$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:

```
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])
```

$$\begin{pmatrix} 1.0 & 1.0i & 3.0+1.0i \\ 3.141592654i & 4.0 & 5.0 \end{pmatrix}$$

`transpose(A) <> htranspose(A)`

$$\begin{pmatrix} 1.0 & 3.141592654i \\ 1.0i & 4.0 \\ 3.0+1.0i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654i \\ -1.0i & 4.0 \\ 3.0-1.0i & 5.0 \end{pmatrix}$$

`delete A:`

Example 2

We compute the product $A^H A$ of a matrix given by a hardware float array. This data type allows matrix multiplication using the operator `*`:

`A := hfarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])`

$$\begin{pmatrix} 1.0 & 1.0i & 3.0 \\ 3.141592654i & 4.0 & 5.0+1.0i \end{pmatrix}$$

`AH:= htranspose(A)`

$$\begin{pmatrix} 1.0 & -3.141592654i \\ -1.0i & 4.0 \\ 3.0 & 5.0-1.0i \end{pmatrix}$$

The product $A^H A$ is Hermitian:

`AH*A = htranspose(AH*A)`

transpose

$$\begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix} = \begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix}$$

delete A, AH:

Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

delete A, B:
`transpose(A) + 2*htranspose(B)`

$$2 \bar{B}^t + A^t$$

Parameters

A

A matrix: either a 2-dimensional array, a 2-dimensional hfarray, or an object of the category `Cat::Matrix`

Return Values

Matrix of the same domain type as A.

Overloaded By

A

MuPAD Functions

[htranspose](#) | [linalg::transpose](#) | [linalg::htranspose](#)

Concepts

- “Transpose Matrices”

htranspose

Purpose The Hermitian transpose of a matrix

Syntax `htranspose(A)`

Description `htranspose(A)` returns the Hermitian transpose A^H of the matrix A (the complex conjugate of the transpose of A).

The Hermitian transpose of the $m \times n$ matrix A is the $n \times m$ matrix B

with $B_{j,i} = \overline{A_{i,j}}$.

If the input is a matrix of category `Cat::Matrix`, then `linalg::htranspose` is called to compute the result. In contrast to the `linalg` routines, the function `htranspose` also operates on arrays and `hfarrays`.

If the argument does not evaluate to a matrix of one of the types mentioned above, symbolic call `htranspose(A)` is returned.

Examples

Example 1

The following matrix is real. Thus, the Hermitian transpose coincides with the transpose:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & \pi \end{pmatrix}$$

```
transpose(A) = htranspose(A)
```

$$\begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix} = \begin{pmatrix} 1 & 3 \\ 2 & \pi \end{pmatrix}$$

In general, this does not hold for complex matrices:

```
A := hfarray(1..2, 1..3, [[1, I, 3 + I], [PI*I, 4, 5]])
```

$$\begin{pmatrix} 1.0 & 1.0i & 3.0+1.0i \\ 3.141592654i & 4.0 & 5.0 \end{pmatrix}$$

`transpose(A) <> htranspose(A)`

$$\begin{pmatrix} 1.0 & 3.141592654i \\ 1.0i & 4.0 \\ 3.0+1.0i & 5.0 \end{pmatrix} \neq \begin{pmatrix} 1.0 & -3.141592654i \\ -1.0i & 4.0 \\ 3.0-1.0i & 5.0 \end{pmatrix}$$

`delete A:`

Example 2

We compute the product $A^H A$ of a matrix given by a hardware float array. This data type allows matrix multiplication using the operator `*`:

`A := hffarray(1..2, 1..3, [[1, I, 3], [PI*I, 4, 5 + I]])`

$$\begin{pmatrix} 1.0 & 1.0i & 3.0 \\ 3.141592654i & 4.0 & 5.0+1.0i \end{pmatrix}$$

`AH:= htranspose(A)`

$$\begin{pmatrix} 1.0 & -3.141592654i \\ -1.0i & 4.0 \\ 3.0 & 5.0-1.0i \end{pmatrix}$$

The product $A^H A$ is Hermitian:

`AH*A = htranspose(AH*A)`

htranspose

$$\begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix} = \begin{pmatrix} 10.8696044 & -11.56637061 i & 6.141592654 - 15.70796327 i \\ 11.56637061 i & 17.0 & 20.0 + 1.0 i \\ 6.141592654 + 15.70796327 i & 20.0 - 1.0 i & 35.0 \end{pmatrix}$$

delete A, AH:

Example 3

If the input does not evaluate to a matrix, then symbolic calls are returned:

delete A, B:
`transpose(A) + 2*htranspose(B)`

$$2 \bar{B}^t + A^t$$

Parameters

A

A matrix: either a 2-dimensional array, a 2-dimensional hfarray, or an object of the category `Cat::Matrix`

Return Values

Matrix of the same domain type as A.

Concepts

- “Transpose Matrices”

traperror

Purpose

Trap errors

Syntax

```
traperror(object)
traperror(object, t)
traperror(object, MaxSteps = s)
```

Description

`traperror(object)` traps errors produced by the evaluation of `object`.

`traperror(object, t)` does the same. Moreover, it stops the evaluation if it is not finished after a real time of `t` seconds.

`traperror` traps errors caused by the evaluation of the object. Syntactical errors, i.e., errors on parsing the object, cannot be caught. The same holds true for fatal errors causing the termination of MuPAD.

`traperror` returns the error code 0 if no error happened. The error code is 1320 if the given time limit `t` is exceeded (“Execution time exceeded”) and 1321 if the given number of “execution steps” is exceeded. The error code is 1028 if the error was raised by the command error.

If `traperror` is called with a numerical second argument, this number is taken as a time limit, measured in seconds, of “process time” (see the documentation of the `time` function for a discussion of this term).

When using the option `MaxSteps = s`, the caller sets a time limit which is not system-dependent, but rather measured in terms of MuPAD evaluation steps.

The number `s` does *not* refer directly to evaluation steps, but rather to a fixed (large) number of steps which may change from one MuPAD release to the next, but is fixed within one release. The number `s` is twice the number of outputs caused by `Pref::report(9)` for a calculation using the maximum time allowed.

If `traperror` has no time limit set and an “Execution time exceeded” error is raised by an enclosing `traperror(..., t)` command, then this error is not trapped by the inner `traperror`. It is trapped by the `traperror` call that has set the time limit. Cf. “Example 5” on page 1-2185.

The object can be an assignment which, for syntactical reasons, must be enclosed in additional brackets. The following code fragment demonstrates a typical application of traperror:

```
if traperror((x := SomeErrorProneFunction())) = 0 then
    DoSomethingWith(x);
else RespondToTheError();
end_if;
```

Use lasterror to reproduce the trapped error.

Examples

Example 1

Errors that happen during the execution of kernel functions have various error codes, depending on the problem. E.g., “Division by zero” produces the error code 1025:

```
y := 1/x: traperror(subs(y, x = 0))
```

```
1025
```

```
lasterror()
```

```
Error: Division by zero. [_power]
```

Example 2

All errors raised using the function error have the error code 1028. Errors during the execution of library functions are of this kind:

```
traperror(error("My error!"))
```

```
1028
```

```
lasterror()
```

```
Error: My error!
```

Example 3

We try to factor a polynomial, but give up after ten seconds:

```
traperror(factor(x^1000 + 4*x + 1), 10)
```

```
1320
```

```
lasterror()
```

```
Error: Execution time exceeded; Evaluating:  
faclib::univ_mod_gcd
```

Example 4

For use inside other routines, it is preferable to use `MaxSteps` instead of a time limit, to achieve consistent results across slower and faster machines:

```
traperror(factor(x^1000 + 4*x + 1), MaxSteps=10)
```

```
1321
```

```
lasterror()
```

```
Error: Execution MaxSteps exceeded [traperror];  
Evaluating: faclib::ddf
```

Note that evaluation steps may take vastly different amounts of time, so even on the same machine, different expressions evaluated with the same value of `MaxSteps` may be terminated after very different lengths of time:

```
time(traperror(factor(x^1000 + 4*x + 1), MaxSteps=1));
time(traperror(while TRUE do 1 end_while, MaxSteps=1));
time(traperror(int(1/sqrt(1/r-1/r0), r=0..r0), MaxSteps=1))
```

2204

40

468

Example 5

Here we have two nested `traperror` calls. The inner call contains an unterminated loop and the outer call has a time limit of 2 seconds. When the execution time is exceeded, this special error is not trapped by the inner `traperror` call. Because of the error, `print(1)` is never executed:

```
traperror((traperror((while TRUE do 1 end)); print(1)), 2)
```

1320

```
lasterror()
```

```
Error: Execution time is exceeded.
```

Parameters

object

Any MuPAD object

t

The time limit: a positive integer

s

The execution limit: a positive integer

traperror

Return Values

Nonnegative integer.

MuPAD Functions

`getlasterror` | `error` | `lasterror`

Purpose Triangular pulse function

Syntax `triangularPulse(a, b, c, x)`
`triangularPulse(a, c, x)`

Description `triangularPulse(a, b, c, x)` represents the triangular function.
`triangularPulse(a, c, x)` is a shortcut for `triangularPulse(a, (a + c)/2, c, x)`.

`triangularPulse(x)` is a shortcut for `triangularPulse(-1, 0, 1, x)`.

`triangularPulse` represents the triangular pulse function. This function is also called the triangle function, hat function, tent function, or sawtooth function.

If `a`, `b`, and `c` are variables or expressions with variables, `triangularPulse` assumes that $a \leq b \leq c$. If `a`, `b`, and `c` are numerical values that do not satisfy this condition, `triangularPulse` throws an error.

If $a < x < b$, the triangular function equals $(x - a) / (b - a)$.

If $b < x < c$, the triangular function equals $(c - x) / (c - b)$.

Otherwise, it equals 0. See “Example 1” on page 1-2188 and “Example 2” on page 1-2188.

If $a = b$ or $b = c$, the triangular function can be expressed in terms of the rectangular function. See “Example 3” on page 1-2188.

If $a = b = c$, `triangularPulse` returns 0. See “Example 4” on page 1-2189.

`triangularPulse(x)` is equivalent to `triangularPulse(-1, 0, 1, x)`. See “Example 5” on page 1-2189.

`triangularPulse(a, c, x)` is equivalent to `triangularPulse(a, (a + c)/2, c, x)`. See “Example 6” on page 1-2189.

`triangularPulse` also accepts infinities as its arguments. See “Example 9” on page 1-2191.

triangularPulse

triangularPulse and tripulse are equivalent.

Examples

Example 1

Compute the triangular pulse function for these input arguments:

```
[triangularPulse(-2, 0, 2, -3), triangularPulse(-2, 0, 2, -1/2),  
triangularPulse(-2, 0, 2, 0), triangularPulse(-2, 0, 2, 3/2),  
triangularPulse(-2, 0, 2, 3)]
```

```
[0, 3/4, 1, 1/4, 0]
```

Example 2

Compute the triangular pulse function for $a < x < b$:

```
triangularPulse(a, b, c, x) assuming a < x < b
```

$$\frac{a-x}{a-b}$$

Compute the triangular pulse function for $b < x < c$:

```
triangularPulse(a, b, c, x) assuming b < x < c
```

$$-\frac{c-x}{b-c}$$

Example 3

Compute the triangular pulse function for $a = b$ and $c = b$:

```
triangularPulse(b, b, c, x) assuming b < c
```

$$\frac{(c-x) \text{rectangularPulse}(b, c, x)}{b-c}$$

`triangularPulse(a, b, b, x)` assuming $a < b$

$$\frac{(a-x) \text{rectangularPulse}(a, b, x)}{a-b}$$

Example 4

For $a = b = c$, the triangular pulse function returns 0:

`triangularPulse(a, a, a, x)`

0

Example 5

Use `triangularPulse` with one input argument as a shortcut for computing `triangularPulse(-1, 0, 1, x)`:

`triangularPulse(x)`

`triangularPulse(-1, 0, 1, x)`

`[triangularPulse(-10), triangularPulse(-3/4), triangularPulse(0),
triangularPulse(2/3), triangularPulse(1)]`

`[0, 1/4, 1, 1/3, 0]`

Example 6

Use `triangularPulse` with three input arguments as a shortcut for computing `triangularPulse(a, (a + c)/2, c, x)`:

triangularPulse

```
triangularPulse(a, c, x)
```

```
triangularPulse(a, a/2 + c/2, c, x)
```

```
[triangularPulse(-10, 10, 3), triangularPulse(-1/2, -1/4, -2/3), triangularPulse(2, 4, 6), triangularPulse(-1, 4, 0)]
```

```
[7/10, 0, 1, 0, 2/5]
```

Example 7

Rewrite the triangular pulse function in terms of the Heaviside step function:

```
rewrite(triangularPulse(a, b, c, x), heaviside)
```

$$\frac{\text{heaviside}(x-a)(a-x)}{a-b} - \frac{\text{heaviside}(x-b)(a-x)}{a-b} - \frac{\text{heaviside}(x-b)(c-x)}{b-c} + \frac{\text{heaviside}(x-c)(c-x)}{b-c}$$

Example 8

Plot the triangular pulse function:

```
plot(triangularPulse(x), x = -2..2)
```

Example 9

Plot the triangular pulse function for which the argument c is a positive infinity:

```
plot(triangularPulse(-1, 1, infinity, x))
```

triangularPulse

Parameters a, b, c, x
Arithmetical expressions.

Return Values Arithmetical expression.

Overloaded By x

TRUE

Purpose Boolean constant TRUE

Description MuPAD uses a three state logic with the Boolean constants TRUE, FALSE, and UNKNOWN.

The Boolean constants TRUE, FALSE, UNKNOWN are of domain type DOM_BOOL.

See and, or, not for the logical rules of the MuPAD three state logic.

Boolean constants are returned by system functions such as bool and is. These functions evaluate Boolean expressions such as equations and inequalities.

Examples **Example 1**

The Boolean constants may be combined via and, or, and not:

```
(TRUE and (not FALSE)) or UNKNOWN
```

```
TRUE
```

Example 2

The function bool serves for reducing Boolean expressions such as equations or inequalities to one of the Boolean constants:

```
bool(x = x and 2 < 3 and 3 <> 4 or UNKNOWN)
```

```
TRUE
```

The function is evaluates symbolic Boolean expressions with properties:

```
assume(x > 2): is(x^2 > 4), is(x^3 < 0), is(x^4 > 17)
```

```
TRUE, FALSE, UNKNOWN
```

```
unassume(x):
```

Example 3

Boolean constants occur in the conditional part of program control structures such as `if`, `repeat`, or `while` statements. The following loop searches for the smallest Mersenne prime larger than 500 (see `numlib::mersenne` for details). The function `isprime` returns `TRUE` if its argument is a prime, and `FALSE` otherwise. Once a Mersenne prime is found, the `while`-loop is interrupted by the `break` statement:

```
p := 500:
while TRUE do
  p := nextprime(p + 1):
  if isprime(2^p - 1) then
    print(p);
    break;
  end_if;
end_while:
```

521

Note that the conditional part of `if`, `repeat`, and `while` statements must evaluate to `TRUE` or `FALSE`. Any other value leads to an error:

```
if UNKNOWN then "true" else "false" end_if
```

Error: Cannot evaluate to Boolean. [if]

```
delete p:
```

or | repeat | while

Purpose Type of an object

Syntax `type(object)`

Description `type(object)` returns the type of the object.

If `object` is not an expression of domain type `DOM_EXPR`, then `type(object)` is equivalent to `domtype(object)`, i.e., `type` returns the domain type of the object.

If `object` is an expression of domain type `DOM_EXPR`, then its type is determined by its 0-th operand (the “operator”). If the operator has a “type” slot, then `type` returns this value, which usually is a string. If the operator has no “type” slot, then `type` returns the string “function”.

In contrast to most other functions, `type` does not flatten arguments that are expression sequences. Cf. “Example 4” on page 1-2204.

Examples

Example 1

If an object is not an expression, its type equals its domain type:

```
type(3)
```

```
DOM_INT
```

Example 2

The operator of a sum is `_plus`; the type slot of that operator is “`_plus`”:

```
type(x + y*z)
```

```
"_plus"
```

`type` evaluates its argument: thereby, the difference of `x` and `y` becomes the sum of `x` and `(-1)*y`. Its type is not “`_subtract`”, but “`_plus`”:

type

```
type(x - y)
```

```
"_plus"
```

Example 3

If the operator of an expression is not a function environment having a type slot, the expression is of type "function":

```
type(f(2))
```

```
"function"
```

Example 4

The following call to `type` is *not* regarded as a call with two arguments, because expression sequences in the argument are not flattened:

```
type((2, 3))
```

```
"_exprseq"
```

Parameters

object

Any MuPAD object

Return Values

Domain type of type `DOM_DOMAIN` or a character string.

Overloaded By

object

Purpose	Delete the properties of an identifier
Syntax	<code>unassume(x)</code>
Description	<p><code>unassume(x)</code> deletes the properties of the identifier <code>x</code>.</p> <p><code>unassume</code> serves for deleting properties of identifiers set via <code>assume</code>. See “Properties” for a description of the property mechanism.</p> <p>If <code>x</code> is a list or a set of identifiers, then the properties of all specified identifiers are deleted.</p> <p>The command <code>delete x</code> deletes the value and the properties of the identifier <code>x</code>.</p>
Examples	<p>Example 1</p> <p>Properties are attached to the identifiers <code>x</code> and <code>y</code>:</p> <pre>assume(x > 0): assume(y < 0): getprop(x), getprop(y) (0, ∞), (-∞, 0) sign(x), sign(y) 1, -1</pre> <p><code>unassume</code> or <code>delete</code> deletes the properties:</p> <pre>unassume(x): delete y: getprop(x), getprop(y) ℂ, ℂ sign(x), sign(y) sign(x), sign(y)</pre>

unassume

The properties of several identifiers can be deleted simultaneously by passing a list or a set to unassume:

```
assume(x > y): unassume([x, y]): getprop(x), getprop(y)
```

\mathbb{C} , \mathbb{C}

Parameters

x

An identifier or a list or a set of identifiers

Return Values

Void object null().

MuPAD Functions

[assume](#) | [delete](#) | [getprop](#) | [is](#)

Purpose	Undefined value
Description	<p>undefined indicates results of mathematically undefined operations.</p> <p>MuPAD uses the special value <code>undefined</code> to indicate the results of operations that are not defined in mathematics.</p> <p>You can use the <code>undefined</code> value as an input. Arithmetical operations involving <code>undefined</code> also return <code>undefined</code>. Multiplying infinities by 0 returns <code>undefined</code>.</p> <p>For floating-point intervals, MuPAD uses the special value <code>RD_NAN</code> instead of <code>undefined</code>. If you use <code>typeset</code> mode, MuPAD displays <code>RD_NAN</code> as <code>NaN</code> in output regions. Multiplying infinities <code>RD_INF</code> and <code>RD_NINF</code> by 0 returns <code>RD_NAN</code>.</p>
Examples	<p>Example 1</p> <p>Perform the following operations with infinities. MuPAD returns the <code>undefined</code> value for these operations:</p> <pre>0*infinity, infinity - infinity, infinity/infinity</pre> <pre>undefined, undefined, undefined</pre> <p>Example 2</p> <p>Compute the limit of the sine function at infinity. Since this limit does not exist (is not mathematically defined), MuPAD returns <code>undefined</code>:</p> <pre>limit(sin(x), x = infinity)</pre> <pre>undefined</pre> <p>Example 3</p> <p>Multiply infinities by 0:</p> <pre>infinity*0, -infinity*0</pre>

MuPAD Functions

FAIL

Concepts

- “Mathematical Constants Available in MuPAD”

Purpose	Physical units
Syntax	<code>unit::nam</code>
Description	<p>Objects such as <code>unit::m</code>, <code>unit::kg</code>, <code>unit::sec</code> etc. represent the physical units “meters”, “kilograms”, “seconds” etc.</p> <p><code>unit</code> domain provides some methods for simplifying and converting arithmetical expressions involving such units.</p> <p><code>unit</code> objects such as <code>unit::m</code> or <code>unit::kg</code> serve for representing physical units. They are domain objects of domain type <code>unit</code>.</p> <p>These objects behave like symbolic names (identifiers) and can be used to build arithmetical expressions involving numbers and symbols such as $3*\text{unit}::\text{m}^2$ or $a*\text{unit}::\text{cm} + b*\text{unit}::\text{inch}^2/\text{unit}::\text{mm}$.</p> <p>Expressions such as $20*\text{unit}::\text{cm} + 0.3*\text{unit}::\text{m}$ involving several units of the same type (‘length,’ ‘mass,’ ‘time’ etc.) are <i>not</i> simplified automatically. Use <code>unit::convert</code>, <code>unit::simplify</code>, <code>simplify</code>, or <code>Simplify</code> to convert all subexpressions to common units. These routines are described further down below.</p> <p>On input, use the prefix <code>unit::</code> as in <code>unit::mm</code>, <code>unit::km</code> for millimeters, kilometers etc. On the screen, this prefix is stripped off. For example, $1.23*\text{unit}::\text{mm}$ is displayed as 1.23 mm.</p> <p>The available units are listed further down below.</p> <p>Note that some units such as <code>unit::mm</code>, <code>unit::millimeter</code> and <code>unit::millimeters</code> represent the same physical unit. Use an interactive command such as <code>info(unit::oz)</code> to find information on <code>unit::oz</code> including all the alternative names that can be used in MuPAD. Cf. “Example 6” on page 1-2223.</p>

Note Beware: If you mix different MuPAD units representing the same physical unit, *no automatic simplifications* are done! Use `simplify` to simplify an expression such as `2*unit::m + 3*unit::meter` to `5*unit::m`.

