default).
- 'native'      Samples in the native data type found in the file.

*siz* = wavread(*filename*, 'size') returns the size of the audio data contained in *filename* instead of the actual audio data, returning the vector *siz* = [*samples channels*].

## Output Scaling

The range of values in *y* depends on the data format *fmt* specified. Some examples of output scaling based on typical bit-widths found in a WAV file are given below for both 'double' and 'native' formats.

## Native Formats

Number of Bits	MATLAB Data Type	Data Range
8	uint8 (unsigned integer)	$0 \leq y \leq 255$
16	int16 (signed integer)	$-32768 \leq y \leq +32767$
24	int32 (signed integer)	$-2^{23} \leq y \leq 2^{23}-1$
32	single (floating point)	$-1.0 \leq y < +1.0$

**Double Formats**

Number of Bits	MATLAB Data Type	Data Range
N<32	double	-1.0 ≤ y < +1.0
N=32	double	-1.0 ≤ y ≤ +1.0 Note: Values in y might exceed -1.0 or +1.0 for the case of N=32 bit data samples stored in the WAV file.

wavread supports multi-channel data, with up to 32 bits per sample.

wavread supports Pulse-code Modulation (PCM) data format only.

**Examples**

Create a WAV file from the example file handel.mat, and read portions of the file back into MATLAB.

```
% Create WAV file in current folder.
load handel.mat

hfile = 'handel.wav';
wavwrite(y, Fs, hfile)
clear y Fs

% Read the data back into MATLAB, and listen to audio.
[y, Fs, nbits, readinfo] = wavread(hfile);
sound(y, Fs);

% Pause before next read and playback operation.
duration = numel(y) / Fs;
pause(duration + 2)

% Read and play only the first 2 seconds.
nsamples = 2 * Fs;
[y2, Fs] = wavread(hfile, nsamples);
```

# wavread

---

```
sound(y2, Fs);
pause(4)

% Read and play the middle third of the file.
sizeinfo = wavread(hfile, 'size');

tot_samples = sizeinfo(1);
startpos = tot_samples / 3;
endpos = 2 * startpos;

[y3, Fs] = wavread(hfile, [startpos endpos]);
sound(y3, Fs);
```

## See Also

```
mmfileinfo | audioinfo | audiowrite | audioread | audioplayer
| audiorecorder | sound
```

**Purpose** Record sound using PC-based audio input device

---

**Note** wavrecord has been removed. Use audiorecorder instead.

---

**Syntax**

```
y = wavrecord(n,Fs)
y = wavrecord(__ ,ch)
y = wavrecord(__ , 'dtype')
```

**Description** `y = wavrecord(n,Fs)` records `n` samples of an audio signal, sampled at a rate of `Fs` Hz (samples per second). The default value for `Fs` is 11025 Hz.

`y = wavrecord( __ ,ch)` uses `ch` number of input channels from the audio device. `ch` can be either 1 or 2, for mono or stereo, respectively. The default value for `ch` is 1.

`y = wavrecord( __ , 'dtype')` uses the data type specified by the string `'dtype'` to record the sound. The following table lists the string values for `'dtype'` along with the corresponding bits per sample and acceptable data range for `y`.

<b>dtype</b>	<b>Bits/sample</b>	<b>y Data Range</b>
'double'	16	$-1.0 \leq y < +1.0$
'single'	16	$-1.0 \leq y < +1.0$
'int16'	16	$-32768 \leq y \leq +32767$
'uint8'	8	$0 \leq y \leq 255$

**Tips** Standard sampling rates for PC-based audio hardware are 8000, 11025, 22050, and 44100 samples per second. Stereo signals are returned as two-column matrices. The first column of a stereo audio matrix corresponds to the left input channel, while the second column corresponds to the right input channel.

# wavrecord

---

The `wavrecord` function is for use only with 32-bit Microsoft Windows operating systems. To record audio data from audio input devices on other platforms, use `audiorecorder`.

## Examples

Record 5 seconds of 16-bit audio sampled at 11025 Hz. Play back the recorded sound using `wavplay`. Speak into your audio device (or produce your audio signal) while the `wavrecord` command runs.

```
Fs = 11025;
y = wavrecord(5*Fs,Fs,'int16');
wavplay(y,Fs);
```

## See Also

`audiorecorder` | `audioinfo` | `audioread` | `audiowrite`

**Purpose** Write WAVE (.wav) sound file

---

**Note** wavwrite will be removed in a future release. Use audiowrite instead.

---

**Syntax**

```
wavwrite(y, filename)
wavwrite(y, Fs, filename)
wavwrite(y, Fs, N, filename)
```

**Description** wavwrite(y, filename) writes the data stored in the variable *y* to a WAVE file called *filename*. The *filename* input is a string enclosed in single quotes. The data has a sample rate of 8000 Hz and is assumed to be 16-bit. Each column of the data represents a separate channel. Therefore, stereo data should be specified as a matrix with two columns.

wavwrite(y, Fs, filename) writes the data stored in the variable *y* to a WAVE file called *filename*. The data has a sample rate of *Fs* Hz and is assumed to be 16-bit.

wavwrite(y, Fs, N, filename) writes the data stored in the variable *y* to a WAVE file called *filename*. The data has a sample rate of *Fs* Hz and is *N*-bit, where *N* is 8, 16, 24, or 32.

### Input Data Ranges

The range of values in *y* depends on the number of bits specified by *N* and the data type of *y*. The following tables list the valid input ranges based on the value of *N* and the data type of *y*.

If *y* contains integer data:

N Bits	y Data Type	y Data Range	Output Format
8	uint8	$0 \leq y \leq 255$	uint8
16	int16	$-32768 \leq y \leq +32767$	int16
24	int32	$-2^{23} \leq y \leq 2^{23} - 1$	int32

If  $y$  contains floating-point data:

<b>N Bits</b>	<b>y Data Type</b>	<b>y Data Range</b>	<b>Output Format</b>
8	single or double	$-1.0 \leq y < +1.0$	uint8
16	single or double	$-1.0 \leq y < +1.0$	int16
24	single or double	$-1.0 \leq y < +1.0$	int32
32	single or double	$-1.0 \leq y \leq +1.0$	single

For floating point data where  $N < 32$ , amplitude values are clipped to the range  $-1.0 \leq y < +1.0$ .

---

**Note** 8-, 16-, and 24-bit files are type 1 integer pulse code modulation (PCM). 32-bit files are written as type 3 normalized floating point.

---

## See Also

`mmfileinfo` | `audioinfo` | `audioread` | `audiowrite` | `audioplayer`  
| `audiorecorder` | `sound`

**Purpose**

Open Web page or file in browser

**Syntax**

```
web
web(url)
web(url,opt)
web(url,opt1,...,optN)

stat = web(___)
[stat,h] = web(___)
[stat,h,url] = web(___)
```

**Description**

`web` opens an empty MATLAB Web browser.

`web(url)` opens the page specified by `url` in the MATLAB Web browser. If multiple browsers are open, the page displays in the one that was most recently used.

`web(url,opt)` opens the page using the specified browser option, such as `'-new'` to create a new browser instance or `'-browser'` to use the system browser.

`web(url,opt1,...,optN)` opens the page using one or more browser options.

`stat = web( ___ )` returns the status of the operation: 0 if successful, 1 or 2 if unsuccessful. You can include any of the input arguments in previous syntaxes.

`[stat,h] = web( ___ )` returns a handle to a MATLAB Web browser that allows you to close it using the command `close(h)`. If you do not specify any inputs to the `web` function, such as `[stat,h] = web`, then the handle corresponds to the most recently used MATLAB Web browser.

[stat,h,url] = web( \_\_\_ ) returns the URL of the current page in the MATLAB Web browser.

## Input Arguments

### url - Web page address or file location

string

Web page address or file location, specified as a string. File locations can include an absolute or relative path.

If url corresponds to a file in the installed product documentation, then the page displays in the MATLAB Help browser instead of the Web browser.

**Example:** 'http:\\www.mathworks.com'

**Example:** 'myfolder/myfile.html'

### opt - Browser option

'-browser' | '-new' | '-noaddressbox' | '-notoolbar'

Browser option, specified as one of the following strings. Options can appear in any order.

- '-browser' Opens the page in a system browser window instead of the MATLAB Web browser. On Microsoft Windows and Apple Macintosh platforms, the operating system determines the system Web browser. On other systems, the default is the Mozilla® Firefox® browser, but you can change the default using MATLAB Web preferences.
- '-new' Opens the page in a new MATLAB Web browser window. Does not apply to the system browser.

- '-noaddressbox' Opens the page in a browser that does not display the address box. Only applies to new instances of the MATLAB Web browser.
- '-notoolbar' Opens the page in a browser that does not display a toolbar or address box. Only applies to new instances of the MATLAB Web browser.

**Example:** '-new', '-noaddressbox'

## Output Arguments

### **stat - Browser status**

0 | 1 | 2

Browser status, returned as an integer with one of these values:

- 0 Found and launched system browser.
- 1 Could not find system browser.
- 2 Found, but could not launch system browser.

### **h - Handle to most recent MATLAB Web browser**

scalar

Handle to the most recent MATLAB Web browser, returned as a scalar instance of the associated Java class.

If you do not request the handle when you open the page, be aware that this handle might not correspond to your most recent use of the `web` function. Other MATLAB functionality also uses the `web` function, such as links to external sites from the Help browser.

### **url - Current page address**

string

Current page address in the most recent MATLAB Web browser, returned as a string.

## Examples

### Web Page in MATLAB Web Browser

Open the MathWorks Web site home page.

```
url = 'http://www.mathworks.com';
web(url)
```

Open the page in a new instance of the browser that does not include a toolbar.

```
web(url, '-new', '-notoolbar')
```

### File in MATLAB Web Browser

View an HTML file that resides on your system.

Create an HTML file by publishing an example program file. Copy the program file to the current folder so that the code can run during the publishing process.

```
program = fullfile(matlabroot, 'help', 'techdoc', ...
 'matlab_env', 'examples', 'fourier_demo2.m');
copyfile(program);
htmlFile = publish('fourier_demo2.m');
```

View a file by specifying the file name.

```
web(htmlFile)
```

Alternatively, you can use the `file:///` URL scheme, as long as you include the full path. The `publish` function returns the path in the `htmlFile` output.

```
url = ['file:///', htmlFile];
web(url)
```

### Web Page in System Browser

Open the MathWorks Web site home page in the system browser.

```
url = 'http://www.mathworks.com';
```

```
web(url, '-browser')
```

### Email from System Browser

Send email from your system browser's default mail application using the `mailto:` URL scheme.

To run this example, replace the value for `email` with a valid email address.

```
email = 'myaddress@provider.ext';
url = ['mailto:',email];
web(url)
```

### Handle to MATLAB Web Browser

Open the MathWorks Web site home page, and then close the browser using its handle.

```
url = 'http://www.mathworks.com';
[stat,h] = web(url);
```

Close the browser window.

```
close(h)
```

### Text Displayed in MATLAB Web Browser

View formatted text using the `text://` URL scheme.

```
web('text://<html><h1>Hello World</h1></html>')
```

## Tips

- If you plan to deploy an application that calls the `web` function using the MATLAB Compiler product, then use the `'-browser'` option.
- If you are displaying Japanese streaming text in the MATLAB Web browser, specify a header that includes the `charset` attribute. For example:

```
web(['text://<html><head><meta http-equiv="content-type" ' ...
 'content="text/html; charset=utf-8"></head><body>TEXT</body></html>'])
```

## See Also

`urlread` | `urlwrite`

## Concepts

- “Web Browsers and MATLAB”
- “Specify Proxy Server Settings for Connecting to the Internet”
- “Specify the System Browser for UNIX Platforms”

## Purpose

Day of week

## Syntax

```
DayNumber = weekday(D)
[DayNumber,DayName] = weekday(D)
[DayNumber,DayName] = weekday(D,DayForm)
[DayNumber,DayName] = weekday(D,language)
[DayNumber,DayName] = weekday(D,DayForm,language)
```

## Description

`DayNumber = weekday(D)` returns a number representing the day of the week for each element in `D`.

`[DayNumber,DayName] = weekday(D)` additionally returns abbreviated English names for the day of the week, in `DayName`.

`[DayNumber,DayName] = weekday(D,DayForm)` returns the name for the day of the week in the format specified by `DayForm`, in US English.

`[DayNumber,DayName] = weekday(D,language)` returns the abbreviated name for the day of the week in the language of the locale specified in `language`.

`[DayNumber,DayName] = weekday(D,DayForm,language)` returns the name for the day of the week in the specified format and in the language of the specified locale. You can specify `DayForm` and `language` in either order.

## Input Arguments

### **D - Serial date numbers or date strings**

vector | matrix | string | cell array of strings | character array

Serial date numbers or date strings. Date numbers can be specified as a vector or matrix. Date strings can be specified as a single string, a cell array of strings, or a character array. If `D` is a cell array of strings, it must be 1-by-`n` or `n`-by-1.

# weekday

---

If D is a single date string, a cell array of date strings, or a character array of date strings, the date strings can be in one of the following formats.

Date String Format	Example
dd-mmm-yyyy	01-Mar-2000
mm/dd/yyyy	03/01/2000
yyyy-mm-dd	2000-03-01

For date strings in other formats, first convert them to serial date numbers using the `datenum` function, before passing them to `weekday`.

## Data Types

single | double | int8 | int16 | int32 | int64 | uint8 | uint16 | uint32 | uint64 | char | cell

## DayForm - Format of output day names

'short' (default) | 'long'

Format of the output day names, specified as one of the following strings.

DayForm	Format of DayName Names	Example
'short'	Abbreviated name	Mon
'long'	Full name	Monday

## language - Output language of day names

'en\_US' (default) | 'local'

Output language of day names in `DayName`, specified as one of the following strings.

language	Description
'en_US'	US English
'local'	Language of the current locale

## Output Arguments

### DayNumber - Value representing day of week

array of integers in the range [1,7]

Value representing the day of the week, returned as an array of integers in the range [1,7], where 1 represents Sunday, and 7 represents Saturday.

- If input D is a numeric array, then the size of DayNumber is equivalent to the size of D.
- If input D is a cell array of strings, then DayNumber is an m-by-1 vector, where m is equivalent to the length of D.

### DayName - Name of day of week

character array

Name of the day of the week, returned as a character array. The content of DayName depends on DayForm.

- If DayForm is 'short', then DayName contains an abbreviated name (for example, Tues).
- If DayForm is 'long', then DayName contains the full name of the weekday (for example, Tuesday).

DayName is m-by-n, where m is the number of serial date numbers or date strings in D.

## Examples

### Return Day of Week of a Date String

Determine the day of the week of December 21, 2012.

```
D = '21-Dec-2012';
[DayNumber,DayName] = weekday(D)
```

# weekday

---

```
DayNumber =
```

```
 6
```

```
DayName =
```

```
Fri
```

December 21, 2012 falls on a Friday.

## **Return Full Day Names of Multiple Date Numbers**

Return the full name of the day of the week for a vector of serial date numbers.

```
D = [734999;735015];
DayForm = 'long';
[DayNumber,DayName] = weekday(D,DayForm)
```

```
DayNumber =
```

```
 5
```

```
 7
```

```
DayName =
```

```
Thursday
```

```
Saturday
```

## **Return Full Day Names in Local Language**

Return day names in U.S. English using the language input argument.

```
D = 728647;
DayForm = 'long';
language = 'en_US';
```

```
[DayNumber, DayName] = weekday(D, DayForm, language)
```

```
DayNumber =
```

```
2
```

```
DayName =
```

```
Monday
```

In U.S. English, the name of the day of the week is Monday.

Return day names in the language of the current locale.

```
language = 'local';
```

```
[DayNumber, DayName] = weekday(D, DayForm, language)
```

```
DayNumber =
```

```
2
```

```
DayName =
```

```
Lundi
```

In a French locale, the name of the day of the week is Lundi.

## **Return Day of Week of a Date String in Custom Format**

Determine the day of the week for a date specified in the format `mmm.dd.yyyy`. Call `datenum` inside of `weekday` to specify the format of the input date string.

```
[DayNumber, DayName] = weekday(datenum('Dec.21.2012', 'mmm.dd.yyyy'))
```

```
DayNumber =
```

# weekday

---

6

DayName =

Fri

## See Also

[datenum](#) | [datevec](#) | [eomday](#)

**Purpose** List MATLAB files in folder

**Syntax**

```

what
what folderName
what className
what packageName
s = what(' folderName ')

```

**Description**

what lists the path for the current folder, and lists all files and folders relevant to MATLAB found in the current folder. Files listed are M, MAT, MEX, MDL, SLX, and P-files. Folders listed are all class and package folders.

what *folderName* lists path, file, and folder information for *folderName*.

what *className* lists path, file, and folder information for method folder *@className*. For example, what cfit lists the MATLAB files and folders in toolbox/curvefit/curvefit/@cfit.

what *packageName* lists path, file, and folder information for package folder *+packageName*. For example, what commsrc lists the MATLAB files and folders in toolbox/comm/comm/+commsrc.

s = what(' *folderName* ') returns the results in a structure array with the fields shown in the following table.

Field	Description
path	Path to folder
m	Cell array of MATLAB program file names
mat	Cell array of MAT-file names
mex	Cell array of MEX-file names
mdl	Cell array of MDL-file names
slx	Cell array of SLX-file names
p	Cell array of P-file names

# what

Field	Description
classes	Cell array of class folders
packages	Cell array of package folders

## Examples

List the MATLAB files and folders in C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012b:

```
what audiovideo

MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo

FileFormatInfo

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo\+audiovideo

internal writer

MATLAB Code files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

Contents auinfo mmcompinfo wavplay
audiodevinfo auread mmfileinfo wavread
audioinfo auwrite movie2avi wavrecord
audioplayerreg avgate mu2lin wavwrite
audioread avifinfo prefspanel
audiorecorderreg aviinfo sound
audiouniquename aviread soundsc
audiowrite lin2mu wavfinfo

MAT-files in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

chirp handel splat
gong laughter train
```

Classes in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

```
VideoReader audioplayer avifile
VideoWriter audiorecorder mmreader
```

Packages in folder C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\audiovideo

```
audiovideo
```

---

Obtain a structure array containing the file and folder names in `toolbox/matlab/codetools` that are relevant to MATLAB, where *Rnnnn* represents the folder for the MATLAB release, for example, R2012a:

```
s = what('codetools')
```

```
s =
```

```
 path: 'C:\Program Files\MATLAB\Rnnnn\toolbox\matlab\codetools'
 m: {77x1 cell}
 mat: {0x1 cell}
 mex: {0x1 cell}
 mdl: {0x1 cell}
 slx: {0x1 cell}
 p: {0x1 cell}
 classes: {2x1 cell}
 packages: {3x1 cell}
```

---

Find the supporting files for one of the packages in the Communications System Toolbox product:

```
p1 = what('comm');
p1.packages
ans =
```

# what

---

```
'gpu'
'internal'

ans =

 'internal'.
.
.
p2 = what('commsrc');
p2.m
ans =
 'abstractJitter.m'
 'abstractPulse.m'
 'combinedjitter.m'
 'diracjitter.m'
 'periodicjitter.m'
 'randomjitter.m'
```

## See Also

**Purpose** Release Notes

---

**Note** whatsnew will be removed in a future release.

---

**Syntax** whatsnew

**Description** whatsnew displays the MATLAB Release Notes in the Help browser, presenting information about new features, problems from previous releases that have been fixed in the current release, and compatibility issues.

**See Also** help | version

# which

---

**Purpose** Locate functions and files

**Syntax**

```
which item
which fun1 in fun2

which ___ -all

str = which(item)
str = which(fun1,'in',fun2)

str = which(___, '-all')
```

**Description** `which item` displays the full path for `item`.

- If `item` is a MATLAB function in an M or P file, or a Simulink model in an SLX or MDL file, then `which` displays the full path for the corresponding file. `item` must be on the MATLAB path.
- If `item` is a method in a loaded Java class, then `which` displays the package, class, and method name for that method.
- If `item` is a workspace variable, then `which` displays a message identifying `item` as a variable.
- If `item` is a file name including the extension, and it is in the current working folder or on the MATLAB path. then `which` displays the full path of `item`.

If `item` is an overloaded function or method, then `which item` returns only the path of the first function or method found.

`which fun1 in fun2` displays the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`which ___ -all` displays the paths to all items on the MATLAB path with the requested name. Such items include methods of instantiated

classes. You can use `-all` with the input arguments of any of the previous syntaxes.

`str = which(item)` returns the full path for `item` in the string, `str`.

`str = which(fun1, 'in', fun2)` returns the path to function `fun1` that is called by file `fun2`. Use this syntax to determine whether a local function is being called instead of a function on the path. This syntax does not locate nested functions.

`str = which(___, '-all')` returns the results of `which` in the string or cell array of strings, `str`. You can use this syntax with any of the input arguments in the previous syntax group.

## Input Arguments

### **item - Function or file to locate**

string

Function or file to locate, specified as a string. When using the function form of `which`, enclose all input strings in single quotes. `item` can be in one of the following forms.

Form of the <code>item</code> Input	Path to Display
<code>fun</code>	Display full path for <code>fun</code> , which can be a MATLAB function, Simulink model,
<code>private/fun</code>	Limit the search to private functions named <code>fun</code> . For example, <code>which private/orthog</code> or <code>which('private/orthog')</code> displays the path for <code>orthog.m</code> in the <code>/private</code> subfolder of the parent folder.
<code>fun(a1, ..., an)</code>	Display the path to the implementation of function <code>fun</code> which would be invoked if called with the input arguments <code>a1, ..., an</code> . Use this syntax to query overloaded functions. See the Example, "Locate Function Invoked with Given Input Arguments" on page 1-7700.

## **fun1 - Function to locate**

string

Function to locate, specified as a string. `fun1` can be the name of a function, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see “Locate Function Invoked with Given Input Arguments” on page 1-7700.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

## **fun2 - Calling file**

string

Calling file, specified as a string. `fun2` can be the name of a file, or it can be in the form `fun(a1,...,an)`. For more information about the form, `fun(a1,...,an)`, see “Locate Function Invoked with Given Input Arguments” on page 1-7700.

When using the function form of `which`, enclose all input strings in single quotes, for example, `which('myfun1','in','myfun2')`.

## **Output Arguments**

### **str - Function or file location**

string | cell array of strings

Function or file location, returned as a string, or returned as a cell array of strings if you use `'-all'`.

- If `item` is a workspace variable, then `str` is the string `'variable'`.
- If `str` is a cell array of strings, then each row of `str` identifies a function, and the functions are in order of precedence.

## **Examples**

### **Locate MATLAB Function**

Locate the `pinv` function.

```
which pinv
```

```
matlabroot\toolbox\matlab\matfun\pinv.m
```

`pinv` is in the `matfun` folder of MATLAB.

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('pinv');
```

### **Locate Method in a Loaded Java Class**

Create an instance of the Java class. This loads the class into MATLAB.

```
myDate = java.util.Date;
```

Locate the `setMonth` method.

```
which setMonth
```

```
setMonth is a Java method % java.util.Date method
```

### **Locate Private Function**

Find the `orthog` function in a private folder.

```
which private/orthog
```

```
matlabroot\toolbox\matlab\elmat\private\orthog.m
% Private to elmat
```

MATLAB displays the path for `orthog.m` in the `/private` subfolder of `toolbox/matlab/elmat`.

### **Determine if Local Function is Called**

Determine which `parseargs` function is called by `area.m`.

```
which parseargs in area
```

```
matlabroot\toolbox\matlab\specgraph\area.m (parseargs)
% Subfunction of area
```

# which

---

You also can use function syntax to return the path to a string, `str`. When using the function form of `which`, enclose all input strings in single quotes.

```
str = which('parseargs','in','area');
```

## Locate Function Invoked with Given Input Arguments

Suppose you have a `matlab.io.MatFile` object that corresponds to the example MAT-file 'topography.mat':

```
matObj = matfile('topography.mat');
```

Display the path of the implementation of `who` that is invoked when called with the input argument (`matObj`).

```
which who(matObj)
```

```
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
% matlab.io.MatFile method
```

Store the result to a string.

```
str = which('who(matObj)')
```

```
str =
matlabroot\toolbox\matlab\iofun\+matlab\+io\MatFile.m
```

If you do not specify the input argument (`matObj`), then `which` returns only the path of the first function or method found.

```
which who
```

```
built-in (matlabroot\\toolbox\matlab\general\who)
```

## Locate All Items with Given Name

Display the paths to all items on the MATLAB path with the name `fopen`.

```
which fopen -all
```

```

built-in (matlabroot\toolbox\matlab\iofun\ fopen)
matlabroot\toolbox\matlab\iofun\@serial\ fopen.m % serial me
matlabroot\toolbox\shared\instrument\@icinterface\ fopen.m % icinterfa
matlabroot\toolbox\instrument\instrument\@i2c\ fopen.m
% i2c method

```

## Return Path Names as Strings

Return the results of `which` in the string `str`.

You must use the function form of `which`, enclosing all arguments in parentheses and single quotes.

```

str = which('private/stradd', '-all');
whos str

```

Name	Size	Bytes	Class	Attributes
str	2x1	650	cell	

## Tips

- For more information about how MATLAB uses scope and precedence when calling a function, see “Function Precedence Order”.

## Limitations

- When the class is not loaded, `which` only finds methods if they are defined in separate files in an `@`-folder and are not in any packages.

## See Also

`dir` | `doc` | `exist` | `lookfor` | `mfilename` | `path` | `type` | `what` | `who` | `fileparts` |

# while

---

**Purpose** Repeatedly execute statements while condition is true

**Syntax** `while expression`  
`statements`  
`end`

**Description** `while expression, statements, end` repeatedly executes one or more MATLAB program *statements* in a loop as long as an expression remains true.

An evaluated expression is true when the result is nonempty and contains all nonzero elements (logical or real numeric). Otherwise, the expression is false.

Expressions can include relational operators (such as `<` or `==`) and logical operators (such as `&&`, `||`, or `~`). MATLAB evaluates compound expressions from left to right, adhering to operator precedence rules.

---

**Note** Within the condition *expression* of an `if` or `while` statement, logical operators `&` and `|` behave as short-circuit operators. This behavior is the same as `&&` and `||`, respectively. Since `&&` and `||` consistently short-circuit in `if` and `while` condition expressions and statements, it is good practice to use `&&` and `||` instead of `&` and `|` within *expression*.

---

## Tips

- If you inadvertently create an infinite loop (that is, a loop that never ends on its own), stop execution of the loop by pressing **Ctrl+C**.
- To programmatically exit the loop, use a `break` statement. To skip the rest of the instructions in the loop and begin the next iteration, use a `continue` statement.
- You can nest any number of `while` statements. Each `while` statement requires an end keyword.

**Examples**

Find the first integer  $n$  for which `factorial(n)` is a 100-digit number.

```
n = 1;
nFactorial = 1;
while nFactorial < 1e100
 n = n + 1;
 nFactorial = nFactorial * n;
end
```

---

Count the number of lines of code in the file `magic.m`, skipping all blank lines and comments.

```
fid = fopen('magic.m','r');
count = 0;
while ~feof(fid)
 line = fgetl(fid);
 if isempty(line) || strncmp(line,'% ',1) || ~ischar(line)
 continue
 end
 count = count + 1;
end
fprintf('%d lines\n',count);
fclose(fid);
```

---

Find the root of the polynomial  $x^3 - 2x - 5$  using interval bisection.

```
a = 0; fa = -Inf;
b = 3; fb = Inf;
while b-a > eps*b
 x = (a+b)/2;
 fx = x^3-2*x-5;
 if fx == 0
 break
 elseif sign(fx) == sign(fa)
 a = x; fa = fx;
 end
end
```

# while

---

```
 else
 b = x; fb = fx;
 end
end
disp(x)
```

---

Take advantage of short-circuiting to avoid error or warning messages.

```
x = 42;
while exist('myfunction.m') && (myfunction(x) >= pi)
 disp('Condition is true')
 break
end
```

<b>Purpose</b>	Change axes background color
<b>Syntax</b>	<pre>whitebg whitebg(fig) whitebg(ColorSpec) whitebg(fig, ColorSpec) whitebg(fig, ColorSpec) whitebg(fig)</pre>
<b>Description</b>	<p><code>whitebg</code> complements the colors in the current figure.</p> <p><code>whitebg(fig)</code> complements colors in all figures specified in the vector <code>fig</code>.</p> <p><code>whitebg(ColorSpec)</code> and <code>whitebg(fig, ColorSpec)</code> change the color of the axes, which are children of the figure, to the color specified by <code>ColorSpec</code>. Without a figure specification, <code>whitebg</code> or <code>whitebg(ColorSpec)</code> affects the current figure and the root's default properties so subsequent plots and new figures use the new colors.</p> <p><code>whitebg(fig, ColorSpec)</code> sets the default axes background color of the figures in the vector <code>fig</code> to the color specified by <code>ColorSpec</code>. Other axes properties and the figure background color can change as well so that graphs maintain adequate contrast. <code>ColorSpec</code> can be a 1-by-3 RGB color or a color string such as 'white' or 'w'.</p> <p><code>whitebg(fig)</code> complements the colors of the objects in the specified figures. This syntax is typically used to toggle between black and white axes background colors, and is where <code>whitebg</code> gets its name. Include the root window handle (0) in <code>fig</code> to affect the default properties for new windows or for <code>clf reset</code>.</p>
<b>Tips</b>	<p><code>whitebg</code> works best in cases where all the axes in the figure have the same background color.</p> <p><code>whitebg</code> changes the colors of the figure's children, with the exception of shaded surfaces. This ensures that all objects are visible against the new background color. <code>whitebg</code> sets the default properties on the root such that all subsequent figures use the new background color.</p>

# whitebg

---

## Examples

Set the background color to blue-gray.

```
whitebg([0 .5 .6])
```

Set the background color to blue.

```
whitebg('blue')
```

## See Also

[ColorSpec](#) | [colordef](#)

**Purpose**

List variables in workspace

**Syntax**

```
who
who(variables)
who(location)
who(variables,location)
c = who(variables,location)
```

**Description**

`who` lists in alphabetical order all variables in the currently active workspace.

`who(variables)` lists only the specified variables.

`who(location)` lists variables in the specified location: 'global' for the global workspace, or '-file' for a MAT-file. For MAT-files, you must also include the file name as an input.

`who(variables,location)` lists the specified variables in the specified location. The `location` input can appear before or after `variables`.

`c = who(variables,location)` stores the names of the variables in cell array `c`. Specifying `variables` and `location` is optional.

**Tips**

- The `who` function displays the variable list unless you specify an output argument.
- When used within a nested function, the `who` function lists the variables in the workspaces of that function and all functions containing that function, grouped by workspace. This applies whether you call `who` from your function code or from the MATLAB debugger.

**Input Arguments****variables**

Strings that specify the variables to list. Use one of these forms:

# who

---

*var1, var2, ...*

List the specified variables. Use the '\*' wildcard to match patterns. For example, `who('A*')` lists all variables that start with A.

'-regexp', *expressions*

List variables whose names match the specified regular expressions.

**Default:** '\*' (all variables)

## location

String that indicates whether to list variables from the global workspace or from a file:

'global'

Global workspace.

'-file', *filename*

MAT-file. The *filename* input can include the full, relative, or partial path.

**Default:** '' (current workspace)

## Output Arguments

**c**

Cell array of strings that correspond to each variable name.

## Examples

Display information about variables in the current workspace whose names start with the letter a:

```
who a*
```

---

Show variables stored in MAT-file `durer.mat`:

```
who -file durer
```

This code returns:

Your variables are:

```
X caption map
```

---

Store the variable names from `durer.mat` in cell array `durerInfo`:

```
durerInfo = who('-file', 'durer');
```

Display the contents of cell array `durerInfo`:

```
for k=1:length(durerInfo)
 disp(durerInfo{k})
end
```

This code returns:

```
X
 caption
 map
```

---

Suppose that a file `mydata.mat` contains variables with names that start with `java` and end with `Array`. Display information about those variables:

```
whos -file mydata -regexp \<java.*Array\>
```

---

Call `who` within a nested function (`get_date`):

```
function who_demo
date_time = datestr(now);

[str pos] = textscan(date_time, '%S%S%S', ...
 1, 'delimiter', '- :');
```

# who

---

```
get_date(str);

function get_date(d)
 day = d{1};
 mon = d{2};
 year = d{3};
 who
end

end
```

When you run `who_demo`, the `who` function displays the variables by function workspace (although the name of the function does not appear in the output):

Your variables are:

```
d mon ans pos
day year date_time str
```

## Alternatives

To view the variables in the workspace, use the Workspace browser. To view the contents of MAT-files, use the Details Panel of the Current Folder browser..

<b>Purpose</b>	Names of variables in MAT-file				
<b>Syntax</b>	<pre>varlist = who(matObj) varlist = who(matObj,variables)</pre>				
<b>Description</b>	<p><code>varlist = who(matObj)</code> lists alphabetically all variables in the MAT-file associated with <code>matObj</code>. Optionally, returns the list in cell array <code>varlist</code>.</p> <p><code>varlist = who(matObj,variables)</code> lists the specified variables.</p>				
<b>Input Arguments</b>	<p><b>matObj</b> Object created by the <code>matfile</code> function.</p> <p><b>variables</b> Names of variables in the MAT-file corresponding to <code>matObj</code>. Use one of these forms:</p> <table><tr><td><code>var1,...,varN</code></td><td>Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>who(matobj,'A*')</code>.</td></tr><tr><td><code>'-regexp',expressions</code></td><td>Regular expression strings that describe variable names.</td></tr></table>	<code>var1,...,varN</code>	Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>who(matobj,'A*')</code> .	<code>'-regexp',expressions</code>	Regular expression strings that describe variable names.
<code>var1,...,varN</code>	Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>who(matobj,'A*')</code> .				
<code>'-regexp',expressions</code>	Regular expression strings that describe variable names.				
<b>Output Arguments</b>	<p><b>varlist</b> Cell array of strings that correspond to each variable name.</p>				
<b>Examples</b>	<p>Display a list of variables in the example file <code>topography.mat</code>:</p> <pre>matObj = matfile('topography.mat'); who(matObj)</pre> <p>This code returns:</p>				

Your variables are:

topo          toplegend    topomap1    topomap2

## See Also

[matfile](#) | [whos](#)

**Purpose**

List variables in workspace, with sizes and types

**Syntax**

```
whos
whos(variables)
whos(location)
whos(variables,location)
```

```
S = whos(__)
```

**Description**

whos displays in alphabetical order all variables in the currently active workspace, with information about their sizes and types.

whos(variables) displays only the specified variables.

whos(location) displays variables in the specified location.

whos(variables,location) displays the specified variables in the specified location. The location and variables inputs can appear in either order.

S = whos( \_\_ ) stores information about the variables in structure array, S, using no input arguments, or any of the input arguments from the previous syntaxes.

**Input Arguments****variables - Variables to display**

strings

Variables to display, specified as one or more strings in one of the following forms.

# whos

Form of Variables Input	Variable Names
<code>var1 ... varN</code>	List the named variables, specified as individual strings. Use the '*' wildcard to match patterns. For example, <code>whos('A*')</code> lists all variables in the workspace that start with A.
<code>'-regexp',expr1 ... exprN</code>	List only the variables that match the regular expressions, specified as strings. For example, <code>whos('-regexp','^Mon','^Tues')</code> lists only the variables in the workspace that begin with Mon or Tues.

## location - Location of variables

`'global' | 'file',filename`

Location of variables, specified as one of the following strings.

Value of location	Location of Variables
<code>'global'</code>	Global workspace.
<code>'-file',filename</code>	MAT-file. The <i>filename</i> input can include the full, relative, or partial path. For example, <code>whos('file','myFile.mat')</code> lists all variables in the MAT-file named <i>myFile.mat</i> .  <code>whos('-file',filename)</code> does not return the sizes of any MATLAB objects in file <i>filename</i> .

## Output Arguments

### S - Information about variables

nested structure array

Information about variables, returned as a nested structure array that contains a scalar struct for each variable. Each scalar struct contains these fields.

Field	Description
name	Name of the variable.
size	Dimensions of the variable array.
bytes	Number of bytes allocated for the variable array.
class	Class of the variable. If the variable has no value, class is '(unassigned)'.
global	True if the variable is global; otherwise, false.
sparse	True if the variable is sparse; otherwise, false.
complex	True if the variable is complex; otherwise, false.
nesting	Structure with these fields: <ul style="list-style-type: none"> <li>function — Name of the nested or outer function that defines the variable.</li> <li>level — Nesting level of that function.</li> </ul>
persistent	True if the variable is persistent; otherwise, false.

## Examples

### Display Information About Workspace Variables

Display information about variables in the current workspace whose names start with the letter a.