Expressions such as `unit::kg*(unit::m/unit::s)^2` can be used to represent a composite unit. You can convert them to other units such as `unit::Joule` via `unit::convert`.

Some of the conversion factors between the various units are given by exact rational numbers (e.g., `unit::inch = 127/50*unit::cm`), while others are linked by floating-point factors (e.g., `unit::cal = 4.1868*unit::Joule`). Use `float` to approximate exact values by floats. Use `numeric::rationalize` to approximate floats by rational numbers.

Most system functions such as `diff`, `factor`, `normal` etc. accept expressions containing units, treating the units like symbolic identifiers. See “Example 8” on page 1-2224.

The available units are listed below. If the required unit is not available, you can use `unit::newUnit` to add your own unit to the unit domain. See “Example 3” on page 1-2220.

Length:

- `am`, `f` (= Fermi = fermi), `XU` (= `Xu` = `xu` = `XE`), `pm`
- `Ao` (= Angstroem = angstroem = Angstrom = angstrom)
- `nm` (= nanometer = nanometers)
- `My` (= micron = microns = micrometer = micrometers)
- `mm` (= millimeter = millimeters), `cm` (= centimeter = centimeters)
- `dm` (= decimeter = decimeters), `m` (= meter = meters)
- `dam`, `hm`, `km` (= kilometer = kilometers), `Mm`, `Gm`, `Tm`, `Pm`, `Em`
- `pt` (= point = points), `inch` (= inches = zoll = Zoll)

- ft (= foot = feet), ft_US (= foot_US = feet_US)
- yd (= yard = yards = Elle = Ellen), mile (= miles), nmile, inm (= INM)
- AU (= AE), ly (= lightyear = lightyears = Lj = lj), pc (= parsec)
- ch, fm (= fathom = fathoms), fur (= furlong = furlongs), gg, hand
- li (= link = links), line, mil, rod (= perch = pole), span

Mass:

- ag, fg, pg, ng, mcg (= mcgram = mcgrams = microgram = micrograms)
- mg (= milligram = milligrams), cg, dg, g (= gram = grams), hg
- kg (= kilogram = kilograms), Mg, Gg, Tg, Pg, Eg
- t, kt, Mt, ct (= carat = Kt = Karat = karat)
- oz (= ounce = ounces = Unze = Unzen = unze = unzen)
- lb (= pound = pounds), stone, cwt (= sh_cwt)
- cwt_UK (= long_cwt = gross_cwt), tn (= ton = short_ton), ton_UK
- long_ton (= gross_ton), slug, gr, dr, quarter, cental
- Pfd (= Pfund = pfund), Ztr (= Zentner = zentner)
- dz (= Doppelzentner = doppelzentner)

Time:

- as, fs, ps, ns (= nsec = nanosec = nanosecond = nanoseconds)
- mcsec (= mcsecond = mcseconds = microsec = microsecond = microseconds)
- ms (= msec = millisec = millisecond = milliseconds), cs, ds
- s (= sec = second = seconds = Sekunde = Sekunden), das, hs, ks
- Ms, Gs, Ts, Es, Ps, min (= minute = minutes = Minute = Minuten)

- h (= hour = hours = Stunde = Stunden), d (= day = days = Tag = Tage)
- week (= weeks = Woche = Wochen), month (= months = Monat = Monate)
- year (= years = Jahr = Jahre)

Temperature:

- K (= kelvin = Kelvin), Fahrenheit (= fahrenheit), Celsius (= celsius)
- Rankine (= rankine), Reaumur (= reaumur)

Plain Angle:

- degree (= degrees), rad (= radian)

Solid Angle:

- sr (= steradian)

Data Size, Storage Capacity:

- bit (= Bit) kbit (= kBit), Mbit (= MBit), Gbit (= GBit), Tbit (= TBit)
- byte (= Byte), kbyte (= kByte), Mbyte (= MByte), Gbyte (= GByte)
- Tbyte (= TByte)

Data Rate (Bits per Second):

- bps

Signal Rate (= Frequency):

- Bd (= Baud = baud)

Velocity:

- knot, knot_UK, mach

Acceleration:

- Gal, gn

Force:

- aN, fN, nN, pN, mcN, mN, cN, dN, N (= Newton = newton), daN, hN, kN, MN, GN
- TN, PN, EN, p (= pond = Pond), kp (= kilopond = Kilopond), dyn, pdl, lbf
- ozf, tonf

Torque (= Energy):

- aNm, fNm, pNm, nNm, mcNm, mNm, cNm, dNm, Nm (= Newtonmeter = newtonmeter)
- daNm, hNm, kNm, MNm, GNm, TNm, PNm, ENm, kpm

Angular Momentum:

- aNms, fNms, pNms, nNms, mcNms, mNms, cNms, dNms
- Nms (= Newtonmetersec = newtonmetersec)
- daNms, hNms, kNms, MNms, GNms, PNms, ENms, TNms

Energy, Work:

- aJ (= aWs), fJ (= fWs), pJ (= pWs), nJ (= nWs), mcJ (= mcWs = microWs)
- mJ (= mJoule = mjoule = mWs), cJ (= cWs), dJ (= dWs)
- J (= Joule = joule = Ws), daJ (= daWs), hJ (= hWs)
- kJ (= kJoule = kjoule = kWs), MJ (= MJoule = Mjoule = MWs)

- GJ (= GWs), TJ (= TWs), PJ (= PWs), EJ (= EWs), Wh, kWh, MWh, GWh
- cal (= Calory = calory), kcal, aeV, feV, peV, neV, mceV, meV, ceV, deV, eV
- daeV, heV, keV, MeV, GeV, TeV, PeV, EeV, PSh, erg, Btu, therm

Power:

- aW, fW, pW, nW, mcW (= mcWatt = mcwatt = microW = microWatt = microwatt)
- mW (= mWatt = mwatt), cW, dW, W (= Watt = watt), daW, hW
- kW (= kWatt = kwatt), MW (= MWatt = Mwatt), GW (= GWatt = Gwatt)
- TW, PW, EW, PS, hp (= bhp)

Frequency:

- aHz, fHz, pHz, nHz, mcHz, mHz, cHz, dHz, Hz (= Hertz = hertz), daHz, hHz
- kHz (= kHzertz = khertz), MHz (= MHzertz = Mhertz)
- GHz (= GHzertz = Ghertz), THz, PHz, EHz

Pressure, Stress:

- aPa, fPa, pPa, nPa, mcPa, mPa, cPa, dPa, Pa (= Pascal = pascal)
- daPa, hPa (= hPascal = hpascal), kPa, MPa, GPa, TPa, PPa, EPa
- mcbars (= mcBar = microbar = microBar), mbar (= mBar), bar (= Bar)
- kbar (= kBar), at (= ata = atu), atm, mmH₂O (= mmWS), mH₂O (= mWS)
- inH₂O, ftH₂O, mmHg, mHg, inHg, psi, Torr

Area:

- a (= are = Ar), ac (= acre), b (= barn), ha (= hectare = Hektar)

- ro (= rood), township, circ_mil, circ_inch

Volume:

- al, fl, pl, nl, mcl, ml, cl, dl, l (= Liter = liter = Litre = litre), dal
- hl, kl, Ml, Gl, Tl, Pl, El, gal (= gallon), gal_UK, barrel, bu_UK, chaldron
- pottle, pint_UK, pk_UK, qt_UK, gill, gill_UK, floz, floz_UK, fldr, fldr_UK
- minim, minim_UK, liq_qt, liq_pt, dry_bu, dry_pk, bbl, dry_gal, dry_qt, dry_pt

European Currency:

- cent (= Cent), EUR (= EURO = Euro), ATS, DEM (= DM), BEF, ESP, FIM, FRF, LUF
- NLG, PTE, IEP, ITL

Molecular Substance:

- fmol, amol, pmol, nmol, mcmol (= mMol = micromol = microMol)
- mmol (= mMol), cmol, dmol, mol (= Mol), damol, hmol, kmol (= kMol), Mmol
- Gmol, Tmol, Pmol, Emol

Electric Current, Amperage:

- aA, fA, pA, nA (= nAmpere = nampere)
- mA (= microA = microAmpere = microampere), mA (= mAmpere = mampere)
- cA, dA, A (= ampere = Ampere), daA, hA, kA (= kAmpere = kampere), MA, GA

- TA, PA, EA, Bi (= Biot = biot), Gb (= Gilbert = gilbert)

Electric Voltage:

- aV, fV, pV, nV (= nanoV = nVolt = nvolt)
- mV (= microV = mcVolt = mcvolt), mV (= mVolt = mvolt), cV, dV
- V (= Volt = volt), daV, hV
- kV (= kVolt = kvolt)
- MV (= MVolt = Mvolt), GV (= GVolt = Gvolt), TV, PV, EV

Electric Resistance:

- aOhm (= aohm), fOhm (= fohm), pOhm (= pohm), nOhm (= nohm)
- mOhm (=mcohm = microOhm = microohm)
- mOhm (= mohm = milliOhm = milliohm), dOhm (= dohm), cOhm (= cohmm)
- Ohm (= ohm), daOhm (= daohm), hOhm (= hohm), kOhm (= kohm), MOhm (= Mohm)
- GOhm (= Gohm), TOhm (= Tohm), POhm (= Pohm), EOhm (= Eohm)

Electric Charge:

- aC, fC, pC, nC, mC, mC, cC, dC, C (= Coulomb = coulomb), daC, hC, kC, MC, GC, TC
- PC, EC

Electric Capacity:

- aF, fF, pF (= pFarad = pfarad), nF (= nFarad = nfarad)
- mF (= mcFarad = mcfarad = microF = microFarad = microfarad)
- mF (= mFarad = mfarad), cF, dF, F (= Farad = farad), daF, hF
- kF (= kFarad = kfarad) , MF, GF, TF, PF, EF

Electric Conductance:

- S (= Siemens = siemens)

Magnetic Inductance:

- H (= Henry = henry)

Magnetic Flux Density, Magnetic Inductivity:

- T (= Tesla = tesla), G (= Gauss = gauss)

Magnetic Flux:

- Wb (= Weber = weber), M (= Maxwell = maxwell)

Magnetic Field Strength:

- Oe (= Oersted = oersted)

Magnetomotive Force (= Electric Current):

- Gb (= Gilbert = gilbert)

Luminous Intensity:

- fcd, acd, pcd, ncd, mccd, mcd, ccd, dcd, cd (= candela = Candela),
dacd, hcd
- kcd, Mcd, Gcd, Tcd, Pcd, Ecd, HK, IK

Luminance:

- sb (= stilb), asb (= apostilb)

Luminous Flux:

- lm (= lumen)

Illuminance:

- lx (= lux), ph (= phot), nx

Radiation:

- langley

Radioactivity:

- aBq, fBq, pBq, nBq, mCBq, mBq, cBq, dBq, Bq (= Becquerel = becquerel), daBq
- hBq, kBq, MBq, GBq, TBq, PBq, EBq, Ci (= Curie)

Equivalent Dosage:

- aSv, fSv, pSv, nSv, mCSv, mSv, cSv, dSv
- Sv (= Sievert = sievert), daSv, hSv, kSv, MSv, GSv, TSv, PSv, ESv
- arem, frem, prem, nrem, mcrem, mrem, crem, drem
- rem (= Rem), darem, hrem, krem, Mrem, Grem, Trem, Prem, Erem

Absorbed Dosage:

- aGy, fGy, pGy, nGy, mCGy, mGy, cGy, dGy, Gy (= Gray = gray), daGy, hGy, kGy, MGy, GGy
- TGy, PGy, EGy, rd

Ionising Dosage:

- R (= Roentgen)

Lens Power:

- dpt (= diopter = diopetre)

Dynamic Viscosity:

- P (= Poise)

Kinematic Viscosity:

- St (= Stokes)

Mass Per Length:

- tex, den (= denier)

Examples

Example 1

Units not convertible are left alone by `unit::convert`:

```
unit::convert(1.23*unit::kg*unit::inch^2/unit::mm, unit::cm)
```

```
79.35468 cm kg
```

```
unit::convert(unit::km/unit::hour, unit::m/unit::sec)
```

$$\frac{5 \text{ m}}{18 \text{ sec}}$$

Example 2

`unit::simplify` favors kg over pounds:

```
unit::simplify(1.23*unit::kg^2/unit::pound*unit::inch^2/unit::mm)
```

```
68.87681995 inch kg
```

Example 3

We add new velocity units to the unit domain:

```
unit::newUnit(SpeedOfLight = 300000*unit::km/unit::sec)
```

`SpeedOfLight`

Now, the unit `unit::SpeedOfLight` exists and can be used like any other unit in the unit domain. We use it to define yet another velocity unit:

```
unit::newUnit(Warp9 = 1.516*unit::SpeedOfLight)
```

`Warp9`

We convert the velocity of 123.4 miles per hour into the new speed units:

```
unit::convert(123.4*unit::mile/unit::hour, unit::SpeedOfLight)
```

`0.0000001838824533 SpeedOfLight`

```
unit::convert(123.4*unit::mile/unit::hour, unit::Warp9)
```

`0.0000001212944943 Warp9`

We verify the new units:

```
unit::convert(unit::SpeedOfLight, unit::km/unit::sec)
```

`300000 $\frac{\text{km}}{\text{sec}}$`

```
unit::convert(unit::Warp9, unit::SpeedOfLight)
```

1.516 SpeedOfLight

```
unit::convert(unit::Warp9, unit::km/unit::sec)
```

$$454800.0 \frac{\text{km}}{\text{sec}}$$

Example 4

We create a symbolic expression involving different units of type 'length':

```
27*unit::cm + 30*unit::mm
```

$$27 \text{ cm} + 30 \text{ mm}$$

This expression is not simplified automatically. We apply simplify:

```
simplify(%)
```

$$30 \text{ cm}$$

We convert this length to inch:

```
unit::convert(%, unit::inch)
```

$$\frac{1500 \text{ inch}}{127}$$

```
float(%)
```

$$11.81102362 \text{ inch}$$

Here is another example for simplification and conversion:

```
1234*unit::g + 1.234*unit::kg*unit::m^2/unit::inch^2
```

$$1234 \text{ g} + 1.234 \frac{\text{kg m}^2}{\text{inch}^2}$$

```
simplify(%)
```

```
1913937.825 g
```

```
unit::convert(%, unit::ounce)
```

```
67512.17003 ounce
```

The target unit in `unit::convert` may be an expression:

```
unit::convert(unit::pound*unit::km/unit::hour,  
              unit::kg*unit::m/unit::s)
```

$$\frac{45359237 \frac{\text{kg m}}{\text{s}}}{360000000}$$

Example 5

The probably most interesting method of the unit domain is the conversion routine `unit::convert`. Given any expression involving units, you can specify a target unit which is to be used to express the units:

```
unit::convert(unit::ounce, unit::kilogram)
```

$$\frac{45359237 \text{ kilogram}}{1600000000}$$

The target unit needs not be of the same physical type as the expression that is to be rewritten. In the following example, we wish to rewrite a torque (given in “Newton meters”) in terms of units involving the power unit “Watt.” Note that a torque is an energy, i.e., “power” multiplied by “time”:

```
unit::convert(1.23*unit::Nm, unit::W)
```

$$1.23 \text{ W s}$$

We wish to rewrite “Newton meters” in terms of units involving “centimeters”:

```
unit::convert(unit::Nm, unit::cm)
```

$$10000 \frac{\text{cm}^2 \text{ kg}}{\text{s}^2}$$

The target unit may be a composite expression. We wish to rewrite “Newton meters” in terms of “grams,” “centimeters,” and “milliseconds”:

```
unit::convert(unit::Nm, unit::g*unit::cm^2/unit::msec^2)
```

$$10 \frac{\text{cm}^2 \text{ g}}{\text{msec}^2}$$

Example 6

The `info` command provides information on units. In particular, it lists alternative names that can be used in MuPAD:

```
info(unit::nm)
```

```
nanometer: a length unit
```

Alternative names: `unit::nanom`, `unit::nanometer`, `unit::nanometers`,

`info(unit::Joule)`

`joule`: a unit of energy

Alternative names: `unit::J`, `unit::Joule`, `unit::Newtonmeter`, `unit::N`

Example 7

We use `unit::convert2SIunits` to convert a mass expressed in non-metric units to SI base units:

```
mass := 2*unit::cal*unit::msec^2/unit::inch^2 - 45*unit::carat
```

$$2 \frac{\text{cal msec}^2}{\text{inch}^2} - 45 \text{ carat}$$

```
unit::convert2SIunits(mass)
```

```
0.003979105958 kg
```

```
delete mass:
```

Example 8

Most system functions such as `diff`, `factor`, `normal` etc. treat units like ordinary symbolic identifiers:

```
diff(x/unit::m*exp(-x^2/unit::m^2), x)
```

$$e^{-x^2 \frac{1}{m^2}} \frac{1}{m} - \left(2x^2 e^{-x^2 \frac{1}{m^2}} \right) \frac{1}{m^3}$$

```
factor(%)
```

$$- \frac{2x^2 - m^2}{e^{\frac{x^2}{m^2}}} \frac{1}{m^3}$$

```
normal((4*unit::m^2 - a^2*unit::m^2)/(2*unit::m - a*unit::m))
```

$$2m + am$$

Parameters

nam

The name of the physical unit, see the list below. Some units such as `unit::mm` and `unit::millimeter` represent the same physical unit.

Methods

convert - Convert an expression to other units

`convert(x, targetunit)` converts all units in the arithmetical expression `x` to multiples of the `targetunit` if possible. The `targetunit` may be one of the unit objects of type 'length,' 'mass' etc. It may also be an arithmetical expression such as `unit::km/unit::sec`. In this case, `x` is rewritten in terms of the units found in `targetunit`.

convert2SIunits - Rewrite to SI units

`convert2SIunits(x)` rewrites all units in the arithmetical expression `x` in terms of corresponding SI base units.

simplify - Combine like units in an expression

`unit::simplify(x)` converts all units in the arithmetical expression `x` to some basic unit found in `x`, i.e., all length units are expressed by the same length unit, all mass units are expressed by the same mass unit, all time units are expressed by the same time unit etc.

newUnit - Define a new unit

`newUnit(newname = expression)`

`unit::newUnit(newname = f*oldunit)` creates a new unit that may be addressed by `unit::newname`. Its name `newname` must be an identifier. It is declared as the `f`-fold of some unit `oldunit` that must be an expression such as `unit::mm/unit::sec` involving units provided by the unit domain. The conversion factor `f` must be an arithmetical expression (typically, a numerical conversion factor).

display - Format for output

`display(x)` formats the screen output of the arithmetical expression `x` such that the units appear as a separate factor at the end of each term.

findUnits - Find all units in expression

`findUnits(x)` returns a set of all units found in the arithmetical expression `x`.

Celsius2Fahrenheit - Convert degrees Celsius to degrees Fahrenheit

`unit::Celsius2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Fahrenheit.

Celsius2Kelvin - Convert degrees Celsius to Kelvin

`unit::Celsius2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Kelvin.

Celsius2Rankine - Convert degrees Celsius to degrees Rankine

`unit::Celsius2Rankine(x)` converts a numerical value x representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Rankine.

Celsius2Reaumur - Convert degrees Celsius to degrees Reaumur

`unit::Celsius2Reaumur(x)` converts a numerical value x representing a temperature in degrees Celsius into a numerical value representing this temperature in degrees Reaumur.

Fahrenheit2Celsius - Convert degrees Fahrenheit to degrees Celsius

`unit::Fahrenheit2Celsius(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Celsius.

Fahrenheit2Kelvin - Convert degrees Fahrenheit to Kelvin

`unit::Fahrenheit2Kelvin(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Kelvin.

Fahrenheit2Rankine - Convert degrees Fahrenheit to degrees Rankine

`unit::Fahrenheit2Rankine(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Rankine.

Fahrenheit2Reaumur - Convert degrees Fahrenheit to degrees Reaumur

`unit::Fahrenheit2Reaumur(x)` converts a numerical value x representing a temperature in degrees Fahrenheit into a numerical value representing this temperature in degrees Reaumur.

Kelvin2Fahrenheit - Convert Kelvin to degrees Fahrenheit

`unit::Kelvin2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Fahrenheit.

Kelvin2Celsius - Convert Kelvin to degrees Celsius

`unit::Kelvin2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Celsius.

Kelvin2Rankine - Convert Kelvin to degrees Rankine

`unit::Kelvin2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Rankine.

Kelvin2Reaumur - Convert Kelvin to degrees Reaumur

`unit::Kelvin2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Kelvin into a numerical value representing this temperature in degrees Reaumur.

Rankine2Fahrenheit - Convert degrees Rankine to degrees Fahrenheit

`unit::Rankine2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Fahrenheit.

Rankine2Kelvin - Convert degrees Rankine to Kelvin

`unit::Rankine2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Kelvin.

Rankine2Celsius - Convert degrees Rankine to degrees Celsius

`unit::Rankine2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Celsius.

Rankine2Reaumur - Convert degrees Rankine to degrees Reaumur

`unit::Rankine2Reaumur(x)` converts a numerical value `x` representing a temperature in degrees Rankine into a numerical value representing this temperature in degrees Reaumur.

Reaumur2Fahrenheit - Convert degrees Reaumur to degrees Fahrenheit

`unit::Reaumur2Fahrenheit(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Fahrenheit.

Reaumur2Kelvin - Convert degrees Reaumur to Kelvin

`unit::Reaumur2Kelvin(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Kelvin.

Reaumur2Rankine - Convert degrees Reaumur to degrees Rankine

`unit::Reaumur2Rankine(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Rankine.

Reaumur2Celsius - Convert degrees Reaumur to degrees Celsius

`unit::Reaumur2Celsius(x)` converts a numerical value `x` representing a temperature in degrees Reaumur into a numerical value representing this temperature in degrees Celsius.

universe

Purpose Set-theoretical universe

Description universe represents the set-theoretical universe of all objects.
universe is the only element of the domain `stdlib::Universe`.
The standard set operations such as union, intersection and subtraction can be used with universe.

Examples **Example 1**

We show some basic set operations involving universe:

```
universe union {a}
```

```
universe
```

```
universe intersect {a}
```

```
{a}
```

```
{a} minus universe
```

```
∅
```

See Also

MuPAD Domains DOM_SET

MuPAD Functions union | intersect | minus

Purpose Remove protection of identifiers

Syntax `unprotect(x)`

Description `unprotect(x)` removes any write protection of the identifier `x`.
`unprotect(x)` is equivalent to `protect(x, ProtectLevelNone)`.
`unprotect` does not evaluate its argument. Cf. “Example 2” on page 1-2231.

Examples **Example 1**

`unprotect` allows to assign values to system functions:

```
unprotect(sign): sign(x) := 1
```

```
1
```

However, we strongly advise not to change identifiers protected by the system. We undo the previous assignment:

```
delete sign(x): protect(sign, ProtectLevelError):
```

Example 2

`unprotect` does not evaluate its argument. Here the identifier `x` is unprotected and not its value `y`:

```
x := y: protect(y): unprotect(x): y := 1
```

```

```

```
Warning: Protected variable
```

unprotect

```
'y' overwritten. [_assign]
```

```
1
```

```
unprotect(y): delete x, y:
```

Example 3

The identifier `a` is protected with various levels. `unprotect` returns the previous protection level:

```
protect(a):  
unprotect(a)
```

```
ProtectLevelWarning
```

```
protect(a, ProtectLevelError):  
unprotect(a)
```

```
ProtectLevelError
```

At this place, `a` is not protected:

```
unprotect(a)
```

```
ProtectLevelNone
```

Parameters

x

An identifier

Return Values

Previous protection level of `x`: either `ProtectLevelError` or `ProtectLevelWarning` or `ProtectLevelNone` (see `protect`).

See Also

**MuPAD
Functions**

protect

use

Purpose Use library functions by a short name

Syntax `use(L, <Alias>, f1, f2, ...)`
`use(L, <Alias>)`

Description `use(L, f)` 'exports' the public function `L::f` of the library `L` to the global namespace such that it can be accessed as `f` without the prefix `L`.

`use(L)` exports all public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an *alias* is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`use(L, f1, f2, ...)` exports the given functions `f1`, `f2`, ... of `L`. However, if one of the identifiers already has a value, the corresponding function is not exported. A warning is printed instead. An error is returned if one of the identifiers is not the name of a public library function.

`use(L)` exports all public functions of `L`.

A function that is already exported will not be exported twice.

`use` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1`, `f2`, ..., if any.

The function `info` displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function `append` from the library `listlib` is such an example.

Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

Examples

Example 1

We export the public function `invphi` of the library `numlib` and then undo the export:

```
numlib::invphi(4!)
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

use(numlib, invphi):
invphi(4!)
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

unuse(numlib, invphi):
invphi(4!)
invphi(24)
```

We export and unexport all public functions of the library `numlib`:

```
use(numlib):
invphi(100)
```

```
Warning: Identifier 'contfrac' already has a value. It is not ex
```

Use

```
[101, 125, 202, 250]
```

As you can see `use` issued a warning because `contfrac` already has a value. Here, the reason in the existence of a global function `contfrac` (which makes use of `numlib::contfrac` for numerical arguments).

```
unuse(numlib):  
invphi(100)
```

```
invphi(100)
```

Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

```
invphi := 17:  
use(numlib, invphi)
```

```
Warning: Identifier 'invphi' already has a value. It is not exported.
```

Parameters

L

The library: a domain

f1, f2, ...

Public functions of L: identifiers

Options

Alias

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f := L::f`.

Return Values

Void object `null()` of type `DOM_NULL`.

Algorithms

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function `info` and for exporting. The names of functions exported from a library `L` are stored in the set `L::_exported`.

See Also**MuPAD Functions**

`unuse` | `:=` | `alias` | `delete` | `info`

Related Examples

- “Avoid Name Conflicts Between MuPAD Objects and Library Functions”

unuse

Purpose Undo the use command

Syntax `unuse(L, f1, f2, ...)`
`unuse(L)`

Description `unuse(L, f)` undoes the export of the public function `L::f` of the library `L` such that it is no longer available as `f`.

`unuse(L)` undoes the export of all previously exported public functions of the library `L`.

A library contains *public* functions which may be called by the user. The collection of these functions forms the *interface* of the library. (There may be other, private, functions, too, which are not intended to be called by the user directly, and are not documented.) The standard way of accessing the public function `f` from the library `L` is via `L::f`. When the function `f` is *exported*, it can be accessed more briefly as `f`. Technically, exporting means that the global identifier `f` is assigned the value `L::f`. Alternatively, when the option `Alias` is used, an *alias* is created.

Unexporting the library function `f` means that the value of the global identifier `f` is deleted. Afterwards, the library function is available only as `L::f`.

`unuse(L, f1, f2, ...)` unexports all given functions of `L`. Note that `unuse` does not evaluate the identifiers. Thus, it is not necessary to use `hold` to protect them from being evaluated.

`unuse(L)` unexports all public functions of the library `L`.

`unuse` evaluates its first argument `L`, but it does not evaluate the remaining arguments `f1, f2, ...`, if any.

The function `info` displays the interface functions and the exported functions of a library.

Some libraries have functions that are always exported. These functions cannot be unexported. The function `append` from the library `listlib` is such an example.

Environment Interactions

When a function is exported, it is assigned to the corresponding global identifier. When it is unexported, the corresponding identifier is deleted.

Examples

Example 1

We export the public function `invphi` of the library `numlib` and then undo the export:

```
numlib::invphi(4!)
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

use(numlib, invphi):
invphi(4!)
[35, 39, 45, 52, 56, 70, 72, 78, 84, 90]

unuse(numlib, invphi):
invphi(4!)
invphi(24)
```

We export and unexport all public functions of the library `numlib`:

```
use(numlib):
invphi(100)
```

Warning: Identifier 'contfrac' already has a value. It is not ex

```
[101, 125, 202, 250]
```

unuse

As you can see `use` issued a warning because `contfrac` already has a value. Here, the reason in the existence of a global function `contfrac` (which makes use of `numlib::contfrac` for numerical arguments).

```
unuse(numlib):  
invphi(100)
```

```
invphi(100)
```

Example 2

`use` issues a warning if a function cannot be exported since the corresponding identifier already has a value:

```
invphi := 17:  
use(numlib, invphi)
```

```
Warning: Identifier 'invphi' already has a value. It is not exported.
```

Parameters

L

The library: a domain

f1, f2, ...

Public functions of L: identifiers

Options

Alias

Use `alias(f = L::f)` to create an alias `f` for `L::f` rather than exporting `L::f` by the assignment `f := L::f`.

Return Values

Void object `null()` of type `DOM_NULL`.

Algorithms

The names of the public functions of a library `L` are stored in the set `L::interface`. This set is used by the function `info` and for exporting.

The names of functions exported from a library `L` are stored in the set `L::_exported`.

See Also**MuPAD
Functions**

`use` | `:=` | `alias` | `delete` | `info`

Concepts

- “Use the MuPAD Libraries”

userinfo

Purpose Print progress information

Note userinfo has been removed. Use print instead.

Syntax

```
userinfo(<Text>, <NoNL>, n, message1, message2, )  
userinfo(<Text>, <NoNL>, n1 .. n2, message1, message2, )
```

Description userinfo(n, message) prints a message if an information level larger or equal to n is set via setuserinfo.

userinfo(n1..n2, message) prints a message if the information level set by setuserinfo is between n1 and n2.

userinfo must not be used on the interactive level. It should be built into the body of a procedure or of a domain method to print status information such as the chosen algorithm, intermediate results etc. If a userinfo command is built into a procedure by the name f, say, then it is activated by setting an appropriate information level via setuserinfo(f, n). The information is printed during subsequent calls to f.

The print output consists of the evaluation of the message arguments, possibly followed by the name of the procedure (see the function setuserinfo). Strings are printed without quotes. The pretty printer is not used. Unless one of the options Text or NoNL is given, the message arguments are separated by commas in the output. Unless the option NoNL is given, the print output is preceded by the string "Info: " and a new line is started after the output.

The information level of a single procedure, of all procedures of a domain, or, of all procedures in general can be specified using setuserinfo. All three levels may apply to a procedure simultaneously.

Most of the functions in the MuPAD library provide status information via userinfo.

Environment Interactions

userinfo prints the messages on the screen, if an appropriate information level is set.

Parameters

n, n₁, n₂

The information levels: positive integers

message₁, message₂, ...

Arbitrary MuPAD objects. Typically, character strings.

Options

Text

Do not separate the arguments by commas in the output

NoNL

Do not separate the arguments by commas in the output, do not start a new line after the output, and do not precede the output by the string "Info: ".

Return Values

Void object of type DOM_NULL.

Algorithms

userinfo does not evaluate the messages unless they are printed.

The global table of information levels for all procedures can be obtained by the call `setuserinfo()`.

See Also

MuPAD Functions

`print` | `setuserinfo` | `warning`

val

Purpose Value of an object

Syntax `val(object)`

Description `val(object)` replaces every identifier in `object` by its value.

`val` does not perform any simplification of the result.

If the result of `val` is a set, duplicate elements are removed from that set.

`val` does not work recursively, i.e., if the value of an identifier in turn contains identifiers, then these are not replaced by their values. See “Example 3” on page 1-2245.

`val` does not flatten its argument. Hence, an expression sequence is accepted as argument. Cf. “Example 2” on page 1-2244.

Examples

Example 1

`val` replaces identifiers by their values, but does not call arithmetical functions such as `_plus`:

```
a := 0: val(a*b + 4 + 0)
```

```
0 b+4+0
```

Duplicate elements in sets are removed:

```
a := b: val({a, b, a*0})
```

```
{b, 0 b}
```

```
delete a:
```

Example 2

`val` does not flatten its argument, nor does it remove void objects of type `DOM_NULL`:

```
a := null(): val((a, null()))  
null(), null()
```

However, it is not legal to pass several arguments:

```
val(a, null())
```

```
Error: The number of arguments is incorrect. [val]
```

```
delete a:
```

Example 3

val does not recursively substitute values for the identifiers:

```
delete a, b: a := b: b := c: val(a)  
  
b
```

Parameters

object

Any MuPAD object

Return Values

“evaluated” object.

See Also

MuPAD Functions

eval | hold | level | LEVEL | MAXLEVEL

vectorPotential

Purpose Vector potential of a three-dimensional vector field

Syntax `vectorPotential(j, [x1, x2, x3], <Test>)`

Description `vectorPotential(j, x)` returns the vector potential of the vector field

$\vec{j}(\vec{x})$ with respect to \vec{x} . This is a vector field \vec{v} with $\text{curl}_{\vec{x}}(\vec{v}) = \vec{j}$.

The vector potential of a vector function j exists if and only if the divergence of j is zero. It is uniquely determined.

If the vector potential of j does not exist, then `vectorPotential` returns `FALSE`.

If j is a vector then the component ring of j must be a field (i.e., a domain of category `Cat::Field`) for which definite integration can be performed.

If j is given as a list of three arithmetical expressions, then `vectorPotential` returns a vector of the domain `Dom::Matrix()`.

`vectorPotential` and `linalg::vectorPotential` are equivalent.

Examples

Example 1

We check if the vector function $\vec{j}(x, y, z) = \left(x^2 y, -\frac{y^2 x}{2}, -x y z\right)$ has a vector potential:

```
delete x, y, z:  
vectorPotential(  
  [x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z], Test  
)
```

TRUE

The answer is yes, so let us compute the vector potential of \vec{j} :

```
vectorPotential(  
  [x^2*y, -1/2*y^2*x, -x*y*z], [x, y, z]  
)
```

$$\begin{pmatrix} -\frac{x y^2 z}{2} \\ -x^2 y z \\ 0 \end{pmatrix}$$

We check the result:

```
curl(%, [x, y, z])
```

$$\begin{pmatrix} x^2 y \\ -\frac{x y^2}{2} \\ -x y z \end{pmatrix}$$

Example 2

The vector function $\vec{j} = (x^2, 2y, z)$ does not have a vector potential:

```
vectorPotential([x^2, 2*y, z], [x, y, z])
```

FALSE

Parameters

i

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3×1 or 1×3 matrix of a domain of category `Cat::Matrix`)

x₁, x₂, x₃

(indexed) identifiers

vectorPotential

Options

Test

Check whether the vector field j has a vector potential and return TRUE or FALSE, respectively.

Return Values

Vector with three components, i.e., an 3×1 or $1 \times n$ matrix of a domain of category `Cat::Matrix`, or a boolean value.

See Also

MuPAD Functions

`curl` | `divergence` | `gradient` | `laplacian` | `potential`

Purpose Version number of the MuPAD library

Syntax `version()`

Description `version()` returns the version number of the installed MuPAD library. The call `Pref::kernel()` returns the version number of the installed MuPAD kernel. The version numbers of the kernel and the library may differ: `version` refers to the library, whereas the call `Pref::kernel()` returns the version number of the kernel.

Examples **Example 1**

The version of this MuPAD library is:

```
version()
```

```
[6, 0, 0]
```

Return Values Version number: a list of three nonnegative integers.

See Also

MuPAD Functions `buildnumber` | `Pref::kernel`

warning

Purpose Print a warning message

Syntax warning(message)

Description warning(message) prints the message with the prefix "Warning:".
warning may be used to print information about potential problems in an algorithm. E.g., it is used in `limit` to provide hints.

Examples **Example 1**

A warning:

```
warning("You should not do this!");
```

```
Warning: You should not do this!
```

Example 2

This example shows a simple procedure which divides two numbers. If the second argument is omitted, a warning is printed and the computation continues:

```
mydivide := proc(x, y)
begin
  if args(0) < 2 then
    warning("Denominator not given, using 1.");
    y := 1;
  end_if:
  x/y
end_proc:
mydivide(10)
```

```
Warning: Denominator not given, using 1. [mydivide]
```

10

Parameters

message

A character string

Return Values

Void object of type DOM_NULL.

See Also

MuPAD Functions

error | print

whittakerM

Purpose The Whittaker M function

Syntax whittakerM(a, b, z)

Description The whittakerM function $M_{a,b}(z)$ is related to the confluent hypergeometric function ${}_1F_1(a, b, z) = \Phi(a, b, z)$ by the formula:

$$M_{a,b}(z) = e^{-\frac{z}{2}} z^{\frac{1}{2}+b} \Phi\left(\frac{1}{2}+b-a, 1+2b, z\right),$$

The WhittakerM function is defined for complex arguments a , b , and z .

For most of the values of the parameters, an unevaluated function call is returned. Cf. “Example 1” on page 1-2252.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. “Example 2” on page 1-2253.

Note MuPAD defines ${}_1F_1(a, a, z) = e^z$ for all complex numbers a . As a consequence, the MuPAD whittakerM differs from the corresponding function in M. Abramowitz and I. A. Stegun, “Handbook of Mathematical Functions” when $\frac{1}{2}+b-a$ and $1+2b$ are negative integers and $\frac{1}{2}+b-a \geq 1+2b$. Some of the formulas in Chapter 13 of the “Handbook of Mathematical Functions” do not hold for the MuPAD whittakerM with such arguments. Cf. “Example 4” on page 1-2254.