```
whos('a*')
```

### Display Variables Stored in a MAT-File

Display all variables stored in the MAT-file, `durer.mat`.

```
whos('-file','durer.mat')
```

Name	Size	Bytes	Class	Attributes
X	648x509	2638656	double	
caption	2x28	112	char	
map	128x3	3072	double	

Show only variables in the MAT-file with names that end with ion.

```
whos('-file','durer.mat','-regexp','ion$')
```

Name	Size	Bytes	Class	Attributes
caption	2x28	112	char	

## Store Variable Information in a Structure Array

Store information about the variables in `durer.mat` in structure array `S`.

```
S = whos('-file','durer.mat');
```

Display the contents of `S`.

```
for k = 1:length(S)
 disp([' ' S(k).name ...
 ' ' mat2str(S(k).size) ...
 ' ' S(k).class]);
end
```

```
X [648 509] double
caption [2 28] char
map [128 3] double
```

## Create Function to Display Variable Attribute Information

In the Editor, create a function that creates variables with various persistent, global, sparse, and complex attributes, and then displays information about them.

```
function show_attributes
persistent p;
global g;
p = 1;
g = 2;
s = sparse(eye(5));
c = [4+5i 9-3i 7+6i];
whos
```

When you call the function, `show_attributes` displays the attributes.

```
show_attributes
```

Name	Size	Bytes	Class	Attributes
c	1x3	48	double	complex
g	1x1	8	double	global
p	1x1	8	double	persistent
s	5x5	128	double	sparse

### Call whos Within a Nested or Anonymous Function

Create a function, `whos_demo`, that contains a nested function, `get_date`. Call `whos` within the nested function.

```
function whos_demo
date_time = datestr(now);

C = strsplit(date_time,{'-',' '});
get_date(C);

 function get_date(d)
 day = d{1};
 mon = d{2};
 year = d{3};
 whos
 end
```

# whos

---

```
end
```

When you run the `whos_demo` function, `whos` displays the variables of the nested `get_date` function, and all functions that contain it, grouped by function workspace. This applies whether you call `whos` from your function code or from the MATLAB debugger.

```
whos_demo
```

Name	Size	Bytes	Class	Attributes
---- get_date -----				
d	1x3	372	cell	
day	1x2	4	char	
mon	1x3	6	char	
year	1x13	26	char	
---- whos_demo -----				
C	1x3	372	cell	
ans	0x0	0	(unassigned)	
date_time	1x20	40	char	

When called within an anonymous function, variables in the anonymous function also display in a group, titled with the function's signature

## Tips

- You also can view the contents of MAT-files using the Details Panel of the Current Folder browser.

## Algorithms

`whos` returns the number of bytes each variable occupies in the workspace, not in a MAT-file. Version 7 MAT-files and later are compressed, so the number of bytes in the file is typically fewer than the number of bytes required in the workspace.

## See Also

`clear` | `exist` | `what` | `who`

## Concepts

- “What Is the MATLAB Workspace?”

<b>Purpose</b>	Names, sizes, and types of variables in MAT-file				
<b>Syntax</b>	<pre>details = whos(matObj) details = whos(matObj,variables)</pre>				
<b>Description</b>	<p><code>details = whos(matObj)</code> returns information about all variables in the MAT-file associated with <code>matObj</code>.</p> <p><code>details = whos(matObj,variables)</code> returns information about the specified variables.</p>				
<b>Input Arguments</b>	<p><b>matObj</b> Object created by the <code>matfile</code> function.</p> <p><b>variables</b> Names of variables in the MAT-file corresponding to <code>matObj</code>. Use one of these forms:</p> <table border="0" style="margin-left: 40px;"> <tr> <td style="padding-right: 20px;"><code>var1,...,varN</code></td> <td>Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>whos(matobj, 'A*')</code>.</td> </tr> <tr> <td style="padding-right: 20px;"><code>'-regex',expressions</code></td> <td>Regular expression strings that describe variable names.</td> </tr> </table>	<code>var1,...,varN</code>	Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>whos(matobj, 'A*')</code> .	<code>'-regex',expressions</code>	Regular expression strings that describe variable names.
<code>var1,...,varN</code>	Comma-separated list of variable name strings. Optionally, match patterns with the '*' wildcard, such as <code>whos(matobj, 'A*')</code> .				
<code>'-regex',expressions</code>	Regular expression strings that describe variable names.				
<b>Output Arguments</b>	<p><b>details</b> Structure array with these fields (identical to the structure returned by the <code>whos</code> function):</p> <table border="0" style="margin-left: 40px;"> <tr> <td style="padding-right: 40px;"><code>name</code></td> <td>Variable name</td> </tr> <tr> <td style="padding-right: 40px;"><code>size</code></td> <td>Dimensions of the variable</td> </tr> </table>	<code>name</code>	Variable name	<code>size</code>	Dimensions of the variable
<code>name</code>	Variable name				
<code>size</code>	Dimensions of the variable				

bytes	Number of bytes allocated for the array when you load the entire variable
class	Class (data type) of the variable
global	Whether the variable is global (true or false)
sparse	Whether the variable is sparse
complex	Whether the variable is complex
nesting	Structure with these fields: <ul style="list-style-type: none"><li>• <code>function</code> — Name of the nested or outer function that defines the variable</li><li>• <code>level</code> — Nesting level</li></ul>
persistent	Whether the variable is persistent

## Examples

Display a list of variables in the example file `topography.mat`:

```
matObj = matfile('topography.mat');
whos(matObj)
```

This code returns:

Name	Size	Bytes	Class	Attributes
topo	180x360	518400	double	
topolegend	1x3	24	double	
topomap1	64x3	1536	double	
topomap2	128x3	3072	double	

---

Without loading any data, find the size and number of dimensions of the variable `topo` in `topography.mat`:

```
matObj = matfile('topography.mat');
info = whos(matObj, 'topo');
```

```
sizeX = info.size
nDimsX = length(sizeX)
```

This code returns:

```
sizeX =
 180 360

nDimsX =
 2
```

## See Also

[matfile](#) | [size](#)

# width

---

**Purpose** Number of table variables

**Syntax** `W = width(T)`

**Description** `W = width(T)` returns the number of variables in table T.  
`width(T)` is equivalent to `size(T,2)`.

**Input Arguments** **T - Input table**  
table

Input table, specified as a table.

Variables in a table can have multiple columns, but `width(T)` only counts the number of variables.

## **Examples** **Number of Variables in Table**

Create a table, T.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure,'RowNames',LastName)
```

```
T =
```

	Age	Height	Weight	BloodPressure	
	—	—	—	—	
Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Find the number of variables in table T.

```
W = width(T)
```

```
W =
```

```
 4
```

T contains 4 variables; width does not count the row names.

The variable BloodPressure counts as one variable even though it contains two columns.

height | size | numel
```

# wilkinson

---

**Purpose** Wilkinson's eigenvalue test matrix

**Syntax** `W = wilkinson(n)`

**Description** `W = wilkinson(n)` returns one of J. H. Wilkinson's eigenvalue test matrices. It is a symmetric, tridiagonal matrix with pairs of nearly, but not exactly, equal eigenvalues.

**Examples** `wilkinson(7)`

`ans =`

```
 3 1 0 0 0 0 0
 1 2 1 0 0 0 0
 0 1 1 1 0 0 0
 0 0 1 0 1 0 0
 0 0 0 1 1 1 0
 0 0 0 0 1 2 1
 0 0 0 0 0 1 3
```

The most frequently used case is `wilkinson(21)`. Its two largest eigenvalues are both about 10.746; they agree to 14, but not to 15, decimal places.

**See Also** `eig` | `gallery` | `pascal`

**Purpose** Open file in appropriate application (Windows)

**Syntax** `winopen(fileName)`

**Description** `winopen(fileName)` opens `fileName` in the associated Microsoft Windows application. The application is associated with the extension in `fileName` in the Windows operating system. `filename` is a string enclosed in single quotes. `winopen` uses a Windows shell command, and performs the same action as double-clicking the file in the Windows Explorer program. That is, `winopen` calls the application associated with the file extension to open the file. Use an absolute or relative path for `fileName`.

**Examples** Open the file `thesis.doc`, located in the current folder, in the Microsoft Word program:

```
winopen('thesis.doc')
```

---

Open `myresults.html` in the system Web browser:

```
winopen('D:/myfiles/myresults.html')
```

---

On Microsoft Windows platforms, open the current folder in the Windows Explorer tool:

```
winopen(cd)
```

---

To open a file on the MATLAB path, use `winopen` with `which`. For example, to open the `meshgrid` function in the Editor, use:

```
winopen(which('meshgrid'))
```

**See Also** `dos` | `open` | `web`

# winqueryreg

---

**Purpose** Item from Windows registry

**Syntax**

```
valnames = winqueryreg('name', 'rootkey', 'subkey')
value = winqueryreg('rootkey', 'subkey', 'valname')
value = winqueryreg('rootkey', 'subkey')
```

**Description** `valnames = winqueryreg('name', 'rootkey', 'subkey')` returns all value names in `rootkey\subkey` of Microsoft Windows operating system registry to a cell array of strings. The first argument is the literal quoted string, 'name'.

`value = winqueryreg('rootkey', 'subkey', 'valname')` returns the value for value name `valname` in `rootkey\subkey`.

If the value retrieved from the registry is a string, `winqueryreg` returns a string. If the value is a 32-bit integer, `winqueryreg` returns the value as an integer of the MATLAB software type `int32`.

`value = winqueryreg('rootkey', 'subkey')` returns a value in `rootkey\subkey` that has no value name property.

---

**Note** The literal **name** argument and the `rootkey` argument are case-sensitive. The `subkey` and `valname` arguments are not.

---

**Tips** This function works only for the following registry value types:

- strings (REG\_SZ)
- expanded strings (REG\_EXPAND\_SZ)
- 32-bit integer (REG\_DWORD)

**Examples** **Example 1**

Get the value of CLSID for the MATLAB sample Microsoft COM control `mwsampctrl.2`:

```
winqueryreg 'HKEY_CLASSES_ROOT' 'mwsamp.mwsampctrl.2\clsid'
```

```
ans =
 {5771A80A-2294-4CAC-A75B-157DCDDD3653}
```

## Example 2

Get a list in variable `mousechar` for registry subkey `Mouse`, which is under subkey `Control Panel`, which is under root key `HKEY_CURRENT_USER`.

```
mousechar = winqueryreg('name', 'HKEY_CURRENT_USER', ...
 'control panel\mouse');
```

For each name in the `mousechar` list, get its value from the registry and then display the name and its value:

```
for k=1:length(mousechar)
 setting = winqueryreg('HKEY_CURRENT_USER', ...
 'control panel\mouse', mousechar{k});
 str = sprintf('%s = %s', mousechar{k}, num2str(setting));
 disp(str)
end
```

```
ActiveWindowTracking = 0
DoubleClickHeight = 4
DoubleClickSpeed = 830
DoubleClickWidth = 4
MouseSpeed = 1
MouseThreshold1 = 6
MouseThreshold2 = 10
SnapToDefaultButton = 0
SwapMouseButtons = 0
```

# wk1info

---

**Purpose** Determine whether file contains 1-2-3 WK1 worksheet

---

**Note** wk1info has been removed.

---

**Syntax** [extens, typ] = wk1info(filename)

**Description** [extens, typ] = wk1info(filename) returns the string 'WK1' in extens, and '1-2-3 Spreadsheet' in typ if the file filename contains a readable worksheet. The filename input is a string enclosed in single quotes.

**Examples** This example returns information on spreadsheet file matA.wk1:

```
[extens, typ] = wk1info('matA.wk1')

extens =
 WK1
typ =
 123 Spreadsheet
```

**See Also** xlsread | xlswrite | dlmread | dlmwrite

## Purpose

Read Lotus 1-2-3 WK1 spreadsheet file into matrix

---

**Note** wk1read has been removed.

---

## Syntax

```
M = wk1read(filename)
M = wk1read(filename,r,c)
M = wk1read(filename,r,c,range)
```

## Description

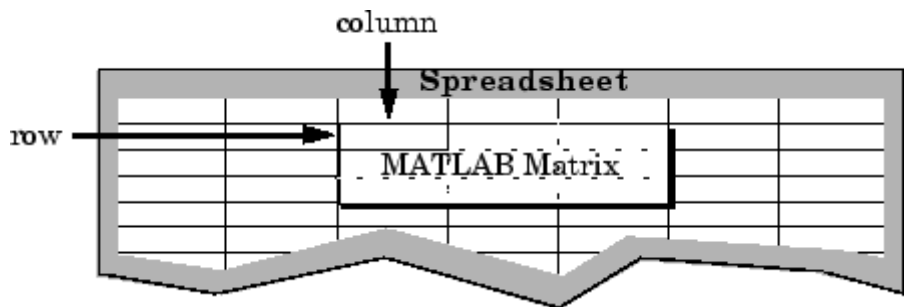

`M = wk1read(filename)` reads a Lotus1-2-3 WK1 spreadsheet file into the matrix `M`. The `filename` input is a string enclosed in single quotes.

`M = wk1read(filename,r,c)` starts reading at the row-column cell offset specified by  $(r,c)$ . `r` and `c` are zero based so that `r=0, c=0` specifies the first value in the file.

`M = wk1read(filename,r,c,range)` reads the range of values specified by the parameter `range`, where `range` can be

- A four-element vector specifying the cell range in the format

```
[upper_left_row upper_left_col lower_right_row lower_right_col]
```

- A cell range specified as a string, for example, 'A1...C5'
- A named range specified as a string, for example, 'Sales'

## Examples

Create a 8-by-8 matrix A and export it to Lotus spreadsheet matA.wk1:

```
A = [1:8; 11:18; 21:28; 31:38; 41:48; 51:58; 61:68; 71:78]
A =
```

1	2	3	4	5	6	7	8
11	12	13	14	15	16	17	18
21	22	23	24	25	26	27	28
31	32	33	34	35	36	37	38
41	42	43	44	45	46	47	48
51	52	53	54	55	56	57	58
61	62	63	64	65	66	67	68
71	72	73	74	75	76	77	78

```
wk1write('matA.wk1', A);
```

To read in a limited block of the spreadsheet data, specify the upper left row and column of the block using zero-based indexing:

```
M = wk1read('matA.wk1', 3, 2)
M =
```

33	34	35	36	37	38
43	44	45	46	47	48
53	54	55	56	57	58
63	64	65	66	67	68
73	74	75	76	77	78

To select a more restricted block of data, you can specify both the upper left and lower right corners of the block you want imported. Read in a range of values from row 4, column 3 (defining the upper left corner) to row 6, column 6 (defining the lower right corner). Note that, unlike the second and third arguments, the range argument [4 3 6 6] is one-based:

```
M = wk1read('matA.wk1', 3, 2, [4 3 6 6])
M =
```

33	34	35	36
43	44	45	46
53	54	55	56

**See Also**

xlsread

# wk1write

## Purpose

Write matrix to Lotus 1-2-3 WK1 spreadsheet file

---

**Note** wk1write has been removed.

---

## Syntax

```
wk1write(filename,M)
wk1write(filename,M,r,c)
```

## Description

wk1write(filename,M) writes the matrix M into a Lotus1-2-3 WK1 spreadsheet file named filename. The filename input is a string enclosed in single quotes.

wk1write(filename,M,r,c) writes the matrix starting at the spreadsheet location (r,c). r and c are zero based so that r=0, c=0 specifies the first cell in the spreadsheet.

## Examples

Write a 4-by-5 matrix A to spreadsheet file matA.wk1. Place the matrix with its upper left corner at row 2, column 3 using zero-based indexing:

```
A = [1:5; 11:15; 21:25; 31:35]
```

```
A =
```

1	2	3	4	5
11	12	13	14	15
21	22	23	24	25
31	32	33	34	35

```
wk1write('matA.wk1', A, 2, 3)
```

```
M = wk1read('matA.wk1')
```

```
M =
```

```
 0 0 0 0 0 0 0 0
 0 0 0 0 0 0 0 0
 0 0 0 1 2 3 4 5
 0 0 0 11 12 13 14 15
 0 0 0 21 22 23 24 25
 0 0 0 31 32 33 34 35
```

## See Also

[dlmwrite](#) | [dlmread](#) | [xlswrite](#) | [xlsread](#)

# workspace

---

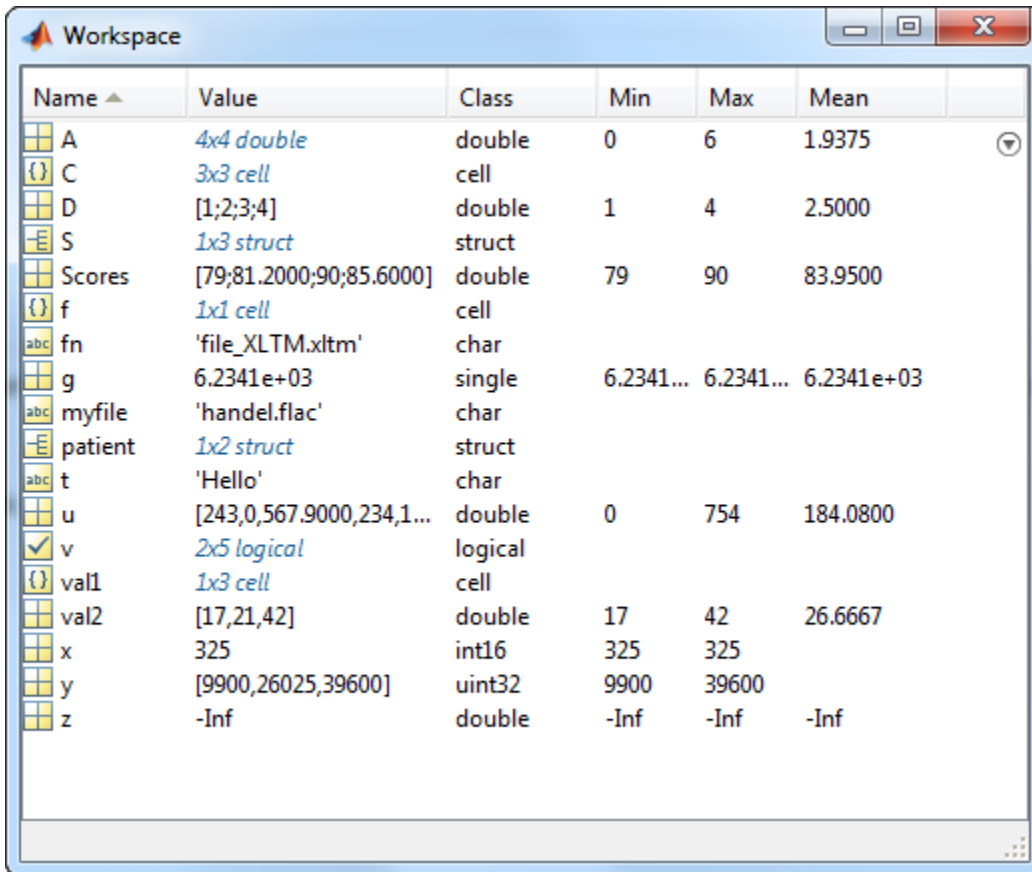

**Purpose** Open Workspace browser to manage workspace

**Syntax** workspace

**Description** workspace displays the Workspace browser, a graphical user interface that allows you to view and manage the contents of the workspace in MATLAB. It provides a graphical representation of the whos display, and allows you to perform the equivalent of the clear, load, open, and save functions.

The Workspace browser also displays and automatically updates statistical calculations for each variable, which you can choose to show or hide.

Name ▲	Value	Class	Min	Max	Mean	
A	4x4 double	double	0	6	1.9375	
C	3x3 cell	cell				
D	[1;2;3;4]	double	1	4	2.5000	
S	1x3 struct	struct				
Scores	[79;81.2000;90;85.6000]	double	79	90	83.9500	
f	1x1 cell	cell				
fn	'file_XLTM.xltn'	char				
g	6.2341e+03	single	6.2341...	6.2341...	6.2341e+03	
myfile	'handel.flac'	char				
patient	1x2 struct	struct				
t	'Hello'	char				
u	[243,0,567.9000,234,1...	double	0	754	184.0800	
v	2x5 logical	logical				
val1	1x3 cell	cell				
val2	[17,21,42]	double	17	42	26.6667	
x	325	int16	325	325		
y	[9900,26025,39600]	uint32	9900	39600		
z	-Inf	double	-Inf	-Inf	-Inf	

You can edit a value directly in the Workspace browser for small numeric and character arrays. To see and edit a graphical representation of larger variables and for other classes, double-click the variable in the Workspace browser. The variable displays in the Variables editor, where you can view the full contents and make changes.

## How To

- “What Is the MATLAB Workspace?”

# writetable

---

**Purpose** Write table to file

**Syntax**  
`writetable(T)`  
`writetable(T,filename)`  
`writetable( ____,Name,Value)`

**Description** `writetable(T)` writes the table, `T`, to a comma delimited text file. The file name is the workspace variable name of the table, appended with the extension `.txt`. If `writetable` cannot construct the file name from the input table name, then it writes to the file `table.txt`.

Each column of each variable in `T` becomes a column in the output file. The variable names of `T` become column headings in the first line of the file.

`writetable(T,filename)` writes table `T` to a file with the name and extension specified by `filename`.

`writetable` determines the file format based on the specified extension. The extension must be one of the following:

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

`writetable( ____,Name,Value)` writes the table to a file with additional options specified by one or more `Name,Value` pair arguments and can include any of the input arguments in previous syntaxes.

For example, you can specify whether to write the variable names as column headings in the output file.

## **Input Arguments**

**T - Input table**  
`table`

Input table, specified as a table.

**filename - Name of file to write**

string

Name of file to write, specified as a string. If `filename` includes the file's extension, then `writetable` determines the file format from the extension. Otherwise, `writetable` creates a comma separated text file and appends the extension `.txt`. Alternatively, you can specify `filename` without the file's extension, and then include the `'FileType'` name-value pair arguments to indicate the type of file.

If `filename` does not exist in your current folder, then `writetable` creates the file. `writetable` overwrites any existing file.

**Example:** `'myData.xls'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'WriteVariableNames',false` indicates that the variable names should not be included as the first row of the output file.

## 'FileType' - Type of file

`'text' | 'spreadsheet'`

Type of file, specified as the comma-separated pair consisting of `'FileType'` and the string `'text'` or `'spreadsheet'`.

The `'FileType'` name-value pair must be used with the `filename` input argument. You do not need to specify the `'FileType'` name-value pair argument if the file type can be determined from an extension in the `filename` input argument.

- `.txt`, `.dat`, or `.csv` for delimited text files
- `.xls`, `.xlsb`, `.xlsm`, or `.xlsx` for Excel spreadsheet files

**Example:**

```
writetable(T,'mySpreadsheet','FileType','spreadsheet')
```

## **'WriteVariableNames' - Indicator for writing variable names as column headings**

true (default) | false | 1 | 0

Indicator for writing variable names as column headings, specified as the comma-separated pair consisting of 'WriteVariableNames' and either true, false, 1, or 0.

true	writetable includes variable names as the column headings of the output. This is the default behavior.  If both the 'WriteVariablesNames' and 'WriteRowNames' logical indicators are true, then writetable uses the first dimension name from the property T.Properties.DimensionNames as the column heading for the first column of the output.
false	writetable does not include variable names in the output.

## **'WriteRowNames' - Indicator for writing row names in first column**

false (default) | true | 0 | 1

Indicator for writing row names in first column, specified as the comma-separated pair consisting of 'WriteRowNames' and either false, true, 0, or 1.

true	writetable includes the row names from T as the first column of the output.  If both the 'WriteVariablesNames' and 'WriteRowNames' logical indicators are true, then writetable uses the first dimension name from the property T.Properties.DimensionNames as the column heading for the first column of the output.
false	writetable does not include the row names from T in the output. This is the default behavior.

**'Delimiter' - Field delimiter character**

string

Field delimiter character, specified as the comma-separated pair consisting of 'Delimiter' and one of the following strings:

' , '	Comma. This is the default behavior.
' comma '	
' ' '	Space
' space '	
' \t '	Tab
' tab '	
' ; '	Semicolon
' semi '	
'   '	Vertical bar
' bar '	

You can use the 'Delimiter' name-value pair only for delimited text files.

**Example:** 'Delimiter', 'space'

**'Sheet' - Worksheet to write to**

string containing worksheet name | positive integer indicating worksheet index

Worksheet to write to, specified as the comma-separated pair consisting of 'Sheet' and a string containing the worksheet name or a positive integer indicating the worksheet index. The worksheet name string cannot contain a colon (:). To determine the names of sheets in a spreadsheet file, use `[status,sheets] = xlsinfo(filename)`.

If the sheet does not exist, then writetable adds a new sheet at the end of the worksheet collection. If the sheet is an index larger than the number of worksheets, then writetable appends empty sheets until

# writetable

the number of worksheets in the workbook equals the sheet index. In either case, writetable generates a warning indicating that it has added a new worksheet.

You can use the 'Sheet' name-value pair only with spreadsheet files.

**Example:** 'Sheet',2

## 'Range' - Rectangular portion of worksheet to write to string

Rectangular portion of worksheet to write to, specified as the comma-separated pair consisting of 'Range' and a string in one of the following forms.

Form of the Value of Range	Description
'Corner1'	<p><i>Corner1</i> specifies the first cell of the region to write. writetable writes table T beginning at this cell.</p> <p><b>Example:</b> 'Range', 'D2'</p>
'Corner1:Corner2'	<p><i>Corner1</i> and <i>Corner2</i> are two opposing corners that define the region to write. For example, 'D2:H4' represents the 3-by-5 rectangular region between the two corners D2 and H4 on the worksheet. The 'Range' name-value pair argument is not case sensitive, and uses Excel A1 reference style (see Excel help).</p> <p>If the range you specify is larger than the size of the input table T, Excel software fills the remainder of the region with #N/A. If the range specified is smaller than the size of the input table T, then writetable writes only the subset that fits into the range.</p> <p><b>Example:</b> 'Range', 'D2:H4'</p>

The 'Range' name-value pair can only be used with Excel files.

## Examples

### Write Table to Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

T =

Var1	Var2	Var3	Var4
M	45	45	'NY'
F	41	32	'CA'
M	40	34	'MA'

Write the table, T, to a comma delimited text file.

```
writetable(T)
```

writetable outputs a text file named T.txt.

Display the contents of the file.

```
type 'T.txt'
```

```
Var1,Var2_1,Var2_2,Var3,Var4
M,45,45,NY,1
F,41,32,CA,0
M,40,34,MA,0
```

writetable appends a unique suffix to the variable name, Var2, above the two columns of corresponding data.

### Write Table to Space Delimited Text File

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

# writetable

---

```
T =
 Var1 Var2 Var3 Var4

 M 45 45 'NY' true
 F 41 32 'CA' false
 M 40 34 'MA' false
```

Write the table, T, to a space delimited text file, called myData.txt.

```
writetable(T,'myData.txt','Delimiter',' ')
```

Display the contents of the file.

```
type 'myData.txt'
```

```
Var1 Var2_1 Var2_2 Var3 Var4
M 45 45 NY 1
F 41 32 CA 0
M 40 34 MA 0
```

writetable appends a unique suffix to the variable name, Var2, above the two columns of corresponding data.

## Write Table to Text File Including Row Names

Create a table.

```
LastName = {'Smith';'Johnson';'Williams';'Jones';'Brown'};
Age = [38;43;38;40;49];
Height = [71;69;64;67;64];
Weight = [176;163;131;133;119];
BloodPressure = [124 93; 109 77; 125 83; 117 75; 122 80];
```

```
T = table(Age,Height,Weight,BloodPressure,...
 'RowNames',LastName)
```

```
T =
 Age Height Weight BloodPressure

 38 71 176 [124 93]
 43 69 163 [109 77]
 38 64 131 [125 83]
 40 67 133 [117 75]
 49 64 119 [122 80]
```

Smith	38	71	176	124	93
Johnson	43	69	163	109	77
Williams	38	64	131	125	83
Jones	40	67	133	117	75
Brown	49	64	119	122	80

Write the table, T, to a comma delimited text file, called myPatientData.dat.

```
writetable(T,'myPatientData.dat','WriteRowNames',true)
```

Display the contents of the file.

```
type 'myPatientData.dat'
```

```
Row, Age, Height, Weight, BloodPressure_1, BloodPressure_2
Smith, 38, 71, 176, 124, 93
Johnson, 43, 69, 163, 109, 77
Williams, 38, 64, 131, 125, 83
Jones, 40, 67, 133, 117, 75
Brown, 49, 64, 119, 122, 80
```

The first column, which contains the row names, has the column heading, Row. This is the first dimension name for the table from the property T.Properties.DimensionNames.

### Write Table to Specific Sheet and Range in Spreadsheet

Create a table.

```
T = table(['M';'F';'M'],[45 45;41 32;40 34],...
 {'NY';'CA';'MA'},[true;false;false])
```

```
T =
```

Var1	Var2	Var3	Var4
_____	_____	_____	_____

# writetable

---

M	45	45	'NY'	true
F	41	32	'CA'	false
M	40	34	'MA'	false

Write the table, `T`, to a spreadsheet, called `myData.xls`. Include the data on the second sheet in the 5-by-5 region with corners at B2 and F6.

```
writetable(T, 'myData.xls', 'Sheet', 2, 'Range', 'B2:F6')
```

Excel fills the row of the spreadsheet from B6 to F6 with #N/A since the range specified is larger than the size of the input table `T`.

## Algorithms

Excel converts Inf values to 65535. MATLAB converts NaN values to empty cells.

## Tips

- In the cases below, `writetable` creates a file that does not represent `T` exactly. Then, if you use `readtable` to read that file and create a new table, the result might not have the same format or contents as the original table. Save `T` as a MAT-file if you need to import it again as a table with the same data and organization.
  - `writetable` outputs numeric variables using long g format, and categorical or character variables as unquoted strings in text files.
  - For variables that have more than one column, `writetable` appends a unique identifier to the variable name to use as the column headings.
  - For output variables that have more than two dimensions, `writetable` outputs these variables as two dimensional where the trailing dimensions are collapsed. For example, `writetable` outputs a 4-by-3-by-2 variable as if its size were 4-by-6.
  - For variables with a `cell` data type, `writetable` outputs the contents of each cell as a single row, in multiple fields. If the contents are other than numeric, logical, character, or categorical, then `writetable` outputs a single empty field.

**See Also**    `table` | `readtable`

# Tiff.write

---

**Purpose** Write entire image

**Syntax** `tiffobj.write(imageData)`  
`tiffobj.write(Y,Cb,Cr)`

**Description** `tiffobj.write(imageData)` writes `imageData` to TIFF file associated with the Tiff object, `tiffobj`. The write method breaks the data into strips or tiles, depending on the value of the `RowsPerStrip` tag, or the `TileLength` and `TileWidth` tags.

`tiffobj.write(Y,Cb,Cr)` writes the YCbCr component data to the TIFF file. Use this syntax only for images with a YCbCr photometric interpretation.

## **Examples** Write Image Data

Write tags and image data to a new TIFF file.

Read sample data into an array, `imdata`. Create a Tiff object associated with a new file, `myfile.tif`, and open the file for writing.

```
imdata = imread('example.tif');
t = Tiff('myfile.tif','w');
```

Set tag values.

```
t.setTag('ImageLength',size(imdata,1));
t.setTag('ImageWidth',size(imdata,2));
t.setTag('Photometric',Tiff.Photometric.RGB);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',size(imdata,3));
t.setTag('TileWidth',128);
t.setTag('TileLength',128);
t.setTag('Compression',Tiff.Compression.JPEG);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
t.setTag('Software','MATLAB');
```

Write the image data to the TIFF file.

```
t.write(imdata);
t.close();
```

Tiff.writeDirectory

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”

# Tiff.writeDirectory

---

**Purpose** Create new IFD and make it current IFD

**Syntax** `tiffobj.writeDirectory()`

**Description** `tiffobj.writeDirectory()` create a new image file directory (IFD) and makes it the current IFD. Tiff object methods operate on the current IFD. If you are creating a TIFF file that only contains one image, you do not need to use this method. With single-image TIFF files, just close the Tiff object to write data to the file.

**Examples** Open a TIFF file for modification and create a new IFD in the file. `writeDirectory` makes the newly created IFD the current IFD. Replace the name `myfile.tif` with the name of a TIFF file on your MATLAB path.

```
t = Tiff('myfile.tif', 'r+');
dnum = t.currentDirectory();
t.writeDirectory();
dnum = t.currentDirectory();
```

**References** This method corresponds to the `TIFFWriteDirectory` function in the LibTIFF C API. To use this method, you must be familiar with the TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

**See Also** `Tiff.write` | `Tiff.close`

**Tutorials**

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose** Write data to specified strip

**Syntax** `tiffobj.writeEncodedStrip(stripNumber,imageData)`  
`tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)`

**Description** `tiffobj.writeEncodedStrip(stripNumber,imageData)` writes the data in `imageData` to the strip specified by `stripNumber`. Strip identification numbers are one-based. If `imageData` has fewer bytes than fit into a strip, `writeEncodedStrip` silently pads the strip. If `imageData` has more bytes than fit into a strip, `writeEncodedStrip` issues a warning and truncates the data. To determine the size of a strip, view the value of the `RowsPerStrip` tag.

`tiffobj.writeEncodedStrip(stripNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tag.

## Examples **Write Image Data to Strips**

Open a Tiff object for writing and set tag values.

```
t = Tiff('myfile.tif','w');
t.setTag('ImageLength',32);
t.setTag('ImageWidth',32);
t.setTag('Photometric',Tiff.Photometric.MinIsBlack);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',1);
t.setTag('RowsPerStrip',16);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write data to the first and second strips.

```
t.writeEncodedStrip(1,ones(16,32,'uint8'));
t.writeEncodedStrip(2,2*ones(16,32,'uint8'));
t.close();
```

**References** This method corresponds to the `TIFFWriteEncodedStrip` function in the LibTIFF C API. To use this method, you must be familiar with the

# Tiff.writeEncodedStrip

---

TIFF specification and technical notes. View this documentation at [LibTIFF - TIFF Library and Utilities](#).

## See Also

`Tiff.writeEncodedTile`

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

**Purpose**

Write data to specified tile

**Syntax**

```
tiffobj.writeEncodedTile(tileNumber,imageData)
tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)
```

**Description**

`tiffobj.writeEncodedTile(tileNumber,imageData)` writes the data in `imageData` to the tile specified by `tileNumber`. Tile identification numbers are one-based. If `imageData` has fewer bytes than fit into a tile, `writeEncodedTile` silently pads the tile. If `imageData` has more bytes than fit into a tile, `writeEncodedTile` issues a warning and truncates the data. To determine the size of a tile, view the value of the `tileLength` and `tileWidth` tags.

`tiffobj.writeEncodedTile(tileNumber,Y,Cb,Cr)` writes the YCbCr component data to the specified tile. You must set the `YCbCrSubSampling` tags.

**Examples****Write Image Data to Tiles**

Open a Tiff object for writing and set tag values.

```
t = Tiff('myfile.tif','w');
t.setTag('ImageLength',32);
t.setTag('ImageWidth',32);
t.setTag('Photometric',Tiff.Photometric.MinIsBlack);
t.setTag('BitsPerSample',8);
t.setTag('SamplesPerPixel',1);
t.setTag('TileWidth',16);
t.setTag('TileLength',16);
t.setTag('PlanarConfiguration',Tiff.PlanarConfiguration.Chunky);
```

Write data to four tiles.

```
t.writeEncodedTile(1,ones(16,16,'uint8'));
t.writeEncodedTile(2,2*ones(16,16,'uint8'));
t.writeEncodedTile(3,3*ones(16,16,'uint8'));
t.writeEncodedTile(4,4*ones(16,16,'uint8'));
t.close();
```

# Tiff.writeEncodedTile

---

## See Also

`Tiff.writeEncodedStrip`

## Tutorials

- “Exporting Image Data and Metadata to TIFF Files”
- “Reading Image Data and Metadata from TIFF Files”

## Purpose

Write video data to file

## Syntax

```
writeVideo(writerObj,img)
writeVideo(writerObj,images)
writeVideo(writerObj,frame)
writeVideo(writerObj,mov)
```

## Description

`writeVideo(writerObj,img)` writes data from an image to a video file.

`writeVideo(writerObj,images)` writes a sequence of color images to a video file.

`writeVideo(writerObj,frame)` writes a frame to the video file associated with `writerObj`.

`writeVideo(writerObj,mov)` writes a MATLAB movie to a video file. `MOV` is an array of frame structures.

You must call `open(writerObj)` before calling `writeVideo`.

## Input Arguments

### **writerObj**

VideoWriter object created by the `VideoWriter` function.

### **img**

When creating AVI or MPEG-4 files, `img` is an array of `single`, `double`, or `uint8` values representing a grayscale or RGB color image, which `writeVideo` writes as an RGB video frame. Data of type `single` or `double` must be in the range `[0,1]`, except when writing Indexed AVI files.

When creating Motion JPEG 2000 files, `img` is an array of `uint8`, `int8`, `uint16`, or `int16` values representing a monochrome or RGB color image.

For grayscale, monochrome, or indexed data, `img` must be two-dimensional: height-by-width. For color data that is not indexed, `img` is three-dimensional: height-by-width-by-3. The height and width must be consistent for all frames within a file. For more information, see “Image Types”.

# VideoWriter.writeVideo

---

## images

Four-dimensional array of grayscale (height-by-width-by-1-by-frames) or RGB (height-by-width-by-3-by-frames) images.

## frame

Structure typically returned by the `getframe` function that contains two fields: `cdata` and `colormap`. If the `colormap` is not empty, `writeVideo` expects a two-dimensional (height-by-width) array `cdata`. The height and width must be consistent for all frames within a file. `colormap` can contain a maximum of 256 entries.

The profile of `writerObj` and the size of `cdata` determine how the `writeVideo` method uses `frame`.

profile of VideoWriter object	Size of cdata	Behavior of writeVideo
'Indexed AVI' or 'Grayscale AVI'	2-dimensional (height-by-width)	Use frame as provided. For 'Grayscale AVI', colormap should be empty.
	3-dimensional (height-by-width-by-3)	Error
All other profiles	2-dimensional (height-by-width)	Construct RGB image frames using the colormap field
	3-dimensional (height-by-width-by-3)	Colormap field ignored. Construct RGB image frames using the cdata field

## **mov**

1-by-F array of frame structures, where F is the number of images.  
Each frame structure contains fields `cdata` and `colormap`.

## **Examples**

### **AVI File from Animation**

Write a sequence of frames to a compressed AVI file, `peaks.avi`.

Prepare the new file.

```
writerObj = VideoWriter('peaks.avi');
open(writerObj);
```

Generate initial data and set axes and figure properties.

```
Z = peaks; surf(Z);
axis tight
set(gca, 'nextplot', 'replacechildren');
set(gcf, 'Renderer', 'zbuffer');
```

Setting the `Renderer` property to `zbuffer` or `Painters` works around limitations of `getframe` with the OpenGL renderer on some Windows systems.

Create a set of frames and write each frame to the file.

```
for k = 1:20
 surf(sin(2*pi*k/20)*Z,Z)
 frame = getframe;
 writeVideo(writerObj,frame);
end
```

```
close(writerObj);
```

### **MPG to AVI Conversion**

Convert an example file, `xylophone.mp4`, to an uncompressed AVI file:

# VideoWriter.writeVideo

---

Create objects to read and write the video, and open the AVI file for writing.

```
readerObj = VideoReader('xylophone.mp4');
writerObj = VideoWriter('transcoded_xylophone.avi', ...
 'Uncompressed AVI');
```

```
open(writerObj);
```

Read and write each frame.

```
for k = 1:readerObj.NumberOfFrames
 img = read(readerObj,k);
 writeVideo(writerObj,img);
end
```

```
close(writerObj);
```

[close](#) | [getframe](#) | [VideoReader](#) | [VideoWriter](#) | [movie2avi](#) | [open](#)

**Purpose**

Label x-axis

**Syntax**

```
xlabel(str)
xlabel(str,Name,Value)

xlabel(axes_handle, ___)

h = xlabel(___)
```

**Description**

`xlabel(str)` labels the *x*-axis of the current axes with the string, `str`. Each axes graphics object has one predefined *x*-axis label. Reissuing the `xlabel` command causes the new label to replace the old label. Labels appear beneath the axis in a two-dimensional view and to the side or beneath the axis in a three-dimensional view.

`xlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`xlabel(axes_handle, ___ )` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = xlabel( ___ )` returns the handle to the text object used as the *x*-axis label. The handle is useful when making future modifications to the label.

**Input Arguments****str - Text to display as x-axis label**

string

Text to display as the *x*-axis label, specified as a string or the name of a function that returns a string.

**Example:** 'myLabel'

**axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Color','red','FontSize',12` adds an x-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

### 'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green

RGB Value	Short Name	Long Name
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### **'FontAngle' - Character slant**

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### **'FontName' - Font name**

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName','Courier'

### **'FontSize' - Font size**

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize',12.5

## 'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $\frac{1}{72}$  inch

---

**Note** When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits', 'inches', 'FontSize', 0.3 in the argument list.

---

## 'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

### 'Interpreter' - Character interpretation

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** `'Interpreter','latex'`

## Output Arguments

### **h** - Handle to text object used as x-axis label

scalar

Handle to the text object used as the *x*-axis label, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the label.

# xlabel

---

## Examples

### Label x-Axis with String

```
figure
plot((1:10).^2)
xlabel('Population')
```

MATLAB® displays Population beneath the x-axis.

**Label x-Axis with Numeric Input**

```
figure
plot((1:10).^2)
xlabel(123)
```

MATLAB® displays 123 beneath the *x*-axis.

**Create Multiline Label**

Create a multiline label using a multiline cell array.

# xlabel

---

```
figure
plot((1:10).^2)
xlabel({date;'Population';'in Years'})
```

## Include SuperScript or Subscript in Label

Use the '^' and '\_' characters to include superscripts and subscripts in the axis labels. Use braces to modify more than one character.

```
t = linspace(0,1);
```

```
y = exp(t);
figure
plot(t,y);
xlabel('t_{seconds}');
ylabel('e^t')
```

### Create Label and Set Font Properties

Use Name, Value pair arguments to set the font size, font weight, and text color properties of the x-axis label.

# xlabel

---

```
figure
plot((1:10).^2)
xlabel('Population','FontSize',12,...
 'FontWeight','bold','Color','r')
```

'FontSize',12 displays the label text in 12-point font.  
'FontWeight','bold' makes the text bold. 'Color','r' sets the text color to red.

### **Label x-Axis of Specific Axes**

Create a figure with two subplots and return the axes handles, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

# xlabel

---

Label the  $x$ -axis of the top plot by referring to its axes handle, `s(1)`.

```
xlabel(s(1), 'Population')
```

### Label x-Axis and Return Object Handle

Label the  $x$ -axis and return the handle to the text object used as the label.

```
figure
plot((1:10).^2)
str = 'Population';
h = xlabel(str);
```

# xlabel

---

MATLAB® returns the object handle in the output variable, `h`.

Set the color of the label to red, using the handle.

```
set(h, 'Color', 'red')
```

**See Also**

[strings](#) | [ylabel](#) | [zlabel](#) | [text](#) | [title](#)

**Concepts**

- “Add Axis Labels to Graph Using Plot Tools”  
Text Properties

# ylabel

---

## Purpose

Label y-axis

## Syntax

```
ylabel(str)
ylabel(str,Name,Value)

ylabel(axes_handle, ___)

h = ylabel(___)
```

## Description

`ylabel(str)` labels the *y*-axis of the current axes with the string, `str`. Every axes has one predefined *y*-axis label. Reissuing the `ylabel` command causes the new label to replace the old label. Labels appear beside the axis in a two-dimensional view and to the side or in front of the axis in a three-dimensional view.

`ylabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`ylabel(axes_handle, ___ )` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = ylabel( ___ )` returns the handle to the text object used as the *y*-axis label. The handle is useful when making future modifications to the label.

## Input Arguments

### **str - Text to display as y-axis label**

string

Text to display as the *y*-axis label, specified as a string or the name of a function that returns a string.

**Example:** 'myLabel'

### **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Color','red','FontSize',12` adds a y-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

#### 'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of `'Color'` and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green

RGB Value	Short Name	Long Name
[0 0 1]	b	blue
[1 1 1]	w	white
[0 0 0]	k	black

**Example:** 'Color',[0 1 0]

**Example:** 'Color','green'

### **'FontAngle' - Character slant**

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

**Example:** 'FontAngle','italic'

### **'FontName' - Font name**

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

**Example:** 'FontName','Courier'

### **'FontSize' - Font size**

10 points (default) | scalar

---

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize',12.5

#### 'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $1/72$  inch

---

**Note** When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits', 'inches', 'FontSize', 0.3 in the argument list.

---

#### 'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

**Example:** `'FontWeight','bold'`

### 'Interpreter' - Character interpretation

`'tex'` (default) | `'latex'` | `'none'`

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** `'Interpreter','latex'`

## Output Arguments

### **h** - Handle to text object used as y-axis label

scalar

Handle to the text object used as the *y*-axis label, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the label.

**Examples**      **Label y-Axis with String**

```
figure
plot((1:10).^2)
ylabel('Population')
```

MATLAB® displays Population beside the y-axis.

## Label y-Axis with Numeric Input

```
figure
plot((1:10).^2)
ylabel(123)
```

MATLAB® displays 123 beside the y-axis.

### Create Multiline Label

Create a multiline label using a multiline cell array.

```
figure
plot((1:10).^2)
ylabel({'2010'; 'Population'; 'in Years'})
```

### Include SuperScript or Subscript in Label

Use the '^' and '\_' characters to include superscripts and subscripts in the axis labels. Use braces to modify more than one character.

```
t = linspace(0,1);
```

# ylabel

---

```
y = exp(t);
figure
plot(t,y);
xlabel('t_{seconds}')
ylabel('e^t')
```

## Create y-Axis Label and Set Font Properties

Use Name, Value pairs to set the font size, font weight, and text color properties of the y-axis label.

```
figure
plot((1:10).^2)
ylabel('Population','FontSize',12,...
 'FontWeight','bold','Color','r')
```

'FontSize',12 displays the label text in 12-point font.  
'FontWeight','bold' makes the text bold. 'Color','r' sets the text color to red.

## Label y-Axis of Specific Axes

Create two subplots and return the axes handles, s(1) and s(2).

```
figure
s(1) = subplot(2,1,1);
plot((1:10).^2)
s(2) = subplot(2,1,2);
plot((1:10).^3)
```

Label the  $y$ -axis of the top plot by referring to its axes handle, `s(1)`.

```
ylabel(s(1), 'Population')
```

### Label y-Axis and Return Object Handle

Label the  $y$ -axis and return the handle to the text object used as the label.

```
figure
```

# ylabel

---

```
plot((1:10).^2)
str = 'Population';
h = ylabel(str);
```

MATLAB® returns the object handle in the output variable, h.  
Set the color of the label to red, using the handle.

```
set(h, 'Color', 'red')
```

**See Also**

**Concepts**

- “Add Axis Labels to Graph Using Plot Tools”  
Text Properties

# zlabel

---

## Purpose

Label z-axis

## Syntax

```
zlabel(str)
zlabel(str,Name,Value)

zlabel(axes_handle, ___)

h = zlabel(___)
```

## Description

`zlabel(str)` labels the z-axis of the current axes with the string, `str`. Every axes has one predefined z-axis label. Reissuing the `zlabel` command causes the new label to replace the old label.

`zlabel(str,Name,Value)` additionally specifies the text object properties using one or more `Name,Value` pair arguments.

`zlabel(axes_handle, ___ )` adds the label to the axes specified by `axes_handle`. This syntax allows you to specify the axes to which to add a label. `axes_handle` can precede any of the input argument combinations in the previous syntaxes.

`h = zlabel( ___ )` returns the handle to the text object used as the z-axis label. The handle is useful when making future modifications to the label.

## Input Arguments

### **str - Text to display as z-axis label**

string

Text to display as the z-axis label, specified as a string or the name of a function that returns a string.

**Example:** 'myLabel'

### **axes\_handle - Axes handle**

handle

Axes handle, which is the reference to an axes object. Use the `gca` function to get the handle to the current axes, for example, `axes_handle = gca;`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Color','red','FontSize',12` adds an z-axis label with red, 12-point font.

In addition to the following, you can specify other text object properties using `Name`, `Value` pair arguments. See [Text Properties](#).

#### 'Color' - Text color

[0 0 0] (black) (default) | 3-element RGB vector | string

Text color, specified as the comma-separated pair consisting of 'Color' and a 3-element RGB vector or a string containing the short or long name of the color. The RGB vector is a 3-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range [0 1].

The following table lists the predefined colors and their RGB equivalents.

RGB Value	Short Name	Long Name
[1 1 0]	y	yellow
[1 0 1]	m	magenta
[0 1 1]	c	cyan
[1 0 0]	r	red
[0 1 0]	g	green
[0 0 1]	b	blue

RGB Value	Short Name	Long Name
[1 1 1]	w	white
[0 0 0]	k	black

Example: 'Color',[0 1 0]

Example: 'Color','green'

### **'FontAngle' - Character slant**

'normal' (default) | 'italic' | 'oblique'

Character slant, specified as the comma-separated pair consisting of 'FontAngle' and one of these values: 'normal', 'italic', or 'oblique'. MATLAB uses the FontAngle property to select a font from those available on your particular system. Generally, setting this property to italic or oblique selects a slanted font.

Example: 'FontAngle','italic'

### **'FontName' - Font name**

'Helvetica' (default) | string | 'FixedWidth'

Font name, specified as the comma-separated pair consisting of 'FontName' and a string. The string specifies the name of the font to use for the text object. To display and print properly, this must be a font that your system supports.

To use a fixed-width font that looks good in any locale, use the case-sensitive string 'FixedWidth'. This eliminates the need to hard-code the name of a fixed-width font, which might not display text properly on systems that do not use ASCII character encoding.

Example: 'FontName','Courier'

### **'FontSize' - Font size**

10 points (default) | scalar

Font size, specified as the comma-separated pair consisting of 'FontSize' and a scalar in units determined by the FontUnits property. The default value for FontUnits is points.

**Example:** 'FontSize',12.5

#### 'FontUnits' - Font size units

'points' (default) | 'normalized' | 'inches' | 'centimeters' | 'pixels'

Font size units, specified as the comma-separated pair consisting of 'FontUnits' and one of the following strings:

- 'points'
- 'normalized'
- 'inches'
- 'centimeters'
- 'pixels'

When the value of FontUnits is 'normalized', MATLAB interprets the value of FontSize as a fraction of the height of the parent axes. When you resize the axes, MATLAB modifies the screen FontSize accordingly. points, inches, centimeters, and pixels are absolute units. 1 point =  $1/72$  inch

---

**Note** When setting both the FontSize and the FontUnits, you must set the FontUnits property first so that MATLAB can correctly interpret the specified FontSize. For example, to set the font size to 0.3 inches, call 'FontUnits', 'inches', 'FontSize', 0.3 in the argument list.

---

#### 'FontWeight' - Weight of text characters

'normal' (default) | 'bold' | 'light' | 'demi'

Weight of text characters, specified as the comma-separated pair consisting of 'FontWeight' and one of the following strings:

# zlabel

---

- 'normal'
- 'bold'
- 'light'
- 'demi'

MATLAB uses the `FontWeight` property to select a font from those available on your particular system. Generally, setting this property to 'bold' or 'demi' causes MATLAB to use a bold font.

**Example:** 'FontWeight','bold'

## 'Interpreter' - Character interpretation

'tex' (default) | 'latex' | 'none'

Character interpretation, specified as the comma-separated pair consisting of 'Interpreter' and one of the following strings.

Interpreter value	Result
'tex'	Supports a subset of plain TeX markup language. See the <code>String</code> property for a list of supported TeX instructions.
'latex'	Supports a basic subset of the LaTeX markup language.
'none'	Interprets all characters as literal characters.

**Example:** 'Interpreter','latex'

## Output Arguments

### **h** - Handle to text object used as z-axis label

scalar

Handle to the text object used as the *z*-axis label, returned as a scalar. This is a unique identifier, which you can use to query and modify the properties of the label.

**Examples****Label z-Axis with String**

```
figure
surf(peaks)
zlabel('Height')
```

MATLAB® displays Height beside the z-axis.

## Label z-Axis with Numeric Input

```
figure
surf(peaks)
zlabel(123)
```

MATLAB® displays 123 beside the z-axis.

### Create Multiline z-Axis Label

Create a multiline label using a multiline cell array.

```
figure
surf(peaks)
zlabel({'First Line';'Second Line'})
```

### Label z-Axis and Set Font Properties

Use Name, Value pairs to set the font size, font weight, and text color properties of the z-axis label.

```
figure
```

# zlabel

---

```
surf(peaks)
zlabel('Elevation','FontSize',12,...
 'FontWeight','bold','Color','r');
```

'FontSize',12 displays the label text in 12-point font.  
'FontWeight','bold' makes the text bold. 'Color','r' sets the text color to red.

### **Label z-Axis of Specific Axes**

Create two subplots and return the handles to the axes objects, `s(1)` and `s(2)`.

```
figure
s(1) = subplot(2,1,1);
surf(peaks(30))
s(2) = subplot(2,1,2);
surf(peaks(45))
```

# zlabel

---

Label the z-axis of each plot by referring to the axes handles, `s(1)` and `s(2)`.

```
zlabel(s(1), 'Height1')
zlabel(s(2), 'Height2')
```

### Label z-Axis and Return Object Handle

Label the  $z$ -axis and return the handle to the text object used as the label.

```
figure
surf(peaks)
str = 'Population Change';
h = zlabel(str);
```

# zlabel

---

MATLAB® returns the object handle in the output variable, `h`.  
Set the color of the label to red, using the handle.

```
set(h,'Color','red')
```

**See Also**

strings | ylabel | xlabel | text | title

**Concepts**

- “Add Axis Labels to Graph Using Plot Tools”  
Text Properties

**Purpose** Set or query  $x$ -axis limits

**Syntax**

```
xlim
xlim([xmin xmax])
xlim('mode')
xlim('auto')
xlim('manual')
xlim(axes_handle,...)
```

**Description**

`xlim` with no arguments returns the limits of the current axes.

`xlim([xmin xmax])` sets the axis limits in the current axes to the specified values.

`xlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`xlim('auto')` sets the axis limit mode to `auto`.

`xlim('manual')` sets the axis limit mode to `manual`.

`xlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`xlim` sets or queries values of the axes object `XLim`, and `XLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

**Examples****Specify Axis Limits**

Set the  $x$ -axis and  $y$ -axis limits to match the range of data.

```
[x,y] = meshgrid(-1.75:.2:3.25);
z = x.*exp(-x.^2-y.^2);
```

```
figure
surf(x,y,z)
xlim([-1.75,3.25])
ylim([-1.75,3.25])
```

## Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

## See Also

`ylim` | `zlim` | `axis`

**How To**

- XLim
- YLim
- ZLim
- Understanding Axes Aspect Ratio

**Purpose** Set or query *y*-axis limits

**Syntax**

```
ylim
ylim([ymin ymax])
ylim('mode')
ylim('auto')
ylim('manual')
ylim(axes_handle,...)
```

**Description**

`ylim` with no arguments returns the limits of the current axes.

`ylim([ymin ymax])` sets the axis limits in the current axes to the specified values.

`ylim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`ylim('auto')` sets the axis limit mode to `auto`.

`ylim('manual')` sets the axis limit mode to `manual`.

`ylim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`ylim` sets or queries values of the axes object `YLim` and `YLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

## Examples

### Specify Axis Limits

Set the  $x$ -axis and  $y$ -axis limits to match the range of data.

```
[x,y] = meshgrid(-1.75:.2:3.25);
z = x.*exp(-x.^2-y.^2);
```

```
figure
surf(x,y,z)
xlim([-1.75,3.25])
ylim([-1.75,3.25])
```

## Alternatives

To control the upper and lower axis limits on a graph, use the Property Editor, one of the plotting tools . For details, see The Property Editor.

## See Also

`xlim` | `zlim` | `axis`

# zlim

---

**Purpose** Set or query z-axis limits

**Syntax**

```
zlim
zlim([zmin zmax])
zlim('mode')
zlim('auto')
zlim('manual')
zlim(axes_handle,...)
```

**Description**

`zlim` with no arguments returns the limits of the current axes.

`zlim([zmin zmax])` sets the axis limits in the current axes to the specified values.

`zlim('mode')` returns the current value of the axis limits mode, which can be either `auto` (the default) or `manual`.

`zlim('auto')` sets the axis limit mode to `auto`.

`zlim('manual')` sets the axis limit mode to `manual`.

`zlim(axes_handle,...)` performs the set or query on the axes identified by the first argument, `axes_handle`. When you do not specify an axes handle, it operates on the current axes.

**Tips**

`zlim` sets or queries values of the axes object `ZLim` and `ZLimMode` property.

When the axis limit mode is set to `auto` (the default), MATLAB uses limits, which are round numbers, to span the range of the data being displayed. Setting a value for any of the limits also sets the corresponding mode to `manual`. If you set the limits on an existing graph and want to maintain these limits while adding more graphs, use the `hold` command.

---

**Note** High-level plotting functions like `plot` and `surf` reset both the modes and the limits.

---

## Examples Specify z-Axis Limits

Specify the z-axis limits for the graph.

```
[x,y] = meshgrid([-1.75:.2:3.25]);
z = x.*exp(-x.^2-y.^2);
```

```
figure
surf(x,y,z)
zlim([-0.35,0.3])
```

# zlim

---

<b>Purpose</b>	Determine if file contains Microsoft Excel spreadsheet
<b>Syntax</b>	<pre>status = xlsfinfo(filename) [status,sheets] = xlsfinfo(filename) [status,sheets,xlFormat] = xlsfinfo(filename)</pre>
<b>Description</b>	<p><code>status = xlsfinfo(filename)</code> indicates if <code>filename</code> is a file that the <code>xlsread</code> function can read.</p> <p><code>[status,sheets] = xlsfinfo(filename)</code> additionally returns the name of each spreadsheet in the file.</p> <p><code>[status,sheets,xlFormat] = xlsfinfo(filename)</code> also returns the format description that Excel returns for the file. On systems without Excel for Windows, <code>xlFormat</code> is an empty string, <code>''</code>.</p>
<b>Input Arguments</b>	<p><b>filename - Name of file</b> string Name of file, specified as a string. <b>Example:</b> <code>'myFile.xlsx'</code></p> <p><b>Data Types</b> char</p>
<b>Output Arguments</b>	<p><b>status - Type of file</b> string Type of file, returned as a string.</p> <ul style="list-style-type: none"><li>• If <code>filename</code> is a file that <code>xlsread</code> can read, then <code>status</code> is a descriptive string, such as <code>'Microsoft Excel Spreadsheet'</code>.</li><li>• If <code>filename</code> is not a file that <code>xlsread</code> can read, then <code>status</code> is an empty string, <code>''</code>.</li><li>• If MATLAB cannot find the file, then <code>xlsfinfo</code> returns an error.</li></ul>

## **sheets - Worksheet names**

1-by-n cell array of strings

Worksheet names, returned as a 1-by-n cell array of strings, where n is the number of worksheets in the file. Each cell contains the name of a worksheet. If `xlsread` cannot read a particular worksheet, the corresponding cell contains an error message.

If `xlsfinfo` cannot read the file, then `sheets` contains an error message.

## **xlFormat - File format description returned by Excel**

string

File format description returned by Excel, returned as a string.

On Windows systems with Excel software, `xlFormat` is a nonempty string, such as one of the following.

'xlOpenXMLWorkbook'	Spreadsheet in XLSX format (Excel 2007 or later)
'xlWorkbookNormal' or 'xlExce18'	Spreadsheet in XLS format (compatible with Excel 97-2003)
'xlCSV'	File in comma-separated value (CSV) format
'xlHtml' or 'xlWebArchive'	Spreadsheet exported to HTML format

On all other systems, `xlFormat` is an empty string, ''.

## **Examples**

### **View Information About Spreadsheet File**

Create a sample Excel file named `myExample.xlsx`.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

Call `xlsfinfo` to get information about the file.

```
[status,sheets,xlFormat] = xlsfinfo('myExample.xlsx')
```

```
status =
```

```
Microsoft Excel Spreadsheet
```

```
sheets =
```

```
 'Sheet1' 'Sheet2' 'Sheet3'
```

```
xlFormat =
```

```
xlOpenXMLWorkbook
```

`status` is a descriptive string indicating that the `xlsread` function can read the sample file.

## Tips

- If `xlsfinfo` warns that it cannot start an ActiveX server, then the COM server, which is part of the typical Excel installation, is unavailable. In this case, consider reinstalling your Excel software. On systems with Excel for Windows, `xlsfinfo` uses the COM server to obtain information.

## Limitations

- `xlsfinfo` supports only 7-bit ASCII characters.

## See Also

`xlsread` | `xlswrite`

# xlsread

---

**Purpose** Read Microsoft Excel spreadsheet file

**Syntax**

```
num = xlsread(filename)
num = xlsread(filename, sheet)
num = xlsread(filename, xlRange)
num = xlsread(filename, sheet, xlRange)
num = xlsread(filename, sheet, xlRange, 'basic')
[num, txt, raw] = xlsread(___)

___ = xlsread(filename, -1)
```

```
[num, txt, raw, custom] = xlsread(filename, sheet, xlRange, '',
 functionHandle)
```

**Description** `num = xlsread(filename)` reads data from the first worksheet in the Microsoft Excel spreadsheet file named `filename` and returns the numeric data in array `num`.

On Windows systems with Microsoft Excel software, `xlsread` reads any file format recognized by your version of Excel.

If your system does not have Excel for Windows, `xlsread` operates in basic import mode, and reads only XLS, XLSX, XLSM, XLTX, and XLTM files.

`num = xlsread(filename, sheet)` reads the specified worksheet.

`num = xlsread(filename, xlRange)` reads data from the specified range, `xlRange`, of the first worksheet in the file.

`num = xlsread(filename, sheet, xlRange)` reads from the specified sheet and range, `xlRange`.

`num = xlsread(filename, sheet, xlRange, 'basic')` reads data from the spreadsheet in basic mode, the default on systems without Excel for

Windows. If you do not specify all the arguments, use empty strings as placeholders, for example, `num = xlsread(filename, '', '', 'basic')`.

`[num,txt,row] = xlsread( ___ )` additionally returns the text fields in cell array `txt`, and the unprocessed data (numbers and text) in cell array `raw` using any of the input arguments in the previous syntaxes. If `xlRange` is specified, leading blank rows and columns in the worksheet that precede rows and columns with data are returned in `raw`.

`___ = xlsread(filename, -1)` opens an Excel window to interactively select data. Select the worksheet, drag and drop the mouse over the range you want, and click **OK**. This syntax is supported only on Windows systems with Excel software.

`[num,txt,row,custom] = xlsread(filename, sheet, xlRange, '', functionHandle)` reads from the spreadsheet, executes the function associated with `functionHandle` on the data, and returns the final results as numeric data in array `num`. The `xlsread` function optionally returns the text fields in cell array `txt`, the unprocessed data (numbers and text) in cell array `raw`, and the second output from the function associated with `functionHandle` in array `custom`. The `xlsread` function does not change the data stored in the spreadsheet. This syntax is supported only on Windows systems with Excel software.

## Input Arguments

### **filename - Name of file to read**

string

Name of the file to read, specified as a string. If you do not include an extension, `xlsread` searches for a file with the specified name and a supported Excel extension. `xlsread` can read data saved in files that are currently open in Excel for Windows.

**Example:** `'myFile.xlsx'`

### **Data Types**

char

## **sheet - Worksheet to read**

string | positive integer

Worksheet to read, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`. For XLS files in `basic` mode, `sheet` is case sensitive.
- Positive integer that indicates the worksheet index. Not supported for XLS files in `basic` mode.

## **xlRange - Rectangular portion of the worksheet to read**

string

Rectangular portion of the worksheet to read, specified as a string.

Specify `xlRange` using the syntax '`C1:C2`', where `C1` and `C2` are two opposing corners that define the region to read. For example, '`D2:H4`' represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help).

Range selection is not supported when reading XLS files in `basic` mode. In this case, use `' '` in place of `xlRange`.

If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as '`D2:D2`'). Otherwise, `xlsread` interprets the input as a worksheet name (such as '`sales`' or '`D2`').

If you specify `sheet`, then `xlRange`:

- Does not need to include a colon and opposite corner to describe a single cell.
- Can refer to a named range that you defined in the Excel file (see the Excel help).

## **Data Types**

char

**'basic' - Flag to request reading in basic mode**

literal string

Flag to request reading in basic mode, specified as the literal string, 'basic'.

basic mode is the default for systems without Excel for Windows. In basic mode, xlsread:

- Reads XLS, XLSX, XLSM, XLTX, and XLTM files only.
- Does not support an x1Range input when reading XLS files. In this case, use '' in place of x1Range.
- Does not support function handle inputs.
- Imports all dates as Excel serial date numbers. Excel serial date numbers use a different reference date than MATLAB date numbers.

**functionHandle - Handle to a custom function**

function handle

Handle to a custom function, starting with the symbol @. Supported only on Windows systems with Excel software. xlsread reads from the spreadsheet, executes your function on a copy of the data, and returns the final results. xlsread does not change the data stored in the spreadsheet.

When xlsread calls the custom function, it passes a range interface from the Excel application to provide access to the data. The custom function must include this interface both as an input and output argument. (See the Examples.)

**Example:** @myFunctionHandle

**Output Arguments****num - Numeric data**

matrix

Numeric data, returned as a matrix of double values. The array does not contain any information from header lines, or from outer rows or columns that contain nonnumeric data. Text data in inner spreadsheet rows and columns appear as NaN in the num output.

## **txt - Text data**

cell array

Text data, returned as a cell array. Numeric values in inner spreadsheet rows and columns appear as empty strings, '', in txt.

For XLS files in basic import mode, the txt output contains empty strings, '', in place of leading columns of numeric data that precede text data in the spreadsheet. In all other cases, txt does not contain these additional columns.

Undefined values (such as '#N/A') appear in the txt output as '#N/A', except for XLS files in basic mode.

## **raw - Unprocessed data**

cell array

Unprocessed data from the worksheet, returned as a cell array. Contains both numeric and text data.

On systems with Excel for Windows, undefined values (such as '#N/A') appear in the raw output as 'ActiveX\_VT\_ERROR:'. For XLSX, XLSM, XLTX, and XLTM files on other systems, undefined values appear as '#N/A'.

## **custom - Second output of the function corresponding to functionHandle**

defined by the function

Second output of the function corresponding to functionHandle. The value and data type of custom are determined by the function.

## **Examples**

### **Read Data from First Worksheet Into Numeric Array**

Create an Excel file named myExample.xlsx.

```
values = {1, 2, 3 ; 4, 5, 'x' ; 7, 8, 9};
headers = {'First', 'Second', 'Third'};
xlswrite('myExample.xlsx', [headers; values]);
```

Sheet1 of myExample.xlsx contains:

First	Second	Third
1	2	3
4	5	x
7	8	9

Read data from the first worksheet.

```
filename = 'myExample.xlsx';
A = xlsread(filename)
```

```
A =
 1 2 3
 4 5 NaN
 7 8 9
```

xlsread returns the numeric data in array A.

### Read a Specific Range of Data

Read a specific range of data from the Excel file in the previous example.

```
filename = 'myExample.xlsx';
sheet = 1;
xlRange = 'B2:C3';
```

```
subsetA = xlsread(filename, sheet, xlRange)
```

```
subsetA =
 2 3
 5 NaN
```

### Read a Column of Data

Read the second column of data from the Excel file in the first example.

```
filename = 'myExample.xlsx';

columnB = xlsread(filename, 'B:B')
```

```
columnB =
 2
 5
 8
```

For better performance, specify the row numbers in the range, as shown in the previous example.

## Request Numeric, Text, and Unprocessed Data

Request the numeric data, text, and a copy of the unprocessed (raw) data from the Excel file in the first example.

```
[ndata, text, alldata] = xlsread('myExample.xlsx')
```

```
ndata =
 1 2 3
 4 5 NaN
 7 8 9
```

```
text =
 'First' 'Second' 'Third'
 '' '' ''
 '' '' 'x'
```

```
alldata =
 'First' 'Second' 'Third'
 [1] [2] [3]
 [4] [5] 'x'
 [7] [8] [9]
```

`xlsread` returns numeric data in array `ndata`, text data in cell array `text`, and unprocessed data in cell array `alldata`.