Environment Interactions When called with floating-point arguments, these functions are sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples **Example 1**

Unevaluated calls are returned for exact or symbolic arguments:

whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)

$$M_{a,b}(x), W_{-\frac{3}{2}, \frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:

whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)

0.00000001666553264, 0.7522527781

Example 2

Explicit expressions are returned for some specific values of the parameters:

whittakerM(0, b, x), whittakerW(0, b, x), whittakerW(-3/2, 1/2, x), whittakerM(-3/2, 0, x), whittakerW(a, -a + 1/2, x)

$$4^b \sqrt{x} \Gamma(b+1) I_b\left(\frac{x}{2}\right), \frac{x^{b+\frac{1}{2}} K_b\left(\frac{x}{2}\right)}{\sqrt{\pi} x^b}, \frac{4}{3 \sqrt{\pi}}, \sqrt{x} e^{\frac{x}{2}} (x+1), x^{1-a} x^{2a-1} e^{-\frac{x}{2}}$$

Example 3

The functions diff, float, limit, and series handle expressions involving the Whittaker functions

diff(whittakerM(a,b,z),z), float(whittakerW(-3/2,1/2,0))

$$\frac{M_{a+1,b}(z) \left(a+b+\frac{1}{2}\right)}{z} - \left(\frac{a}{z} - \frac{1}{2}\right) M_{a,b}(z), 0.7522527781$$

series(whittakerW(-3/2,1/2,x),x,3)

whittakerM

$$\frac{4}{3\sqrt{\pi}} + x \left(\frac{2\sigma_1}{\sqrt{\pi}} - \frac{2}{3\sqrt{\pi}} \right) + x^2 \left(\frac{2 \left(\frac{5 \text{EULER}}{4} - \frac{5 \ln(2)}{2} + \frac{5 \ln(x)}{4} + \frac{17}{24} \right)}{\sqrt{\pi}} - \frac{\sigma_1}{\sqrt{\pi}} + \frac{1}{6\sqrt{\pi}} \right) + O(x^3)$$

where

$$\sigma_1 = \text{EULER} - 2 \ln(2) + \ln(x) + \frac{5}{3}$$

Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, "Handbook of Mathematical Functions" may not hold for the MuPAD whittakerM functions. For example, Formula 13.4.32

$$z \frac{\partial}{\partial z} M_{a,b}(z) = \left(\frac{z}{2} - a \right) M_{a,b}(z) + \left(a + b + \frac{1}{2} \right) M_{a+1,b}(z)$$

is not satisfied for $a = 0$ and $b = -\frac{3}{2}$:

```
expand(x*diff(whittakerM(0, -3/2, x), x), x) <>  
x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))
```

$$- \frac{e^{-\frac{x}{2}}}{2} - \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq \frac{e^{-\frac{x}{2}}}{2} + \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x}$$

Parameters

a, b, z

arithmetical expressions

Return Values

Arithmetical expression.

**Overloaded
By** z

Algorithms $M_{a,b}(z)$ and $W_{a,b}(z)$ satisfy Whittaker's differential equation:

$$\frac{\partial^2}{\partial z^2} y + \left(-\frac{1}{4} + \frac{a}{z} + \frac{\frac{1}{4} - b^2}{z^2} \right) y = 0$$

See Also

**MuPAD
Functions** [whittakerW](#) | [hypergeom](#) | [kummerU](#)

whittakerW

Purpose The Whittaker W function

Syntax whittakerW(a, b, z)

Description The whittakerW function $W_{a,b}(z)$ is related to the confluent hypergeometric function $kummerU(a, b, z) = U(a, b, z)$ by the formula:

$$W_{a,b}(z) = e^{-\frac{z}{2}} z^{\frac{1}{2}+b} U\left(\frac{1}{2}+b-a, 1+2b, z\right)$$

The WhittakerW function is defined for complex arguments a , b , and z .

For most of the values of the parameters, an unevaluated function call is returned. Cf. “Example 1” on page 1-2256.

Explicit symbolic expressions are returned for some particular values of the parameters. Cf. “Example 2” on page 1-2257.

Environment Interactions When called with floating-point arguments, these functions are sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples Example 1

Unevaluated calls are returned for exact or symbolic arguments:

```
whittakerM(a, b, x), whittakerW(-3/2, 1/2, 1)
```

$$M_{a,b}(x), W_{-\frac{3}{2}, \frac{1}{2}}(1)$$

Floating point values are returned for floating-point arguments:

```
whittakerM(-2, 0.5, -50), whittakerW(-3/2, 1/2, 0.0)
```

```
0.00000001666553264, 0.7522527781
```

Example 2

Explicit expressions are returned for some specific values of the parameters:

`whittakerM(0, b, x)`, `whittakerW(0, b, x)`, `whittakerW(-3/2, 1/2, x)`,
`whittakerM(-3/2, 0, x)`, `whittakerW(a, -a + 1/2, x)`

$$4^b \sqrt{x} \Gamma(b+1) I_b\left(\frac{x}{2}\right), \frac{x^{b+\frac{1}{2}} K_b\left(\frac{x}{2}\right)}{\sqrt{\pi} x^b}, \frac{4}{3\sqrt{\pi}}, \sqrt{x} e^{\frac{x}{2}} (x+1), x^{1-a} x^{2a-1} e^{-\frac{x}{2}}$$

Example 3

The functions `diff`, `float`, `limit`, and `series` handle expressions involving the Whittaker functions

`diff(whittakerM(a,b,z),z)`, `float(whittakerW(-3/2,1/2,0))`

$$\frac{M_{a+1,b}(z) \left(a+b+\frac{1}{2}\right)}{z} - \left(\frac{a}{z} - \frac{1}{2}\right) M_{a,b}(z), 0.7522527781$$

`series(whittakerW(-3/2,1/2,x),x,3)`

$$\frac{4}{3\sqrt{\pi}} + x \left(\frac{2\sigma_1}{\sqrt{\pi}} - \frac{2}{3\sqrt{\pi}}\right) + x^2 \left(\frac{2\left(\frac{5\text{EULER}}{4} - \frac{5\ln(2)}{2} + \frac{5\ln(x)}{4} + \frac{17}{24}\right)}{\sqrt{\pi}} - \frac{\sigma_1}{\sqrt{\pi}} + \frac{1}{6\sqrt{\pi}}\right) + O(x^3)$$

where

$$\sigma_1 = \text{EULER} - 2 \ln(2) + \ln(x) + \frac{5}{3}$$

Example 4

For some values of the input parameters, recurrence and differential relations in Chapter 13 of M. Abramowitz and I. A. Stegun, "Handbook

whittakerM

of Mathematical Functions” may not hold for the MuPAD whittakerM functions. For example, Formula 13.4.32

$$z \frac{\partial}{\partial z} M_{a,b}(z) = \left(\frac{z}{2} - a\right) M_{a,b}(z) + \left(a + b + \frac{1}{2}\right) M_{a+1,b}(z)$$

is not satisfied for $a = 0$ and $b = -\frac{3}{2}$:

```
expand(x*diff(whittakerM(0, -3/2, x), x) <>  
x/2*whittakerM(0, -3/2, x) - whittakerM(1, -3/2, x))
```

$$-e^{-\frac{x}{2}} - \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x} \neq e^{-\frac{x}{2}} + \frac{x e^{-\frac{x}{2}}}{4} - \frac{e^{-\frac{x}{2}}}{x}$$

Parameters

a, b, z

arithmetical expressions

Return Values

Arithmetical expression.

Overloaded By

z

Algorithms

$M_{a,b}(z)$ and $W_{a,b}(z)$ satisfy Whittaker's differential equation:

$$\frac{\partial^2}{\partial z^2} y + \left(-\frac{1}{4} + \frac{a}{z} + \frac{1-b^2}{z^2}\right) y = 0$$

**MuPAD
Functions**

whittakerM | hypergeom | kummerU

wrightOmega

Purpose The Wright ω function

Syntax `wrightOmega(x)`

Description $\omega(x)$ is defined in terms of Lambert's W function as

$\omega(x) = W_{\left[\frac{\Im(x)}{\pi}\right]}(e^x)$
For $x \neq t - i\pi$ with $t \leq -1$, $y = \omega(x)$ is a solution of the equation $y + \ln(y) = x$. The complete solution set of this equation is

$$y = \begin{cases} \emptyset & \text{if } \Re(x) \leq -1 \wedge \Im(x) = -\pi \\ \{\omega(x), \omega(x - 2\pi i)\} & \text{if } \Re(x) \leq -1 \wedge \Im(x) = \pi \\ \{\omega(x)\} & \text{otherwise} \end{cases}$$

A floating-point value is computed if the argument is a floating point value. Unevaluated symbolic calls are returned for most exact arguments. For some special cases explicit symbolic representations are returned.

Environment Interactions When called with a floating-point argument, the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples **Example 1**

Most calls with exact arguments return themselves unevaluated:

```
wrightOmega(1/2); wrightOmega(I*PI);
```

$$\omega\left(\frac{1}{2}\right)$$

$$\omega(\pi i)$$

Some special arguments return explicit symbolic representations:

```
wrightOmega(-1+I*PI); wrightOmega(ln(2)+6*PI*I);
```

-1

$W_3(2)$

If the argument is a floating-point value, then a floating-point result will be returned:

```
wrightOmega(0.5)
```

0.7662486082

Parameters

x

An arithmetical expression, the “argument”

Return Values

Arithmetical expression

See Also

MuPAD Functions

`lambertW`

write

Purpose

Write values of variables into file

Syntax

```
write(<Bin | Text>, <Encoding = "encodingValue">,
filename, <x1, x2, >)
write(<Encoding = "encodingValue">, n, <x1, x2, >)
```

Description

`write` serves for storing information from the current MuPAD session in a file. The file contains the values of identifiers of the current session. These identifiers are assigned the stored values when this file is read into another MuPAD session via the function `read`.

`write(filename, x1, x2, ...)` stores the current values of the identifiers x_1, x_2 etc. to the file `filename`.

`write(filename)` stores the values of all identifiers defined in the current session to the file `filename`.

`write(n)` and `write(n, x1, x2, ...)` store the data in the file associated with the file descriptor `n`.

`write(..., Encoding = "encodingValue", ...)` stores the current values of identifiers in the specified encoding only when writing in `Text` mode. For the supported encodings, see “Options” on page 1-2267. You can use this option with any of the previously specified syntaxes.

If the file is specified by its name, `write` creates a new file or overwrites an existing file; `write` opens and closes the file automatically.

If `WRITEPATH` does not have a value, `write` interprets the file name as a pathname relative to the “working folder”.

Note that the meaning of “working folder” depends on the operating system. On Microsoft Windows systems and on Mac OS X systems, the “working folder” is the folder where MATLAB is installed. On UNIX systems, it is the current working folder in which MATLAB was started. When started from a menu or desktop item, this is typically the user’s home folder.

Also absolute path names are processed by `write`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Cf. “Example 2” on page 1-2264. In this case, the data written by `write` are appended to the corresponding file. The file is not closed automatically by `write` and must be closed by a subsequent call to `fclose`.

Note that `fopen(filename)` opens the file in read-only mode. A subsequent `write` command to this file causes an error. Use the `Write` or `Append` option of `fopen` to open the file for writing.

The file descriptor 0 represents the screen.

`write` stores procedures with the option `noExpose` in encrypted format.

Note `write` stores the *values* of the given identifiers, not *their full evaluation*! Cf. “Example 3” on page 1-2265.

Environment Interactions

The function is sensitive to the environment variable `WRITEPATH`. If this variable has a value, the file is created in the corresponding folder. Otherwise, the file is created in the “working folder.”

Examples

Example 1

The variable `a` and its value `b + 1` are stored in a file named `test`:

```
a := b + 1:
fid := fopen(TempFile, Write, Text):
write(fid, a):
```

Use `fname` to return the name of the temporary file you created:

```
file := fname(fid):
```

The content of this file is displayed via `ftextinput`:

```
ftextinput(file)
```

write

```
"a := hold(_plus)(hold(b), 1):"
```

Delete the value of a. Reading the file test restores the previous value:

```
delete a:  
read(file):  
a
```

```
b+1
```

For identifiers that have no value, write writes a delete command to the file:

```
delete a:  
write(Text, 0, a):  
  
delete a:
```

Example 2

The file test is opened for writing using the MuPAD binary format:

```
fid := fopen(TempFile):  
file := fname(fid):  
n := fopen(file, Write)
```

```
17
```

This number is the descriptor of the file and can be used in a write command:

```
a := b + 1:  
write(n, a):  
fclose(n):
```

```
delete a:
read(file):
a

b+1
```

Clean up:

```
delete n, a:
```

Example 3

The value $b + 1$ is assigned to the identifier a . After assigning the value 2 to b , complete evaluation of a yields 3:

```
a := b + 1:
b := 2:
a

3
```

Note, however, that the value of a is the expression $b + 1$. This value is stored by a `write` command:

```
fid := fopen(TempFile, Write, Text):
write(fid, a):
file := fname(fid):
ftextinput(file)

"a := hold(_plus)(hold(b), 1)."
```

Consequently, this value is restored after reading the file into a MuPAD session:

```
delete a, b:
read(file):
```

write

```
a
```

```
b+1
```

```
delete a:
```

Example 4

write, when writing binary format, can store procedures with the option noExpose set. They are encrypted before writing:

```
f := proc(a)
  option noExpose;
begin
  print(a, a^2, a*a);
end_proc:

write("hidden_proc.mb", f):

delete f:

read("hidden_proc.mb"):

f(-2...3);
expose(f)

-2.0 ... 3.0, 0.0 ... 9.0, -6.0 ... 9.0

proc(a)
  name f;
  option noDebug, noExpose;
begin
  /* Hidden */
end_proc
```

This is the intention behind option `noExpose`: You can develop code you wish not to publish, then include option `noExpose` in your sources, rerun your tests, use `write` to write a binary version of your library and distribute that.

Example 5

To specify the encoding to write data, use `Encoding`. The `Encoding` option applies only to text files that are opened using a file name and not a file descriptor. Write the value of the identifier `a:="abc "` into a temporary file in the encoding `UTF-8` :

```
a:="abc    ":
write(Text,Encoding="UTF-8","write_test",a):
```

Specify the correct encoding to read the file:

```
read("write_test", Encoding="UTF-8")
```

```
"abcäöü"
```

Parameters

filename

The name of a file: a character string

x_1, x_2, \dots

identifiers

n

A file descriptor provided by `fopen`: a nonnegative integer

Options

Bin, Text

With `Bin`, the data are stored in the MuPAD binary format. With `Text`, standard ASCII format is used. The default is `Bin`.

In ASCII format, assignments of the form `identifier := hold(value):` or `delete identifier:` are written into the file. See “Example 1” on page 1-2263.

Encoding

This option lets you specify the character encoding to use. The allowed encodings are:

"Big5"	"ISO-8859-1"	"windows-932"
"EUC-JP"	"ISO-8859-2"	"windows-936"
"GBK"	"ISO-8859-3"	"windows-949"
"KSC_5601"	"ISO-8859-4"	"windows-950"
"Macintosh"	"ISO-8859-9"	"windows-1250"
"Shift_JIS"x	"ISO-8859-13"	"windows-1251"
"US-ASCII"	"ISO-8859-15"	"windows-1252"
"UTF-8"		"windows-1253"
		"windows-1254"
		"windows-1257"

The default encoding is system dependent. If you specify the encoding incorrectly, characters might read incorrectly. Characters unrecognized by the encoding are replaced by the default substitution character for the specified encoding.

Encodings not listed here can be specified but might not produce correct results.

Return Values

Void object of type `DOM_NULL`.

print | protocol | read | READPATH | WRITEPATH

zeta

Purpose

The Riemann zeta function

Syntax

`zeta(z)`
`zeta(z, n)`

Description

`zeta(z)` represents the Riemann zeta function $\zeta(z) = \sum_{k=1}^{\infty} \frac{1}{k^z}$.

`zeta(z, n)` represents the n-th derivative $\sum_{k=1}^{\infty} \frac{(-\ln(k))^n}{k^z}$ of the zeta function.

The series converge only if the real part of z is greater than 1. The definition of the zeta function is extended to the entire complex plane, except for a simple pole $z = 1$, by analytic continuation.

The calls `zeta(z)` and `zeta(z, 0)` are equivalent.

A floating-point result is returned for floating-point arguments z .

The following special exact values are implemented:

$$\zeta(0) = -\frac{1}{2}, \quad \zeta(0, 1) = -\frac{\ln(\pi)}{2} - \frac{\ln(2)}{2},$$
$$\zeta(z) = 0 \text{ for even integers } z < 0,$$

$$\zeta(z) = -\frac{\text{bernoulli}(1-z)}{\Gamma(z)} \text{ for odd integers } z \text{ satisfying } -\text{Pref::autoExpansionLimit}() \leq z < 0,$$

$$\zeta(z) = \frac{(2\pi)^z |\text{bernoulli}(z)|}{\Gamma(z)} \text{ for even integers } z \text{ satisfying } 0 \leq z \leq \text{Pref::autoExpansionLimit}(),$$

$$\zeta(\infty) = 1, \quad \zeta(\infty, n) = 0 \text{ for } n > 0.$$

`zeta` returns a symbolic function call, if the argument does not evaluate to one of the above numbers.

Note Floating point evaluation is rather slow for large values of n . Further, for large n , evaluation for $\Re(z) < 0$ is much slower than the evaluation for $\Re(z) \geq 0$.

Environment Interactions

When called with a floating-point argument z , the function is sensitive to the environment variable DIGITS which determines the numerical working precision.

Examples

Example 1

We demonstrate some calls with exact and symbolic input data:

`zeta(-6), zeta(-5), zeta(-4), zeta(-3), zeta(-2), zeta(-1)`

$$0, -\frac{1}{252}, 0, \frac{1}{120}, 0, -\frac{1}{12}$$

`zeta(0), zeta(2), zeta(3), zeta(4), zeta(5), zeta(6), zeta(7)`

$$-\frac{1}{2}, \frac{\pi^2}{6}, \zeta(3), \frac{\pi^4}{90}, \zeta(5), \frac{\pi^6}{945}, \zeta(7)$$

`zeta(1/2), zeta(1 + I, 1), zeta(z^2 - I, 2)`

$$\zeta\left(\frac{1}{2}\right), \zeta'(1+i), \zeta''(z^2-i)$$

Here are some values of the derivative of the zeta function:

`zeta(0, 1), zeta(infinity, 1)`

$$-\frac{\ln(2)}{2} - \frac{\ln(\pi)}{2}, 0$$

Floating point values are computed for floating-point arguments:

```
zeta(-1001.0), zeta(12.3, 1), zeta(0.5 + 14.13472514*I, 2)  
- 1.348590824 101771, - 0.0001389996909, - 0.614409794 - 0.2297836439 i
```

zeta has a pole at the point $z = 1$:

```
zeta(1)
```

```
Error: Singularity. [zeta]
```

Example 2

Looking for nontrivial roots of the Zeta function, we plot the function $f(z) = |\zeta(z)|$ along the “critical line” of complex numbers with real part $\frac{1}{2}$:

```
plotfunc2d(abs(zeta(1/2 + y*I)), y = 0..30, Mesh = 500, AxesTitles
```

The following calls search for numerical roots along the critical line:

```
numeric::solve(zeta(1/2 + I*y), y = 10..20),
numeric::solve(zeta(1/2 + I*y), y = 20..22),
numeric::solve(zeta(1/2 + I*y), y = 22..26)
```

```
{14.13472514}, {21.02203964}, {25.01085758}
```

Parameters

z

An arithmetical expression

n

An arithmetical expression representing a nonnegative integer

zeta

Return Values

Arithmetical expression.

MuPAD Functions

`bernoulli`

Purpose

Combine lists

Syntax

```
zip(list1, list2, f)
zip(list1, list2, f, default)
```

Description

`zip(list1, list2, f)` combines two lists via a function `f`. It returns a list whose i -th entry is `f(list1[i], list2[i])`. Its length is the minimum of the lengths of the two input lists.

`zip(list1, list2, f, default)` returns a list whose length is the maximum of the lengths of the two input lists. The shorter list is padded with the `default` value.

If `f` produces the void object of type `DOM_NULL`, then this element is removed from the resulting list.

`zip` is recommended for fast manipulation of lists. It is a function of the system kernel.