## Execute a Function on a Worksheet and Return Numeric Data

In the Editor, create a function to process data from a worksheet. In this case, set values outside the range [-3, 3] to -3 or 3.

```
function [Data] = setMinMax(Data)

 minval = -3; maxval = 3;

 for k = 1:Data.Count
 v = Data.Value{k};
 if v > maxval || v < minval
 if v > maxval
 Data.Value{k} = maxval;
 else
 Data.Value{k} = minval;
 end
 end
 end
end
```

In the Command Window, add data to myExample.xlsx.

```
misc = pi*gallery('normaldata',[10,3],1);
xlswrite('myExample.xlsx',misc,'MyData');
```

Worksheet MyData contains the following values, which range from -6.6493 to 3.4845:

2.7156	-6.1744	1.8064
0.2959	-2.3383	-2.7210
-2.6764	-1.7351	-6.6493
2.7442	-2.5752	-3.0300
-1.3761	3.4845	0.6683
-1.3498	-1.9319	1.5014
-3.4643	-0.8000	0.3162
1.2448	-0.8477	0.9344
-3.0314	-5.2527	1.7912
0.5292	-5.8938	-5.1035

Read the data from the worksheet, and reset any values outside the range [-3, 3]. Specify the sheet name, but use '' as placeholders for the xlRange and 'basic' inputs.

```
trim = xlsread('myExample.xlsx','MyData','','',@setMinMax)
```

```
trim =
 2.7156 -3.0000 1.8064
 0.2959 -2.3383 -2.7210
 -2.6764 -1.7351 -3.0000
 2.7442 -2.5752 -3.0000
 -1.3761 3.0000 0.6683
 -1.3498 -1.9319 1.5014
 -3.0000 -0.8000 0.3162
 1.2448 -0.8477 0.9344
 -3.0000 -3.0000 1.7912
 0.5292 -3.0000 -3.0000
```

## Request Custom Output

Execute a function on a worksheet and display the custom index output.

In the Editor, modify the function `setMinMax` from the previous example to return the indices of the changed elements (custom output).

```
function [Data,indices] = setMinMax(Data)

 minval = -3; maxval = 3;
 indices = [];

 for k = 1:Data.Count
 v = Data.Value{k};
 if v > maxval || v < minval
 if v > maxval
 Data.Value{k} = maxval;
 else
 Data.Value{k} = minval;
 end
 indices = [indices k];
 end
 end
```

Read the data from the worksheet MyData, and request the custom index output, idx.

```
[trim,txt,row,idx] = xlsread('myExample.xlsx',...
'MyData','', '@setMinMax);
disp(idx)
```

```
7 9 11 15 19 20 23 24 30
```

## Algorithms

- If you do not specify `xlRange`, then `xlsread` ignores leading blank rows and columns in the worksheet that precede your data.
- If you specify `xlRange`, then leading blank rows and columns in the worksheet that precede your data are returned in `row`, but not in `num` or `txt`.
- When the specified `xlRange` overlaps merged cells:
  - On Windows systems with Excel, `xlsread` expands the range to include all merged cells.
  - On systems without Excel for Windows, `xlsread` returns data for the specified range only, with empty or NaN values for merged cells.
- `xlsread` imports formatted dates as strings (such as '10/31/96'), except in `basic` mode and on systems without Excel for Windows.

## Limitations

- `xlsread` reads only 7-bit ASCII characters.
- `xlsread` does not support non-contiguous ranges.

## Concepts

- “When to Convert Dates from Excel Files”

# xlswrite

---

## Purpose

Write Microsoft Excel spreadsheet file

## Syntax

```
xlswrite(filename,A)
xlswrite(filename,A,sheet)
xlswrite(filename,A,xlRange)
xlswrite(filename,A,sheet,xlRange)
```

```
status = xlswrite(___)
[status,message] = xlswrite(___)
```

## Description

`xlswrite(filename,A)` writes array `A` to the first worksheet in Excel file, `filename`, starting at cell `A1`.

`xlswrite(filename,A,sheet)` writes to the specified worksheet.

`xlswrite(filename,A,xlRange)` writes to the rectangular region specified by `xlRange` in the first worksheet of the file.

`xlswrite(filename,A,sheet,xlRange)` writes to the specified sheet and range, `xlRange`.

`status = xlswrite( ___ )` returns the status of the write operation, and can include any of the input arguments in previous syntaxes. When the operation is successful, `status` is 1. Otherwise, `status` is 0.

`[status,message] = xlswrite( ___ )` additionally returns any warning or error message generated by the write operation in structure `message`.

## Input Arguments

**filename - Name of file to write**

string

Name of file to write, specified as a string.

If `filename` does not exist, `xlswrite` creates a file, determining the format based on the specified extension. To create a file compatible with Excel 97-2003 software, specify an extension of `.xls`. To create files in Excel 2007 formats, specify an extension of `.xlsx`, `.xlsb`, or `.xlsm`. If you do not specify an extension, `xlswrite` uses the default, `.xls`.

**Example:** `'myFile.xlsx'`

## **A - Data to write**

`matrix` | `cell array`

Data to write, specified as a two-dimensional numeric or character array, or, if each cell contains a single element, a cell array.

If `A` is a cell array containing something other than a scalar numeric or a string, then `xlswrite` silently leaves the corresponding cell in the spreadsheet empty.

The maximum size of array `A` depends on the associated Excel version. For more information on Excel specifications and limits, see the Excel help.

**Example:** `[10,2,45;-32,478,50]`

**Example:** `{92.0,'Yes',45.9,'No'}`

## **Data Types**

`single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `cell`

## **sheet - Worksheet name**

`string` | `positive integer`

Worksheet name, specified as one of the following:

- String that contains the worksheet name. Cannot contain a colon (:). To determine the names of the sheets in a spreadsheet file, use `xlsfinfo`.
- Positive integer that indicates the worksheet index.

# xlswrite

---

If `sheet` does not exist, `xlswrite` adds a new sheet at the end of the worksheet collection. If `sheet` is an index larger than the number of worksheets, `xlswrite` appends empty sheets until the number of worksheets in the workbook equals `sheet`. In either case, `xlswrite` generates a warning indicating that it has added a new worksheet.

## **xlRange - Rectangular portion of the worksheet to write**

string

Rectangular portion of the worksheet to write, specified as a string.

Specify `xlRange` using the syntax '`C1:C2`', where `C1` and `C2` are two opposing corners that define the region to write. For example, '`D2:H4`' represents the 3-by-5 rectangular region between the two corners `D2` and `H4` on the worksheet. The `xlRange` input is not case sensitive, and uses Excel A1 reference style (see Excel help). `xlswrite` does not recognize named ranges.

- If you do not specify `sheet`, then `xlRange` must include both corners and a colon character, even for a single cell (such as '`D2:D2`'). Otherwise, `xlswrite` interprets the input as a worksheet name (such as '`D2`').
- If you specify `sheet`, then `xlRange` can specify only the first cell (such as '`D2`'). `xlswrite` writes input array `A` beginning at this cell.
- If `xlRange` is larger than the size of input array `A`, Excel software fills the remainder of the region with `#N/A`. If `xlRange` is smaller than the size of `A`, then `xlswrite` writes only the subset that fits into `xlRange` to the file.

## **Output Arguments**

### **status - Status of the write operation**

1 | 0

Status of the write operation, returned as either 1 (true) or 0 (false). When the write operation is successful, `status` is 1. Otherwise, `status` is 0.

### **message - Error or warning generated during the write operation**

structure array

Error or warning generated during the write operation, returned as a structure array containing two fields:

**message**        Text of the warning or error message, returned as a string.

**identifier**    Message identifier, returned as a string.

## Examples

### Write Data to a Spreadsheet

Write a 7-element vector to an Excel file, `testdata.xlsx`.

```
filename = 'testdata.xlsx';
A = [12.7, 5.02, -98, 63.9, 0, -.2, 56];
xlswrite(filename,A)
```

### Write Data to a Specific Sheet and Range in a Spreadsheet

Write mixed text and numeric data to an Excel file, `testdata.xlsx`, starting at cell E1 of Sheet2.

```
filename = 'testdata.xlsx';
A = {'Time', 'Temperature'; 12,98; 13,99; 14,97};
sheet = 2;
xlRange = 'E1';
xlswrite(filename,A,sheet,xlRange)
```

## Tips

- If your system has Microsoft Office 2003 software, but you want to create a file in an Excel 2007 format, install the Office 2007 Compatibility Pack.
- Excel and MATLAB can store dates as strings (such as '10/31/96') or serial date numbers (such as 729329). If your array `A` includes serial date numbers, convert the dates to strings using `datestr` before calling `xlswrite`. Alternatively, see “When to Convert Dates from Excel Files”.

# xlswrite

---

- To write data to Excel files with custom formats (such as fonts or colors), access the Windows COM server directly using `actxserver` rather than `xlswrite`. For example, Technical Solution 1-QLD4K uses `actxserver` to establish a connection between MATLAB and Excel, writes data to a worksheet, and specifies the colors of the cells.

## Algorithms

Excel converts `Inf` values to 65535. MATLAB converts `NaN` values to empty cells.

If your system does not have Excel for Windows, or if the COM server (part of the typical installation of Excel) is unavailable, then the `xlswrite` function:

- Writes array `A` to a text file in comma-separated value (CSV) format.
- Ignores the `sheet` and `xlRange` arguments.
- Generates an error when input array `A` is a cell array.

<b>Purpose</b>	Read XML document and return Document Object Model node
<b>Syntax</b>	<code>DOMnode = xmlread(filename)</code>
<b>Description</b>	<code>DOMnode = xmlread(filename)</code> reads the specified XML file and returns a Document Object Model node representing the document.
<b>Tips</b>	<p>The display for a properly parsed document is <code>[#document: null]</code>. For example,</p> <pre>xDoc = xmlread('info.xml')</pre> <p>returns</p> <pre>xDoc = [#document: null]</pre>
<b>Input Arguments</b>	<p><b>filename</b></p> <p>String enclosed in single quotation marks that specifies the name of the local file or URL.</p>
<b>Output Arguments</b>	<p><b>DOMnode</b></p> <p>Document Object Model node, as defined by the World Wide Web consortium. For more information, see “What Is an XML Document Object Model (DOM)?”.</p>
<b>Examples</b>	<p>The root element in an XML file sometimes includes an <code>xsi:noNamespaceSchemaLocation</code> attribute. The value of this attribute is the name of the preferred schema file. Call the <code>getAttribute</code> method to get this value:</p> <pre>xDoc = xmlread(fullfile(matlabroot,'toolbox',...                         'matlab','general','info.xml'));  xRoot = xDoc.getDocumentElement; schema = char(xRoot.getAttribute('xsi:noNamespaceSchemaLocation'))</pre>

This code returns:

```
schema =
http://www.mathworks.com/namespace/info/v1/info.xsd
```

---

Create functions that parse data from an XML file into a MATLAB structure array with fields Name, Attributes, Data, and Children:

```
function theStruct = parseXML(filename)
% PARSEXML Convert XML file to a MATLAB structure.
try
 tree = xmlread(filename);
catch
 error('Failed to read XML file %s.',filename);
end

% Recurse over child nodes. This could run into problems
% with very deeply nested trees.
try
 theStruct = parseChildNodes(tree);
catch
 error('Unable to parse XML file %s.',filename);
end

% ----- Local function PARSECHILDNODES -----
function children = parseChildNodes(theNode)
% Recurse over node children.
children = [];
if theNode.hasChildNodes
 childNodes = theNode.getChildNodes;
 numChildNodes = childNodes.getLength;
 allocCell = cell(1, numChildNodes);

 children = struct(
 'Name', allocCell, 'Attributes', allocCell, ...
```

```
 'Data', allocCell, 'Children', allocCell);

 for count = 1:numChildNodes
 theChild = childNodes.item(count-1);
 children(count) = makeStructFromNode(theChild);
 end
end

% ----- Local function MAKESTRUCTFROMNODE -----
function nodeStruct = makeStructFromNode(theNode)
% Create structure of node info.

nodeStruct = struct(
 'Name', char(theNode.getNodeName), ...
 'Attributes', parseAttributes(theNode), ...
 'Data', '', ...
 'Children', parseChildNodes(theNode));

if any(strcmp(methods(theNode), 'getData'))
 nodeStruct.Data = char(theNode.getData);
else
 nodeStruct.Data = '';
end

% ----- Local function PARSEATTRIBUTES -----
function attributes = parseAttributes(theNode)
% Create attributes structure.

attributes = [];
if theNode.hasAttributes
 theAttributes = theNode.getAttributes;
 numAttributes = theAttributes.getLength;
 allocCell = cell(1, numAttributes);
 attributes = struct('Name', allocCell, 'Value', ...
 allocCell);

 for count = 1:numAttributes
```

# xmlread

---

```
 attrib = theAttributes.item(count-1);
 attributes(count).Name = char(attrib.getName);
 attributes(count).Value = char(attrib.getValue);
 end
end
```

**Purpose** Logical exclusive-OR

**Syntax** `C = xor(A, B)`

**Description** `C = xor(A, B)` performs an exclusive OR operation on the corresponding elements of arrays A and B. The resulting element `C(i, j, ...)` is logical true (1) if `A(i, j, ...)` or `B(i, j, ...)`, but not both, is nonzero.

A	B	C
Zero	Zero	0
Zero	Nonzero	1
Nonzero	Zero	1
Nonzero	Nonzero	0

**Examples** Given `A = [0 0 pi eps]` and `B = [0 -2.4 0 1]`, then

```
C = xor(A,B)
C =
 0 1 1 0
```

To see where either A or B has a nonzero element and the other matrix does not,

```
spy(xor(A,B))
```

**See Also** `all` | `any` | `find` | `and` | `or` | `not` | Logical Operators: Short Circuit

**Concepts**

- “Truth Table for Logical Operations”

# xslt

---

**Purpose** Transform XML document using XSLT engine

**Syntax**

```
result = xslt(source, style, dest)
[result,style] = xslt(___)
xslt(___ , '-web')
```

**Description** `result = xslt(source, style, dest)` transforms an XML document using a stylesheet and returns the resulting document's URL. The function uses these inputs, the first of which is required:

- `source` is the filename or URL of the source XML file. `source` can also specify a DOM node.
- `style` is the filename or URL of an XSL stylesheet.
- `dest` is the filename or URL of the desired output document. If `dest` is absent or empty, the function uses a temporary filename. If `dest` is `'-tostring'`, the function returns the output document as a MATLAB string.

`[result,style] = xslt( ___ )` returns a processed stylesheet appropriate for passing to subsequent XSLT calls as `style`. This prevents costly repeated processing of the stylesheet.

`xslt( ___ , '-web')` displays the resulting document in the Help Browser.

**Tips** MATLAB uses the Saxon XSLT processor, version 6.5.5, which supports XSLT 1.0 expressions. For more information, see <http://saxon.sourceforge.net/saxon6.5.5/>

For additional information on writing XSL stylesheets, see the World Wide Web Consortium (W3C®) web site, <http://www.w3.org/Style/XSL/>.

**Examples** This example converts the file `info.xml` using the stylesheet `info.xsl`, writing the output to the file `info.html`. It launches the resulting HTML file in the MATLAB Web Browser.

```
xslt('info.xml', 'info.xsl', 'info.html', '-web')
```

**See Also**

```
xmlread | xmlwrite
```

# zeros

---

## Purpose

Create array of all zeros

## Syntax

```
X = zeros
X = zeros(n)
X = zeros(sz1, ..., szN)
X = zeros(sz)

X = zeros(classname)
X = zeros(n, classname)
X = zeros(sz1, ..., szN, classname)
X = zeros(sz, classname)

X = zeros('like', p)
X = zeros(n, 'like', p)
X = zeros(sz1, ..., szN, 'like', p)
X = zeros(sz, 'like', p)
```

## Description

`X = zeros` returns the scalar 0.

`X = zeros(n)` returns an n-by-n matrix of zeros.

`X = zeros(sz1, ..., szN)` returns an sz1-by-...-by-szN array of zeros where sz1, ..., szN indicates the size of each dimension. For example, `zeros(2,3)` returns a 2-by-3 array of zeros.

`X = zeros(sz)` returns an array of zeros where the size vector, sz, defines `size(X)`. For example, `zeros([2,3])` returns a 2-by-3 array of zeros.

`X = zeros(classname)` returns a scalar 0 where the string, classname, specifies the data type. For example, `zeros('int8')` returns a scalar, 8-bit integer 0.

`X = zeros(n,classname)` returns an n-by-n array of zeros of data type `classname`.

`X = zeros(sz1,...,szN,classname)` returns an sz1-by-...-by-szN array of zeros of data type `classname`.

`X = zeros(sz,classname)` returns an array of zeros where the size vector, `sz`, defines `size(X)` and `classname` defines `class(X)`.

`X = zeros('like',p)` returns a scalar 0 with the same data type, sparsity, and complexity (real or complex) as the numeric variable, `p`.

`X = zeros(n, 'like', p)` returns an n-by-n array of zeros like `p`.

`X = zeros(sz1,...,szN, 'like', p)` returns an sz1-by-...-by-szN array of zeros like `p`.

`X = zeros(sz, 'like', p)` returns an array of zeros like `p` where the size vector, `sz`, defines `size(X)`.

## **Input Arguments**

### **n - Size of square matrix**

integer value

Size of square matrix, specified as an integer value, defines the output as a square, n-by-n matrix of zeros.

- If `n` is 0, then `X` is an empty matrix.
- If `n` is negative, then it is treated as 0.

### **Data Types**

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### **sz1,...,szN - Size of each dimension**

two or more integer values

Size of each dimension, specified as two or more integer values, defines X as a sz1-by...-by-szN array.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### sz - Output size

row vector of integer values

Output size, specified as a row vector of integer values. Each element of this vector indicates the size of the corresponding dimension.

- If the size of any dimension is 0, then X is an empty array.
- If the size of any dimension is negative, then it is treated as 0.
- If any trailing dimensions greater than 2 have a size of 1, then the output, X, does not include those dimensions.

**Example:** sz = [2,3,4] defines X as a 2-by-3-by-4 array.

### Data Types

double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64

### classname - Output class

'double' (default) | 'single' | 'int8' | 'uint8' | ...

Output class, specified as 'double', 'single', 'int8', 'uint8', 'int16', 'uint16', 'int32', 'uint32', 'int64', or 'uint64'.

### Data Types

char

**p - Prototype**

numeric variable

Prototype, specified as a numeric variable.

**Data Types**double | single | int8 | int16 | int32 | int64 | uint8 |  
uint16 | uint32 | uint64**Complex Number Support:** Yes**Examples****Square Array of Zeros**

Create a 4-by-4 array of zeros.

```
X = zeros(4)
```

```
X =
```

```
 0 0 0 0
 0 0 0 0
 0 0 0 0
 0 0 0 0
```

**3-D Array of Zeros**

Create a 2-by-3-by-4 array of zeros.

```
X = zeros(2,3,4);
```

```
size(X)
```

```
ans =
```

```
 2 3 4
```

**Size Defined by Existing Array**

Define a 3-by-2 array A.

```
A = [1 4 ; 2 5 ; 3 6];
```

```
sz = size(A)
```

```
sz =
```

```
 3 2
```

Create an array of zeros that is the same size as A

```
X = zeros(sz)
```

```
X =
```

```
 0 0
 0 0
 0 0
```

## Nondefault Numeric Data Type

Create a 1-by-3 vector of zeros whose elements are 32-bit unsigned integers.

```
X = zeros(1,3,'uint32'),
class(X)
```

```
X =
```

```
 0 0 0
```

```
ans =
```

```
uint32
```

## Complex Zero

Create a scalar 0 that is not real valued, but instead is complex like an existing array.

Define a complex vector.

```
p = [1+2i 3i];
```

Create a scalar 0 that is complex like p.

```
X = zeros('like',p)
```

```
X =
```

```
0.0000 + 0.0000i
```

### **Sparse Array**

Define a 10-by-10 sparse matrix.

```
p = sparse(10,10,pi);
```

Create a 2-by-3 matrix of zeros that is sparse like p.

```
X = zeros(2,3,'like',p)
```

```
X =
```

```
All zero sparse: 2-by-3
```

### **Size and Numeric Data Type Defined by Existing Array**

Define a 2-by-3 array of 8-bit unsigned integers.

```
p = uint8([1 3 5 ; 2 4 6]);
```

Create an array of zeros that is the same size and data type as p.

```
X = zeros(size(p),'like',p),
class(X)
```

```
X =
```

```
0 0 0
0 0 0
```

# zeros

---

```
ans =
```

```
uint8
```

## Concepts

- “Class Support for Array-Creation Functions”
- “Preallocating Arrays”

---

<b>Purpose</b>	Compress files into zip file
<b>Syntax</b>	<pre>zip(zipfile,files) zip(zipfile,files,rootfolder) entrynames = zip(zipfile,files,rootfolder)</pre>
<b>Description</b>	<p><code>zip(zipfile,files)</code> creates a zip file with the name <code>zipfile</code> from the list of files and folders specified in <code>files</code>. Folders recursively include all of their content.</p> <p><code>zip(zipfile,files,rootfolder)</code> specifies the path for <code>files</code> relative to <code>rootfolder</code> instead of the current folder.</p> <p><code>entrynames = zip(zipfile,files,rootfolder)</code> returns a string cell array of the names of the files contained in <code>zipfile</code>. Specifying <code>rootfolder</code> is optional.</p>
<b>Input Arguments</b>	<p><b>zipfile</b></p> <p>String that specifies the name of the zip file. If <code>zipfile</code> has no extension, MATLAB appends the <code>.zip</code> extension.</p> <p>If <code>files</code> includes relative paths, the zip file also contains relative paths. The zip file does not include absolute paths.</p> <p><b>files</b></p> <p>String or cell array of strings containing the list of files or folders to include in <code>zipfile</code>.</p> <p>Individual files that are on the MATLAB path can be specified as partial path names. Otherwise an individual file can be specified relative to the current folder or with an absolute path.</p> <p>Folders must be specified relative to the current folder or with absolute paths. On UNIX systems, folders can also start with <code>~/</code> or <code>~username/</code>, which expands to the current user's home folder or the specified user's home folder, respectively. The wildcard character <code>*</code> can be used when specifying files or folders, except when relying on the MATLAB path to resolve a file name or partial path name.</p>

## **rootfolder**

String that specifies the root of the paths for the files to zip.

Relative paths in the zip file reflect the relative paths in files, and do not include path information from `rootfolder`.

**Default:** current folder ('.')

## **Output Arguments**

### **entrynames**

Cell array of strings that contain the paths to the files in `zipfile`. If `files` includes relative paths, `entrynames` also contains relative paths.

## **Examples**

### **Zip a File**

Create a zip file of the file `membrane.m`, which is in the MATLAB general folder. Save the zip file `tmwlogo.zip` in the current folder.

```
file = fullfile(matlabroot,'toolbox','matlab','general','membrane.m');
zip('tmwlogo',file);
```

### **Zip Selected Files**

Suppose that your system has a folder named `d:/myfiles`. Zip the files `membrane.m` and `logo.m`, which are on the MATLAB search path, into a file named `tmwlogo.zip`.

```
myfile = fullfile('d:','myfiles','tmwlogo.zip');
zip(myfile,{'membrane.m','logo.m'});
```

Zip all `.m` and `.mat` files in the current folder to the file `backup.zip`.

```
zip('backup',{'*.m','*.mat'});
```

## Zip a Folder

Suppose that your current folder contains a subfolder named `mywork`. Zip the contents of all subfolders of `mywork`, and store the relative paths in the zip file.

```
zip('myfiles.zip','mywork');
```

## Zip Between Folders

Suppose that you have files `thesis.doc` and `defense.ppt` in `d:/PhD`. Zip these files into `thesis.zip`, one level up from the current folder.

```
zip('../thesis.zip',{'thesis.doc','defense.ppt'],'d:/PhD');
```

## Create Zip Archive of Web Page

Create a zip archive of a Web page.

Locate the list of files at the MATLAB Central File Exchange uploaded within the past 7 days, that contain "Simulink."

```
filex = 'http://www.mathworks.com/matlabcentral/fileexchange/';
params = {'duration','7','term','simulink'};
```

Save the Web content to a file.

```
urlwrite(filex,'contains_simulink.html','get',params);
```

Create a zip archive of the retrieved Web page, using the `zip` function.

```
zip('simulink_matches.zip','contains_simulink.html');
```

`zip` creates a zip archive named `simulink_matches.zip` that contains the file, `contains_simulink.html`.

## Alternatives

To zip files in the Current Folder browser, select the files, right-click to open the context menu, and then select **Create Zip File**.

# zip

---

## **See Also**

`gzip` | `gunzip` | `tar` | `untar` | `unzip`

**Purpose** Turn zooming on or off or magnify by factor

**Syntax**

```
zoom on
zoom off
zoom out
zoom reset
zoom
zoom xon
zoom yon
zoom(factor)
zoom(fig, option)
h = zoom(figure_handle)
```

**Description** `zoom on` turns on interactive zooming. When interactive zooming is enabled in a figure, pressing a mouse button while your cursor is within an axes zooms into the point or out from the point beneath the mouse. Zooming changes the axes limits. When using zoom mode, you

- Zoom in by positioning the mouse cursor where you want the center of the plot to be and either
  - Press the mouse button or
  - Rotate the mouse scroll wheel away from you (upward).
- Zoom out by positioning the mouse cursor where you want the center of the plot to be and either
  - Simultaneously press **Shift** and the mouse button, or
  - Rotate the mouse scroll wheel toward you (downward).

Each mouse click or scroll wheel click zooms in or out by a factor of 2.

Clicking and dragging over an axes when zooming in is enabled draws a rubberband box. When you release the mouse button, the axes zoom in to the region enclosed by the rubberband box.

Double-clicking over an axes returns the axes to its initial zoom setting in both zoom-in and zoom-out modes.

`zoom off` turns interactive zooming off.

`zoom out` returns the plot to its initial zoom setting.

`zoom reset` remembers the current zoom setting as the initial zoom setting. Later calls to `zoom out`, or double-clicks when interactive zoom mode is enabled, will return to this zoom level.

`zoom` toggles the interactive zoom status between off and on (restoring the most recently used zoom tool).

`zoom xon` and `zoom yon` set `zoom on` for the  $x$ - and  $y$ -axis, respectively.

`zoom(factor)` zooms in or out by the specified zoom factor, without affecting the interactive zoom mode. Values greater than 1 zoom in by that amount, while numbers greater than 0 and less than 1 zoom out by  $1/\text{factor}$ .

`zoom(fig, option)` Any of the preceding options can be specified on a figure other than the current figure using this syntax.

`h = zoom(figure_handle)` returns a *zoom mode object* for the figure `figure_handle` for you to customize the mode's behavior.

## Using Zoom Mode Objects

Access the following properties of zoom mode objects via `get` and modify some of them using `set`.

- *Enable* 'on' | 'off' — Specifies whether this figure mode is currently enabled on the figure
- *FigureHandle* <handle> — The associated figure handle, a read-only property that cannot be set
- *Motion* 'horizontal' | 'vertical' | 'both' — The type of zooming enabled for the figure
- *Direction* 'in' | 'out' — The direction of the zoom operation
- *RightClickAction* 'InverseZoom' | 'PostContextMenu' — The behavior of a right-click action

A value of 'InverseZoom' causes a right-click to zoom out. A value of 'PostContextMenu' displays a context menu. This setting persists between MATLAB sessions.

- `UIContextMenu <handle>` — Specifies a custom context menu to be displayed during a right-click action

This property is ignored if the `RightClickAction` property has been set to 'on'.

## Zoom Mode Callbacks

You can program the following callbacks for zoom mode operations.

- `ButtonDownFilter <function_handle>` — Function to intercept `ButtonDown` events

The application can inhibit the zoom operation under circumstances the programmer defines, depending on what the callback returns. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function [res] = myfunction(obj,event_obj)
% obj handle to the object clicked on
% event_obj struct for event data (empty in this release)
% res [output] a logical flag determines whether the zoom
% operation should take place(for 'res' set
% to 'false' or the 'ButtonDownFcn' property
% of the object should take precedence (when
% 'res' is 'true')
```

- `ActionPreCallback <function_handle>` — Function to execute before zooming

Set this callback if you want to execute code when a zoom operation starts. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj handle to the figure clicked on
% event_obj object containing struct of event data
```

The event data has the following field.

Axes	The handle of the axes that is being zoomed
------	---------------------------------------------

- `ActionPostCallback <function_handle>` — Function to execute after zooming

Set this callback if you want to execute code when a zoom operation finishes. The input function handle should reference a function with two implicit arguments (similar to Handle Graphics object callbacks), as follows:

```
function myfunction(obj,event_obj)
% obj handle to the figure clicked on
% event_obj object containing struct of event data
% (same as the event data of the
% 'ActionPreCallback' callback)
```

## Zoom Mode Utility Functions

The following functions in zoom mode query and set certain of its properties.

- `flags = isAllowAxesZoom(h,axes)` — Function querying permission to zoom axes

Calling the function `isAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, as input returns a logical array of the same dimension as the axes handle vector, which indicates whether a zoom operation is permitted on the axes objects.

- `setAllowAxesZoom(h,axes,flag)` — Function to set permission to zoom axes

Calling the function `setAllowAxesZoom` on the zoom object, `h`, with a vector of axes handles, `axes`, and a logical scalar, `flag`, either allows or disallows a zoom operation on the axes objects.

- `info = getAxesZoomMotion(h,axes)` — Function to get style of zoom operations

Calling the function `getAxesZoomMotion` on the zoom object, `H`, with a vector of axes handles, `axes`, as input returns a character cell array of the same dimension as the axes handle vector, which indicates the type of zoom operation for each axes. Possible values for the type of operation are 'horizontal', 'vertical', or 'both'.

- `setAxesZoomMotion(h,axes,style)` — Function to set style of zoom operations

Calling the function `setAxesZoomMotion` on the zoom object, `h`, with a vector of axes handles, `axes`, and a character array, `style`, sets the style of zooming on each axes.

## Examples

### Example 1 — Entering Zoom Mode

Plot a graph and turn on Zoom mode:

```
plot(1:10);
zoom on
% zoom in on the plot
```

### Example 2 — Constrained Zoom

Create zoom mode object and constrain to *x*-axis zooming:

```
plot(1:10);
h = zoom;
set(h,'Motion','horizontal','Enable','on');
% zoom in on the plot in the horizontal direction.
```

### Example 3 — Constrained Zoom in Subplots

Create four axes as subplots and set zoom style differently for each by setting a different property for each axes handle:

```
ax1 = subplot(2,2,1);
plot(1:10);
h = zoom;
ax2 = subplot(2,2,2);
plot(rand(3));
```

```
setAllowAxesZoom(h,ax2,false);
ax3 = subplot(2,2,3);
plot(peaks);
setAxesZoomMotion(h,ax3,'horizontal');
ax4 = subplot(2,2,4);
contour(peaks);
setAxesZoomMotion(h,ax4,'vertical');
% Zoom in on the plots.
```

### Example 4 – Coding a ButtonDown Callback

Create a `ButtonDown` callback for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zooming behavior:

```
function demo
% Allow a line to have its own 'ButtonDownFcn' callback.
hLine = plot(rand(1,10));
set(hLine,'ButtonDownFcn','disp(''This executes'')');
set(hLine,'Tag','DoNotIgnore');
h = zoom;
set(h,'ButtonDownFilter',@mycallback);
set(h,'Enable','on');
% mouse click on the line
%
function [flag] = mycallback(obj,event_obj)
% If the tag of the object is 'DoNotIgnore', then return true.
objTag = get(obj,'Tag');
if strcmpi(objTag,'DoNotIgnore')
 flag = true;
else
 flag = false;
end
```

### Example 5 – Coding Pre- and Post-Callback Behavior

Create callbacks for pre- and post-buttonDown events for zoom mode objects to trigger. Copy the following code to a new file, execute it, and observe zoom behavior:

```
function demo
% Listen to zoom events
plot(1:10);
h = zoom;
set(h,'ActionPreCallback',@myprecallback);
set(h,'ActionPostCallback',@mypostcallback);
set(h,'Enable','on');
%
function myprecallback(obj,evd)
disp('A zoom is about to occur.');
```

```
%
function mypostcallback(obj,evd)
newLim = get(evd.Axes,'XLim');
msgbox(sprintf('The new X-Limits are [%.2f %.2f].',newLim));
```

### Example 6 – Creating a Context Menu for Zoom Mode

Coding a context menu that lets the user to switch to Pan mode by right-clicking:

```
figure;plot(magic(10))
hCMZ = uicontextmenu;
hZMenu = uimenu('Parent',hCMZ,'Label','Switch to pan',...
'Callback','pan(gcf,'on')');
hZoom = zoom(gcf);
set(hZoom,'UIContextMenu',hCMZ);
zoom('on')
```

You cannot add items to the built-in zoom context menu, but you can replace it with your own.

# zoom

---

## Tips

zoom changes the axes limits by a factor of 2 (in or out) each time you press the mouse button while the cursor is within an axes. You can also click and drag the mouse to define a zoom area, or double-click to return to the initial zoom level.

You can create a zoom mode object once and use it to customize the behavior of different axes, as Example 3 illustrates. You can also change its callback functions on the fly.

---

**Note Do not change figure callbacks within an interactive mode.** While a mode is active (when panning, zooming, etc.), you will receive a warning if you attempt to change any of the figure's callbacks and the operation will not succeed. The one exception to this rule is the figure `WindowButtonMotionFcn` callback, which can be changed from within a mode. Therefore, if you are creating a GUI that updates a figure's callbacks, the GUI should somehow keep track of which interactive mode is active, if any, before attempting to do this.

---

When you assign different zoom behaviors to different subplot axes via a mode object and then link them using the `linkaxes` function, the behavior of the axes you manipulate with the mouse carries over to the linked axes, regardless of the behavior you previously set for the other axes.

## Alternatives

Use the Zoom tools  on the figure toolbar to zoom in or zoom out on a plot, or select **Zoom In** or **Zoom Out** from the figure's **Tools** menu. For details, see “Zooming in Graphs”.

## See Also

`linkaxes` | `pan` | `rotate3d`

**Purpose** Close Webcam preview window

**Syntax** `closePreview(cam)`

**Description** `closePreview(cam)` closes the Webcam preview window for the webcam object `cam`. You can close the preview at any time using the `closePreview` function. If you do not explicitly close the preview, it closes when you clear the webcam object.

## Examples **Close Webcam Preview**

This example shows how to close the Webcam preview window.

Find the name of your camera using the `webcamlist` function to ensure that MATLAB is discovering your camera(s).

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
 'Dell Camera C250'
```

Create the object. If you use the `webcam` function with the name of the camera (as a string) as the input argument, it creates the object and connects it to the camera with that name. You can use the exact name that is displayed by the `webcamlist` function. In the example above it would be 'Logitech Webcam 250'. You can also use a shortened version of the name, for example, the brand of the camera. In this case you could simply use 'Logitech' and it connects to the Logitech® Webcam. Use `cam` as the name of the object.

```
cam = webcam('Logitech')
```

```
cam =
```

```
webcam with properties:
```

# closePreview

---

```
 Name: 'Logitech Webcam 250'
 Resolution: '640x480'
 AvailableResolutions: {1x11 cell}
 Exposure: -4
 Gain: 253
 Saturation: 32
 WhiteBalance: 8240
 ExposureMode: 'auto'
 Sharpness: 48
 Brightness: 128
 BacklightCompensation: 1
 Contrast: 32
```

See that it creates the object and connects to the Logitech Webcam.

Preview the image from the Webcam.

```
preview(cam)
```

The preview window opens and displays live video stream from your camera. The preview dynamically updates, so if you change a property while previewing, the image changes to reflect the property change.

Close the preview.

```
closePreview(cam)
```

The preview window closes.

After you preview the image, the next steps are optionally changing any properties you need to set, and then acquiring images using the `snapshot` function. For more information on these steps, see the topics listed below.

## Related Examples

- “Connecting to Webcams”
- “Acquiring Images from Webcams”
- “Setting Properties for Webcam Acquisition”

**Purpose** Preview live video data from Webcam

**Syntax** `preview(cam)`

**Description** `preview(cam)` creates a preview window that displays live video data for webcam object `cam`. The size of the preview image is determined by the value of the `Resolution` property. The preview window shows a live RGB image from the Webcam and displays the camera name, resolution, frame rate, and the timestamp. Timestamp is the elapsed time since the object was created. To preview your image, call the `preview` function on the object name, which is `cam` in this example.

## Examples **Preview Webcam Image**

This example shows how to preview Webcam images.

Find the name of your camera using the `webcamlist` function to ensure that MATLAB is discovering your camera(s).

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
 'Dell Camera C250'
```

Create the object. If you use the `webcam` function with the name of the camera (as a string) as the input argument, it will create the object and connect it to the camera with that name. You can use the exact name that is displayed by the `webcamlist` function. In the example above it is `'Logitech Webcam 250'`. You can also use a shortened version of the name, for example, the brand of the camera. In this case you could simply use `'Logitech'` and it connects to the Logitech Webcam. Use `cam` as the name of the object.

```
cam = webcam('Logitech')

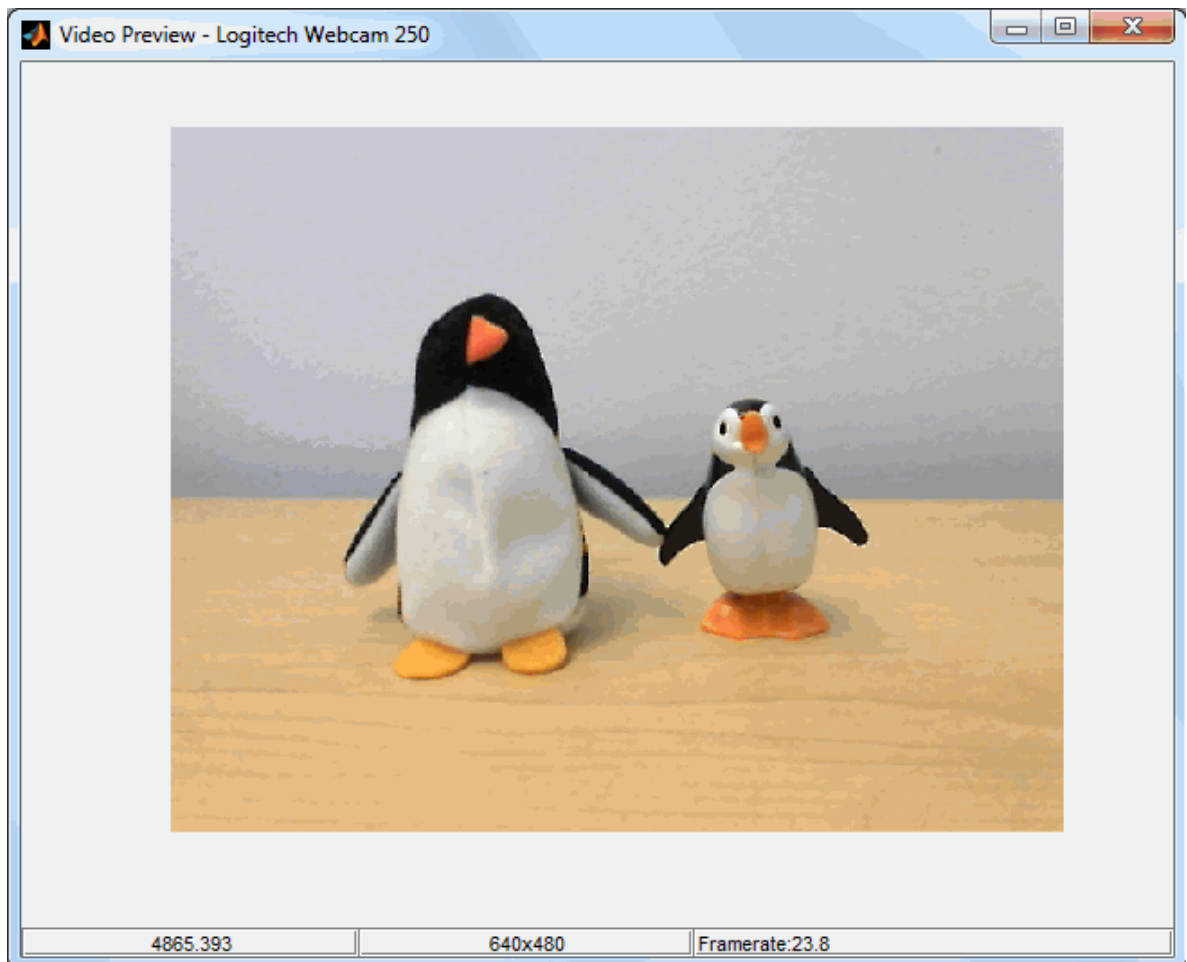

cam =
webcam with properties:
 Name: 'Logitech Webcam 250'
 Resolution: '640x480'
 AvailableResolutions: {1x11 cell}
 Exposure: -4
 Gain: 253
 Saturation: 32
 WhiteBalance: 8240
 ExposureMode: 'auto'
 Sharpness: 48
 Brightness: 128
 BacklightCompensation: 1
 Contrast: 32
```

See that it created the object and connected to the Logitech Webcam.

Preview the image from the Webcam.

```
preview(cam)
```

The preview window opens and displays live video stream from your camera. The preview dynamically updates, so if you change a property while previewing, the image changes to reflect the property change. The banner of the preview window shows the camera name. The lower portion of the window shows the timestamp in seconds, resolution, and the frame rate in frames per second. Timestamp is the elapsed time since the object was created.

After you preview the image, the next steps are optionally changing any properties you need to set, and then acquiring images using the snapshot function. For more information on these steps, see the topics listed below.

## **Related Examples**

- “Connecting to Webcams”
- “Acquiring Images from Webcams”
- “Setting Properties for Webcam Acquisition”

**Purpose** Acquire single image frame from a Webcam

**Syntax** `img = snapshot(cam);`

**Description** `img = snapshot(cam);` acquires a single image from the Webcam `cam` and assigns it to the variable `img`. The `snapshot` function returns the current frame. Calling `snapshot` in a loop returns a new frame each time. The returned image is always an RGB image. `snapshot` uses the camera's default resolution or another resolution that you specify using the `Resolution` property.

## Examples **Acquire One Image Frame from Webcam**

This example shows how to acquire and display one image frame from a Webcam.

Find the name of your camera using the `webcamlist` function to ensure that MATLAB is discovering your camera(s).

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
 'Dell Camera C250'
```

Create the object. If you use the `webcam` function with the name of the camera (as a string) as the input argument, it creates the object and connects it to the camera with that name. You can use the exact name that is displayed by the `webcamlist` function. In the example above it would be `'Logitech Webcam 250'`. You can also use a shortened version of the name, for example, the brand of the camera. In this case you could simply use `'Logitech'` and it would connect to the Logitech Webcam. Use `cam` as the name of the object.

# snapshot

---

```
cam = webcam('Logitech')

cam =

webcam with properties:

 Name: 'Logitech Webcam 250'
 Resolution: '640x480'
 AvailableResolutions: {1x11 cell}
 Exposure: -4
 Gain: 253
 Saturation: 32
 WhiteBalance: 8240
 ExposureMode: 'auto'
 Sharpness: 48
 Brightness: 128
 BacklightCompensation: 1
 Contrast: 32
```

See that it creates the object and connects to the Logitech Webcam.

Preview the image from the Webcam.

```
preview(cam)
```

The preview window opens and displays live video stream from your camera. The preview dynamically updates, so if you change a property while previewing, the image changes to reflect the property change.

Close the preview.

```
closePreview(cam)
```

The preview window closes.

Acquire a single image from the camera using the `snapshot` function and assign it to the variable `img`.

```
img = snapshot(cam);
```

Display the acquired image.

```
imshow(img)
```

The `imshow` function is part of the Image Processing Toolbox. If you do not have that, you can use the `image` function that is part of MATLAB.

```
image(img)
```

Clean up by clearing the object.

```
clear('cam');
```

## **Related Examples**

- “Connecting to Webcams”
- “Acquiring Images from Webcams”
- “Setting Properties for Webcam Acquisition”

# webcam

---

**Purpose** Create webcam object to acquire images from Webcams

**Syntax**

```
cam = webcam
cam = webcam(devicenumber)
cam = webcam('cameraname')
```

**Description** `cam = webcam` creates the webcam object `cam` and connects to the single Webcam on your system. If you have multiple cameras and you use the `webcam` function with no input argument, it creates the object and connects it to the first camera it finds. This is the first camera listed in the output of the `webcamlist` function.

When the `webcam` object is created, it connects to the camera, establishes exclusive access, and starts streaming data. You can then preview the data and acquire images using the `snapshot` function.

`cam = webcam(devicenumber)` creates a webcam object `cam` where `devicenumber` is a numeric scalar value that identifies a particular Webcam by its index number. When you use the `webcam` function with an index as the input argument, it creates the object corresponding to that index and connects it to that camera. The index corresponds to the order of cameras in the cell array returned by `webcamlist` when you have multiple cameras connected.

Note that you cannot create more than one object connected to the same device, and trying to do that generates an error.

`cam = webcam('cameraname')` creates a webcam object `cam` where `cameraname` is a string value that identifies a particular Webcam by its name. When you use the `webcam` function with the name of the camera as the input argument, it creates the object and connects it to the camera with that name. You can use the exact name that is displayed by the `webcamlist` function, such as 'Logitech Webcam 250'. You can also use a shortened version of the name, for example, the brand of the camera. In this example you could simply use 'Logitech' and it would connect to the Logitech Webcam.

When the `webcam` object is created, it connects to the camera, establishes exclusive access, and starts streaming data from the camera. You can then preview the data and acquire images using the `snapshot` function.

Note that you cannot create more than one object connected to the same device, and trying to do that generates an error.

## Input Arguments

### **devicenumber - Device number of your camera**

numeric scalar

Device number of your hardware, specified as a numeric scalar. This number identifies a particular Webcam by its index number. It creates the object corresponding to that index and connects it to that camera. The index corresponds to the order of cameras in the cell array returned by `webcamList` when you have multiple cameras connected.

**Example:** `cam = webcam(2)`

### **Data Types**

double

### **cameraname - Name of your camera**

character string

Name of your camera, specified as a character string. This argument creates a `webcam` object `cam` where `cameraname` is a string value that identifies a particular Webcam by its name. When you use the `webcam` function with the name of the camera as the input argument, it creates the object and connects it to the camera with that name. You can use the exact name that is returned by the `webcamList` function, such as 'Logitech Webcam 250'. You can also use a shortened version of the name, for example, the brand of the camera. In this example you could simply use 'Logitech' and it would connect to the Logitech Webcam.

**Example:** `cam = webcam('Logitech')`

### **Data Types**

char

## Examples

### Create a Webcam Object Using No Arguments

This example shows how to create a `webcam` object with no arguments.

Find the name of your camera using the `webcamlist` function to ensure that MATLAB is discovering your camera(s).

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
 'Dell Camera C250'
```

If you use the `webcam` function with no input argument, it creates the object and connects it to the first camera it finds. This will be the first camera shown on the list if you have multiple cameras. If you only have one camera connected to your system, it uses that one. So in the example shown above, it creates the object using the Logitech camera, since that appears in the `webcamlist` output first. In this example, use `cam` as the name of the object.

```
cam = webcam
```

```
cam =
```

```
webcam with properties:
```

```
 Name: 'Logitech Webcam 250'
 Resolution: '640x480'
 AvailableResolutions: {1x11 cell}
 Exposure: -4
 Gain: 253
 Saturation: 32
 WhiteBalance: 8240
 ExposureMode: 'auto'
 Sharpness: 48
 Brightness: 128
 BacklightCompensation: 1
 Contrast: 32
```

See that it created the object and connected to the Logitech Webcam.

## Create a Webcam Object Using Device Number as an Index

This example shows how to create a webcam object using the device number as an index.

Find the name of your camera using the `webcamlist` function to ensure that MATLAB is discovering your camera(s).

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
 'Dell Camera C250'
```

If you use the `webcam` function with an index as the input argument, it creates the object corresponding to that index and connects it to that camera. The index corresponds to the order of cameras in the cell array returned by `webcamlist` when you have multiple cameras connected. So in the example shown above, device 1 is the Logitech camera and device 2 is the built-in Dell® Webcam. Use `cam` as the name of the object.

```
cam = webcam(2)
```

```
cam =
```

```
webcam with properties:
```

```
 Name: 'Dell Camera C250'
 Resolution: '320x240'
AvailableResolutions: ('320x240' '160x120' '80x60')
 Brightness: 128
 Contrast: 32
 Gain: 0
```

See that it created the object and connected to the Dell Webcam. If you only have one camera, you do not need to use the index. You can use the `webcam` function with no input argument and it creates the object

with the single camera that is connected. The index is useful when you have multiple cameras.

### Create a Webcam Object Using Camera Name

This example shows how to create a webcam object using the camera name.

Find the name of your camera using the `webcamlist` function to ensure that MATLAB is discovering your camera(s).

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
 'Dell Camera C250'
```

If you use the `webcam` function with the name of the camera (as a string) as the input argument, it creates the object and connects it to the camera with that name. You can use the exact name that is displayed by the `webcamlist` function. In the example above it would be `'Logitech Webcam 250'`. You can also use a shortened version of the name, for example, the brand of the camera. In this case you could simply use `'Logitech'` and it would connect to the Logitech Webcam. Use `cam` as the name of the object.

```
cam = webcam('Logitech')
```

```
cam =
```

```
webcam with properties:
```

```
 Name: 'Logitech Webcam 250'
 Resolution: '640x480'
AvailableResolutions: {1x11 cell}
 Exposure: -4
 Gain: 253
 Saturation: 32
```

# webcam

---

```
WhiteBalance: 8240
ExposureMode: 'auto'
 Sharpness: 48
 Brightness: 128
BacklightCompensation: 1
 Contrast: 32
```

See that it created the object and connected to the Logitech Webcam.

## **Related Examples**

- “Connecting to Webcams”
- “Acquiring Images from Webcams”
- “Setting Properties for Webcam Acquisition”

**Purpose** List of Webcams connected to your system

**Syntax** `webcamlist`

**Description** `webcamlist` returns a list of available UVC-compliant Webcams connected to your system. The function returns a cell array of names of the cameras. This supports the plug and play scenario, where using the `webcamlist` function again in the same MATLAB session returns an updated list of cameras if you plug in different cameras during the session.

The name of the camera that is shown in this output, for example 'Logitech Webcam 250', is the name you can use to create the Webcam object in order to acquire images.

## **Examples** **Display Single Webcam**

This example shows the output with a single camera.

If you have a single Webcam connected to your system, the output of `webcamlist` shows the one camera.

```
webcamlist
```

```
ans =
```

```
 'Logitech Webcam 250'
```

## **Display Multiple Internal and External Webcams**

This example shows the output with multiple cameras, including both internal and external.

If you have multiple Webcams connected to your system, the output shows all the cameras in a cell array.

# webcamlist

---

```
webcamlist
```

```
ans =
```

```
'Dell Camera C250'
'Logitech Webcam 250'
```

In this case it sees the built-in Webcam in the Dell computer, and a connected USB Webcam.

## Display Multiple External Webcams

This example shows the output with multiple cameras, including only external.

In this case, there are two cameras connected by USB ports.

```
webcamlist
```

```
ans =
```

```
'Logitech Webcam 250'
'Logitech Webcam Pro 9000'
```

# Functions — Alphabetical List

---

# cameraboard

---

**Purpose** Create connection to Raspberry Pi Camera Board Module

**Syntax**  
`mycamera = cameraboard(mypi)`  
`mycamera = cameraboard(mypi,Name,Value)`

**Description** `mycamera = cameraboard(mypi)` connects to a Camera Board and returns a handle, `mycamera`. You can capture video and still images by using `mycamera` with the `record`, `stop`, and `snapshot` methods.

`mycamera = cameraboard(mypi,Name,Value)` uses name-value pair arguments to override the default values of writable Camera Board properties. You can use these properties to control image properties such as size, resolution, orientation, exposure, and special effects.

Name must appear inside single quotes (' '). You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## Input Arguments

### **mypi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `mypi`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:**

### **'Resolution' - Image dimensions**

'640x480' (default) | '160x120' | '320x240' | '800x600' |  
'1024x768' | '1280x720' | '1920x1080'

Image dimensions, specified as a string.

You can only specify this value when you create the `mycamera` handle.

**Example:** '1024x768'

### **Data Types**

char

### **'Quality' - JPEG image quality**

10 (default) | integer from 0 to 100

JPEG image quality, specified as a scalar from 1 to 100 (low to high).

The value of this parameter is inversely related to the amount of compression the camera performs upon the JPEG images. A value of 1 applies maximum compression, while a value of 100 applies minimal compression.

You can only specify this value when you create the `mycamera` handle.

**Example:** 10

### **Data Types**

double

### **'Rotation' - Degrees of clockwise rotation**

0 (default) | 90 | 180 | 270

Degrees of clockwise rotation, specified as 0, 90, 180, or 270.

Use this value to alter the orientation of the images captured by the Camera Board.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** 180

### **Data Types**

double

## **'HorizontalFlip' - Enable horizontal flip**

0 (default) | 1

Enable horizontal flip, specified as a logical value.

Use this value to reverse the left and right orientation of the images captured by the Camera Board.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** 1

### **Data Types**

logical

## **'VerticalFlip' - Flip image vertically**

0 (default) | 1

Flip image vertically, specified as a logical value.

Use this value to reverse the top and bottom orientation of the images captured by the Camera Board.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** 1

### **Data Types**

logical

## **'FrameRate' - Video frame rate**

30 (default) | integer from 2 to 30

Video frame rate, specified as a scalar from 2 to 30 frames per second (fps).

You can only specify this value when you create the `mycamera` handle.

**Example:**

### **Data Types**

double

## **'Brightness' - Image brightness**

50 (default) | integer from 0 to 100

Image brightness, specified as a scalar from 0 to 100 (low to high).

You can specify this value when you create the mycamera handle, and later by writing a new value to the property that has the same name.

**Example:** 60

### **Data Types**

double

## **'Contrast' - Image contrast**

0 (default) | integer from -100 to 100

Image contrast, specified as a scalar from -100 to 100 (low to high).

You can specify this value when you create the mycamera handle, and later by writing a new value to the property that has the same name.

**Example:** 60

### **Data Types**

double

## **'Saturation' - Image color saturation**

0 (default) | integer from -100 to 100

Image color saturation, specified as a scalar from -100 to 100 (low to high).

You can specify this value when you create the mycamera handle, and later by writing a new value to the property that has the same name.

**Example:** 60

### **Data Types**

double

## **'Sharpness' - Image sharpness**

0 (default) | integer from -100 to 100

Image sharpness, specified as a scalar from -100 to 100 (low to high).

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** 60

## Data Types

double

## 'ExposureMode' - Exposure mode

'auto' (default) | 'night' | 'nightpreview' | 'backlight' | 'spotlight' | 'sports' | 'snow' | 'beach' | 'verylong' | 'fixedfps' | 'antishake' | 'fireworks'

Exposure mode, specified as a string.

Select the exposure mode for a variety of conditions, indicated by the name of the mode, or let the camera select the best mode (auto).

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** 'backlight'

## Data Types

char

## 'ExposureCompensation' - Exposure compensation

0 (default) | integer from -10 to 10

Exposure compensation, specified as a scalar from -10 to 10 (low to high).

Fine tune the automatic exposure. For example, if a backlit subject is too dark when `ExposureMode` is 'backlight', increase the value of `ExposureCompensation`.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** -1

## Data Types

double

### 'AWBMode' - Automatic white balance mode

'auto (default) | 'off' | 'sun' | 'cloud' | 'shade' | 'tungsten' | 'fluorescent' | 'incandescent' | 'flash' | 'horizon'

Automatic white balance mode, specified as a string.

Select the white balance mode for a variety of conditions, indicated by the name of the mode, or let the camera select the best mode (auto).

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

This mode adjusts the hue of the image to match the color temperature of various light sources.

For example, tungsten light bulbs tend to produce images that have an orange hue. To reduce this effect, set `AWBMode` to `auto` or `tungsten`. To keep this effect, set `AWBMode` to `off`. To heighten this effect, set `AWBMode` to `auto` or `shade`.

**Example:** `'backlight'`

## Data Types

char

### 'MeteringMode' - Metering mode

'average' (default) | 'spot' | 'backlit' | 'matrix'

Metering mode, specified as a string.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

This mode selects which portion of the image determines exposure.

- `average` — Uses values from across the scene, with a moderate bias toward values near the center.
- `spot` — Uses values from a very narrow area in the center of the image.

- `backlit` — Uses a cluster of lower values near the center of the image.
- `matrix` — Uses a values from grid of specific points in the image.

**Example:** `'backlight'`

## **Data Types**

`char`

### **'ImageEffect' - Special effect**

```
'none (default) | 'negative' | 'solarise' | 'sketch' | 'denoise'
| 'emboss' | 'oilpaint' | 'hatch' | 'gpen' | 'pastel' |
'watercolour' | 'film' | 'blur' | 'saturation' | 'colourswap' |
'washedout' | 'posterise' | 'colourpoint' | 'colourbalance' |
'cartoon'
```

Special effect, specified as a string.

Select the special effect indicated by the name of the mode, or disable special effects (auto).

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

**Example:** `'cartoon'`

## **Data Types**

`char`

### **'VideoStabilization' - Video stabilization**

```
'off' (default) | 'on'
```

Video stabilization, specified as a string.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

Activate built-in video stabilization to reduce effects of vibration.

**Example:** `'on'`

## Data Types

char

### 'ROI' - Region of interest

[0.00 0.00 1.00 1.00] (default)

Region of interest (ROI), specified as a vector of four values: x, y, width, height.

You can specify this value when you create the `mycamera` handle, and later by writing a new value to the property that has the same name.

ROI defines which portion of the camera sensor to use. You can use this definition to perform digital panning and zooming while you record video.

For still images (`snapshot`) and video (`record`), the camera “smooths” ROI changes by applying them gradually over a sequence of image frames.

The following values define the starting point and size of the ROI:

- X, the vertical starting point, from 0.0000 to 1.0000 (top to bottom)
- Y, the horizontal starting point, from 0.0000 to 1.0000 (left to right)
- Height, from 0.0000 to 1.0000 (small to large)
- Width, from 0.0000 to 1.0000 (small to large)

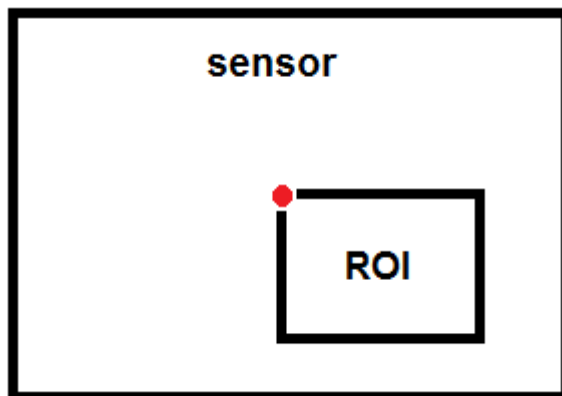

The following illustration shows how X and Y position the ROI relative to the Camera Board sensor:

- The red dot is at X = 0.00 and Y = 0.00.
- The blue dot is at X = 1.00, Y = 1.00.

The following illustration represents the ROI from entering:

```
mycam.ROI = [0.50 0.50 0.33 0.33]
```

The 0.50 0.50 values place the top left corner of the ROI in the center of the sensor. The 0.33 0.33 values resize the ROI to one-third of the sensor. If ROI exceeds the dimensions of the sensor, the method that you are using produces the following error: `Index exceeds matrix dimensions.`

**Example:** [0.50 0.50 0.33 0.33]

### Data Types

double

## Output Arguments

### **mycamera - Connection to Raspberry Pi™ Camera Board**

handle

Connection to a Raspberry Pi Camera Board.

You can use `mycamera` with the following methods:

- `record`
- `stop`
- `snapshot`

You can use `mycamera` to read and write the properties specified by the “Name-Value Pair Arguments” on page 2-2.

You can use `mycamera` to read the value of the `Recording` property, which indicates whether the Camera Board is recording video.

## Examples

### **Use the Camera Board**

You can create a connection to the Camera Board, take a photograph, and record video.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Create a connection to the Camera Board while changing the resolution, and assign that connection to a handle, `mycam`. The handle displays the Camera Board properties.

```
mycam = cameraboard(mypi, 'Resolution', '1280x720')
```

```
mycam =
```

```
Cameraboard with Properties:
```

# cameraboard

---

```
Name: Camera Board
Resolution: '1280x720' (View available resolutions)
Quality: 10 (1 to 100)
Rotation: 0 (0, 90, 180 or 270)
HorizontalFlip: 0
VerticalFlip: 0
FrameRate: 30 (2 to 30)
Recording: 0

Picture Settings
Brightness: 50 (0 to 100)
Contrast: 0 (-100 to 100)
Saturation: 0 (-100 to 100)
Sharpness: 0 (-100 to 100)

Exposure and AWB
ExposureMode: 'auto' (View available exposure modes)
ExposureCompensation: 0 (-10 to 10)
AWBMode: 'auto' (View available AWB modes)
MeteringMode: 'average' (View available metering modes)

Effects
ImageEffect: 'none' (View available image effects)
VideoStabilization: 'off'
ROI: [0.00 0.00 1.00 1.00] (0.0 to 1.0 [top, left, width, height])
```

Import and display a sequence of ten snapshots on your host computer.

```
for ii = 1:10
img = snapshot(mycam);
imagesc(img);
drawnow;
end
```

If the image is upside down, change the orientation of the image.

```
mycam.Rotation = 180;
```

You can use the same approach to change the values of many mycamera properties listed in the "Name-Value Pair Arguments" for cameraboard.

Record a 60 second video.

```
record(mycam, 'myvideo.mp4', 60)
```

Stop recording before the 60 seconds have elapsed.

```
stop(mycam)
```

Copy the video from the board to your host computer.

```
getFile(myapi, 'myvideo.mp4', 'C:\MATLAB')
```

Delete the video file from the board to free up space.

```
deleteFile(myapi, 'myvideo.mp4')
```

# configureDigitalPin

---

## Purpose

Configure GPIO pin as input or output

## Syntax

```
configureDigitalPin(myPi, pinNumber, direction)
```

## Description

`configureDigitalPin(myPi, pinNumber, direction)` configures a specific GPIO pin as a digital input or output.

## Input Arguments

### **myPi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

### **pinNumber - GPIO pin number**

pin number

GPIO pin number, specified as a scalar. This argument does not accept vectors because the hardware cannot access multiple pins simultaneously.

To get a list of valid pin numbers, enter `myPi.AvailableDigitalPins`.

**Example:** `12`

### **Data Types**

double

### **direction - Pin direction**

input | output

Pin direction, specified as a string. Configures the pin as an input or an output. Accepts partial inputs.

**Example:** `'input'`

### **Data Types**

char

## Examples

### Configure Pin as Digital Input and Read Its Logical Value

You can configure a pin as digital input and read its logical value.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

The `AvailableDigitalPins` property shows the list of digital pins that are available.

Redisplay `AvailableDigitalPins`.

```
mypi.AvailableDigitalPins
```

```
ans =
```

```
Columns 1 through 13
```

```
 4 7 8 9 10 11 14 15 17 18 22 23 24
```

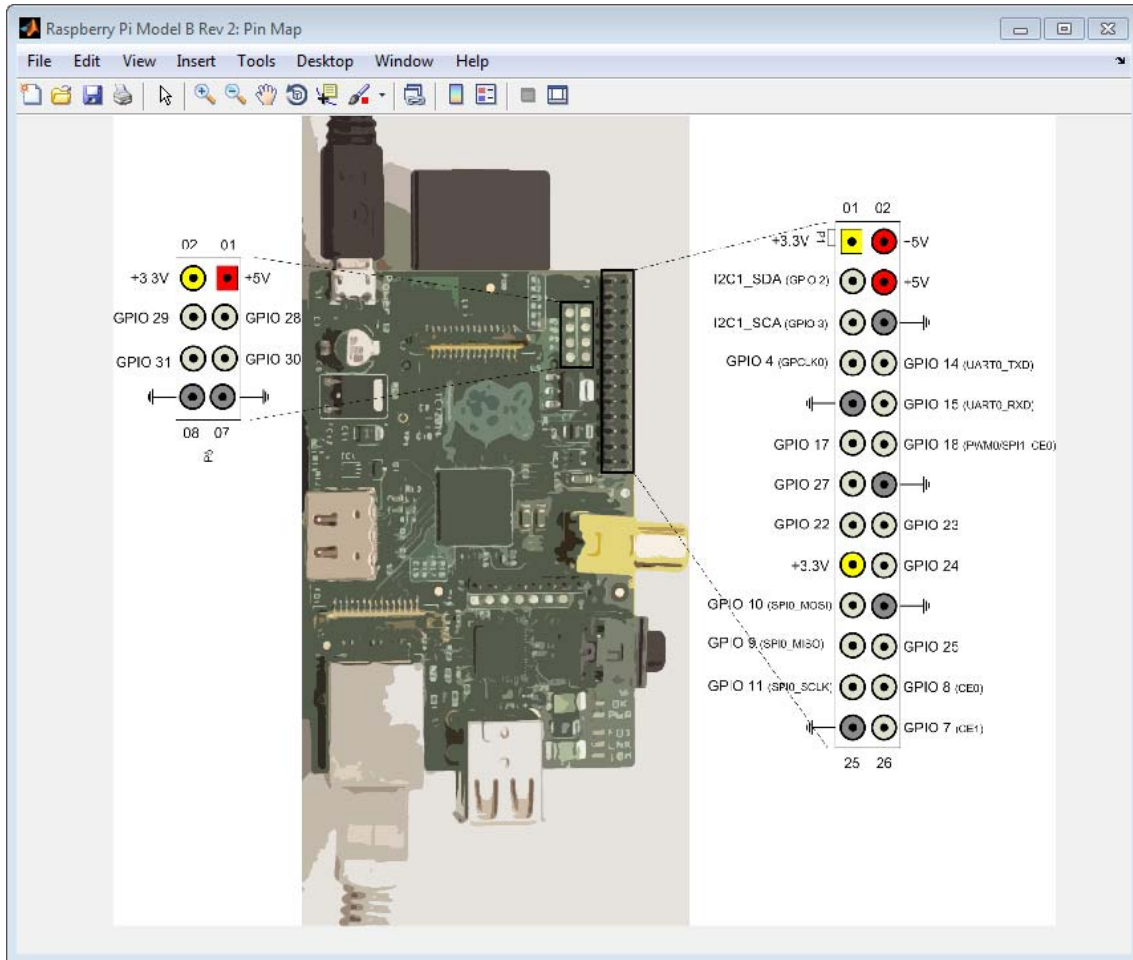

```
Columns 14 through 17
```

```
 25 27 30 31
```

Show the location of the GPIO 4.

# configureDigitalPin

```
showPins(myPi)
```

Connect the digital device you are using to GPIO 4.

Configure pin 4 as a digital input.

```
configureDigitalPin(myPi,4,'input')
```

Read the value from pin 4.

```
readDigitalPin(myPi,4)
```

```
ans =
```

```
1
```

## Configure Pin as Digital Output and Write Its Logical Value

You can configure a pin as digital output and write its logical value.

Create a connection to the Raspberry Pi board.

```
myPi = raspi
```

```
myPi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
 AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
 AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

The `AvailableDigitalPins` property shows the list of digital pins that are available.

Redisplay `AvailableDigitalPins`.

```
myPi.AvailableDigitalPins
```

```
ans =
```

```
Columns 1 through 13
```

# configureDigitalPin

---

```
4 7 8 9 10 11 14 15 17 18 22 23 24
```

```
Columns 14 through 17
```

```
25 27 30 31
```

Show the location of the GPIO 4.

```
showPins(myPi)
```

Connect the digital device you are using to GPIO 4.

Configure pin 4 as a digital output.

```
configureDigitalPin(mypi,4,'output')
```

Write a logical value of 1 to pin 4.

# configureDigitalPin

---

```
writeDigitalPin(mypi,4,1)
```

**Purpose** Delete file on target hardware

**Syntax** `deleteFile(myPi, fileName)`

**Description** `deleteFile(myPi, fileName)`

**Input Arguments** **myPi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

**fileName - File to delete**

file name

File to delete, specified as a string. You can delete a file on the Raspberry Pi hardware. When you specify the file name, you can use path information and wildcards.

**Example:**  `'/home/pi/cap.jpg'`

**Example:**  `'/home/pi/*.jpg'`

**Data Types**

cell

**Examples** **Delete File on Raspberry Pi Hardware**

You can delete a file on the Raspberry Pi hardware.

```
deleteFile(myPi, '/home/pi/cap.jpg');
```

**Delete Multiple Files on Raspberry Pi Hardware**

You can delete multiple files on the Raspberry Pi hardware using a wildcard character, `*`.

```
deleteFile(myPi, '/home/pi/*.jpg')
```

## Use the Camera Board

You can create a connection to the Camera Board, take a photograph, and record video.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Create a connection to the Camera Board while changing the resolution, and assign that connection to a handle, mycam. The handle displays the Camera Board properties.

```
mycam = cameraboard(mypi, 'Resolution', '1280x720')
```

```
mycam =
```

```
Cameraboard with Properties:
```

```
 Name: Camera Board
 Resolution: '1280x720' (View available resolutions)
 Quality: 10 (1 to 100)
 Rotation: 0 (0, 90, 180 or 270)
HorizontalFlip: 0
VerticalFlip: 0
 FrameRate: 30 (2 to 30)
 Recording: 0

Picture Settings
 Brightness: 50 (0 to 100)
 Contrast: 0 (-100 to 100)
 Saturation: 0 (-100 to 100)
 Sharpness: 0 (-100 to 100)

Exposure and AWB
 ExposureMode: 'auto' (View available exposure modes)
 ExposureCompensation: 0 (-10 to 10)
 AWBMode: 'auto' (View available AWB modes)
```

```

 MeteringMode: 'average' (View available metering modes)

Effects
 ImageEffect: 'none' (View available image effects)
 VideoStabilization: 'off'
 ROI: [0.00 0.00 1.00 1.00] (0.0 to 1.0 [top, left, width, height])

```

Import and display a sequence of ten snapshots on your host computer.