Examples**Example 1**

The fastest way of adding the entries of two lists is to 'zip' them via the function `_plus`:

```
zip([a, b, c, d], [1, 2, 3, 4], _plus)
```

```
[a+1, b+2, c+3, d+4]
```

If the input lists have different lengths, then the shorter list determines the length of the returned list:

```
zip([a, b, c, d], [1, 2], _plus)
```

```
[a+1, b+2]
```

The longer list determines the length of the returned list if a value for padding the shorter list is provided:

zip

```
zip([a, b, c, d], [1, 2], _plus, 17)
```

```
[a+1, b+2, c+17, d+17]
```

Parameters

list1, list2

lists of arbitrary MuPAD objects

f

Any MuPAD object. Typically, a function of two arguments.

default

Any MuPAD object

Return Values

List.

Overloaded By

list1, list2

Purpose Z transform

Syntax ztrans(f, k, z)

Description ztrans(f, k, z) computes the Z transform of the expression $f = f(k)$ with respect to the index k at the point z .

The Z transform $F(z)$ of the function $f(k)$ is defined as follows:

$$F(z) = \sum_{k=0}^{\infty} \frac{f(k)}{z^k}$$

If ztrans cannot find an explicit representation of the transform, it returns an unevaluated function call. See “Example 4” on page 1-2279.

If f is a matrix, ztrans applies the Z transform to all components of the matrix.

To compute the inverse Z transform, use iztrans.

Examples **Example 1**

Compute the Z transform of these expressions:

`ztrans(1/k!, k, z)`

$$e^{\frac{1}{z}}$$

`ztrans(sin(k), k, z)`

$$\frac{z \sin(1)}{z^2 - 2 \cos(1) z + 1}$$

Example 2

Compute the Z transform of this expression and then simplify the result:

```
ztrans(cos(a*k + b), k, z)
```

$$\frac{z \cos(b) (z - \cos(a))}{z^2 - 2 \cos(a) z + 1} - \frac{z \sin(a) \sin(b)}{z^2 - 2 \cos(a) z + 1}$$

```
Simplify(%)
```

$$- \frac{z (\cos(a - b) - z \cos(b))}{z^2 - 2 \cos(a) z + 1}$$

Example 3

Compute the Z transform of this expression with respect to the variable k:

```
F := ztrans(2*k + 3, k, z)
```

$$\frac{3z}{z-1} + \frac{2z}{(z-1)^2}$$

Evaluate the Z transform of the expression at the points $z = 2a + 3$ and $z = 1 + i$. You can evaluate the resulting expression F using | (or its functional form evalAt):

```
F | z = 2*a + 3
```

$$\frac{3(2a+3)}{2a+2} + \frac{2(2a+3)}{(2a+2)^2}$$

Also, you can evaluate the Z transform at a particular point directly:

```
ztrans(2*k + 3, k, 1 + I)
```

$$1 - 5i$$

Example 4

If `ztrans` cannot find an explicit representation of the transform, it returns an unevaluated call:

```
ztrans(f(k), k, z)
```

$$ztrans(f(k), k, z)$$

`iztrans` returns the original expression:

```
iztrans(%, z, k)
```

$$f(k)$$

Example 5

Compute the following Z transforms that involve Kronecker's Delta function and the Heaviside function:

```
ztrans(f(k)*kroneckerDelta(k, 1) + g(k)*kroneckerDelta(k, -5), k, z)
```

$$\frac{f(1)}{z}$$

```
ztrans(binomial(k, 2)*heaviside(5 - k), k, z)
```

$$\frac{z}{(z-1)^3} + \frac{5}{z^5} + \frac{6z - \frac{z^6}{(z-1)^3} + 3z^2 + z^3}{z^5}$$

Simplify the last expression using `simplify`:

```
simplify(%)
```

$$\frac{z^3 + 3z^2 + 6z + 5}{z^5}$$

Example 6

Compute the Z transforms of this expression that involves the Heaviside function:

```
ztrans(heaviside(k - 3), k, z)
```

$$\frac{\frac{1}{z-1} + \frac{1}{2}}{z^3}$$

Note that MuPAD uses the value $\text{heaviside}(0) = 1/2$. You can define a different value for $\text{heaviside}(0)$:

```
unprotect(heaviside):  
heaviside(0) := 1:
```

For better performance, MuPAD remembers the previously computed value of the Z transform. To force the system to recalculate the transform, clear its remember table:

```
ztrans(Remember, Clear):
```

For details about the remember mechanism, see Remember Mechanism.

Defining a different value for $\text{heaviside}(0)$ produces a different value of the Z transform:

```
ztrans(heaviside(k - 3), k, z)
```

$$\frac{\frac{1}{z-1} + 1}{z^3}$$

For further computations, restore the original value:

```
heaviside(0) := 1/2:
protect(heaviside):
```

Example 7

Compute the Z transforms of these expressions:

```
ztrans(k*f(k), k, z)
```

$$-z \frac{\partial}{\partial z} ztrans(f(k), k, z)$$

```
ztrans(f(k + 1), k, z)
```

$$z ztrans(f(k), k, z) - z f(0)$$

Parameters

f

Arithmetical expression or matrix of such expressions

k

Identifier or indexed identifier

z

Arithmetical expression representing the evaluation point

Return Values

Arithmetical expression or unevaluated function call of type ztrans. An explicit result can be a `piecewise` object. If the first argument is a matrix, the result is returned as a matrix.

ztrans

**MuPAD
Functions** ztrans::addpattern | iztrans | iztrans::addpattern

**Related
Examples**

- “Z-Transforms”

- Purpose** Add patterns for the Z transform
- Syntax** `ztrans::addpattern(pat, k, z, res, <vars, <conds>>)`
- Description** `ztrans::addpattern(pat, k, z, res)` teaches `ztrans` to return

$$\text{ztrans}(\text{pat}, k, z) = \sum_{k=0}^{\infty} \frac{\text{pat}}{z^k} = \text{res}.$$

The `ztrans` function uses a set of patterns for computing Z transforms. You can extend the set by adding your own patterns. To add a new pattern to the pattern matcher, use `ztrans::addpattern`. MuPAD does not save custom patterns permanently. The new patterns are available in the *current* MuPAD session only.

Variable names that you use when calling `ztrans::addpattern` can differ from the names that you use when calling `ztrans`. See “Example 2” on page 1-2284.

You can include a list of free parameters and a list of conditions on these parameters. These conditions and the result are protected from premature evaluation. This means that you can use `not iszero(a^2 - b)` instead of `hold(_not @ iszero)(a^2 - b)`.

The following conditions treat assumptions on identifiers differently:

- `a^2 - b <> 0` takes into account assumptions on identifiers.
- `not iszero(a^2 - b)` disregards assumptions on identifiers.

See “Example 3” on page 1-2285.

- Environment Interactions** Calling `ztrans::addpattern` changes the expressions returned by future calls to `ztrans`.

Examples **Example 1**

Compute the Z transform of the function `foo`. By default, MuPAD does not have a pattern for this function:

ztrans::addpattern

```
ztrans(foo(k), k, z)
```

```
ztrans(foo(k), k, z)
```

Add a pattern for the Z transform of foo using ztrans::addpattern:

```
ztrans::addpattern(foo(k), k, z, bar(z)):
```

Now ztrans returns the Z transform of foo:

```
ztrans(foo(k), k, z)
```

```
bar(z)
```

After you add a new transform pattern, MuPAD can use that pattern indirectly:

```
ztrans(foo(k + 3), k, z)
```

```

$$z^3 \text{bar}(z) - z \text{foo}(2) - z^2 \text{foo}(1) - z^3 \text{foo}(0)$$

```

Example 2

Define the Z transform of foo(x) using the variables x and y as parameters:

```
ztrans::addpattern(x, x, y, y/(y^2-2*y+1)):
```

The ztrans function recognizes the added pattern even if you use other variables as parameters:

```
ztrans(s, s, t)
```

```

$$\frac{t}{t^2 - 2t + 1}$$

```

Example 3

Use assumptions when adding this pattern for the Z transform:

```
ztrans::addpattern(FOO(x*k), k, z, sin(1/(x-1/2))*BAR(z), [x], [
ztrans(FOO(x*k), k, z) assuming -1 < x < 1
```

$$\sin\left(\frac{1}{x-\frac{1}{2}}\right) \text{BAR}(z)$$

If $|x| \geq 1$, you cannot apply this pattern:

```
ztrans(FOO(x*k), k, z) assuming x >= 1
```

$$\text{ztrans}(\text{FOO}(kx), k, z)$$

If MuPAD cannot determine whether the conditions are satisfied, it returns a piecewise object:

```
ztrans(FOO(x*k), k, z)
```

$$\left\{ \begin{array}{l} \sin\left(\frac{1}{x-\frac{1}{2}}\right) \text{BAR}(z) \text{ if } |x| < 1 \end{array} \right.$$

Note that the resulting expression defining the Z transform of $\text{FOO}(x*k)$ implicitly assumes that the value of x is not $1/2$. A strict definition of the pattern is:

```
ztrans::addpattern(BAR(x*k), k, z, sin(1/(x - 1/2))*FOO(z), [x],
```

If either the conditions are not satisfied or substituting the values into the result gives an error, `ztrans` ignores the pattern. For this particular pattern, you can omit specifying the assumption $x \neq 1/2$. If $x = 1/2$, MuPAD throws an internal “Division by zero.” error and ignores the pattern:

ztrans::addpattern

`ztrans(F00(s/2), s, t)`

`ztrans(F00($\frac{s}{2}$), s, t)`

Parameters

pat

Arithmetical expression in the variable `k` representing the pattern to match

k

Identifier or indexed identifier used as a variable in the pattern

z

Identifier or indexed identifier used as a variable in the result

res

Arithmetical expression in the variable `k` representing the pattern for the result of the transformation

vars

List of identifiers or indexed identifiers used as “pattern variables” (placeholders in `pat` and `res`). You can use pattern variables as placeholders for almost arbitrary MuPAD expressions not containing `k` or `z`. You can restrict them by conditions given in the optional parameter `conds`.

conds

List of conditions on the pattern variables

Return Values

Object of type `DOM_NULL`

- “Use Custom Patterns for Transforms”

ztrans::addpattern

adt – Abstract Datatypes

adt::Heap
adt::Queue
adt::Stack
adt::Tree

adt::Heap

Purpose Abstract data type “Heap”

Syntax `adt::Heap()`

Description `adt::Heap` implements the abstract data type “Heap”.

A “heap” or “priority queue” is a data type that stores a collection of elements. Elements can be compared and the minimal element can be read and deleted from the heap.

In `adt::Heap`, each element is associated with a comparison key, typically a real number. The keys must be comparable with one another using `<`.

To get access to the largest element in an `adt::Heap`, you can simply negate the comparison keys.

`adt::Heap` returns a function environment. This object has slots “insert”, “nops”, “min_pair”, “min_element”, and “delete_min” which allow operations on the heap. See the examples.

`adt::Heap` does not allow access to other elements than the minimal one.

Examples **Example 1**

`adt::Heap()` creates an empty heap:

```
h := adt::Heap()
```

```
adt::Heap(...)
```

The slot “nops” of `h` shows the number of elements in the heap:

```
h::nops()
```

```
0
```

`h::insert` is the method to insert new elements. It expects two arguments: the comparison key and the data. For now, we simply insert some numbers, so we repeat the number in both arguments:

```
h::insert(3,3):  
h::insert(1,1):  
h::insert(2,2):
```

```
h::nops()
```

```
3
```

When retrieving the elements with `h::delete_min`, we see that they are returned in increasing order:

```
h::delete_min(), h::delete_min(), h::delete_min()
```

```
1, 2, 3
```

The heap is now empty:

```
h::nops()
```

```
0
```

Calling `delete_min` on an empty heap returns FAIL:

```
h::delete_min()
```

```
FAIL
```

Algorithms

`adt::Heap` uses a complete binary tree stored in a list. Insertions operate in expected constant time, with a worst case time logarithmic in the number of elements in the heap. For "`delete_min`", both the

adt::Heap

average and the worst-case running time are $O(\log n)$, with n the size of the heap.

MuPAD Functions

[adt::Queue](#) | [adt::Stack](#) | [adt::Tree](#)

Purpose Abstract data type “Queue”

Syntax `adt::Queue(queue)`

Description `adt::Queue` implements the abstract data type “Queue”. To create a queue, an expression sequence of any MuPAD objects can be given to initialize the queue, otherwise an empty queue is built.

Note The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

With `Q := adt::Queue()` an empty queue is built and assigned to the variable `Q`.

Every queue will be displayed as `Queue` followed by a number. This name is generated by `genident`.

Note *All following methods changes the value of Q itself.* A new assignment to the variable (in this example `Q`) is not necessary, in contrast to all other MuPAD functions and data types.

The methods `clear`, `dequeue`, `empty`, `enqueue`, `front`, `length`, `reverse` are available for handling with queues.

Examples

Example 1

Create a new queue with strings as arguments.

```
Q := adt::Queue("1", "2", "3", "4")
```

```
Queue1
```

Show the length of the queue.

adt::Queue

```
Q::length()
```

```
4
```

Fill up the queue with a new element. The queue will be changed by the method, no new assignment to Q is necessary!

```
Q::enqueue("5")
```

```
"5"
```

Show the front of the queue. This method does not change the queue.

```
Q::front(), Q::front()
```

```
"1", "1"
```

After twice getting an element of the queue, the third element is the new front of the queue, and the length is 3.

```
Q::dequeue(), Q::dequeue(), Q::front(), Q::length()
```

```
"1", "2", "3", 3
```

Now revert the queue. The last element will be the first element.

```
Q::reverse(): Q::front()
```

```
"5"
```

Enlarge the queue with "2".

```
Q::enqueue("2"):
```

```
Q::empty()
```

```
FALSE
```

Finally collect all elements of the queue in the list assigned to ARGS, until the queue is empty.

```
ARGS := []: while not Q::empty() do ARGS := append(ARGS, Q::dequeue)
ARGS
```

```
["5", "4", "3", "2"]
```

Parameters

queue

An expression sequence of objects to initialize the queue

Methods

clear - Clear the queue

```
clear()
```

dequeue - Get an element from the queue

```
dequeue()
```

empty - Is the queue empty

```
empty()
```

enqueue - Fill up the queue

```
enqueue(x)
```

front - Front of the queue

```
front()
```

length - Length of the queue

```
length()
```

reverse - Revert the queue

adt::Queue

reverse()

Purpose	Abstract datatype “Stack”
Syntax	<code>adt::Stack(stack)</code>
Description	<code>adt::Stack</code> implements the abstract data type “Stack.” To create a stack, an expression sequence of any MuPAD objects can be given to initialize the stack, otherwise an empty stack is built.

Note The methods `adt::Stack`, like those of all abstract data types, change their argument as a side effect.

With `S := adt::Stack()` an empty stack is built and assigned to the variable `S`.

Note *All following methods change the value of `S` itself.* A new assignment to the variable (in this example `S`) is not necessary, in contrast to most other MuPAD functions and data types.

The stacks created in a session are named `Stack1`, `Stack2`, ... and printed as such.

Examples

Example 1

We create an empty stack, and fill it with some values:

```
S := adt::Stack();  
S::push(a): S::push(b): S::push(c):
```

```
Stack1
```

The stack now contains 3 elements:

adt::Stack

```
S::nops()
```

```
3
```

The top of the stack is the last valued pushed:

```
S::top()
```

```
c
```

Now, we fetch successively the values contains in S; they come back in reversed order:

```
S::pop();
```

```
S::pop();
```

```
S::pop()
```

```
c
```

```
b
```

```
a
```

Now, the stack is empty. Trying to pop again an element from it results in a FAIL value being returned:

```
S::pop()
```

```
FAIL
```

Parameters

stack

An expression sequence of objects to initialize the stack

Return Values

Object of the domain `adt::Stack`

Methods

S::empty - I the stack empty

`S::empty()`

S::nops - Size of the stack

`S::nops()`

S::depth - Depth of the stack

`S::depth()`

S::top - Top element of the stack

`S::top()`

S::push - Push an element on the stack

`S::push(x)`

S::pop - Pop an element from the stack

`S::pop()`

S::reverse - Revert the stack

`S::reverse()`

S::copy - Copy of the stack

`S::copy()`

adt::Tree

Purpose Abstract data type “Tree”

Syntax `adt::Tree(tree)`

Description `adt::Tree` implements the abstract data type “Tree”.

A tree must be given as a special MuPAD list. The first object of the list is the root of the tree. All further objects are leaves or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as leaf of the tree (see “Example 1” on page 2-13).

A tree can be used to display data in tree structure using the function `output::tree` (or the method “`print`” of a tree). The nodes and leaves of the tree will be printed by MuPAD when the tree will be displayed.

A tree can also be used as datatype to keep and handle any MuPAD data.

Note The methods of all abstract data types must be called especially and will result changing the object itself as side effect.

`T := adt::Tree([_plus, 3, 4, [_mult, 5, 3], 1])` builds a tree and assigns it to the variable `T`.

Every tree will be displayed as `Tree` followed by a number. This name is generated by `genident`.

To display the content of a tree, the function `expose` or the method “`print`” of the tree itself must be used.

Note *All following methods changes the value of T itself.* A new assignment to the variable (in this example `T`) is not necessary, in contrast to all other MuPAD functions and data types.

The methods `nops`, `op`, `expr`, `print`, `indent`, `chars` are now available for handling with trees.