```

for ii = 1:10
img = snapshot(mycam);
 imagesc(img);
 drawnow;
end

```

If the image is upside down, change the orientation of the image.

```
mycam.Rotation = 180;
```

You can use the same approach to change the values of many mycamera properties listed in the "Name-Value Pair Arguments" for cameraboard.

Record a 60 second video.

```
record(mycam, 'myvideo.mp4', 60)
```

Stop recording before the 60 seconds have elapsed.

```
stop(mycam)
```

Copy the video from the board to your host computer.

```
getFile(myip, 'myvideo.mp4', 'C:\MATLAB')
```

Delete the video file from the board to free up space.

```
deleteFile(myip, 'myvideo.mp4')
```

**Purpose** Disable I2C interface

**Syntax** `disableI2C(myPi)`

**Description** `disableI2C(myPi)` disables the I2C bus and makes the I2C pins available for use as GPIO pins instead. By default, the I2C bus is enabled.

For example, on a Raspberry Pi Model B Rev 2 board, disabling the I2C bus makes I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3) available for use as GPIO pins.

To reenable I2C, use `enableI2C`.

## Input Arguments

### **myPi - Connection to specific board**

`handle`

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

## Examples

### **Connect and Exchange Data with I2C Devices**

You can connect and exchange data with a pair of I2C devices.

Create a connection to the Raspberry Pi board.

```
myPi = raspi
```

```
myPi =
```

```
Raspi with Properties:
```

```

 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
 AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
```

# disableI2C

---

```
AvailableSPIChannels: {}
AvailableI2CBuses: {'i2c-0' 'i2c-1'}
I2CBusSpeed: 100000
```

Supported peripherals

Redisplay AvailableI2CBuses and I2CBusSpeed.

```
mypi.AvailableI2CBuses
mypi.I2CBusSpeed
```

```
ans =
```

```
'i2c-0' 'i2c-1'
```

```
ans =
```

```
100000
```

Show the location of the I2C pins.

```
showPins(mypi)
```

The pin map shows that, for this model and revision of the board, the i2c-1 bus is available on the GPIO header pins I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3).

After physically connecting your I2C device to the I2C pins, get the addresses of I2C devices attached to the I2C bus, 'i2c-1'.

# disableI2C

---

```
scanI2CBus(mypi, 'i2c-1')
```

```
ans =
```

```
 {'0x55', '0x20'}
```

Create a connection to the I2C sensor at '0x20' and assign that connection to a handle, `i2csensor`.

```
i2csensor = i2cdev(mypi, 'i2c-1', '0x20')
```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two uint8 numbers from the sensor.

```
output1 = read(i2csensor, 2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor, 14);
```

Create a connection to the I2C LED display at '0x55' and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x55
```

```
 TimeOut: 10
```

Write characters to the display.

```
write(i2cdisplay,[hex2dec('20') hex2dec('51')]);
```

Write a scalar hexadecimal value, `hex2dec('08')`, to register 3 on an I2C device.

```
writeRegister(i2cdisplay,3,hex2dec('08'),'uint8');
```

If you are not using I2C, disable I2C to make additional GPIO pins available.

```
disableI2C(mypi)
```

When you use I2C again, enable I2C.

```
enableI2C(mypi)
```

You can only change the `mypi.I2CBusSpeed` property when you enable I2C.

```
disableI2C(mypi);
enableI2C(mypi,400000);
mypi.I2CBusSpeed
```

```
ans =
```

```
40000
```

# disableSPI

---

**Purpose** Disable SPI interface

**Syntax** `disableSPI(myPi)`

**Description** `disableSPI(myPi)` disables the SPI bus and makes the SPI pins available for use as GPIO pins instead. By default, SPI is disabled. This method works only after you have used `enableSPI`.

For example, on a Raspberry Pi Model B Rev 2 board, disabling the SPI bus makes GPIO 10 (SPI0\_MOSI), GPIO 9 (SPI0\_MISO), GPIO 11 (SPI0\_SCLK) available for use as GPIO pins.

**Input Arguments** **myPi - Connection to specific board**  
`handle`

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

**Examples** **Connect and Exchange Data with SPI Devices**

You can connect and exchange data with an SPI device.

Create a connection to the Raspberry Pi board.

```
myPi = raspi
```

```
myPi =
```

```
Raspi with Properties:
```

```
DeviceAddress: 'raspberrypi-computername'
Port: 18725
BoardName: 'Raspberry Pi Model B Rev 2'
AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
```

```
AvailableI2CBuses: {'i2c-0' 'i2c-1'}
I2CBusSpeed: 100000
```

Supported peripherals

By default, SPI is disabled and `AvailableSPIChannels` does not show any channels.

Enable SPI and get the channels.

```
enableSPI(myPi);
myPi.AvailableSPIChannels
```

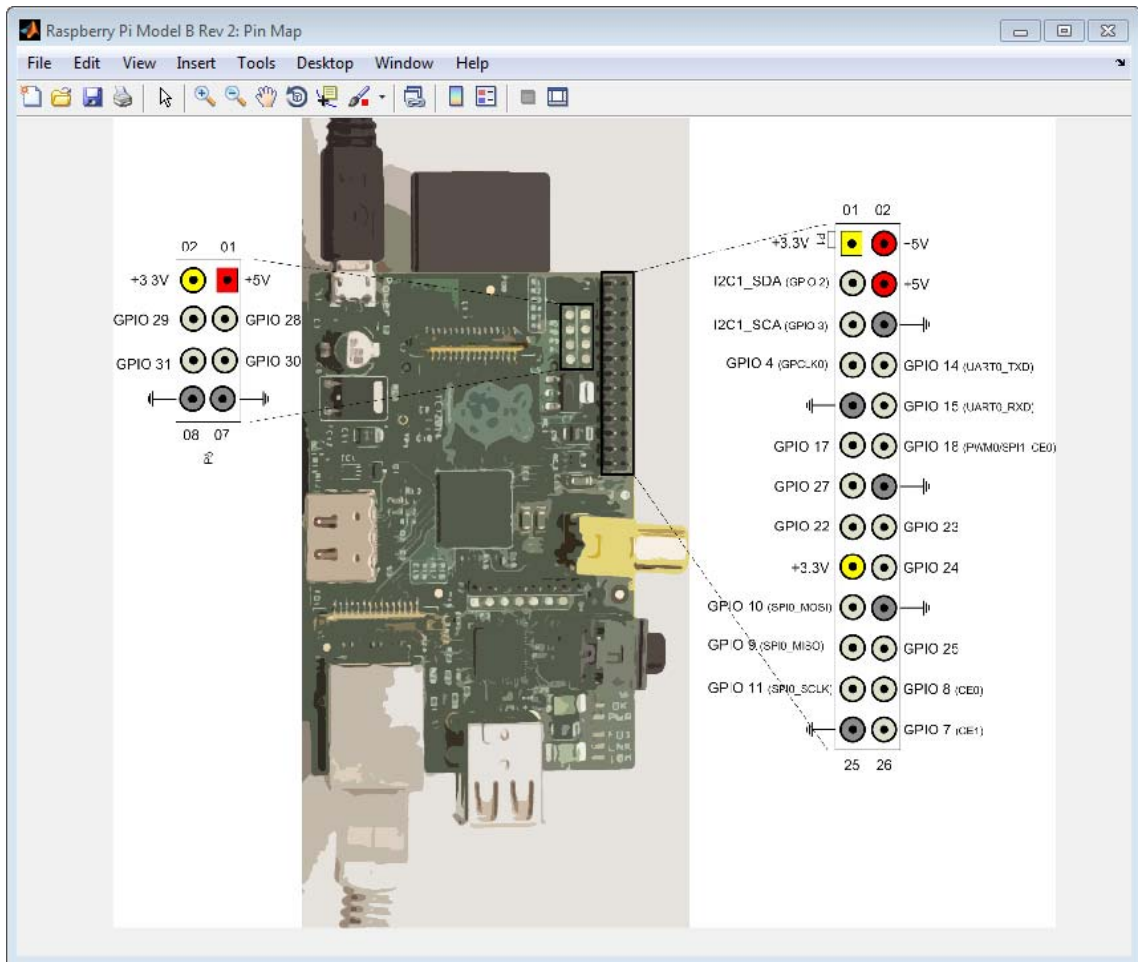

```
ans =
```

```
'CE0' 'CE1'
```

Show the location of the SPI pins, GPIO 10 (SPI0\_MOSI), GPIO 9 (SPI0\_MISO), and GPIO 11 (SPI0\_SCLK), on the GPIO header.

```
showPins(myPi)
```

# disableSPI

After physically connecting your SPI device to the three SPI pins, connect to the SPI device.

```
myspidevice = spidev(mypi, 'CE1', 0)
```

```
myspidevice =
```

```
Spidev with Properties:
 Channel: 'CE1'
 Mode: 0
 BitsPerWord: 8
 Speed: 500000
```

Write data to, and read data from, the SPI device.

```
out = writeRead(myspidevice,[hex2dec('08') hex2dec('D4')])
```

```
out =
 7 211
```

If you are not using SPI, disable SPI to make additional GPIO pins available.

```
disableSPI(mypi)
```

# enableI2C

---

**Purpose** Enable I2C interface

**Syntax** `enableI2C(myPi)`  
`enableI2C(myPi, i2cBusSpeed)`

**Description** `enableI2C(myPi)` enables the I2C bus at the default bus speed, 100000, and makes the GPIO pins available for use as I2C pins instead. By default, the I2C bus is enabled. This method works only after you use `disableI2C`.

For example, on a Raspberry Pi Model B Rev 2 board, enabling the I2C bus makes I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3) available for use as I2C pins.

`enableI2C(myPi, i2cBusSpeed)` enables the I2C bus and overrides the current bus speed.

## Input Arguments

### **myPi - Connection to specific board**

`handle`

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

### **i2cBusSpeed - I2C bus speed**

100000 (default) | 400000

I2C bus speed, specified as a scalar.

**Example:** 100000

### **Data Types**

`double`

## Examples

### **Connect and Exchange Data with I2C Devices**

You can connect and exchange data with a pair of I2C devices.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPICannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

Redisplay AvailableI2CBuses and I2CBusSpeed.

```
mypi.AvailableI2CBuses
```

```
mypi.I2CBusSpeed
```

```
ans =
```

```
 'i2c-0' 'i2c-1'
```

```
ans =
```

```
 100000
```

Show the location of the I2C pins.

```
showPins(mypi)
```

The pin map shows that, for this model and revision of the board, the i2c-1 bus is available on the GPIO header pins I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3).

After physically connecting your I2C device to the I2C pins, get the addresses of I2C devices attached to the I2C bus, 'i2c-1'.

```
scanI2CBus(mypi, 'i2c-1')
```

```
ans =
```

```
 {'0x55', '0x20'}
```

Create a connection to the I2C sensor at '0x20' and assign that connection to a handle, `i2csensor`.

```
i2csensor = i2cdev(mypi, 'i2c-1', '0x20')
```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two uint8 numbers from the sensor.

```
output1 = read(i2csensor, 2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor, 14);
```

Create a connection to the I2C LED display at '0x55' and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
```

```

<b>Purpose</b>	Transfer file from Raspberry Pi hardware to host computer
<b>Syntax</b>	<pre>getFile(myPi,source) getFile(myPi,source,destination)</pre>
<b>Description</b>	<p>getFile(myPi,source) copies the specified file from the Raspberry Pi hardware to the MATLAB Current Folder. Wildcards are supported.</p> <p>getFile(myPi,source,destination) copies the file to a destination path and optional file name.</p>
<b>Input Arguments</b>	<p><b>myPi - Connection to specific board</b>  handle  Connection to a specific board, specified as a handle.  Use raspi to create this connection.  <b>Example:</b> myPi</p> <p><b>source - Path and name of file on Raspberry Pi hardware</b>  path and name file name  Path and file name on the Raspberry Pi hardware, specified as a string. You can use either the absolute path from the root folder, the relative path from the present working folder. Use Linux path and file naming conventions. The default path is /home/pi/.  <b>Example:</b> '.profile'  <b>Example:</b> '/home/pi/.profile'  <b>Example:</b> '/home/pi/.pro*'</p> <p><b>Data Types</b>  char</p> <p><b>destination - Path and name of file on host computer</b>  MATLAB Current Folder (default)   destination path</p>

Path and name of file on host computer, specified as a string. If not specified, `getFile` uses the MATLAB Current Folder and the current file name. Use naming conventions of the operating system on the host computer. This function does not create new folders. Folder names in the path must already exist. Optional.

**Example:** `'C:\Users\myusername\Desktop'`

## Data Types

char

## Examples

### Download a File to the MATLAB Current Folder

You can copy a file, such as `.profile`, from the Raspberry Pi hardware to the MATLAB Current Folder on your host computer.

```
getFile(myip, '/home/pi/.profile')
```

### Download Multiple Files to a Specific Folder on Your Host Computer

You can use a wildcard to copy any matching file or files from the Raspberry Pi hardware to your host computer. You can specify the path of a destination folder. The folder must already exist.

```
getFile(myip, '/home/pi/*.png', 'C:\Users\myusername\Desktop')
```

### Use the Camera Board

You can create a connection to the Camera Board, take a photograph, and record video.

Create a connection to the Raspberry Pi board.

```
myip = raspi;
```

Create a connection to the Camera Board while changing the resolution, and assign that connection to a handle, `mycam`. The handle displays the Camera Board properties.

```
mycam = cameraboard(myip, 'Resolution', '1280x720')
```

```
mycam =
```

```
Cameraboard with Properties:
```

```
 Name: Camera Board
 Resolution: '1280x720' (View available resolutions)
 Quality: 10 (1 to 100)
 Rotation: 0 (0, 90, 180 or 270)
HorizontalFlip: 0
VerticalFlip: 0
 FrameRate: 30 (2 to 30)
 Recording: 0

Picture Settings
 Brightness: 50 (0 to 100)
 Contrast: 0 (-100 to 100)
 Saturation: 0 (-100 to 100)
 Sharpness: 0 (-100 to 100)

Exposure and AWB
 ExposureMode: 'auto' (View available exposure modes)
 ExposureCompensation: 0 (-10 to 10)
 AWBMode: 'auto' (View available AWB modes)
 MeteringMode: 'average' (View available metering modes)

Effects
 ImageEffect: 'none' (View available image effects)
 VideoStabilization: 'off'
 ROI: [0.00 0.00 1.00 1.00] (0.0 to 1.0 [top, left, width, height])
```

Import and display a sequence of ten snapshots on your host computer.

```
for ii = 1:10
img = snapshot(mycam);
imagesc(img);
drawnow;
end
```

If the image is upside down, change the orientation of the image.

```
mycam.Rotation = 180;
```

You can use the same approach to change the values of many mycamera properties listed in the "Name-Value Pair Arguments" for cameraboard.

Record a 60 second video.

```
record(mycam, 'myvideo.mp4', 60)
```

Stop recording before the 60 seconds have elapsed.

```
stop(mycam)
```

Copy the video from the board to your host computer.

```
getFile(mypi, 'myvideo.mp4', 'C:\MATLAB')
```

Delete the video file from the board to free up space.

```
deleteFile(mypi, 'myvideo.mp4')
```

```
system | openShell | putFile | deleteFile | cameraboard
```

---

<b>Purpose</b>	Create connection to I2C device
<b>Syntax</b>	<code>myi2cdevice = i2cdev(myipi,bus,i2cAddress)</code>
<b>Description</b>	<code>myi2cdevice = i2cdev(myipi,bus,i2cAddress)</code> connects to an I2C device and returns a handle, <code>myi2cdevice</code> . You can exchange data with the I2C device by using <code>myi2cdevice</code> with the <code>read</code> , <code>write</code> , <code>readRegister</code> , and <code>writeRegister</code> methods. You can use <code>myi2cdevice</code> to read properties of the I2C device.
<b>Input Arguments</b>	<p><b>myipi - Connection to specific board</b> handle Connection to a specific board, specified as a handle. Use <code>raspi</code> to create this connection. <b>Example:</b> <code>myipi</code></p> <p><b>bus - I2C bus</b> '2c-0'   '2c-1' I2C bus, specified as a string. <b>Example:</b> 'i2c-1'</p> <p><b>Data Types</b> char</p> <p><b>i2cAddress - I2C device address</b> hexadecimal address I2C device address, specified as a string. Use <code>scanI2Cbus</code> to get a list of addresses. The address is a Hexadecimal value. <b>Example:</b> '0x20'</p> <p><b>Data Types</b> char</p>

## Output Arguments

### **myi2cdevice - Connection to specific I2C device**

`handle`

Connection to a specific I2C device, specified as a handle.

You can use `myi2cdevice` with the following methods:

- `read`
- `write`
- `readRegister`
- `writeRegister`

You can read values from the following `myi2cdevice` properties:

- `Bus`
- `I2CAddress`

## Examples

### **Connect and Exchange Data with I2C Devices**

You can connect and exchange data with a pair of I2C devices.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```
DeviceAddress: 'raspberrypi-computername'
Port: 18725
BoardName: 'Raspberry Pi Model B Rev 2'
AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
AvailableI2CBuses: {'i2c-0' 'i2c-1'}
I2CBusSpeed: 100000
```

Supported peripherals

Redisplay AvailableI2CBuses and I2CBusSpeed.

```
mypi.AvailableI2CBuses
mypi.I2CBusSpeed
```

```
ans =
```

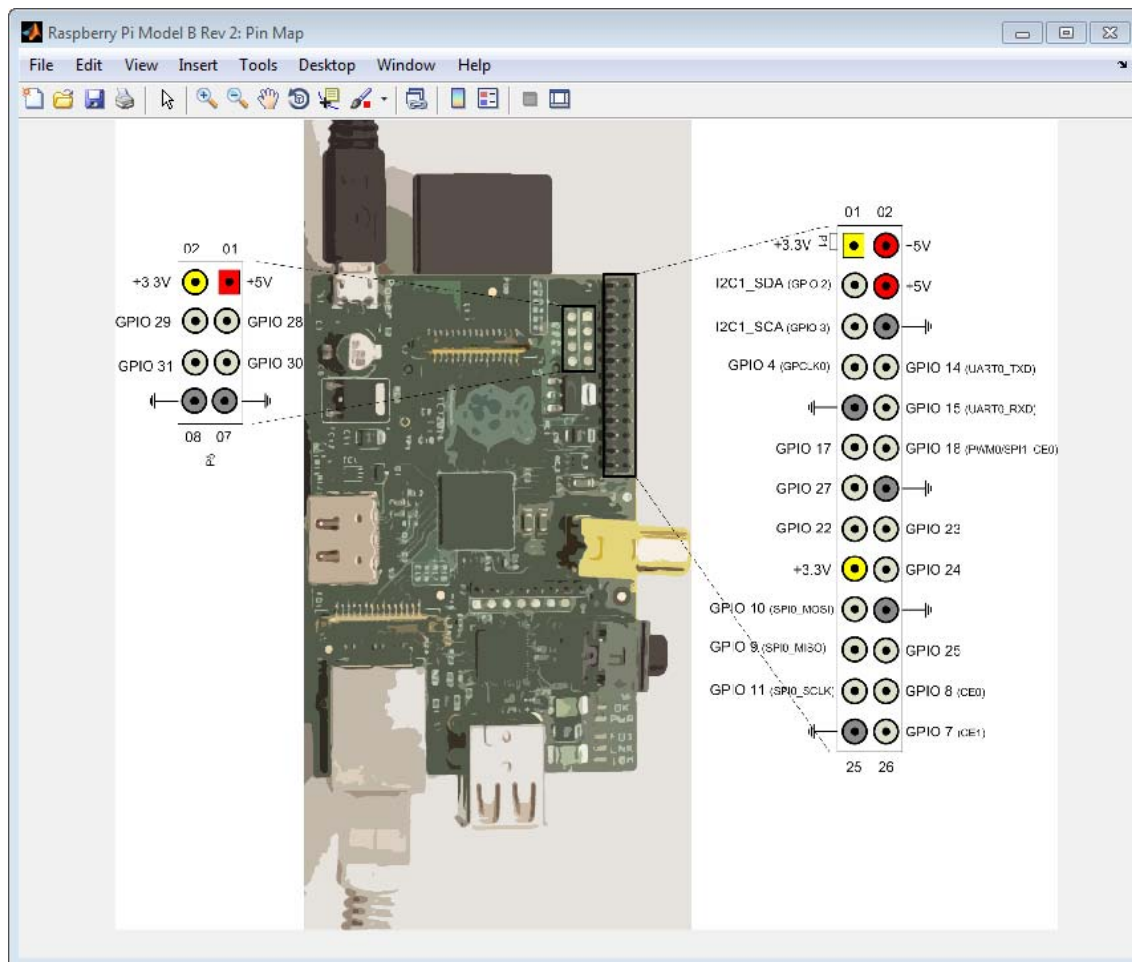

```
 'i2c-0' 'i2c-1'
```

```
ans =
```

```
 100000
```

Show the location of the I2C pins.

```
showPins(mypi)
```

The pin map shows that, for this model and revision of the board, the i2c-1 bus is available on the GPIO header pins I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3).

After physically connecting your I2C device to the I2C pins, get the addresses of I2C devices attached to the I2C bus, 'i2c-1'.

```
scanI2CBus(mypi, 'i2c-1')
```

```
ans =
```

```
 {'0x55', '0x20'}
```

Create a connection to the I2C sensor at '0x20' and assign that connection to a handle, `i2csensor`.

```
i2csensor = i2cdev(mypi, 'i2c-1', '0x20')
```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two `uint8` numbers from the sensor.

```
output1 = read(i2csensor, 2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor, 14);
```

Create a connection to the I2C LED display at '0x55' and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x55
```

```
 TimeOut: 10
```

Write characters to the display.

```
write(i2cdisplay,[hex2dec('20') hex2dec('51')]);
```

Write a scalar hexadecimal value, `hex2dec('08')`, to register 3 on an I2C device.

```
writeRegister(i2cdisplay,3,hex2dec('08'),'uint8');
```

If you are not using I2C, disable I2C to make additional GPIO pins available.

```
disableI2C(mypi)
```

When you use I2C again, enable I2C.

```
enableI2C(mypi)
```

You can only change the `mypi.I2CBusSpeed` property when you enable I2C.

```
disableI2C(mypi);
enableI2C(mypi,400000);
mypi.I2CBusSpeed
```

```
ans =
```

```
40000
```

# putFile

---

**Purpose** Transfer file from host computer to target hardware

**Syntax** `putFile(my_pi, source)`  
`putFile(my_pi, source, destination)`

**Description** `putFile(my_pi, source)` copies the specified file from the MATLAB Current Folder to the current folder (`pwd`) on the Raspberry Pi hardware. Wildcards are supported.

`putFile(my_pi, source, destination)` copies the file to a destination path and optional file name.

## Input Arguments

### **my\_pi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `my_pi`

### **source - Path and name of file on host computer**

MATLAB Current Folder (default) | source path

Path and name of the file on the host computer. Specify the path as a string. You can use an absolute path or a relative path from the MATLAB Current Folder. Use the path and file naming conventions of the operating system on your host computer.

**Example:** `'C:\Work\.profile'`

### **Data Types**

char

### **destination - Destination folder path and optional file name**

destination path

Destination folder path and optional file name, specified as a string. Use Linux path and file naming conventions. Optional.

**Example:**  `'/home/pi/.profile'`

## Data Types

char

## Examples

### Upload a File to the Raspberry Pi Hardware

You can copy a file, such as `out.jpg`, from your host computer to the Raspberry Pi hardware. Use the different file and path conventions of each operating system.

```
putFile(myPi, 'C:\Work\.profile', '/home/pi/.profile');
```

# raspi

---

**Purpose** Create connection to Raspberry Pi hardware

**Syntax**  
`mypi = raspi`  
`mypi = raspi(ipaddress,username,password)`

**Description** `mypi = raspi` creates a connection to the Raspberry Pi board and assigns that connection to a handle. Use this syntax to simply connect or reconnect to the same board.

You do not need to supply the user IP address, user name, and password because `raspi` reuses these settings from the most recent successful connection to a Raspberry Pi board, including the setup process.

After connecting to the board, you can use `mypi` to interact with the Raspberry Pi board and peripheral devices.

To close the connection, use `clear` to remove `mypi` and any other handles that were created using `mypi`.

`mypi = raspi(ipaddress,username,password)` overrides the IP address, user name, and password from the previous connection. Use this syntax to connect to a board whose settings are different from the previous successful connection. Use this syntax after changing the password on a board, or to create a connection to a second board.

---

**Note** The firmware has a default user name, 'pi', and password, 'raspberry'. The pi user has sudo root powers on the command line. It is a good security practice to change the default password to a strong password.

---

**Input Arguments** **ipaddress - IP address or host name of board**  
valid IPv4 address | valid host name

IP address or host name of the board, specified as a string.

**Example:** '169.254.0.2'

---

**Example:** 'raspberrypi-computername'

### Data Types

char

### username - Linux user name

user name

Linux user name, specified as a string.

**Example:** 'pi'

### Data Types

char

### password - Linux user password

password

Linux user password, specified as a string.

---

**Note** The firmware has a default user name, 'pi', and password, 'raspberry'. This user has sudo root powers on the command line. It is a good security practice to change this default password to a strong password.

---

**Example:** 'raspberry'

### Data Types

char

## Output Arguments

### mypi - Connection to specific board

handle

Connection to a specific board, specified as a handle.

You can use `mypi` to connect to add-on peripherals using:

- `serialdev`
- `i2cdev`

- `spidev`
- `cameraboard`

You can use `mypi` with the following methods:

- `configureDigitalPin`
- `readDigitalPin`
- `writeDigitalPin`
- `showPins`
- `writeLED`
- `showLEDs`
- `scanI2Cbus`
- `enableI2C`
- `disableI2C`
- `enableSPI`
- `disableSPI`
- `system`
- `openShell`
- `getFile`
- `putFile`
- `deleteFile`

You can use `mypi` to read the following properties for the Raspberry Pi hardware:

- `DeviceAddress` — IP address or host name
- `Port` — IP port number used for TCP/IP connections
- `BoardName` — Board, model, and revision
- `AvailableLEDs` — Available LEDs

- `AvailableDigitalPins` — Numbers of the available GPIO pins
- `AvailableSPIChannels` — Names of the available SPI channels
- `AvailableI2CBuses` — Names of the available I2C buses
- `I2CBusSpeed` — Speed of the I2C buses

## Examples

### Create a Connection to a Raspberry Pi Board

You can create a connection from the MATLAB software on your host computer to a Raspberry Pi board.

When you create the connection, assign it to a handle. You can use this handle later on to interact with the Raspberry Pi hardware.

You do not need to supply the user IP address, user name, and password because `raspi` reuses these settings from the most recent successful connection to a Raspberry Pi board, including the setup process.

Create a connection and assign it to a handle, `mypi`.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```

 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000

```

```
Supported peripherals
```

Use `mypi` to create a connection to a serial device.

```
myserialdevice = serialdev(mypi, '/dev/ttyAMA0');
```

To close the connection, use `clear` to remove `mypi` and any other handles that were created using `mypi`.

```
clear mypi;
clear myserialdevice;
```

## Create a Connection to a Board That Has Different Settings

You can create a connection to a Raspberry Pi board that has a different IP address, user name, and password from the previous successful connection.

Follow this example to reconnect to a board after you change its settings, or to connect to multiple boards concurrently.

```
mysecondpi = raspi('169.254.0.4', 'rocky', 'bullwinkle')
```

```
mysecondpi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: '169.254.0.4'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

## Create a Connection Using a Host Name

You can use a host name, instead of an IP address, to create a connection to a Raspberry Pi board.

During the setup process, Support Package Installer generated the Raspberry Pi host name by appending the name of your computer to raspberrypi-.

```
mysecondpi = raspi('raspberrypi-computername')
```

```
mysecondpi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

The `DeviceAddress` reflects whether a host name or IP address was used to create the connection.

# raspi\_examples

---

**Purpose** Open featured examples for this support package

**Syntax** `raspi_examples`

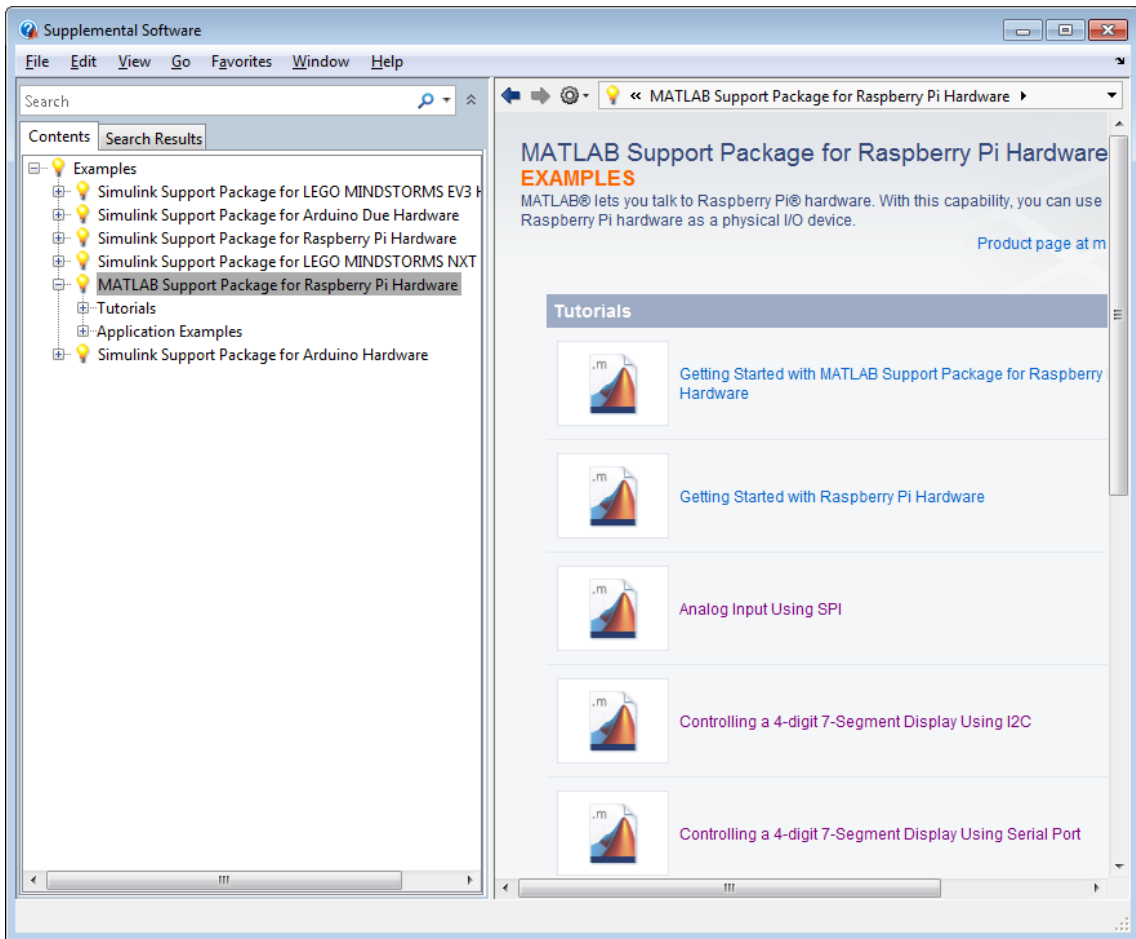

**Description** `raspi_examples` opens the featured examples that are installed with the MATLAB Support Package for Raspberry Pi Hardware.

**Examples** **Open the Featured Examples for MATLAB Support for Raspberry Pi**

In the MATLAB Command Window, enter:

```
raspi_examples
```

A window opens and displays the examples.

# read

---

## Purpose

Read data from I2C device

## Syntax

```
[data] = read(myi2cdevice, count, dataPrecision)
```

## Description

[data] = read(myi2cdevice, count, dataPrecision) returns data from the I2C device as a row vector.

The read method stops when it finishes reading the specified data from the device, or when the timeout period elapses.

## Input Arguments

### **myi2cdevice - Connection to I2C device**

handle

Connection to I2C device, specified as a handle.

Use `i2cdev` to create this connection.

**Example:** `myi2cdevice`

### **count - Size of I2C data**

size of I2C data

Size of I2C data, specified as a scalar. This value is the number of data elements that you expect.

**Example:** `2`

### **Data Types**

`int8` | `int16` | `uint8` | `uint16`

### **dataPrecision - Data precision**

`'uint8 (default)'` | `'int8'` | `'int16'` | `'uint16'`

Data precision, specified as a string. Match the data precision to the size of the register on the device. Optional.

**Example:** `'int16'`

### **Data Types**

`char`

## Output Arguments

### **data - vector of numeric values**

data

Data from the I2C device, returned as a row vector. The number of elements of the row vector is specified by the count argument.

## Examples

### **Connect and Exchange Data with I2C Devices**

You can connect and exchange data with a pair of I2C devices.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

Redisplay AvailableI2CBuses and I2CBusSpeed.

```
mypi.AvailableI2CBuses
```

```
mypi.I2CBusSpeed
```

```
ans =
```

```
 'i2c-0' 'i2c-1'
```

# read

---

```
ans =
```

```
100000
```

Show the location of the I2C pins.

```
showPins(myPi)
```

The pin map shows that, for this model and revision of the board, the i2c-1 bus is available on the GPIO header pins I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3).

After physically connecting your I2C device to the I2C pins, get the addresses of I2C devices attached to the I2C bus, 'i2c-1'.

```
scanI2CBus(mypi, 'i2c-1')
```

```
ans =
```

```
 {'0x55', '0x20'}
```

Create a connection to the I2C sensor at '0x20' and assign that connection to a handle, `i2csensor`.

```
i2csensor = i2cdev(mypi, 'i2c-1', '0x20')
```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two uint8 numbers from the sensor.

```
output1 = read(i2csensor, 2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor, 14);
```

Create a connection to the I2C LED display at '0x55' and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x55
```

```
 TimeOut: 10
```

Write characters to the display.

```
write(i2cdisplay,[hex2dec('20') hex2dec('51')]);
```

Write a scalar hexadecimal value, `hex2dec('08')`, to register 3 on an I2C device.

```
writeRegister(i2cdisplay,3,hex2dec('08'),'uint8');
```

If you are not using I2C, disable I2C to make additional GPIO pins available.

```
disableI2C(mypi)
```

When you use I2C again, enable I2C.

```
enableI2C(mypi)
```

You can only change the `mypi.I2CBusSpeed` property when you enable I2C.

```
disableI2C(mypi);
enableI2C(mypi,400000);
mypi.I2CBusSpeed
```

```
ans =
```

```
40000
```

# read

---

## Purpose

Read data from serial device

## Syntax

```
serialData = read(myserialdevice,count)
serialData = read(myserialdevice,count,precision)
```

## Description

`serialData = read(myserialdevice,count)` returns data from the serial device.