Examples

Example 1

Creating a simple tree with only two leaves. To access and display a tree it must be assigned to a variable:

```
T := adt::Tree(["ROOT", "LEFT", "RIGHT"])
```

```
Tree1
```

The tree will only be printed by its name. To display the tree, the function `expose` or the method `print` of the tree must be used:

```
T::print()
```

```
ROOT
|
+-- LEFT
|
`-- RIGHT
```

```
expose(T)
```

```
ROOT
|
+-- LEFT
|
`-- RIGHT
```

The next tree contains two subtrees as leaves:

adt::Tree

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],  
              ["RROOT", "RLEFT", "RRIGHT"]]):  
T::print()
```

```
ROOT  
|  
+-- LROOT  
|   |  
|   +-- LLEFT  
|   |  
|   \-- LRIGHT  
|  
|-- RROOT  
|   |  
|   +-- RLEFT  
|   |  
|   \-- RRIGHT
```

Example 2

Get the operands of a tree: Also a subtree can be an operand:

```
T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],  
              "MIDDLE",  
              ["RROOT", "RLEFT", "RRIGHT"]]):  
T::op()
```

```
Tree4, "MIDDLE", Tree5
```

Use `expose` to display subtrees:

```
map(%, expose)
```

```
LROOT
```

```
RROOT
```

Get all operands including the root:

```

T::op(0..T::nops())

"ROOT", Tree6, "MIDDLE", Tree7

```

Access to various operands:

```

T::op(0);
T::op(2..3);
T::op([1, 2])

"ROOT"

"MIDDLE", Tree9

"LRIGHT"

```

Example 3

The default characters are ["|", "+", "-", " ", " "]:

```

T := adt::Tree(["ROOT", ["LROOT", "LLEFT", "LRIGHT"],
               ["RROOT", "RLEFT", "RRIGHT"]]);
T::print()

```

```

ROOT
|

```

adt::Tree

```
+-- LROOT
|
|  +-- LLEFT
|  |
|  |  -- LRIGHT
|  |
|  -- RROOT
|  |
|  |  +-- RLEFT
|  |  |
|  |  |  -- RRIGHT
```

The characters can be changed:

```
T::chars(["|", "|", "_", "|", " "]):
T::print()
```

```
ROOT
|
|__ LROOT
|   |
|   |__ LLEFT
|   |
|   |__ LRIGHT
|   |
|__ RROOT
|   |
|   |__ RLEFT
|   |
|   |__ RRIGHT
```

Example 4

A tree visualizes the structure of an expression:

```
T:= adt::Tree([_plus, [_power, [sin, x], 2], [_power, [cos, x], 2]],
T::print()
```

A tree can be converted to a MuPAD expression:

```
T::expr(), simplify(T::expr())
```

```
cos(x)2 + sin(x)2, 1
```

Parameters

tree

The tree, given as a special list (see details)

Methods

nops - Number of operands

nops()

In this example T has 4 operands, the numbers 3, 4, 1 and the subtree `adt::Tree([_mult, 5, 3])`.

op - Operand of a tree

`op(<n>)`

`T::op(n)` returns the specified operands of the tree. `n` can be a number between 0 and `T::nops()` (0 gives the root of the tree), a sequence `i..j` (to return the *i*th to *j*th operand), or a list to specify operands of subtrees (exactly as for the kernel function `op`). `T::op()` returns all operands except the 0-th as expression sequence. See “Example 2” on page 2-14.

expr - Convert a tree to an expression

`expr()`

print - Display a tree

`print()`

indent - Indent width of each operand

`indent(<n>)`

chars - Indent width of each operand

`chars(<list>)`

Ax – Axioms

Ax::canonicalOrder

Ax::canonicalRep

Ax::canonicalUnitNormal

Ax::closedUnitNormals

Ax::efficientOperation

Ax::indetElements

Ax::normalRep

Ax::noZeroDivisors

Ax::systemRep

Ax::canonicalOrder

Purpose Axiom of canonically ordered sets

Description `Ax::canonicalOrder` states that a domain has an order `< (_less)` which is defined by the canonical order of the MuPAD expressions.
This implies that the order of two elements is defined by the system function `_less`.

Purpose

Axiom of canonical representation

Description

`Ax::canonicalRep` states that domain elements are canonically represented, i.e. that each element of the domain has only one unique expression which represents it.

This axiom implies that for an abelian monoid the axiom `Ax::normalRep` also holds. This is not enforced by the category but must be stated by the implementor of a domain.

Ax::canonicalUnitNormal

Purpose Axiom of canonical unit normals

Description Ax::canonicalUnitNormal states that the method "unitNormal" of an integral domain (category Cat::IntegralDomain) returns a unique unit normal.

This means that for each non-zero element x of the integral domain there exists a unique associate among the associate class of x , i.e. for any x and y of a domain dom of category Cat::IntegralDomain where $\text{dom}::\text{associates}(x, y)$ returns TRUE the equation $\text{dom}::\text{equal}(\text{dom}::\text{unitNormal}(x), \text{dom}::\text{unitNormal}(y)) = \text{TRUE}$ must hold.

Note that this axiom does not imply that the unit normals are canonically represented. The unit normals of x and y must be mathematically equal in the sense of the method "equal", they need not be structurally equal as MuPAD objects.

Purpose

Axiom of closed unit normals

Description

`Ax::closedUnitNormals` states that the unit normals of an integral domain are closed under multiplication, i.e., that `dom::equal(x, dom::unitNormal(a) * dom::unitNormal(b)) = TRUE` implies `dom::equal(x, dom::unitNormal(x)) = TRUE` for all elements `x`, `a` and `b` of the domain `dom`.

This axiom may be used only in conjunction with the axiom `Ax::canonicalUnitNormal`. If an integral domain has no unique unit normals, this axiom may not be stated.

Ax::efficientOperation

Purpose	Axiom of efficient operations
Syntax	<code>Ax::efficientOperation(oper)</code>
Description	<p><code>Ax::efficientOperation(oper)</code> states that operation <code>oper</code> can be performed efficiently.</p> <p>The string <code>oper</code> must be the name of the operation's slot in the domain stating the axiom. Examples are <code>"_mult"</code>, <code>"_invert"</code> or <code>"_divide"</code>.</p>
Parameters	<p>oper</p> <p>A string which defines the efficient operation.</p>

Purpose

Axiom that indeterminates may be elements

Description

`Ax::indetElements` states that there exist domain elements that may also be regarded as being transcendental over the domain.

`Ax::indetElements` has no mathematical meaning: elements of a ring are always algebraic (of degree 1) over the ring. However, since there are domains in MuPAD that comprise all MuPAD identifiers, insisting on this viewpoint would mean that polynomials over such domains could not be constructed. Hence MuPAD allows the user to regard an identifier as being transcendental over the set of all identifiers.

Ax::normalRep

Purpose Axiom of normal representation

Description Ax::normalRep states that an abelian monoid has a canonical representation of its zero element, i.e., that there is only one unique expression to represent zero.

If the axiom Ax::normalRep holds for a domain dom, one may test for zero by comparing an element with dom::zero using the system function `_equal`.

Purpose

Axiom of rings with no zero divisor

Description

`Ax::noZeroDivisors` states that a ring without a unit has no zero divisors, i.e., that the product of two non-zero elements is never zero.

Note that an integral domain implicitly has no zero divisors.

Ax::systemRep

Purpose Axiom of façade domains

Description Ax::systemRep states that domain elements are represented by elements of built-in domains.

There are principally two ways to represent the elements of a domain: On the one hand the elements may be created explicitly by the system function `new`, on the other hand one may use the built-in (or basic) domains of MuPAD (like `DOM_INT`) to represent the elements.

Domains which don't create elements of their own but use elements of basic domains instead are called *façade domains*.

The usage of basic domains for the representation has the advantage that system functions may be used directly as methods of the domain without the overhead caused by overloading and procedure calls. But it has some severe limitations, see the domain `Dom::Expression` for details.

The axiom `Ax::systemRep` is used to state that the elements of a domain are represented by basic domains and are not created by `new`.

Cat::SemiGroup
Cat::Set
Cat::SkewField
Cat::SquareMatrix
Cat::UnivariatePolynomial
Cat::VectorSpace

Purpose Base category

Description `Cat::BaseCategory` is the most general super-category of all categories defined by the `Cat` package. Any domain in the `Dom` package is of this category.

The methods defined by `Cat::BaseCategory` are related to type conversion and equality testing, they are not related to an algebraic structure.

Methods Basic Methods

convert - Convert into this domain

```
convert(x)
```

convert_to - Convert to certain type

```
convert_to(x, T)
```

equal - Test for equality

```
equal(x, y)
```

Note that this method does *not* overload the function `_equal`, i.e. the `=` operator. The function `_equal` cannot be overloaded.

expr - Convert into expression

```
expr(x)
```

Conversion Methods

coerce - Coerce into this domain

```
coerce(x)
```

The implementation provided tries to convert `x` into an element of this domain by first calling `dom::convert(x)` and then, if this fails, `x::dom::convert_to(x, dom)`; it returns `FAIL` if both methods fail.

equiv - Test for equivalence

```
equiv(x, y)
```

The implementation provided tries to convert x and y into elements of this domain and then calls `dom::equal` with these elements. It returns FAIL if the conversion fails or the equality test returns UNKNOWN.

new - Create element of this domain

`new(x)`

Given a domain D , an expression of the form $D(x, \dots)$ results in a call of the form `D::new(x, \dots)`.

The implementation provided here tries to convert x by calling `dom::convert(x)` and returns the result. It raises an error if `dom::convert` returns FAIL.

print - Return expression to print an element

`print(x)`

Please do *not* print directly in this method by calling the function `print` for example!

The implementation provided here is `dom::expr`.

testtype - Test type of object

`testtype(x, T)`

This method must return TRUE if it can decide that x is of type T , FALSE if it can decide that x is not of type T and FAIL if it can not decide the test.

This method is called in three different situations: Either if the argument x is of this domain, or if T is this domain, or if T is an element of this domain. Thus the following three situations can arise:

- x is an element of the current domain.

In this case it must be tested if x may be regarded as an element of the type T , which may either be a domain or type expression. By default, this is only true if the domain type of x is T , or if T

is a domain constructor for which `x::dom::hasProp(x, T)` is TRUE. In particular, `x` is, by default, not of type `T` if `T` is a type of the Type library.

- `T` is the current domain.

In this case it must be tested if `x` may be regarded as an element of this domain. By the default implementation provided, this is TRUE only if the domain type of `x` is `dom`.

- `T` is an element of the current domain.

In this case `T` is regarded as a type expression. The default implementation provided returns TRUE if the domain type of `x` is `T`, and FAIL if not. A special rule holds if `T` is a façade domain: in that case, `coerce(x, T)` is called, if this is successful TRUE is returned and FAIL if not.

Technical Methods

new_extelement - Create element of kernel or façade domain

```
new_extelement(x, )
```

When an expression `new(D, x, ...)` is evaluated and `D` is a domain with method "new_extelement", then `D::new_extelement(D, x, ...)` is evaluated and returned as result.

Kernel or façade domains must define this method because otherwise the function `new` would return a “container” element of `D` rather than a “raw” element as intended.

The implementation provided here returns the result of `D::new(x, ...)`.

Cat::AbelianGroup

Purpose Category of Abelian groups

Description Cat::AbelianGroup represents the category of Abelian groups.
A Cat::AbelianGroup is an Abelian monoid with cancellation law where the operation + is invertible.

Categories Cat::CancellationAbelianMonoid

Methods Basic Methods

`_negate` - Return opposite

`_negate(x)`

Mathematical Methods

`equal` - Test for equality

`equal(x, y)`

`intmult` - Return integer multiple

`intmult(x, n)`

`_subtract` - Subtract two elements

`_subtract(x, y)`

Purpose	Category of Abelian monoids		
Description	<p>Cat::AbelianMonoid represents an Abelian monoid.</p> <p>An Cat::AbelianMonoid is an Abelian semi-group with a neutral element <code>dom::zero</code> according to the operation <code>+</code> (<code>_plus</code>).</p> <p>Use the axiom <code>Ax::normalRep</code> to state that zero is always represented in a unique way (i.e. canonically).</p> <p>If an Abelian monoid has not the axiom <code>Ax::normalRep</code> then <code>dom::zero</code> is only one possible representation of the neutral element. An Abelian semi-group must at least have the method <code>"iszero"</code> to test for zero in such a case.</p>		
Axioms	If the domain has <code>Ax::canonicalRep</code> , then <code>Ax::normalRep</code> .		
Categories	Cat::AbelianSemiGroup		
Entries	<table><tr><td><code>"zero"</code></td><td>Must hold the neutral element according to the operation <code>+</code>.</td></tr></table>	<code>"zero"</code>	Must hold the neutral element according to the operation <code>+</code> .
<code>"zero"</code>	Must hold the neutral element according to the operation <code>+</code> .		
Methods	<p>Mathematical Methods</p> <p>intmult - Return integer multiple</p> <pre>intmult(x, n)</pre> <p>iszero - Test if element is zero</p> <pre>iszero(x)</pre>		

Cat::AbelianSemiGroup

Purpose Category of Abelian semi-groups

Description `Cat::AbelianSemiGroup` represents the category of Abelian semi-groups where the operation is written as addition. Hence an `Cat::AbelianSemiGroup` is a set with an associative and commutative operation `+` (`_plus`).

Note that non-Abelian semi-groups with operation `*` have category `Cat::SemiGroup`.

Categories `Cat::BaseCategory`

Methods Basic Methods

`_plus` - Return the sum of its arguments

```
_plus(x, )
```

Mathematical Methods

`intmult` - Return integer multiple

```
intmult(x, n)
```

Purpose	Category of associative algebras
Syntax	<code>Cat::Algebra(R)</code>
Description	<p><code>Cat::Algebra(R)</code> represents the category of associative algebras over the commutative ring <code>R</code>.</p> <p>A <code>Cat::Algebra(R)</code> is a module over a commutative ring <code>R</code> which also is a ring.</p>
Categories	<code>Cat::Ring</code> , <code>Cat::Module(R)</code>
Parameters	R <p>A domain which is a commutative ring. The algebra will be an algebra over this ring.</p>

Cat::CancellationAbelianMonoid

Purpose Category of abelian monoids with cancellation

Description `Cat::CancellationAbelianMonoid` represents the category of Abelian monoids with cancellation.

A `Cat::CancellationAbelianMonoid` is an Abelian monoid where the cancellation law holds according to the operation $+$, i.e. $a + b = a + c$ implies $b = c$.

Categories `Cat::AbelianMonoid`

Methods Basic Methods

`_subtract` - Subtract two elements

`_subtract(x, y)`

Mathematical Methods

`equal` - Test for equality

`equal(x, y)`

The method "iszero" is used to test for zero.

`_negate` - Negate element

`_negate(x)`

`intmult` - Return integer multiple

`intmult(x, n)`

Purpose	Category of commutative rings
Description	<p>Cat::CommutativeRing represents the category of commutative rings.</p> <p>A Cat::CommutativeRing is a ring with unit <code>dom::one</code> where the multiplication <code>* (_mult)</code> is commutative. It is also a right module over itself.</p> <p>This implementation additionally assumes that the elements are always constant with respect to differentiation and derivatives. One must re-implement the methods "diff" and "D" if this assumption is false.</p>
Categories	Cat::Ring, Cat::RightModule(dom)
Methods	<p>Mathematical Methods</p> <p>diff - Differentiate element</p> <p style="padding-left: 40px;"><code>diff(x, <v, >)</code></p> <p>D - Return derivative</p> <p style="padding-left: 40px;"><code>D(1, x)</code></p>

Cat::DifferentialRing

Purpose

Category of ordinary differential rings

Description

`Cat::DifferentialRing` represents the category of ordinary differential rings.

A `Cat::DifferentialRing` is a commutative ring with a single derivation operator D .

A derivation is a linear operator with product rule, i.e.

$(f g)' = f' g + f g'$ holds for all f and g .

Categories

`Cat::PartialDifferentialRing`

Methods

Basic Methods

D - Return derivative

`D(f)`

diff - Differentiation with respect to a variable

`diff(f, x)`

Purpose	Category of entire rings
Description	<p>Cat::EntireRing represents the category of entire rings.</p> <p>An Cat::EntireRing is a ring with unit "one" which has no zero divisors: Given non-zero ring elements a and b the product a times b is never zero.</p>
Axioms	Ax::noZeroDivisors
Categories	Cat::Ring, Cat::RightModule(dom)

Cat::EuclideanDomain

Purpose Category of Euclidean domains

Description `Cat::EuclideanDomain` represents the category of Euclidean domains. A `Cat::EuclideanDomain` is a principal ideal domain with an “Euclidean degree” function `euclideanDegree` and operations `quo` and `rem` computing the Euclidean quotient and Euclidean remainder. The Euclidean degree returns nonnegative integers such that for each non-zero x and y there exist s and r such that $x = ys + r$ and either the Euclidean degree of r is less than that of s or r is zero. In addition s is equal to `quo(x, y)` and r is equal to `rem(x, y)`.

Categories `Cat::PrincipalIdealDomain`

Methods Basic Methods

euclideanDegree - Return Euclidean degree

`euclideanDegree(x)`

divide - Division with remainder

`divide(x, y)`

Mathematical Methods

divide - Exact division

`_divide(x, y)`

gcd - Greatest common divisor

`gcd(x,)`

gcdex - Extended greatest common divisor

`gcdex(x, y)`

idealGenerator - Generator of finitely generated ideal

`idealGenerator(x,)`

quo - Euclidean quotient

`quo(x, y)`

The default implementation provided here uses the basic method "divide".

rem - Euclidean remainder

`rem(x, y)`

The default implementation provided here uses the basic method "divide".

Cat::FactorialDomain

Purpose Category of factorial domains

Description `Cat::FactorialDomain` represents the category of factorial domains (i.e., unique factorization domains).

A `Cat::FactorialDomain` is an integral domain with gcd where an unique factorization can be computed.

The factorization methods are named "`factor`" and "`sqrfree`" and must return elements of the domain `Factored` over this domain.

Categories `Cat::GcdDomain`

Methods **Basic Methods**

factor - Unique factorization

`factor(x)`

See `Factored` for details about the representation of the factorization.

Mathematical Methods

irreducible - Test if element is irreducible

`irreducible(x)`

sqrfree - Square-free factorization

`sqrfree(x)`

See `Factored` for details about the representation of the factorization.

The default implementation provided here uses the method "`factor`" and therefore may be very inefficient.

Purpose	Category of fields
Description	<p><code>Cat::Field</code> represents the category of fields.</p> <p>A <code>Cat::Field</code> is a factorial domain, an Euclidean domain and a skew field. As a Euclidean domain, it has a commutative multiplication * (<code>_mult</code>) and as a skew field, the multiplication is invertible.</p> <p>Many of the methods defined for factorial and Euclidean domains are trivial for a field.</p>
Axioms	<code>Ax::canonicalUnitNormal</code> , <code>Ax::closedUnitNormals</code>
Categories	<code>Cat::EuclideanDomain</code> , <code>Cat::FactorialDomain</code> , <code>Cat::SkewField</code>
Methods	<p>Mathematical Methods</p> <p>associates - Test for associate elements</p> <p><code>associates(x, y)</code></p> <p>_divide - Exact division</p> <p><code>_divide(x, y)</code></p> <p>divide - Division with remainder</p> <p><code>divide(x, y)</code></p> <p>divides - Test if division is exact</p> <p><code>divides(x, y)</code></p> <p>euclideanDegree - Return Euclidean degree</p> <p><code>euclideanDegree(x)</code></p> <p>factor - Unique factorization</p> <p><code>factor(x)</code></p> <p>gcd - Greatest common divisor</p> <p><code>gcd(x,)</code></p>

irreducible - Test if element is irreducible

`irreducible(x)`

isUnit - Test if element is an unit

`isUnit(x)`

quo - Return Euclidean quotient

`quo(x, y)`

rem - Return Euclidean remainder

`rem(x, y)`

sqrfree - Square-free factorization

`sqrfree(x)`

unitNormal - Unit normal form

`unitNormal(x)`

unitNormalRep - Unit normal representation

`unitNormalRep(x)`

Purpose

Category of finite collections

Description

`Cat::FiniteCollection` represents the category of finite collections, i.e., the category of “universal” bags.

A finite collection is a data structure where each element represents a finite bag of “things” of any type.

The elements are numbered $1, \dots, \text{nops}(c)$, where $\text{nops}(c)$ is the number of elements in the bag.

Categories

`Cat::BaseCategory`

Methods

Basic Methods

`_index` - Return element given its index

```
_index(x, i)
```

`map` - Map function on elements

```
map(x, f, <a, >)
```

`nops` - Return number of elements

```
nops(x)
```

`op` - Return certain elements

```
op(x)
```

```
op(x, i)
```

Must return the i -th element of x or FAIL if an element with the given index does not exist.

Operand ranges or paths need not be handled by this method because they are handled directly by `op`.

`set_index` - Change element with given index

```
set_index(x, i, v)
```

Overloads the function `_assign` with an `_index` expression on the left hand side. The result is assigned to `x`.

subs - Substitute in elements

```
subs(x, e = f)
```

subsop - Substitute operands

```
subsop(x, i = v)
```

Technical Methods

mapCanFail - Map function on elements

```
mapCanFail(x, f, <a, >)
```

testEach - Test each element with a predicate

```
testEach(x, f, <a, >)
```

testOne - Test if element exists fulfilling a predicate

```
testOne(x, f, <a, >)
```

Purpose Category of integral domains with gcd

Description `Cat::GcdDomain` represents the category of integral domains with a gcd. A `Cat::GcdDomain` is an integral domain where the greatest common divisor of two elements can be computed by the method "gcd".

Categories `Cat::IntegralDomain`

Methods Basic Methods

gcd - Greatest common divisor

`gcd(x, y)`

The method must satisfy the following conditions:

- 1** `x` and `y` must divide `dom::gcd(x,y)`,
- 2** if `z` divides both `x` and `y`, then `z` must divide `dom::gcd(x,y)`,
- 3** if a domain has the axiom `Ax::canonicalUnitNormal` then `dom::gcd(x,y)` must be equal to `dom::unitNormal(dom::gcd(x,y))`.

Remember that `x` divides `y` if `_divide(x,y)` does not return FAIL.

Mathematical Methods

lcm - Least common multiple

`lcm(x, y)`

Cat::Group

Purpose

Category of groups

Description

Cat::Group represents the category of groups.

A Cat::Group is a (potentially non-Abelian) monoid where the group operation * (_mult) is invertible.

Categories

Cat::Monoid

Methods

Mathematical Methods

_divide - Return quotient

`_divide(x, y)`

Cat::HomogeneousFiniteCollection

Purpose	Category of homogeneous finite collections
Syntax	<code>Cat::HomogeneousFiniteCollection(T)</code>
Description	<code>Cat::HomogeneousFiniteCollection(T)</code> represents the category of homogeneous finite collections (i.e. bags) of elements of the domain <code>T</code> . A <code>Cat::HomogeneousFiniteCollection</code> is a finite collection where each element of the collection must be from the same domain <code>T</code> .
Categories	<code>Cat::FiniteCollection</code> If <code>T</code> is a <code>Cat::OrderedSet</code> , then <code>Cat::OrderedSet</code> .
Parameters	T A domain which must be from the category <code>Cat::BaseCategory</code> . Only elements of this domain may be contained in the collection.
Entries	"elemDom" The parameter domain <code>T</code> .
Methods	Mathematical Methods <code>_less - Compare two elements</code> <code>_less(x, y)</code> Returns TRUE if <code>x</code> is less than <code>y</code> . The collections <code>x</code> and <code>y</code> are ordered by the lexical ordering of their elements.

Cat::HomogeneousFiniteProduct

Purpose Category of homogeneous finite products

Syntax `Cat::HomogeneousFiniteProduct(T)`

Description `Cat::HomogeneousFiniteProduct(T)` represents the category of homogeneous finite products of elements of the domain `T`.

A `Cat::HomogeneousFiniteProduct(T)` is a homogeneous finite collection where each collection has the same number of elements of the domain `T`.

The number of elements must be given by the entry "card", which must be defined by domains of this category. It is not given as a category parameter simply because it is not needed. Thus no unnecessary instances of the category are created.

One could principally implement all the algebraic operations here, but they will be slow if the methods "`_index`" and "`set_index`" are slow, which most often will be the case. So we avoid the work and let the domain implementors do it.

Categories `Cat::HomogeneousFiniteCollection(T)`

If `T` is a `Cat::DifferentialRing`, then `Cat::DifferentialRing`.

If `T` is a `Cat::PartialDifferentialRing`, then `Cat::PartialDifferentialRing`.

If `T` is a `Cat::CommutativeRing`, then `Cat::CommutativeRing`.

If `T` is a `Cat::SkewField`, then `Cat::SkewField`.

If `T` is a `Cat::Ring`, then `Cat::Ring`.

If `T` is a `Cat::Rng`, then `Cat::Rng`.

If `T` is a `Cat::AbelianGroup`, then `Cat::AbelianGroup`.

If `T` is a `Cat::CancellationAbelianMonoid`, then `Cat::CancellationAbelianMonoid`.

If `T` is a `Cat::AbelianMonoid`, then `Cat::AbelianMonoid`.

If T is a Cat::AbelianSemiGroup, then Cat::AbelianSemiGroup.

If T is a Cat::Group, then Cat::Group.

If T is a Cat::Monoid, then Cat::Monoid.

If T is a Cat::SemiGroup, then Cat::SemiGroup.

If T is a Cat::CommutativeRing, then Cat::Algebra(T).

If T is a Cat::Ring, then Cat::LeftModule(T).

If T is a Cat::Ring, then Cat::RightModule(T).

Parameters

T

A domain which must be from the category Cat::BaseCategory.
This defines the domain of the products elements.

Entries

"card"

Must hold the number of elements of a collection.

"characteristic"

Defined if T is a ring: In this case the characteristic of the product domain is the same as that of T.

Methods

Basic Methods

zip - Combine elements

zip(x, y, f)

zipCanFail - Combine elements, may fail

zipCanFail(x, y, f)

Access Methods

nops - Return number of elements

nops(x)

Cat::IntegralDomain

Purpose Category of integral domains

Description `Cat::IntegralDomain` represents the category of integral domains.

A `Cat::IntegralDomain` is a commutative and entire ring which has a “partial” division method `_divide`: If `b` divides `a` then `dom::_divide(a,b)` must return the quotient, otherwise FAIL. The result of the method `_divide` must be unique.

Use the axiom `Ax::canonicalUnitNormal` to state in addition that there exists a canonical unit normal form for each element of the ring. If a ring has the axiom `Ax::canonicalUnitNormal` the method `unitNormal` must return the unique unit normal for a ring element. If the axiom is not valid the method may return any associate.

Use the axiom `Ax::closedUnitNormals` in addition to state that the unit normals which are computed by the method `unitNormal` are closed under multiplication, i.e. that the product of two unit normals returns a unit normal.

These two axioms are not implicitly valid for an `Cat::IntegralDomain` because there are integral domains for which one can't compute a canonical unit normal for each element.

Categories `Cat::EntireRing`, `Cat::CommutativeRing`, `Cat::Algebra(dom)`

Methods Basic Methods

divide - Return quotient

`_divide(x, y)`

The result must be unique:

1 the product `y * dom::_divide(x,y)` must be equal to `x` provided that `y` is not zero and `y` divides `x`,

2 if `x` is equal to `y * z` then `y` must divide `x`.

It is an error if `y` is zero.

isUnit - Test if element is a unit

```
isUnit(x)
```

unitNormal - Return an associate

```
unitNormal(x)
```

If the ring has the axiom `Ax::canonicalUnitNormal` the method must return the unique unit normal of `x`.

An implementation is provided if the ring has *not* the axiom `Ax::canonicalUnitNormal`: In this case simply `x` is returned.

Mathematical Methods

associates - Test if elements are associates

```
associates(x, y)
```

divides - Test if elements divides another

```
divides(x, y)
```

unitNormalRep - Return the unit normal representation

```
unitNormalRep(x)
```

If the ring has the axiom `Ax::canonicalUnitNormal` the method must return the unique unit normal of `x`. The default implementation uses the method "unitNormal" to compute the unit normal `n` in this case.

If the ring does not have the axiom `Ax::canonicalUnitNormal` the method simply returns `[x, dom::one, dom::one]`.

Cat::LeftModule

Purpose Category of left R -modules

Syntax `Cat::LeftModule(R)`

Description `Cat::LeftModule(R)` represents the category of left R-modules.

A `Cat::LeftModule(R)` is an Abelian group together with a rng R (a ring without unit) and a left multiplication `* (_mult)`.

The left multiplication is an operation taking an element of rng R and a module element and returning a module element.

Given ring elements a, b and module elements x, y the following 3 distributive laws must hold:

1 $(ab)x = a(bx),$

2 $(a + b)x = ax + bx,$

3 $a(x + y) = ax + ay.$

Beware: The operation of a non-Abelian semi-group is also written as `* (_mult)`. The method `"_mult"` must handle the situation if a left module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the left multiplication by elements of the rng.

Categories `Cat::AbelianGroup`

Parameters **R**

A domain which must be from the category `Cat::Rng`.

Methods Basic Methods

`_mult` - Left multiplication by a rng element

`_mult(r, x)`

Purpose	Category of matrices
Syntax	<code>Cat::Matrix(R)</code>
Description	<p><code>Cat::Matrix(R)</code> represents the category of matrices over the rng <code>R</code>.</p> <p>A <code>Cat::Matrix(R)</code> is a matrix of arbitrary dimension over a component ring <code>R</code>.</p> <p>In the following description of the methods, we use the following notations for a matrix A from a domain of category <code>Cat::Matrix(R)</code>: $nrows(A)$ denotes the number of rows and $ncols(A)$ the number of columns of A.</p> <p>Further on, a <i>row index</i> is an integer ranges from 1 to $nrows(A)$, and a <i>column index</i> is an integer ranges from 1 to $ncols(A)$.</p>
Categories	<code>Cat::BaseCategory</code>
Parameters	<p>R</p> <p>A domain which must be from the category <code>Cat::Rng</code> (a ring without unit).</p>
Entries	<p><code>"coeffRing"</code> is set to <code>R</code>.</p>
Methods	<p>Basic Methods</p> <p><code>_index</code> - Matrix indexing</p> <p><code>_index(A, i, j)</code></p> <p><code>matdim</code> - Matrix dimension</p> <p><code>matdim(A)</code></p> <p><code>new</code> - Matrix definition</p> <p><code>new(m, n)</code></p>

Of course, this method may implement further possibilities to create matrices (for example, see the method "new" of the domain constructor `Dom::Matrix`).

set_index - Setting matrix components

```
set_index(A, i, j, x)
```

Mathematical Methods

_negate - Negate a matrix

```
_negate(A)
```

_plus - Add matrices

```
_plus(A1, A2, )
```

The matrices must be of the same domain type, otherwise FAIL is returned.

_subtract - Subtract two matrices

```
_subtract(A, B)
```

equal - Test on equality of matrices

```
equal(A, B)
```

identity - Identity matrix

```
identity(n)
```

It only exists if R is of category `Cat::Ring`, i.e., a ring with unit.

iszero - Test on zero matrices

```
iszero(A)
```

Note that there may be more than one representation of the zero matrix of a given dimension if R does not have the axiom `Ax::canonicalRep`.

transpose - Transpose of a matrix

```
transpose(A)
```

Access Methods

col - Extracting columns

```
col(A, c)
```

concatMatrix - Horizontal concatenation of matrices

```
concatMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of rows.

delCol - Deleting columns

```
delCol(A, c)
```

If A only consists of one column then NIL is returned.

delRow - Deleting rows

```
delRow(A, r)
```

If A only consists of one row then NIL is returned.

row - Extracting rows

```
row(A, r)
```

setCol - Replacing columns

```
setCol(A, c, v)
```

setRow - Replacing rows

```
setRow(A, r, v)
```

stackMatrix - Appending of matrices vertically

```
stackMatrix(A, B)
```

An error message is issued if the two matrices do not have the same number of columns.

swapCol - Swapping matrix columns

```
swapCol(A, c1, c2)
```

swapRow - Swapping matrix rows

`swapRow(A, r1, r2)`

Purpose	Category of R-modules
Syntax	<code>Cat::Module(R)</code>
Description	<p><code>Cat::Module(R)</code> represents the category of R-modules.</p> <p>A <code>Cat::Module(R)</code> is a left and right R-module over a commutative ring R.</p> <p>Right and left multiplications must be both implemented by the method <code>"_mult"</code>.</p>
Categories	<code>Cat::LeftModule(R)</code> , <code>Cat::RightModule(R)</code>
Parameters	<p>R</p> <p>A domain which must be from the category <code>Cat::CommutativeRing</code>.</p>

Cat::Monoid

Purpose	Category of monoids		
Description	<p>Cat::Monoid represents the category of monoids.</p> <p>Cat::Monoid is a non-Abelian semi-group with a neutral element one (dom::one) according to the group operation * (_mult).</p>		
Categories	Cat::SemiGroup		
Entries	<table><tr><td>"one"</td><td>Must hold the neutral element according to the operation *.</td></tr></table>	"one"	Must hold the neutral element according to the operation *.
"one"	Must hold the neutral element according to the operation *.		
Methods	<p>Basic Methods</p> <p>_invert - Return inverse</p> <p> _invert(x)</p> <p>Mathematical Methods</p> <p>isone - Test if element is one</p> <p> isone(x)</p> <p>_power - Raise to the nth power</p> <p> _power(x, n)</p> <p> This implementation does "repeated squaring".</p>		

Purpose Category of ordered sets

Description `Cat::OrderedSet` represents the category of ordered sets.
An `Cat::OrderedSet` is a set with a (complete) order relation `< (_less)`.
Use the axiom `Ax::canonicalOrder` to state that elements of a domain are canonically ordered as MuPAD expressions (i.e. ordered with respect to the kernel function `_less`).

Categories `Cat::BaseCategory`

Methods Basic Methods

`_less` - Compare if element is less

`_less(x, y)`

An implementation is provided if this domain has axiom `Ax::canonicalOrder`.

Mathematical Methods

`_leequal` - Compare if element is less or equal

`_leequal(x, y)`

The implementation provided uses the methods "`_less`" and "`equal`".

`max` - Return maximum

`max(x,)`

`min` - Return minimum

`min(x,)`

`sort` - Sort list of elements

`sort(l)`

Cat::PartialDifferentialRing

Purpose Category of partial differential rings

Description `Cat::PartialDifferentialRing` represents the category of partial differential rings.

A `Cat::PartialDifferentialRing` is a commutative ring with a finite set of derivation operators `D_i`.

A derivation is a linear operator with product rule, i.e. $D_i(f * g)$ equals $D_i(f) * g + f * D_i(g)$ for all `f` and `g`.

For many partial differential rings the derivations are differentiations with respect to some indeterminates. Thus in order to support a natural notion it is also supposed that a method "`diff`" exists, such that `diff(f, x)` returns the partial derivation of `f` with respect to the indeterminate `x`.

Categories `Cat::CommutativeRing`

Methods Basic Methods

D - Return derivative

`D(l, x)`

diff - Return partial derivative

`diff(x, <v, >)`

Purpose	Category of multivariate polynomials	
Syntax	Cat::Polynomial(R)	
Description	Cat::Polynomial(R) represents the category of multivariate polynomials over R. A Cat::Polynomial(R) is a multivariate polynomial ring over a commutative coefficient ring R.	
Axioms	If R has Ax::canonicalUnitNormal, then Ax::canonicalUnitNormal. If R has Ax::closedUnitNormals, then Ax::closedUnitNormals.	
Categories	Cat::PartialDifferentialRing, Cat::Algebra(R) If R is a Cat::FactorialDomain, then Cat::FactorialDomain. If R is a Cat::GcdDomain, then Cat::GcdDomain. If R is a Cat::IntegralDomain, then Cat::IntegralDomain.	
Parameters	R	A domain which must be from the category Cat::CommutativeRing.
Entries	"coeffRing"	The coefficient ring R.
	"characteristic"	The characteristic of this domain, which is the same as that of the ring R.
Methods	Basic Methods coeff - Return coefficients coeff(p)	

`coeff(p, x, n)`

`coeff(p, n)`

Must return the coefficient of x^n of p , which is a polynomial in the remaining indeterminates.

Must return the coefficient of x^n of p , where x is the main variable of p .

degree - Return total degree

`degree(p)`

`degree(p, x)`

Must return the degree of p with respect to the indeterminate x .

degreevec - Return degree vector

`degreevec(p)`

evalp - Evaluate at a point

`evalp(p, x = v,)`

More than one evaluation point may be given. The result must be a polynomial in the remaining indeterminates or an element of R .

indets - Return indeterminates

`indets(p)`

lcoeff - Return leading coefficient

`lcoeff(p)`

lmonomial - Return leading monomial

`lmonomial(p)`

lterm - Return leading term

`lterm(p)`

mainvar - Return main variable

`mainvar(p)`

mapcoeffs - Map coefficients

```
mapcoeffs(p, f, <a, >)
```

multcoeffs - Multiply coefficients

```
multcoeffs(p, c)
```

nterms - Return number of terms

```
nterms(p)
```

nthcoeff - Return n-th coefficient

```
nthcoeff(p, n)
```

nthmonomial - Return n-th monomial

```
nthmonomial(p, n)
```

nthterm - Return n-th term

```
nthterm(p, n)
```

tcoeff - Return trailing coefficient

```
tcoeff(p)
```

unitNormal - Return unit normal

```
unitNormal(p)
```

An implementation is provided if R has the axiom `Ax::canonicalUnitNormal`: In this case p is multiplied by an unit of R such that the leading coefficient has unit normal representation in R.

unitNormalRep - Return unit normal representation

```
unitNormalRep(p)
```

An implementation is provided if R has the axiom `Ax::canonicalUnitNormal`.

Mathematical Methods**content - Return content**

`content(p)`

isUnit - Test if element is a unit

`isUnit(p)`

primpart - Return primitive part

`primpart(p)`

poly2list - Convert into a list

`poly2list(p)`

solve - Solve polynomial equation

`solve(p, x, <opt, >)`

`solve(p, x = T, <opt, >)`

`solve(p)`

Solves the polynomial equation $p = 0$ with respect to x over the domain T . See the function `solve` for details about the optional arguments `opt, ...`

The polynomial p must be univariate. Solves the polynomial equation $p = 0$ with respect to the indeterminate of p over the domain R .

Purpose

Category of principal ideal domains

Description

`Cat::PrincipalIdealDomain` represents the category of principal ideal domains.

A `Cat::PrincipalIdealDomain` is an integral domain with `gcd` where each ideal is principal. Note that the method "`idealGenerator`" has to find generators for finitely generated ideals only.

Categories

`Cat::GcdDomain`

Methods

Basic Methods

idealGenerator - Return generator of ideal

```
idealGenerator(x, )
```

Cat::QuotientField

Purpose	Category of quotient fields		
Syntax	<code>Cat::QuotientField(R)</code>		
Description	<p><code>Cat::QuotientField(R)</code> represents the category of quotient fields over R.</p> <p>A <code>Cat::QuotientField</code> is the field of fractions over the integral domain R.</p>		
Categories	<p><code>Cat::Field</code>, <code>Cat::Algebra(R)</code></p> <p>If R has <code>Cat::OrderedSet</code>, then <code>Cat::OrderedSet</code>.</p>		
Parameters	<p>R</p> <p>A domain which must be from the category <code>Cat::IntegralDomain</code>.</p>		
Entries	<table><tr><td>"characteristic"</td><td>The characteristic of this domain, which is the same as that of R.</td></tr></table>	"characteristic"	The characteristic of this domain, which is the same as that of R .
"characteristic"	The characteristic of this domain, which is the same as that of R .		
Methods	<p>Basic Methods</p> <p>denom - Return denominator</p> <p><code>denom(x)</code></p> <p>numer - Return numerator</p> <p><code>numer(x)</code></p> <p>Mathematical Methods</p> <p>equal - Test for equality</p> <p><code>equal(x, y)</code></p> <p>iszero - Test for zero</p> <p><code>iszero(x)</code></p>		

_less - Test if element is less

`_less(x, y)`

retract - Return retracted element

`retract(x)`

The default implementation uses the method "`_divide`" to divide numerator and denominator.

Cat::RightModule

Purpose Category of right R-modules

Syntax `Cat::RightModule(R)`

Description `Cat::RightModule(R)` represents the category of right R-modules.

A `Cat::RightModule` is an Abelian group together with a ring `R` and a right multiplication `* (_mult)`.

The right multiplication is an operation taking an element of ring `R` and a module element and returning a module element.

Given ring elements a, b and module elements x, y the following 3 distributive laws must hold:

1 $x(ab) = (xa)b,$

2 $x(a + b) = xa + xb,$

3 $(x + y)a = xa + ya.$

Beware: The operation of a non-Abelian semi-group is also written as `* (_mult)`. The method `"_mult"` must handle the situation if a right module is also a non-Abelian semi-group. In such a case it must both implement the group operation and the right multiplication by elements of the ring.

Categories `Cat::AbelianGroup`

Parameters **R**

A domain which must be from the category `Cat::Ring`.

Methods Basic Methods

`_mult` - Right multiplication by a ring element

`_mult(x, r)`

Purpose

Category of rings

Description

`Cat::Ring` represents the category of rings.

A `Cat::Ring` is a ring with a unit `dom::one`, i.e., an Abelian group according to the operation `+` (`_plus`) and a non-Abelian monoid according to the operation `*` (`_mult`) where in addition the two distributive laws $a(b + c) = ab + ac$ and $(a + b)c = ac + bc$ hold.

A `Cat::Ring` is also a left module over itself. The left multiplication of the module is also written as `*` (`_mult`).

Note that a ring without unit is a `Cat::Rng`.

Categories

`Cat::Rng`, `Cat::Monoid`, `Cat::LeftModule(dom)`

Entries

"characteristic"

Must hold the characteristic of this ring.

Cat::Rng

Purpose Category of rings without unit

Description `Cat::Rng` represents the category of rings without unit.

A `Cat::Rng` is a ring without a unit, i.e. an Abelian group according to the operation `+` (`_plus`) and a non-Abelian semi-group according to the operation `*` (`_mult`) where in addition the two distributive laws $a(b + c) = ab + ac$ and $(a + b)c = ac + bc$ hold.

Use the axiom `Ax::noZeroDivisors` to state that there are no zero divisors according to `*`, i.e. that the product of non-zero elements never is zero.