The `read` method stops when it finishes reading the specified data from the device, or when the timeout period elapses.

`serialData = read(myserialdevice,count,precision)` overrides the default value for precision.

## Input Arguments

### **myserialdevice - Connection to serial device**

handle

Connection to a serial device, specified as a handle.

Use `serialdev` to create this connection.

**Example:** `myserialdevice`

### **count - Data size**

data size

Data size to read from the serial device, specified as a scalar.

**Example:** `2`

### **Data Types**

double

### **precision - Data precision**

'uint8' (default) | 'char' | 'int8' | 'int16' | 'uint16' | 'int32' | 'uint32' | 'single' | 'double'

Data precision, specified as a string. Optional.

**Example:** `'uint8'`

**Data Types**

char

**Output Arguments****serialData - Data from serial device**

serial data

Data from the serial device, returned in the device- or user-defined format.

**Examples****Connect and Exchange Data with Serial Device**

You can create a connection to a serial device, write data to the device, and read data from the device.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Show the location of the Tx and Rx pins, GPIO 14 (UART0\_TXD) and GPIO 15 (UART0\_RXD), on the GPIO header.

```
showPins(mypi)
```

Raspberry Pi hardware uses +3.3V. Do not connect Raspberry Pi hardware directly to devices that use higher voltages.

Connect the Raspberry Pi serial port to a +3.3V serial device.

- To receive data, connect the RXD pin (GPIO 15 UART0\_RXD) on the Raspberry Pi board to the TXD pin on the serial device.

- To transmit data, connect the TXD pin (GPIO 14 UART0\_TXD) on the Raspberry Pi board to the RXD pin on the serial device.
- Connect a ground pins (GND) on the Raspberry Pi board to the GND pin on the serial device.
- Connect one of the +3.3V pins on the Raspberry Pi board to the VCC pin on the serial device.

Research the values the serial device requires for the baud rate, data bits, parity, and stop bit.

Use `serialdev` to create a connection to the serial device and assign the connection to a handle.

```
myserialdevice = serialdev(mypi, '/dev/ttyAMA0', 9600)
```

```
myserialdevice =
```

```
 Serialdev with Properties:
```

```
 BaudRate: 9600
 DataBits: 8
 Parity: 'none'
 StopBits: 1
 Timeout: 10
```

Write a pair of values to a serial device that requires a specific data type.

```
write(myserialdevice, [10 12], 'uint16')
```

Read a 100-element array of numbers from the serial port.

```
output = read(myserialdevice, 100, 'uint16');
```

Increase the timeout period of the serial port.

```
myserialdevice.Timeout = 20
```

```
myserialdevice =
```

# read

---

Serialdev with Properties:

```
BaudRate: 115200
DataBits: 8
 Parity: 'none'
StopBits: 1
Timeout: 20
```

## See Also

## Related Examples

- “Open Interactive Examples”

## Purpose

Read logical value from GPIO input pin

## Syntax

```
pinvalue = readDigitalPin(myPi, pinNumber)
```

## Description

`pinvalue = readDigitalPin(myPi, pinNumber)` returns the logical value of a digital pin.

This method configures an unconfigured pin as a GPIO input.

If the pin is a GPIO output, or if another interface (I2C, Serial, SPI) is using the pin, this method returns an error message.

## Input Arguments

### **myPi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

### **pinNumber - GPIO pin number**

pin number

GPIO pin number, specified as a scalar. This argument does not accept vectors because the hardware cannot access multiple pins simultaneously.

To get a list of valid pin numbers, enter `myPi.AvailableDigitalPins`.

**Example:** `12`

### **Data Types**

double

## Output Arguments

### **pinvalue - Logical value of pin**

0 | 1

Logical value of the pin, returned as a scalar.

# readDigitalPin

---

## Examples

### Configure Pin as Digital Input and Read Its Logical Value

You can configure a pin as digital input and read its logical value.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

The `AvailableDigitalPins` property shows the list of digital pins that are available.

Redisplay `AvailableDigitalPins`.

```
mypi.AvailableDigitalPins
```

```
ans =
```

```
Columns 1 through 13
```

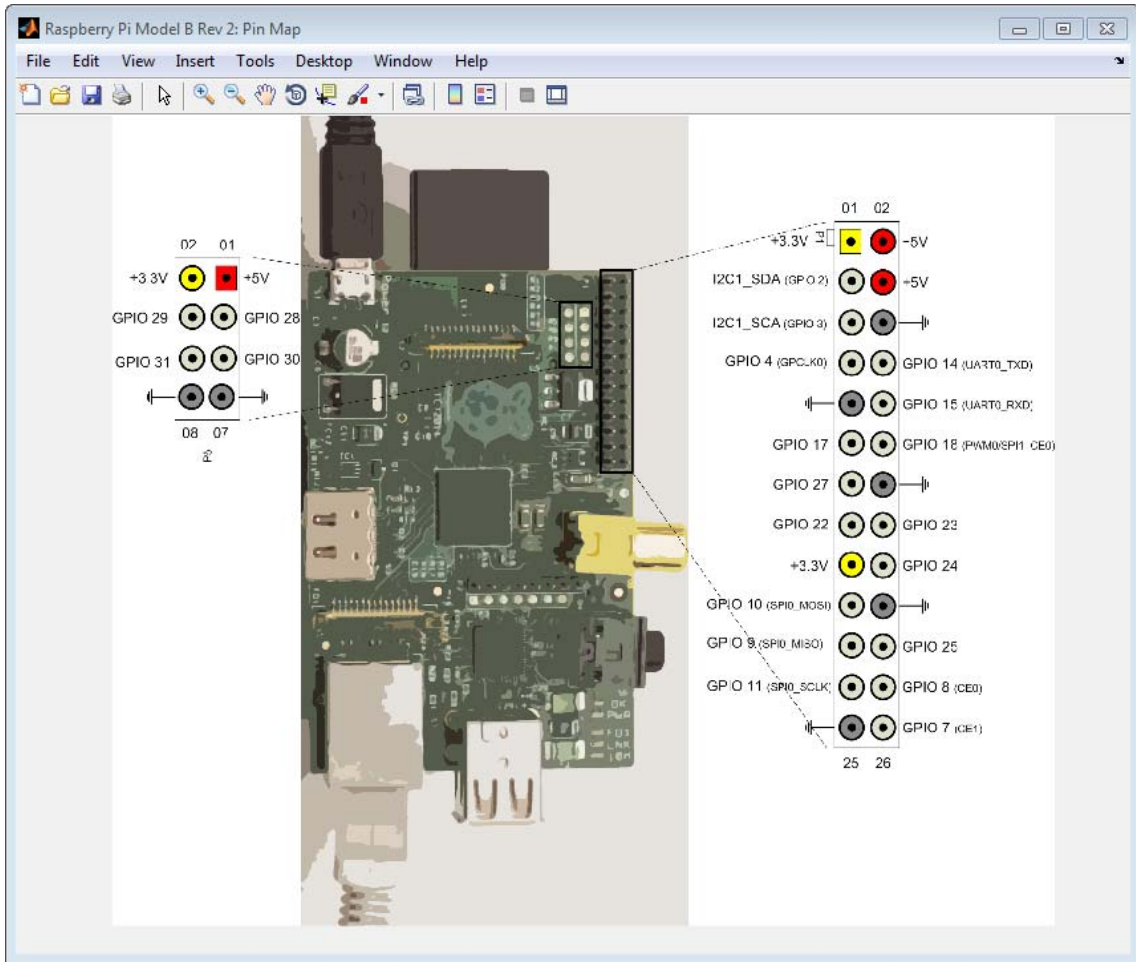

```
 4 7 8 9 10 11 14 15 17 18 22 23 24
```

```
Columns 14 through 17
```

```
 25 27 30 31
```

Show the location of the GPIO 4.

```
showPins(myPi)
```

Connect the digital device you are using to GPIO 4.

Configure pin 4 as a digital input.

```
configureDigitalPin(myPi,4,'input')
```

# readDigitalPin

---

Read the value from pin 4.

```
readDigitalPin(mypi,4)
```

```
ans =
```

```
1
```

## Pressing a button blinks an LED connected to a GPIO pin

You can press a button to blink an LED connected to a GPIO pin.

This example rapidly blinks an LED when you press a button. The button connects from positive voltage to pin 23. Pressing the button closes the circuit, raising the voltage. When `readDigitalPin` detects the positive voltage, `if buttonPressed` becomes true. The program toggles the voltages to pin 24 on and off ten times. Pin 14 connects to an LED, which connects via a resistor to ground.

```
for ii = 1:100
 buttonPressed = readDigitalPin(mypi,23);
 if buttonPressed
 for jj = 1:10
 writeDigitalPin(mypi,24,1);
 pause(0.05);
 writeDigitalPin(mypi,24,0);
 pause(0.05);
 end
 end
 pause(0.1);
end
```

Create a connection to the I2C sensor at `'0x20'` and assign that connection to a handle, `i2csensor`.

```
i2csensor = i2cdev(mypi, 'i2c-1', '0x20')
```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two `uint8` numbers from the sensor.

```
output1 = read(i2csensor,2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor,14);
```

Create a connection to the I2C LED display at `'0x55'` and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
 Bus: i2c-1
 I2CAddress: 0x55
 TimeOut: 10
```

Write characters to the display.

```
write(i2cdisplay,[hex2dec('20') hex2dec('51')]);
```

Write a scalar hexadecimal value, `hex2dec('08')`, to register 3 on an I2C device.

```
writeRegister(i2cdisplay,3,hex2dec('08'),'uint8');
```

If you are not using I2C, disable I2C to make additional GPIO pins available.

```
disableI2C(mypi)
```

When you use I2C again, enable I2C.

```
enableI2C(mypi)
```

You can only change the `mypi.I2CBusSpeed` property when you enable I2C.

```
disableI2C(mypi);
enableI2C(mypi,400000);
mypi.I2CBusSpeed
```

```
ans =
```

```
40000
```

<b>Purpose</b>	Record video from Camera Board
<b>Syntax</b>	<code>record(mycamera, fileName, duration)</code>
<b>Description</b>	<code>record(mycamera, fileName, duration)</code> records video from the Camera Board to a file on Raspberry Pi.
<b>Input Arguments</b>	<p><b>mycamera - Connection to Camera Board</b> handle Connection to a Camera Board, specified as a handle. Use <code>cameraboard</code> to create this connection. <b>Example:</b> <code>mycam</code></p> <p><b>fileName - Video file name</b> video file name Video file name, specified as a string. <b>Example:</b> <code>'myvideo.mp4'</code></p> <p><b>Data Types</b> char</p> <p><b>duration - Duration of recording</b> duration of recording Duration of recording, specified in seconds. <b>Example:</b></p> <p><b>Data Types</b> double</p>
<b>Examples</b>	<p><b>Use the Camera Board</b></p> <p>You can create a connection to the Camera Board, take a photograph, and record video.</p>

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Create a connection to the Camera Board while changing the resolution, and assign that connection to a handle, mycam. The handle displays the Camera Board properties.

```
mycam = cameraboard(mypi, 'Resolution', '1280x720')
```

```
mycam =
```

```
Cameraboard with Properties:
```

```
 Name: Camera Board
 Resolution: '1280x720' (View available resolutions)
 Quality: 10 (1 to 100)
 Rotation: 0 (0, 90, 180 or 270)
HorizontalFlip: 0
VerticalFlip: 0
 FrameRate: 30 (2 to 30)
 Recording: 0

Picture Settings
 Brightness: 50 (0 to 100)
 Contrast: 0 (-100 to 100)
 Saturation: 0 (-100 to 100)
 Sharpness: 0 (-100 to 100)

Exposure and AWB
 ExposureMode: 'auto' (View available exposure modes)
 ExposureCompensation: 0 (-10 to 10)
 AWBMode: 'auto' (View available AWB modes)
 MeteringMode: 'average' (View available metering modes)

Effects
 ImageEffect: 'none' (View available image effects)
 VideoStabilization: 'off'
```

```
ROI: [0.00 0.00 1.00 1.00] (0.0 to 1.0 [top, left, width, height])
```

Import and display a sequence of ten snapshots on your host computer.

```
for ii = 1:10
img = snapshot(mycam);
 imagesc(img);
 drawnow;
end
```

If the image is upside down, change the orientation of the image.

```
mycam.Rotation = 180;
```

You can use the same approach to change the values of many mycamera properties listed in the "Name-Value Pair Arguments" for cameraboard.

Record a 60 second video.

```
record(mycam, 'myvideo.mp4', 60)
```

Stop recording before the 60 seconds have elapsed.

```
stop(mycam)
```

Copy the video from the board to your host computer.

```
getFile(myPi, 'myvideo.mp4', 'C:\MATLAB')
```

Delete the video file from the board to free up space.

```
deleteFile(myPi, 'myvideo.mp4')
```

# serialdev

---

## Purpose

Create connection to serial device

## Syntax

```
myserialdevice = serialdev(myPi,port)
myserialdevice =
serialdev(myPi,port,baudRate,dataBits,parity,
 stopBits)
```

## Description

`myserialdevice = serialdev(myPi,port)` connects to a serial device and returns a handle, `myserialdevice`. You can use `myserialdevice` to exchange data with the serial device using the read and write methods. You can read and write `myserialdevice` properties such as the baud rate.

On the Raspberry Pi hardware, the `/boot/cmdline.txt` file configures `/dev/ttyAMA0` as the serial device and sets the default baud rate to 115200. The serial device connects to the Rx and Tx pins on the GPIO header.

By default, the serial console in the customized version of Raspian Wheezy on your Raspberry Pi hardware is disabled. To use `serialdev`, the serial console must be disabled.

```
myserialdevice =
serialdev(myPi,port,baudRate,dataBits,parity, stopBits)
connects to a serial device using optional arguments to override the
default values for baud rate, data bits, parity, and stop bits. Specify
values for each argument from left to right. To use default
values, omit the right-most arguments.
```

## Input Arguments

### **myPi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

## **port - Serial device path and file name**

serial device

Serial device path and file name, specified as a string.

**Example:**  `'/dev/ttyAMA0'`

### **Data Types**

char

## **baudRate - Serial device baud rate**

115200 (default) | 50 | 75 | 110 | 134 | 150 | 200 | 300 | 600 | 1200 | 1800 | 2400 | 4800 | 9600 | 19200 | 38400 | 57600 | 230400

Serial device baud rate, specified as a scalar. Optional.

**Example:** 9600

### **Data Types**

double

## **dataBits - Data bits per character**

8 (default) | 5 | 6 | 7 | 9

Data bits per character, specified as a scalar. Optional.

**Example:** 8

### **Data Types**

double

## **parity - Parity bit**

'none' (default) | 'odd' | 'even' | 'mark' | 'space'

Parity bit, specified as a string. Optional.

This setting enables and selects the type of parity-bit error detection.

**Example:** `'none'`

### **Data Types**

char

## **stopBits - Stop bits**

1 (default) | 1.5 | 2

Stop bits, specified as a scalar. Optional.

**Example:** 1

## **Data Types**

double

## **Output Arguments**

### **myserialdevice - Connection to specific serial device**

handle

Connection to a specific serial device, specified as a handle.

You can use `myserialdevice` with the following methods:

- `read`
- `write`

You can use `myserialdevice` to read the following properties for the serial device:

- `BaudRate`
- `DataBits`
- `StopBits`
- `Parity`

You can use `myserialdevice` to read and write the `TimeOut` property for the serial device:

## **Examples**

### **Connect and Exchange Data with Serial Device**

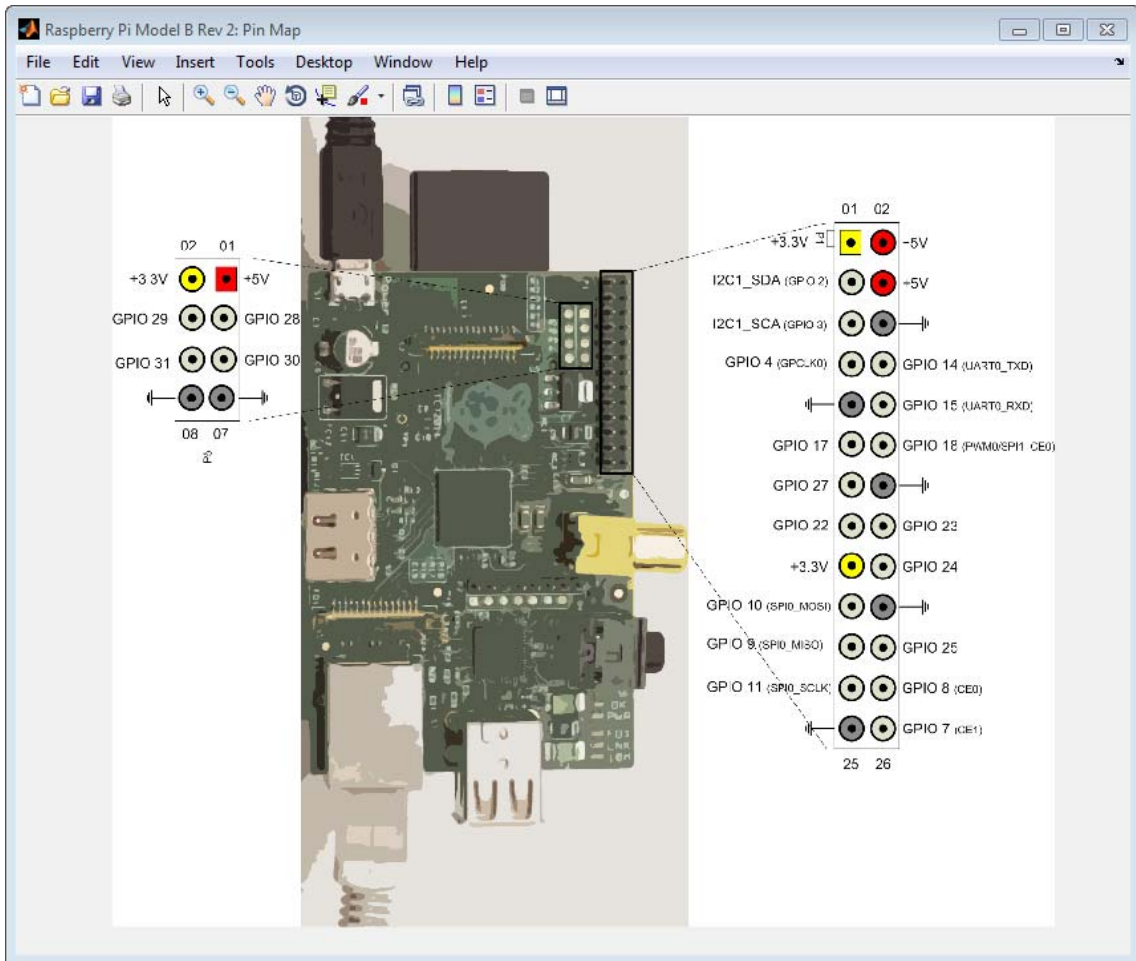

You can create a connection to a serial device, write data to the device, and read data from the device.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Show the location of the Tx and Rx pins, GPIO 14 (UART0\_TXD) and GPIO 15 (UART0\_RXD), on the GPIO header.

```
showPins(myPi)
```

Raspberry Pi hardware uses +3.3V. Do not connect Raspberry Pi hardware directly to devices that use higher voltages.

Connect the Raspberry Pi serial port to a +3.3V serial device.

- To receive data, connect the RXD pin (GPIO 15 UART0\_RXD) on the Raspberry Pi board to the TXD pin on the serial device.
- To transmit data, connect the TXD pin (GPIO 14 UART0\_TXD) on the Raspberry Pi board to the RXD pin on the serial device.
- Connect a ground pins (GND) on the Raspberry Pi board to the GND pin on the serial device.
- Connect one of the +3.3V pins on the Raspberry Pi board to the VCC pin on the serial device.

Research the values the serial device requires for the baud rate, data bits, parity, and stop bit.

Use `serialdev` to create a connection to the serial device and assign the connection to a handle.

```
myserialdevice = serialdev(mypi, '/dev/ttyAMA0', 9600)
```

```
myserialdevice =
```

```
 Serialdev with Properties:
```

```
 BaudRate: 9600
 DataBits: 8
 Parity: 'none'
 StopBits: 1
 Timeout: 10
```

Write a pair of values to a serial device that requires a specific data type.

```
write(myserialdevice, [10 12], 'uint16')
```

Read a 100-element array of numbers from the serial port.

```
output = read(myserialdevice, 100, 'uint16');
```

Increase the timeout period of the serial port.

```
myserialdevice.Timeout = 20
```

```
myserialdevice =
```

```
 Serialdev with Properties:
```

```
 BaudRate: 115200
```

```
 DataBits: 8
```

```
 Parity: 'none'
```

```
 StopBits: 1
```

```
 Timeout: 20
```

# showLEDs

---

**Purpose** Show location, name, and color of user-controllable LEDs

**Syntax** showLEDs(my\_pi)

**Description** showLEDs(my\_pi) displays the location, name, and color of the user-controllable LEDs on the current board.

**Input Arguments** **my\_pi - Connection to specific board**  
handle

Connection to a specific board, specified as a handle.

Use raspi to create this connection.

**Example:** my\_pi

**Examples** **Control the On-Board LED**

You can locate and control the on-board LED, turning it on and off.

Create a connection to the Raspberry Pi board.

```
my_pi = raspi
```

```
my_pi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
 AvailableDigitalPins: [4 14 15 17 18 22 23 24 25 27 30 31]
 AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

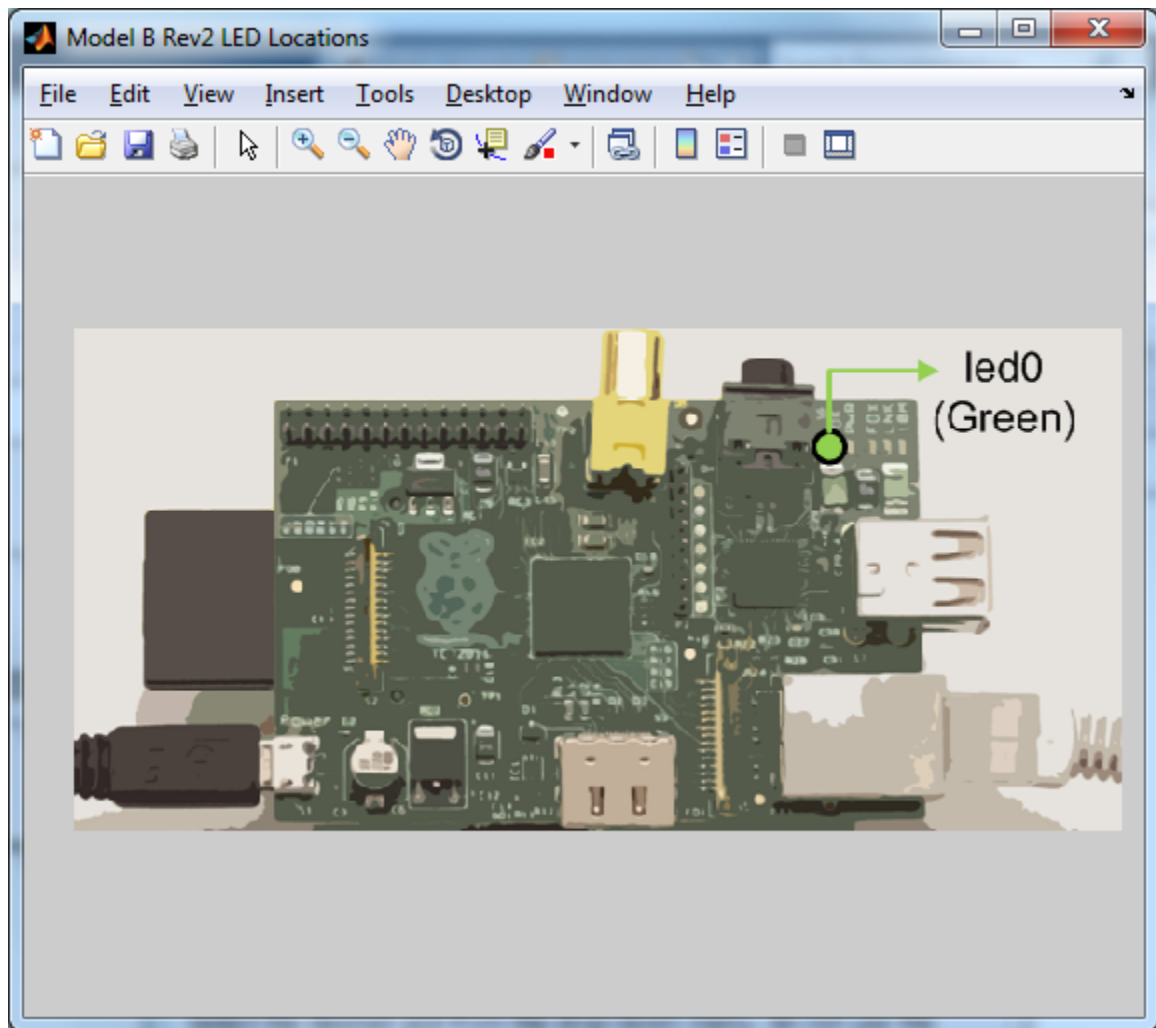

```
Supported peripherals
```

The `AvailableLEDs` property shows the name of the user-controllable LED.

Show the location of the user-controllable LED on the board.

```
showLEDs(myPi)
```

# showLEDs

Turn the specified LED on by setting its value to 1 or true.

```
writeLED(mypi, 'led0', 1)
```

Turn the LED off by setting its value to 0 or false.

```
writeLED(mypi, 'led0', false)
```

Rebooting the Raspberry Pi hardware returns the LED to its previous function as an activity indicator.

# showPins

---

**Purpose** Show diagram of GPIO pins

**Syntax** `showPins(myPi)`

**Description** `showPins(myPi)` displays a diagram of the digital input and output pins on the Raspberry Pi hardware. The diagram is a high-resolution MATLAB figure that supports zooming and panning.

**Input Arguments** **myPi - Connection to specific board**  
`handle`

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

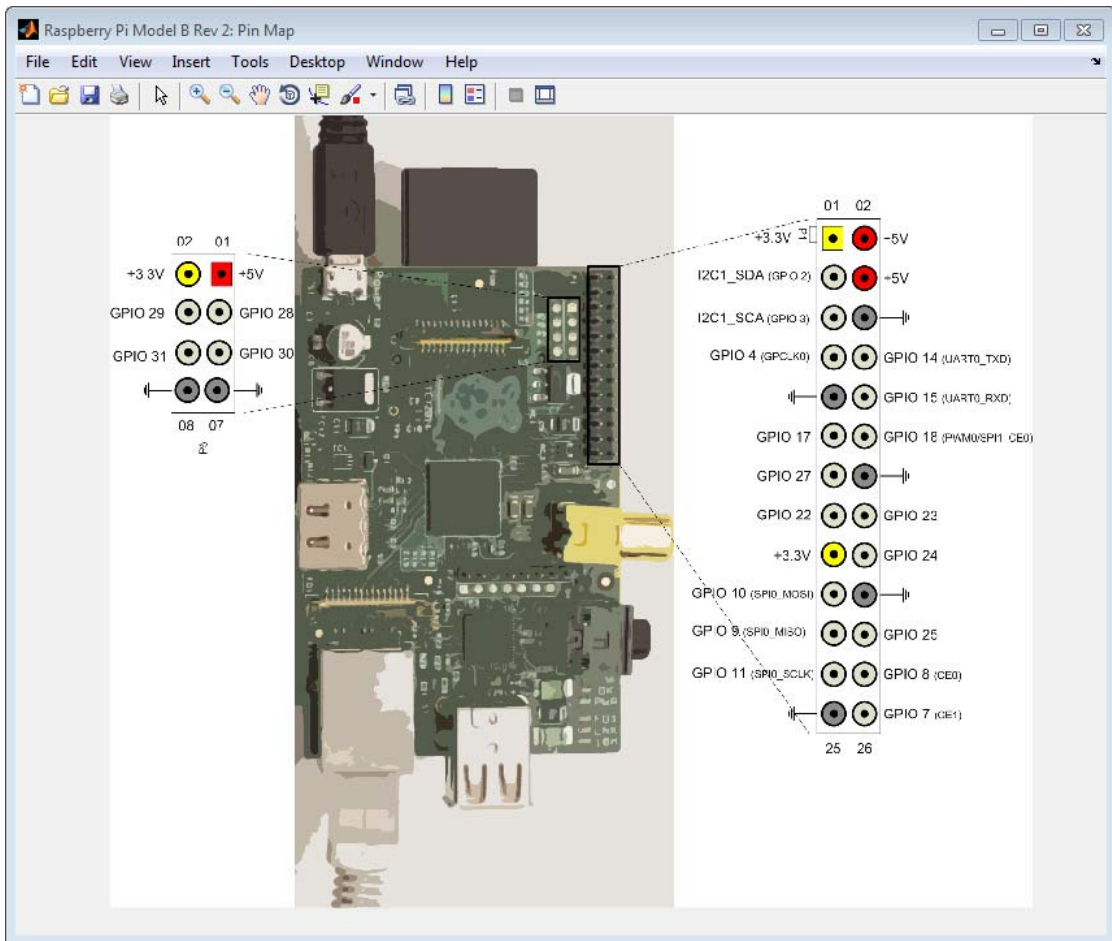

**Example:** `myPi`

**Examples** **Show a Diagram of Raspberry Pi Pins**

You can display a diagram with the name or purpose and location of each GPIO pin on your Raspberry Pi hardware.

Show the location of the pins.

`showPins(myPi)`

# snapshot

---

**Purpose** Capture RGB image from Camera Board

**Syntax** `img = snapshot(mycamera)`

**Description** `img = snapshot(mycamera)` returns a still image from the Camera Board in RGB format.

**Input Arguments** **mycamera - Connection to Camera Board**  
`handle`  
Connection to a Camera Board, specified as a handle.  
Use `cameraboard` to create this connection.  
**Example:** `mycam`

**Output Arguments** **img - RGB image**  
RGB image  
RGB image, returned as an n-by-n-by-3 matrix of values.

**Examples** **Use the Camera Board**

You can create a connection to the Camera Board, take a photograph, and record video.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Create a connection to the Camera Board while changing the resolution, and assign that connection to a handle, `mycam`. The handle displays the Camera Board properties.

```
mycam = cameraboard(mypi, 'Resolution', '1280x720')
```

```
mycam =
```

Cameraboard with Properties:

```

 Name: Camera Board
 Resolution: '1280x720' (View available resolutions)
 Quality: 10 (1 to 100)
 Rotation: 0 (0, 90, 180 or 270)
HorizontalFlip: 0
VerticalFlip: 0
 FrameRate: 30 (2 to 30)
 Recording: 0

Picture Settings
 Brightness: 50 (0 to 100)
 Contrast: 0 (-100 to 100)
 Saturation: 0 (-100 to 100)
 Sharpness: 0 (-100 to 100)

Exposure and AWB
 ExposureMode: 'auto' (View available exposure modes)
 ExposureCompensation: 0 (-10 to 10)
 AWBMode: 'auto' (View available AWB modes)
 MeteringMode: 'average' (View available metering modes)

Effects
 ImageEffect: 'none' (View available image effects)
 VideoStabilization: 'off'
 ROI: [0.00 0.00 1.00 1.00] (0.0 to 1.0 [top, left, width, height])

```

Import and display a sequence of ten snapshots on your host computer.

```

for ii = 1:10
img = snapshot(mycam);
 imagesc(img);
 drawnow;
end

```

If the image is upside down, change the orientation of the image.

```

mycam.Rotation = 180;

```

You can use the same approach to change the values of many mycamera properties listed in the "Name-Value Pair Arguments" for cameraboard.

Record a 60 second video.

```
record(mycam, 'myvideo.mp4', 60)
```

Stop recording before the 60 seconds have elapsed.

```
stop(mycam)
```

Copy the video from the board to your host computer.

```
getFile(myipi, 'myvideo.mp4', 'C:\MATLAB')
```

Delete the video file from the board to free up space.

```
deleteFile(myipi, 'myvideo.mp4')
```

**Purpose**

Create connection to SPI device

**Syntax**

```
mypidevice = spidev(mypi,channel)
mypidevice = spidev(mypi,channel,modespeed)
```

**Description**

`mypidevice = spidev(mypi,channel)` connects to an SPI device and returns a handle, `mypidevice`. You can exchange data with the SPI device by using `mypidevice` with the `writeRead` method. You can use `mypidevice` to read properties of the SPI device.

`mypidevice = spidev(mypi,channel,modespeed)` overrides the default SPI mode, 0, that many SPI devices use.

**Input Arguments****mypi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `mypi`

**channel - SPI channel**

'CE0' | 'CE1'

SPI channel, specified as a string.

**Example:** `'CE1'`

**Data Types**

char

**mode - SPI mode**

0 (default) | 1 | 2 | 3

SPI mode, specified as a scalar. This value determines the clock polarity (CPOL) and phase (CPHA) values.

Mode	CPOL	CPHA
0	0	0
1	0	1
2	1	0
3	1	1

The most common mode is 0.

**Example:** 0

### Data Types

double

### speed - SPI speed

500000 | 1000000 | 2000000 | 4000000 | 8000000 | 16000000 |  
32000000

SPI speed, specified as a scalar.

**Example:** 500000

### Data Types

char

## Output Arguments

### myspidevice - Connection to SPI device

handle

Connection to an SPI device, specified as a handle.

You can use `myspidevice` to exchange data with SPI devices using the `writeRead` method.

You can use `myspidevice` to read the following properties for the SPI connection.

Property Name	Data Type	Dimension	Units
Channel	char	[1,N]	
Mode	double	[1,1]	
BitsPerWord	double	[1,1]	Bits
Speed	double	[1,1]	Clock cycles

## Examples

### Connect and Exchange Data with SPI Devices

You can connect and exchange data with an SPI device.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```

 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

By default, SPI is disabled and `AvailableSPIChannels` does not show any channels.

Enable SPI and get the channels.

```
enableSPI(mypi);
```

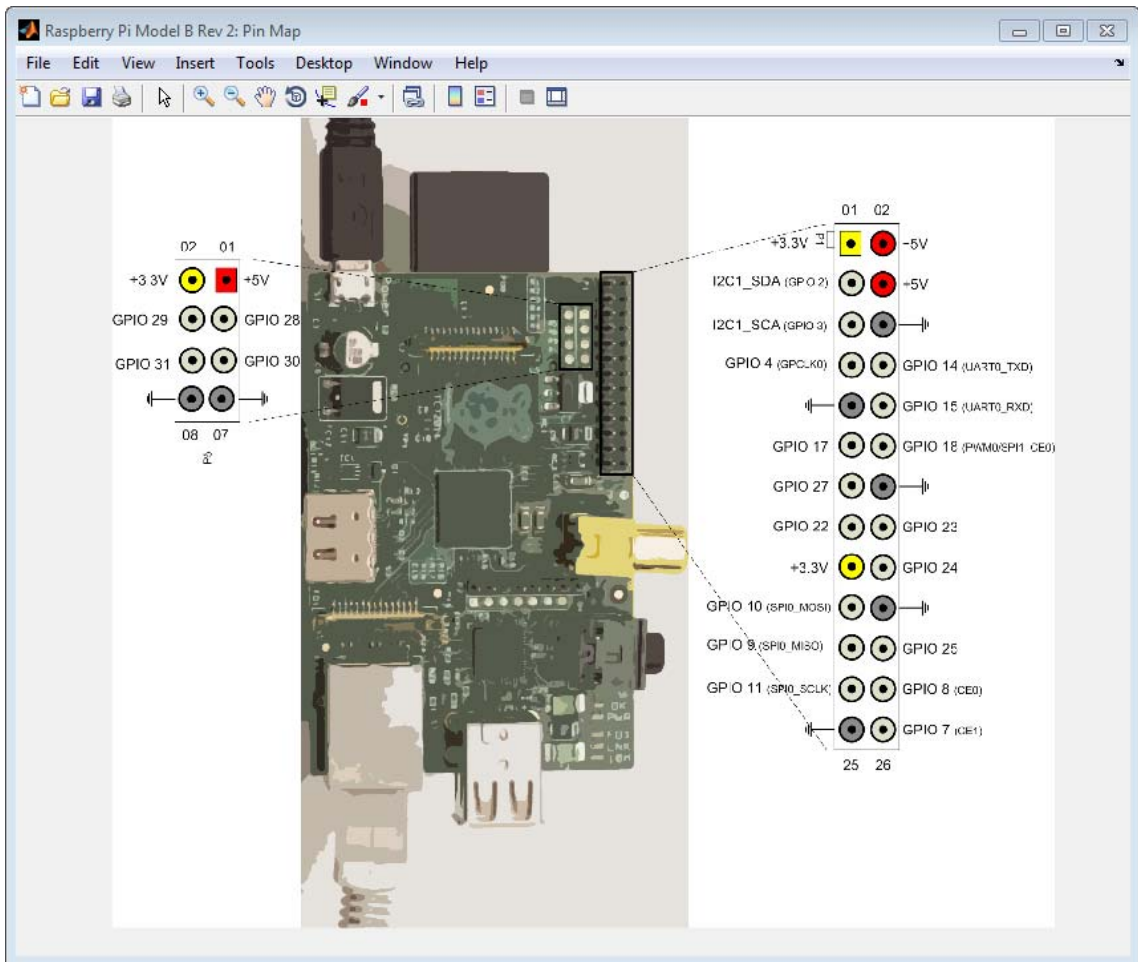

```
mypi.AvailableSPIChannels
```

```
ans =
```

```
 'CE0' 'CE1'
```

Show the location of the SPI pins, GPIO 10 (SPI0\_MOSI), GPIO 9 (SPI0\_MISO), and GPIO 11 (SPI0\_SCLK), on the GPIO header.

```
showPins(mypi)
```

After physically connecting your SPI device to the three SPI pins, connect to the SPI device.

```
myspidevice = spidev(my_pi, 'CE1', 0)
```

```
myspidevice =
```

```
Spidev with Properties:
 Channel: 'CE1'
 Mode: 0
 BitsPerWord: 8
 Speed: 500000
```

Write data to, and read data from, the SPI device.

```
out = writeRead(myspidevice,[hex2dec('08') hex2dec('D4')])
```

```
out =
 7 211
```

If you are not using SPI, disable SPI to make additional GPIO pins available.

```
disableSPI(mypi)
```

**Purpose** Stop video recording from Camera Board

**Syntax** `stop(mycamera)`

**Description** `stop(mycamera)` stops recording video from the Camera Board.

**Input Arguments**

**mycamera - Connection to Camera Board**  
`handle`

Connection to a Camera Board, specified as a handle.

Use `cameraboard` to create this connection.

**Example:** `mycam`

## Examples Use the Camera Board

You can create a connection to the Camera Board, take a photograph, and record video.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Create a connection to the Camera Board while changing the resolution, and assign that connection to a handle, `mycam`. The handle displays the Camera Board properties.

```
mycam = cameraboard(mypi, 'Resolution', '1280x720')
```

```
mycam =
```

```
Cameraboard with Properties:
```

```
 Name: Camera Board
Resolution: '1280x720' (View available resolutions)
 Quality: 10 (1 to 100)
 Rotation: 0 (0, 90, 180 or 270)
HorizontalFlip: 0
```

```
VerticalFlip: 0
FrameRate: 30 (2 to 30)

```

Import and display a sequence of ten snapshots on your host computer.

```
for ii = 1:10
img = snapshot(mycam);
imagesc(img);
drawnow;
end
```

If the image is upside down, change the orientation of the image.

```
mycam.Rotation = 180;
```

You can use the same approach to change the values of many `mycamera` properties listed in the "Name-Value Pair Arguments" for `cameraboard`.

Record a 60 second video.

```
record(mycam, 'myvideo.mp4', 60)
```

Stop recording before the 60 seconds have elapsed.

```
stop(mycam)
```

Copy the video from the board to your host computer.

```
getFile(mypi, 'myvideo.mp4', 'C:\MATLAB')
```

Delete the video file from the board to free up space.

```
deleteFile(mypi, 'myvideo.mp4')
```

# write

---

## Purpose

Write data to I2C device

## Syntax

```
write(myi2cdevice,data,dataPrecision)
```

## Description

`write(myi2cdevice,data,dataPrecision)` writes data to an I2C device.

The write method stops when it finishes writing the specified data to the device, or when the timeout period elapses.

## Input Arguments

### **myi2cdevice - Connection to I2C device**

handle

Connection to I2C device, specified as a handle.

Use `i2cdev` to create this connection.

**Example:** `myi2cdevice`

### **data - Data to write to I2C device**

data

Data to write to I2C device, specified as vector of hexadecimal values.

**Example:** `[hex2dec('20') hex2dec('51')]`

### **Data Types**

`int8` | `int16` | `uint8` | `uint16`

### **dataPrecision - Data precision**

`'uint8 (default)'` | `'int8'` | `'int16'` | `'uint16'`

Data precision, specified as a string. Match the data precision to the size of the register on the device. Optional.

**Example:** `'int16'`

### **Data Types**

`char`

## Examples

### Connect and Exchange Data with I2C Devices

You can connect and exchange data with a pair of I2C devices.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```

 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
 AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
 AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

Redisplay AvailableI2CBuses and I2CBusSpeed.

```
mypi.AvailableI2CBuses
```

```
mypi.I2CBusSpeed
```

```
ans =
```

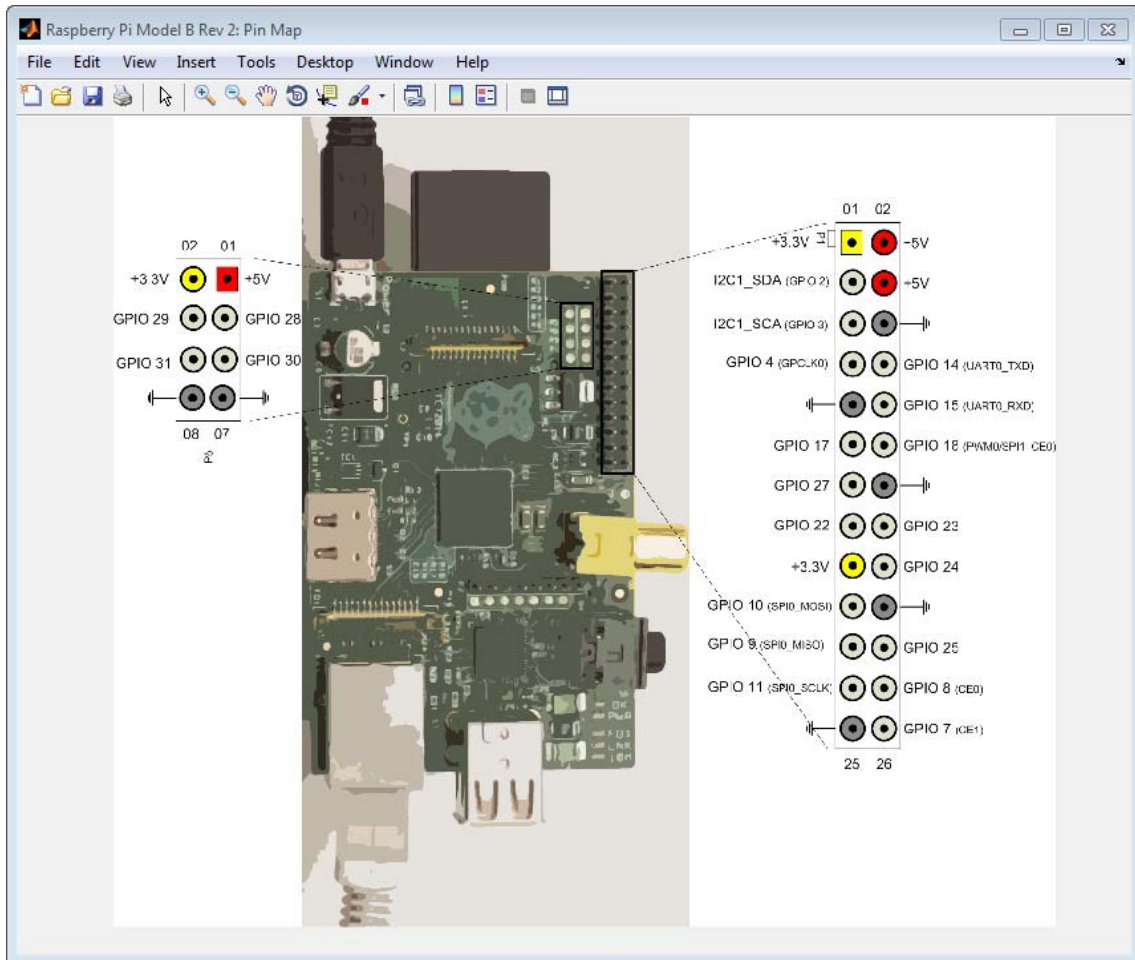

```
'i2c-0' 'i2c-1'
```

```
ans =
```

```
100000
```

Show the location of the I2C pins.

```
showPins(myPi)
```

The pin map shows that, for this model and revision of the board, the i2c-1 bus is available on the GPIO header pins I2C1\_SDA (GPIO 2) and I2C1\_SCL (GPIO 3).

After physically connecting your I2C device to the I2C pins, get the addresses of I2C devices attached to the I2C bus, 'i2c-1'.

```
scanI2CBus(mypi, 'i2c-1')
```

```
ans =
```

```
 {'0x55', '0x20'}
```

Create a connection to the I2C sensor at '0x20' and assign that connection to a handle, `i2csensor`.

```
i2csensor = i2cdev(mypi, 'i2c-1', '0x20')
```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two uint8 numbers from the sensor.

```
output1 = read(i2csensor,2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor,14);
```

Create a connection to the I2C LED display at '0x55' and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

# write

---

```
I2CAddress: 0x55
TimeOut: 10
```

Write characters to the display.

```
write(i2cdisplay,[hex2dec('20') hex2dec('51')]);
```

Write a scalar hexadecimal value, `hex2dec('08')`, to register 3 on an I2C device.

```
writeRegister(i2cdisplay,3,hex2dec('08'),'uint8');
```

If you are not using I2C, disable I2C to make additional GPIO pins available.

```
disableI2C(mypi)
```

When you use I2C again, enable I2C.

```
enableI2C(mypi)
```

You can only change the `mypi.I2CBusSpeed` property when you enable I2C.

```
disableI2C(mypi);
enableI2C(mypi,400000);
mypi.I2CBusSpeed
```

```
ans =
```

```
40000
```

## Related Examples

- “Open Interactive Examples”

<b>Purpose</b>	Write data to serial device
<b>Syntax</b>	<code>write(myserialdevice,data,precision)</code>
<b>Description</b>	<code>write(myserialdevice,data,precision)</code> The write method stops when it finishes writing the specified data to the device, or when the timeout period elapses.
<b>Input Arguments</b>	<p><b>myserialdevice - Connection to serial device</b> handle Connection to a serial device, specified as a handle. Use serialdev to create this connection. <b>Example:</b> myserialdevice</p> <p><b>data - Data to write to serial device</b> data Data to write to the serial device, specified as a vector. <b>Example:</b> [10 12]</p> <p><b>Data Types</b> single   double   int8   int16   int32   uint8   uint16   uint32   char</p> <p><b>precision - Data precision</b> 'uint8' (default)   'uint16'   'uint32'   'int8'   'int16'   'int32'   'char' (default)   'single'   'double'</p> <p>Data precision, specified as a string. Optional. <b>Example:</b> 'uint8'</p> <p><b>Data Types</b> char</p>

## Examples

### Connect and Exchange Data with Serial Device

You can create a connection to a serial device, write data to the device, and read data from the device.

Create a connection to the Raspberry Pi board.

```
mypi = raspi;
```

Show the location of the Tx and Rx pins, GPIO 14 (UART0\_TXD) and GPIO 15 (UART0\_RXD), on the GPIO header.

```
showPins(mypi)
```

Raspberry Pi hardware uses +3.3V. Do not connect Raspberry Pi hardware directly to devices that use higher voltages.

Connect the Raspberry Pi serial port to a +3.3V serial device.

- To receive data, connect the RXD pin (GPIO 15 UART0\_RXD) on the Raspberry Pi board to the TXD pin on the serial device.

- To transmit data, connect the TXD pin (GPIO 14 UART0\_TXD) on the Raspberry Pi board to the RXD pin on the serial device.
- Connect a ground pins (GND) on the Raspberry Pi board to the GND pin on the serial device.
- Connect one of the +3.3V pins on the Raspberry Pi board to the VCC pin on the serial device.

Research the values the serial device requires for the baud rate, data bits, parity, and stop bit.

Use `serialdev` to create a connection to the serial device and assign the connection to a handle.

```
myserialdevice = serialdev(mypi, '/dev/ttyAMA0', 9600)
```

```
myserialdevice =
```

```
 Serialdev with Properties:
```

```
 BaudRate: 9600
 DataBits: 8
 Parity: 'none'
 StopBits: 1
 Timeout: 10
```

Write a pair of values to a serial device that requires a specific data type.

```
write(myserialdevice, [10 12], 'uint16')
```

Read a 100-element array of numbers from the serial port.

```
output = read(myserialdevice, 100, 'uint16');
```

Increase the timeout period of the serial port.

```
myserialdevice.Timeout = 20
```

```
myserialdevice =
```

Serialdev with Properties:

```
BaudRate: 115200
DataBits: 8
Parity: 'none'
StopBits: 1
Timeout: 20
```

# writeDigitalPin

---

**Purpose** Write logical value to GPIO output pin

**Syntax** `writeDigitalPin(myPi, pinNumber, value)`

**Description** `writeDigitalPin(myPi, pinNumber, value)` sets the logical value of a GPIO pin to 0 or 1.

This method configures an unconfigured pin as a GPIO output.

If the pin is a GPIO input, or if another interface (I2C, Serial, SPI) is using the pin, this method returns an error message.

## Input Arguments

### **myPi - Connection to specific board**

handle

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `myPi`

### **pinNumber - GPIO pin number**

pin number

GPIO pin number, specified as a scalar. This argument does not accept vectors because the hardware cannot access multiple pins simultaneously.

To get a list of valid pin numbers, enter `myPi.AvailableDigitalPins`.

**Example:** `12`

### **Data Types**

double

### **value - Logical value of pin**

0 | 1

Logical value of the pin, specified as a scalar.

**Example:** `1`

**Data Types**

double | logical

**Examples****Configure Pin as Digital Output and Write Its Logical Value**

You can configure a pin as digital output and write its logical value.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```

 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

The `AvailableDigitalPins` property shows the list of digital pins that are available.

Redisplay `AvailableDigitalPins`.

```
mypi.AvailableDigitalPins
```

```
ans =
```

```
Columns 1 through 13
```

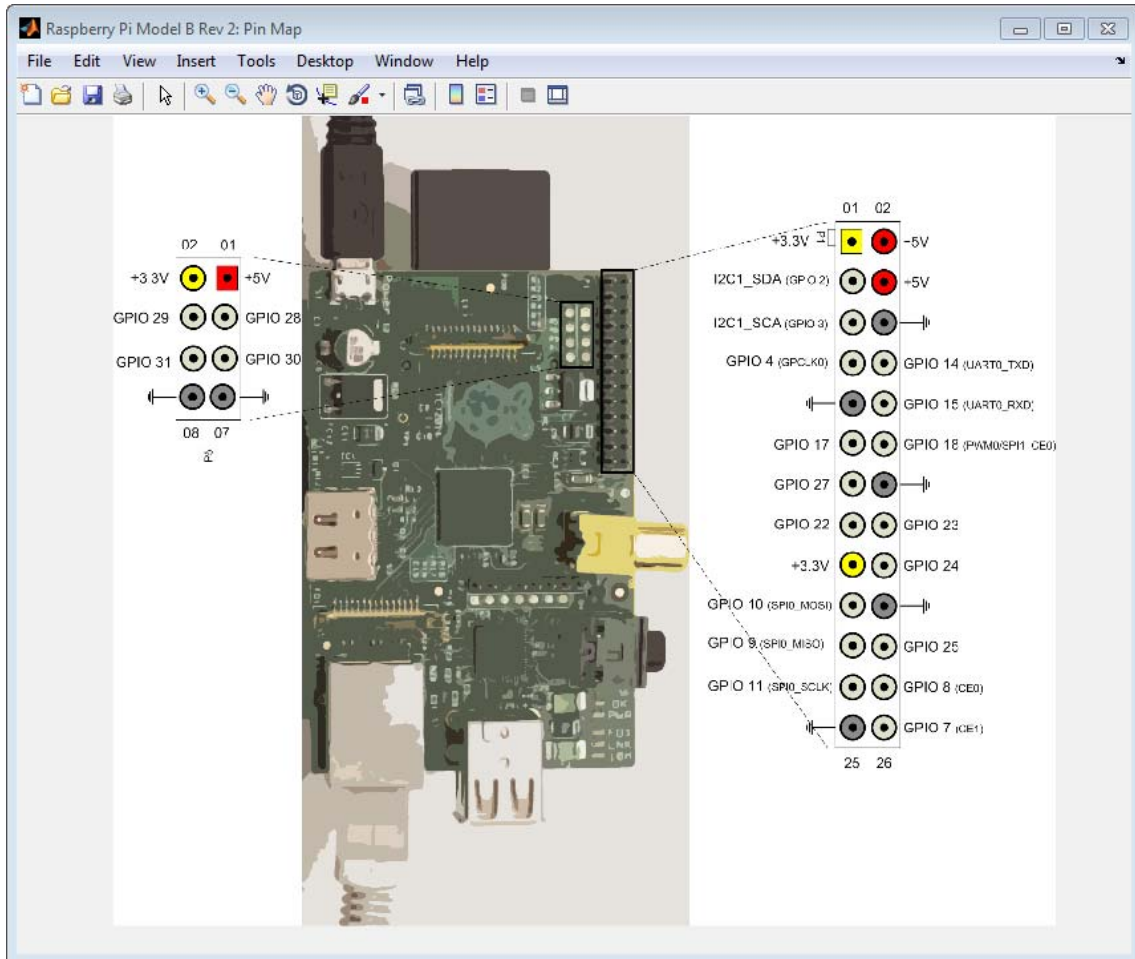

```
 4 7 8 9 10 11 14 15 17 18 22 23 24
```

```
Columns 14 through 17
```

25 27 30 31

Show the location of the GPIO 4.

```
showPins(myPi)
```

Connect the digital device you are using to GPIO 4.

Configure pin 4 as a digital output.

```
configureDigitalPin(mypi,4,'output')
```

Write a logical value of 1 to pin 4.

```
writeDigitalPin(mypi,4,1)
```

## Pressing a button blinks an LED connected to a GPIO pin

You can press a button to blink an LED connected to a GPIO pin.

This example rapidly blinks an LED when you press a button. The button connects from positive voltage to pin 23. Pressing the button closes the circuit, raising the voltage. When `readDigitalPin` detects the positive voltage, `if buttonPressed` becomes true. The program toggles the voltages to pin 24 on and off ten times. Pin 14 connects to an LED, which connects via a resistor to ground.

```
for ii = 1:100
 buttonPressed = readDigitalPin(mypi,23);
 if buttonPressed
 for jj = 1:10
 writeDigitalPin(mypi,24,1);
 pause(0.05);
 writeDigitalPin(mypi,24,0);
 pause(0.05);
 end
 end
 pause(0.1);
end
```

## See Also

"Raspberry Pi Hardware"

## Related Examples

- "Open Interactive Examples"

# writeLED

---

**Purpose** Turn LED on or off

**Syntax** `writeLED(mypi,led,value)`

**Description** `writeLED(mypi,led,value)` overrides the default behavior of the LED and turns it on or off.

## Input Arguments

### **mypi - Connection to specific board**

`handle`

Connection to a specific board, specified as a handle.

Use `raspi` to create this connection.

**Example:** `mypi`

### **led - LED name**

`'led0'`

LED name, specified as a string.

To get the name and location of user-controllable LEDs, use `showLEDs`.

**Example:** `'led0'`

### **Data Types**

`char`

### **value - LED off or on**

`0 | 1 | false | true`

LED off or on, specified as a logical value.

**Example:** `0`

### **Data Types**

`logical`

## Examples

### **Control the On-Board LED**

You can locate and control the on-board LED, turning it on and off.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```
 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000
```

```
Supported peripherals
```

The `AvailableLEDs` property shows the name of the user-controllable LED.

Show the location of the user-controllable LED on the board.

```
showLEDs(mypi)
```

# writeLED

Turn the specified LED on by setting its value to 1 or true.

```
writeLED(mypi, 'led0', 1)
```

Turn the LED off by setting its value to 0 or false.

```
writeLED(mypi, 'led0', false)
```

Rebooting the Raspberry Pi hardware returns the LED to its previous function as an activity indicator.

### Flash the LED in Response to an Input

You can flash the LED in response to an input signal on one of the GPIO pins.

For example, you could use a button and a resistor in series to connect one of the +3.3V outputs to GPIO 23. When you press the button, `readDigitalPin` reads the positive voltage, `if` `buttonPressed` becomes true, and the program flashes the LED ten times.

```
for ii = 1:100
 buttonPressed = readDigitalPin(mypi, 23);
 if buttonPressed
 for jj = 1:10
 writeLED(mypi, 'led0', 1);
 pause(0.05);
 writeLED(mypi, 'led0', 0);
 pause(0.05);
 end
 end
 pause(0.1);
end
```

# writeRead

---

**Purpose** Write data to and read data from SPI device

**Syntax** [outputData] = writeRead(myspidevice,data,dataPrecision)

**Description** [outputData] = writeRead(myspidevice,data,dataPrecision) writes new data to, and reads existing data from, an SPI device.

To read data from an SPI device, you must write data to the device. Supply the `data` argument with the number of values that you expect to read.

The `writeRead` method stops when it finishes writing and reading the specified data from the device.

This method converts data of all other data types to `uint8` for transmission.

## Input Arguments

### **myspidevice - Connection to SPI device**

handle

Connection to an SPI device, specified as a handle.

Use `spidev` to create this connection.

**Example:** `myspidevice`

### **data - Data to write to SPI device**

data

Data to write to the SPI device, or the number of values to read from the SPI device, specified as a vector of hexadecimal values.

**Example:** `[hex2dec('08'), hex2dec('D4')]`

### **Data Types**

`int8` | `int16` | `int32` | `uint8` | `uint16` | `uint32`

### **dataPrecision - Data precision**

`'uint8'` (default) | `'uint16'`

Data precision, specified as a string. Optional.

The `writeRead` method converts data to the data type specified by this argument.

Most SPI devices use `uint8`. Some SPI devices, such as EEPROMs, use `uint16`.

**Example:** `'uint8'`

### Data Types

`char`

## Output Arguments

### **outputData** - Data from SPI device

output data

Data from SPI device, returned as a row vector.

## Examples

### **Connect and Exchange Data with SPI Devices**

You can connect and exchange data with an SPI device.

Create a connection to the Raspberry Pi board.

```
mypi = raspi
```

```
mypi =
```

```
Raspi with Properties:
```

```

 DeviceAddress: 'raspberrypi-computername'
 Port: 18725
 BoardName: 'Raspberry Pi Model B Rev 2'
 AvailableLEDs: {'led0'}
AvailableDigitalPins: [4 7 8 9 10 11 14 15 17 18 22 23 24 25 27 30 31]
AvailableSPIChannels: {}
 AvailableI2CBuses: {'i2c-0' 'i2c-1'}
 I2CBusSpeed: 100000

```

```
Supported peripherals
```

By default, SPI is disabled and `AvailableSPIChannels` does not show any channels.

Enable SPI and get the channels.

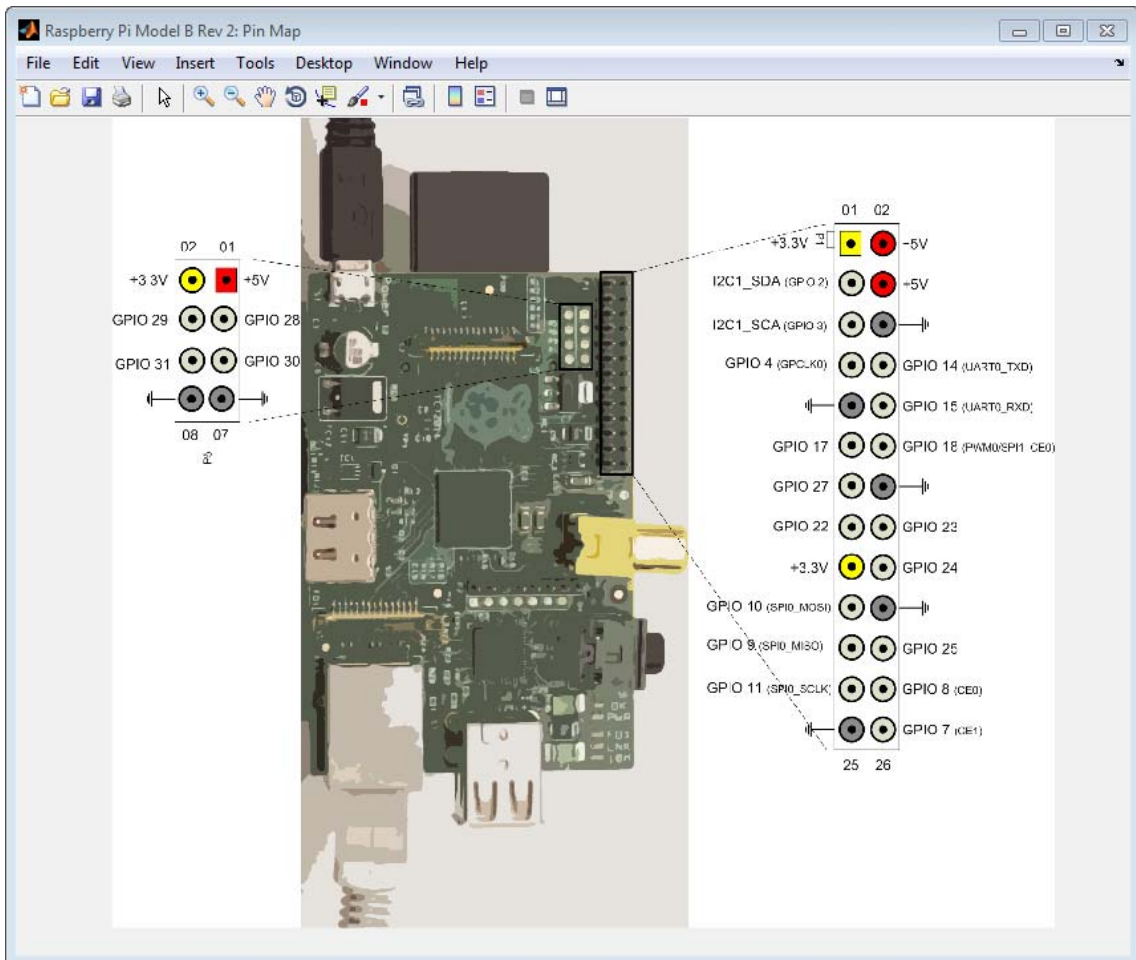

```
enableSPI(myPi);
myPi.AvailableSPIChannels
```

```
ans =
```

```
 'CE0' 'CE1'
```

Show the location of the SPI pins, GPIO 10 (SPI0\_MOSI), GPIO 9 (SPI0\_MISO), and GPIO 11 (SPI0\_SCLK), on the GPIO header.

```
showPins(myPi)
```

After physically connecting your SPI device to the three SPI pins, connect to the SPI device.

```
myspidevice = spidev(my_pi, 'CE1', 0)
```

```
myspidevice =
```

# writeRead

---

```
Spidev with Properties:
 Channel: 'CE1'
 Mode: 0
 BitsPerWord: 8
 Speed: 500000
```

Write data to, and read data from, the SPI device.

```
out = writeRead(myspidevice,[hex2dec('08') hex2dec('D4')])
```

```
out =
 7 211
```

If you are not using SPI, disable SPI to make additional GPIO pins available.

```
disableSPI(mypi)
```

```

```
i2csensor =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x20
```

```
 TimeOut: 10
```

Read two uint8 numbers from the sensor.

```
output1 = read(i2csensor, 2);
```

Read the value of register 14 from the sensor

```
output2 = readRegister(i2csensor, 14);
```

Create a connection to the I2C LED display at '0x55' and assign that connection to a handle, `i2cdisplay`.

```
i2cdisplay = i2cdev(mypi, 'i2c-1', '0x55')
```

```
i2cdisplay =
```

```
I2C with Properties:
```

```
 Bus: i2c-1
```

```
 I2CAddress: 0x55
```

```
 TimeOut: 10
```

# writeRegister

---

Write characters to the display.

```
write(i2cdisplay,[hex2dec('20') hex2dec('51')]);
```

Write a scalar hexadecimal value, `hex2dec('08')`, to register 3 on an I2C device.

```
writeRegister(i2cdisplay,3,hex2dec('08'),'uint8');
```

If you are not using I2C, disable I2C to make additional GPIO pins available.

```
disableI2C(mypi)
```

When you use I2C again, enable I2C.

```
enableI2C(mypi)
```

You can only change the `mypi.I2CBusSpeed` property when you enable I2C.

```
disableI2C(mypi);
enableI2C(mypi,400000);
mypi.I2CBusSpeed
```

```
ans =
```

```
40000
```

# Functions — Alphabetical List

---

# supportPackageInstaller

---

**Purpose** Find and install support for third-party hardware or software

**Syntax** supportPackageInstaller

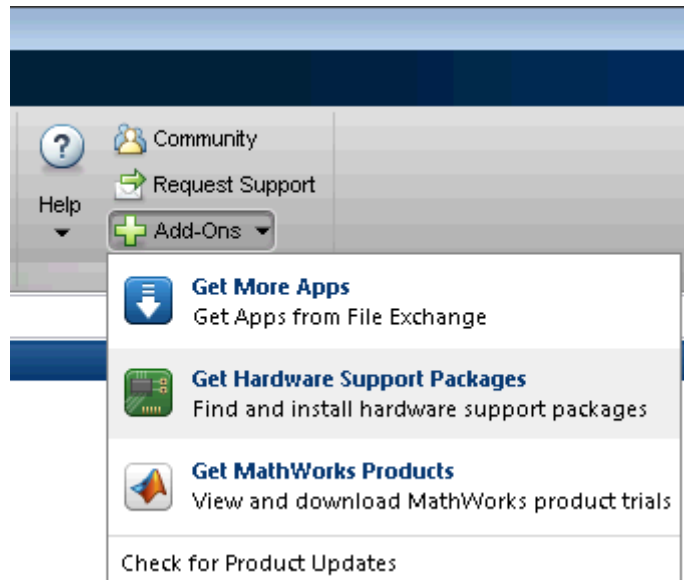

**Description** The supportPackageInstaller function opens *Support Package Installer*.

Support Package Installer can install *support packages*, which add support for specific third-party hardware or software to specific MathWorks products.

To see a list of available support packages, run Support Package Installer and advance to the second screen.

You can also start Support Package Installer in one of the following ways:

- On the MATLAB toolstrip, click **Add-Ons > Get Hardware Support Packages**.

- Double-click a support package installation file (\*.mlpkginstall).

`matlabshared.supportpkg.getInstalled`

# targetupdater

---

**Purpose** Open Support Package Installer and update firmware on third-party hardware

## Syntax

**Description** The targetupdater function skips over the support package installation screens and opens Support Package Installer at the “Update firmware” screen. You can use this function to update the firmware on hardware without repeating the support package installation process.

---

**Tip** Use this function when you have multiple pieces of hardware.

---

The targetupdater function is only available for support packages that have already been installed and that require special firmware or setup steps.

If the **Hardware** parameter does not present an option for your hardware, use the supportPackageInstaller function to open Support Package Installer. Support Package Installer will guide you through the process of installing a support package for your hardware and, if required, updating the firmware.

matlabshared.supportpkg.checkForUpdate |  
matlabshared.supportpkg.getInstalled

# matlabshared.supportpkg.checkForUpdate

---

## Purpose

Get information about installed support packages

## Syntax

```
matlabshared.supportpkg.checkForUpdate
info = matlabshared.supportpkg.checkForUpdate
```

## Description

`matlabshared.supportpkg.checkForUpdate` displays information about support package updates in the MATLAB Command Window. If an update is available, use `supportPackageInstaller` to install the updates.

`info = matlabshared.supportpkg.checkForUpdate` returns a structured array of information about installed support packages.

## Output Arguments

### **info - Return argument from function**

structure created using `matlabshared.supportpkg.checkForUpdate`

Information about support package updates, returned as a structured array.

## Examples

### **Check for support package updates**

```
matlabshared.supportpkg.checkForUpdate
```

```
No support packages need updates.
```

If one or more updates are available, the command line displays that information in the response.

### **Get a structured array of support package updates**

```
info = matlabshared.supportpkg.checkForUpdate
```

```
info =
```

```
 Name: 'Arduino'
InstalledVersion: '3.0'
 BaseProduct: 'Simulink'
```

# matlabshared.supportpkg.checkForUpdate

# matlabshared.supportpkg.getInstalled

---

## Purpose

Get information about installed support packages

## Syntax

```
matlabshared.supportpkg.getInstalled
info = matlabshared.supportpkg.getInstalled
```

## Description

matlabshared.supportpkg.getInstalled displays information about installed support packages in the MATLAB Command Window.

info = matlabshared.supportpkg.getInstalled returns a structured array of information about installed support packages.

## Output Arguments

### info - Return argument from function

structure created using matlabshared.supportpkg.getInstalled

Information about installed support packages, returned as a structured array.

## Examples

### Get a list of installed support packages

```
matlabshared.supportpkg.getInstalled
```

```
Name Version Base Product

Arduino 3.0 Simulink
```

### Get a structured array of installed support packages

```
info = matlabshared.supportpkg.getInstalled
```

```
info =
```

```
 Name: 'Arduino'
InstalledVersion: '3.0'
 BaseProduct: 'Simulink'
```