Categories `Cat::AbelianGroup`, `Cat::SemiGroup`

Purpose Category of semi-groups

Description `Cat::SemiGroup` represents the category of semi-groups.
A `Cat::SemiGroup` represents the category of non-Abelian semi-groups, where the group operation is written as multiplication. Hence a `Cat::SemiGroup` is a set with an associative operation `*` (`_mult`).
Note that Abelian semi-groups with operation `+` have category `Cat::AbelianSemiGroup`.

Categories `Cat::BaseCategory`

Methods Basic Methods

`_mult` - Return product

`_mult(x,)`

Mathematical Methods

`_power` - Return integer power

`_power(x, n)`

Cat::Set

Purpose Category of sets of complex numbers

Description `Cat::Set` represents the category of subsets of the complex numbers. Sets of this category allow set-theoretic operations as well as pointwise arithmetical operations.

The main feature of `Cat::Set` is a particular overloading mechanism. It provides n-ary operators that can handle operands from different domains of category `Cat::Set`, as well as mixed input where some operands are of types not belonging to `Cat::Set`. *Hence, in the methods of `Cat::Set`, operands of arbitrary type are allowed.*

There are three kinds of operators: n-ary (associative and commutative), binary (not assumed to be commutative), and unary (mapping a function). `Cat::Set` provides generic methods for generating these kinds of operators, and uses them to define default methods overloading the common set-theoretic and arithmetical functions.

By default, any operation of sets is defined, but returns unevaluated since the arithmetical or set-theoretic expression cannot be simplified. Each domain of type `Cat::Set` must provide particular slots and tables in order to achieve simplifications in certain special cases.

Arithmetical operations are defined pointwise. It is not an error if some operation is not defined for all elements of a set.

`Cat::Set` is mainly used by domains of sets returned by `solve`.

Categories `Cat::BaseCategory`

Methods **Mathematical Methods**

commassop - Return an n-ary commutative and associative operator for sets

`commassop(operatorname)`

The returned procedure first sorts its operands (which it may do because of commutativity). Those operands not belonging to a domain of category `Cat::Set` are handled by the usual

overloading mechanism, i.e. by the slot `operatorname` of one of their domains. Out of the others, several operands belonging to the same domain are handled by the slot `"homog".operatorname` of that domain. Finally, the returned method tries to combine each possible pair of operands. If they are from the same domain, `"bin".operatorname` is called for them. The following is done if the operands are from different domains: let T1 and T2 be their types; then their `"inhomog".operatorname` slots are used. If such a slot exists in the domain T1, it must contain a table indexed by possible types T2, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a T1, the second being a T2. Conversely, if such a slot exists in the domain T2, it must contain a table indexed by possible types T1, and the entry at that index must be a procedure that carries out the operation for exactly two arguments, the first being a T2, the second being a T1.

The slot `"homog".operatorname`, or a table entry in the slot `"inhomog".operatorname`, may return FAIL in order to indicate that it could not simplify its input; if they are missing, this indicates that a simplification is generally not possible for input of this type. In these cases, the returned procedure proceeds by trying to combine another two of the given arguments.

A slot `"bin".operatorname` usually won't exist, except for the case that there is no `"homog".operatorname`; usually the latter can also take care for the case of exactly two operands.

The whole process is repeated over and over until no new simplifications occur or only one operand is left. If no more simplifications occur, an unevaluated call to the operator is returned, the arguments being all remaining operands that could not be combined further.

binop - Return a binary operator for sets

`binop(operatorname)`

The returned procedure uses the slot `"bin".operatorname` of its first argument if both arguments are of the same type. Otherwise it

uses the slot "inhomogleft".operatorname of its first argument; if that fails, it uses the slot "inhomogright".operatorname of its second argument; each of these slots, if it exists, must contain tables, indexed by the type of the other argument, such that slot(T1, "inhomogleft".operatorname)[T2] and slot(T2, "inhomogright".operatorname)[T1] carry out the operation for objects of type T1 and T2, in this order.

No commutativity of the operation is assumed.

If the slots or table entries do not exist or return FAIL, an unevaluated call to the operator is returned.

homogassop - Return an n-ary operator for sets belonging to the same domain

```
homogassop(operatorname)
```

_union - Union of sets

```
_union(S1, )
```

_intersect - Intersection of sets

```
_intersect(S1, )
```

_plus - Set of sums of set elements

```
_plus(S1, )
```

The sum of sets is computed by the commutative-associative operator generated by "commassop", using the slots "homog_plus" and "inhomog_plus" of the domains of its operands.

_mult - Set of product of set elements

```
_mult(S1, )
```

The product of sets is computed by the commutative-associative operator generated by "commassop", using the slots "homog_mult" and "inhomog_mult" of the domains of its operands.

_minus - Set of subtractions

```
_minus(S1, S2)
```

_power - Pointwise power`_power(S1, S2)`

The power of sets is computed by the binary operator generated by "binop", using the slots "homog_power", "inhomogleft_power", and "inhomogright_power" of its operands.

map - Map an operation to a set`map(S, f)`

By overloading this method in a particular domain, the behavior of sets changes whenever a special function is applied to them.

Cat::SkewField

Purpose Category of skew fields

Description `Cat::SkewField` represents the category of skew fields (division rings).
A `Cat::SkewField` represents a ring with unit where each non-zero element is invertible. This structure is also called division ring in the literature.

Categories `Cat::Ring`

Purpose Category of square matrices

Syntax `Cat::SquareMatrix(R)`

Description `Cat::SquareMatrix(R)` represents the category of square matrices over the rng `R`.

A `Cat::SquareMatrix(R)` represents the rng (ring without unit) of square matrices over the coefficient domain `R`.

Categories `Cat::Rng`, `Cat::Matrix(R)`

If `R` has `Cat::Ring`, then `Cat::Ring`.

Parameters **R**

A domain which must be from the category `Cat::Rng`.

Entries "characteristic"

Defined if `R` is a ring: In this case the characteristic of the matrix domain is the same as that of `R`.

Cat::UnivariatePolynomial

Purpose	Category of univariate polynomials
Syntax	<code>Cat::UnivariatePolynomial(R)</code>
Description	<p><code>Cat::UnivariatePolynomial(R)</code> represents the category of univariate polynomials over R.</p> <p>A <code>Cat::UnivariatePolynomial(R)</code> is a univariate polynomial over the commutative ring R.</p>
Categories	<p><code>Cat::Polynomial(R)</code>, <code>Cat::DifferentialRing</code></p> <p>If R has <code>Cat::Field</code>, then <code>Cat::EuclideanDomain</code>.</p>
Parameters	<p>R</p> <p>A domain which must be from the category <code>Cat::CommutativeRing</code>.</p>
Methods	<p>Basic Methods</p> <p>pdivide - Pseudo-divide polynomials</p> <p><code>pdivide(p, q)</code></p> <p>Must return a sequence (b, s, r) of a ring element b and polynomials s and r such that $multcoeffs(p, b) = sq + r$ holds with $b = lcoeff(q)^{degree(p) - degree(q) + 1}$.</p> <p>pquo - Return pseudo-quotient</p> <p><code>pquo(p, q)</code></p> <p>prem - Return pseudo-remainder</p> <p><code>prem(p, q)</code></p>

Purpose	Category of vector spaces
Syntax	<code>Cat::VectorSpace(F)</code>
Description	<p><code>Cat::VectorSpace(F)</code> represents the category of vector spaces over the field <code>F</code>.</p> <p>A vector space is an Abelian group with an operation <code>+</code> (<code>_plus</code>).</p> <p>The scalar product has to be implemented via the method <code>"_mult"</code>. Other kinds of multiplication are not defined.</p>
Categories	<code>Cat::Module(F)</code>
Parameters	F A domain which must be from the category <code>Cat::Field</code> .
Methods	<p>Basic Methods</p> <p><code>_mult</code> - Return scalar product</p> <p><code>_mult(c, x)</code></p> <p><code>_mult(x, c)</code></p> <p>Must return the scalar product of <code>x</code> and <code>c</code>.</p>

combinat – Combinatorics

combinat::bell
combinat::cartesianProduct
combinat::catalan
combinat::choose
combinat::compositions
combinat::modStirling
combinat::partitions
combinat::permute
combinat::powerset
combinat::stirling1
combinat::stirling2
combinat::subwords

combinat::bell

Purpose Bell numbers

Syntax `combinat::bell(n)`
`combinat::bell(expression)`

Description `combinat::bell(n)` computes the n-th Bell number.

The n-th Bell number is defined by the exponential generating function:

$$e^{e^x - 1} = \sum_{n=0}^{\infty} \frac{\text{bell}(n)}{n!} x^n$$

Often another definition is used. The n-th Bell number is the number of different ways of partitioning the set $\{1, 2, \dots, n\}$ into disjoint nonempty subsets, and $\text{bell}(0)$ is defined to be 1.

Bell numbers are computed using the formula:

- $\text{bell}(0) = 1$

$$\text{bell}(n + 1) = \sum_{i=0}^n \binom{n}{i} \text{bell}(i) \text{ for } n > 0$$

Examples

Example 1

The third Bell number is 5:

```
combinat::bell(3)
```

5

This means that you can partition the set $\{1, 2, 3\}$ into disjoint subsets in 5 different ways. These are $\{\{1, 2, 3\}\}$, $\{\{1\}, \{2, 3\}\}$, $\{\{2\}, \{1, 3\}\}$, $\{\{3\}, \{1, 2\}\}$, and $\{\{1\}, \{2\}, \{3\}\}$. Or, that you can write $105 = 357$ as 5 different products. These are $105 = 335 = 521 = 715 = 357$.

Example 2

If one uses a wrong argument, an error message is returned.

```
combinat::bell(3.4)
```

```
Error: A nonnegative integer is expected. [combinat::bell]
```

Example 3

It can be useful to return the unevaluated function call.

```
a := combinat::bell(x);  
x := 4;  
a ;  
delete(a);
```

```
combinat::bell(x)
```

```
4
```

```
15
```

Parameters

n

Nonnegative integer

expression

An expression of type `Type::Arithmetical` which must be a nonnegative integer if it is a number.

Return Values

Positive integer value if `n` was a nonnegative integer. Otherwise `combinat::bell` returns the unevaluated function call.

combinat::cartesianProduct

Purpose Cartesian product

Syntax `combinat::cartesianProduct(S1, ...)`

Description `combinat::cartesianProduct(S1, ...)` returns the cartesian product of the sets or lists S_1, \dots as a list of lists.

The cartesian product of S_1 through S_n consists of all lists of length n whose i -th entry is an operand of the set or list S_i , for $1 \leq i \leq n$.

Any integer k among the arguments is identified with the set of the first k positive integers.

The ordering of the output is unspecified.

Examples **Example 1**

The following calls are equivalent:

```
combinat::cartesianProduct({1, 2}, {a, b}),  
combinat::cartesianProduct(2, [b, a])
```

```
[[1, a], [2, a], [1, b], [2, b]], [[1, b], [2, b], [1, a], [2, a]]
```

Parameters **S1**

Set, list, or nonnegative integer

Return Values List of lists, each of them having as many operands as there were arguments passed to `combinat::cartesianProduct`.

Purpose

Catalan numbers

Syntax`combinat::catalan(n)`**Description**`combinat::catalan(n)` returns the n -th Catalan number.

The Catalan numbers are ubiquitous in combinatorics. For example, `combinat::catalan(n)` counts the Dyck words of size n , the ordered trees with n nodes, the binary trees with $n+1$ nodes, the complete binary trees with $2n+1$ nodes, the standard tableaux with two rows of size n , the triangulations of a regular $n+2$ -gone, or the non-crossing partitions of $\{1, 2, \dots, n\}$.

`combinat::catalan(n)` is calculated using the formula

$$\text{catalan}(n) = \frac{1}{n+1} \binom{2n}{n}$$

Examples**Example 1**

We compute the first Catalan numbers:

```
combinat::catalan(n) $ n = 0..6
```

```
1, 1, 2, 5, 14, 42, 132
```

Example 2

If one uses a wrong argument, an error message is returned

```
combinat::catalan(-1)
```

```
Error: The type of argument number 1 must be 'Type::NonNegInt'.  
Evaluating: combinat::catalan
```

combinat::catalan

Parameters **n**
Nonnegative integer

Return Values Positive integer.

Purpose Subsets of a given size

Syntax `combinat::choose(S, k)`

Description `combinat::choose(S, k)` returns all subsets of `S` that have exactly `k` elements.

If `S` is an integer, it represents the set of the first `S` positive integers.

Examples **Example 1**

There are three subsets of a three-element set that have exactly two elements:

```
combinat::choose({a, b, c}, 2)
```

```
{a, b}, {a, c}, {b, c}
```

Parameters **s**
Set or nonnegative integer

k
Nonnegative integer

Return Values Sequence of sets.

combinat::compositions

Purpose Compositions of an integer

Syntax `combinat::compositions(n, <MinPart = k>, <MaxPart = l>, <Length = m>)`

Description `combinat::compositions(n)` returns all compositions of the nonnegative integer `n`.

A *composition* of a nonnegative integer `n` is a list of positive integers with total sum `n`.

Examples

Example 1

We output all compositions of the integer 4:

```
combinat::compositions(4)
```

```
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

Example 2

It is possible to output only the compositions of a certain length:

```
combinat::compositions(4, Length=2)
```

```
[[3, 1], [2, 2], [1, 3]]
```

Example 3

The options `MinPart` and `MaxPart` can be used to set constraints on the sizes of all parts. Using `MaxPart`, you can select compositions having only small entries. This is the list of the compositions of 4 with all parts at most 2:

```
combinat::compositions(4, MaxPart=2)
```

```
[[2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

MinPart is complementary to MaxPart and selects compositions having only large parts (it takes a non-negative value). This is the list of the compositions of 4 with all parts at least 2:

```
combinat::compositions(4, MinPart=2)
```

```
[[4], [2, 2]]
```

By default, the parts of a composition have to be positive. This can be changed using the option MinPart. In the following example, the options Length and MinPart are combined together to obtain the list of the compositions of 4 with 3 nonnegative parts:

```
combinat::compositions(4, Length=3, MinPart=0)
```

```
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1], [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],  
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]
```

If no length is given, MinPart=0 is not allowed.

Parameters

n

Nonnegative integer

Options

MinPart

Option, specified as `MinPart = k`

Return only compositions consisting of integers greater or equal than `k`. The option `MinPart = 0` is only allowed if also the option `Length` is given. Default is 1.

MaxPart

Option, specified as `MaxPart = l`

Return only compositions consisting of integers less or equal than `l`.

combinat::compositions

Length

Option, specified as `Length = m`

Return only compositions consisting of exactly m integers.

Purpose	Modified Stirling numbers
Syntax	<code>combinat::modStirling(q, n, k)</code>
Description	<code>combinat::modStirling</code> computes the modified Stirling numbers. <code>combinat::modStirling(q,n,k)</code> takes the elementary symmetric polynomial in n variables of degree k and evaluates it for the values $q + 1, \dots, q + n$. Note that k must not be greater than n .
Examples	Example 1 <pre>combinat::modStirling(2,4,2)</pre> <pre>119</pre>
Parameters	q The argument: an integer n The number of variables: a nonnegative integer k The degree: a nonnegative integer
Return Values	Positive integer.

combinat::partitions

Purpose Partitions of an integer

Syntax `combinat::partitions(n)`

Description `cominat::partitions(n)` returns the number of partitions of the integer n .

A *partition* of a nonnegative integer n is a non-increasing list of positive integers with total sum n .

Examples **Example 1**

There are 5 partitions of 4:

```
combinat::partitions(4)
```

```
5
```

Parameters **n**

Nonnegative integer

Algorithms Counting is done efficiently with Euler's pentagonal formula for small values of n and Hardy-Ramanujan-Rademacher's formula otherwise.

Purpose

Permutations of a list

Syntax

```
combinat::permute(l, <Duplicate>)  
combinat::permute(n, <Duplicate>)
```

Description

For a list l , the call `combinat::permute(l)` returns all permutations of l .

For an integer n , the call `combinat::permute(n)` returns all permutations of the list $[1, \dots, n]$.

A permutation of a list is a list that contains the same elements, and each of them the same number of times, as the original list.

Equivalently, a permutation of a list l of n elements is any $f(l)$ where f is an element of the symmetric group `Dom::SymmetricGroup(n)`. Different f may produce the same $f(l)$; with the option `Duplicate`, every permutation is listed as many times as it occurs in that way; without that option, every permutation is listed only once.

Examples

Example 1

There are six permutations of three letters:

```
combinat::permute([a, b, c])
```

```
[[b, c, a], [c, b, a], [a, c, b], [c, a, b], [a, b, c], [b, a, c]]
```

To permute the first three integers, the following syntax is also possible:

```
combinat::permute(3)
```

```
[[2, 3, 1], [3, 2, 1], [1, 3, 2], [3, 1, 2], [1, 2, 3], [2, 1, 3]]
```

If some list entry occurs several times, the number of permutations decreases:

combinat::permute

```
combinat::permute([a, a, b])
```

```
[[a, b, a], [b, a, a], [a, a, b]]
```

However, the same permutation is listed as often as it can be obtained by applying different elements of the symmetric group S_3 if the option `Duplicate` is given.

```
combinat::permute([a, a, b], Duplicate)
```

```
[[a, b, a], [b, a, a], [a, b, a], [b, a, a], [a, a, b], [a, a, b]]
```

We could have achieved the same by permuting three different symbols and then setting two of them equal:

```
subs(combinat::permute([a, b, c]), c=a)
```

```
[[b, a, a], [a, b, a], [a, a, b], [a, a, b], [a, b, a], [b, a, a]]
```

Parameters

l

List

n

Positive integer

Options

Duplicate

List every permutation as often as it can be produced in different ways by applying some bijective mapping (element of the symmetric group) to the original list.

Purpose	Subsets of a set
Syntax	<code>combinat::powerset(S)</code>
Description	<p>If S is a set, <code>combinat::powerset(S)</code> returns the set of all subsets of S. If l is a list, <code>combinat::powerset(l)</code> returns the set of all sublists of l.</p> <p>The powerset of a list l is the set of all lists that can be obtained by deleting some elements of l and leaving the others in order.</p> <p><code>combinat::powerset</code> has been overloaded for multisets of type <code>Dom::Multiset</code>. The powerset of a multiset S consists of all multisets that contain only elements occurring also in S, each of them at most as many times as it occurs in S.</p>

Examples

Example 1

Given a finite set, `combinat::powerset` returns the powerset (set of all subsets) of the input:

```
combinat::powerset({a, b, c})  
  
{ $\emptyset$ , {c}, {a}, {b}, {b, c}, {a, b}, {a, c}, {a, b, c}}
```

The same works for multisets:

```
combinat::powerset(Dom::Multiset(a, a, b))  
  
{ $\emptyset$ , {[a, 1]}, {[a, 2]}, {[b, 1]}, {[a, 1], [b, 1]}, {[a, 2], [b, 1]}}
```

Example 2

The powerset of a list l of pairwise different elements is the same as the powerset of the set of these elements, except that it consists of lists in which the order of elements is the same as in l :

```
combinat::powerset([c, a, b])
```

combinat::powerset

```
{[], [a], [b], [c], [a, b], [c, a], [c, b], [c, a, b]}
```

In general, the powerset of a list `l` is the same as the powerset of the multiset of its elements, except that it consists of lists in which the original order is preserved:

```
combinat::powerset([a, b, a])
```

```
{[], [a], [b], [a, a], [a, b], [b, a], [a, b, a]}
```

Parameters

s

Set

l

List

Purpose Stirling numbers of the first kind

Syntax `combinat::stirling1(n, k)`

Description `combinat::stirling1(n, k)` computes the Stirling numbers of the first kind.

Let $S(n, k)$ be the number of permutations of n symbols that have exactly k cycles. Then `combinat::stirling1(n, k)` computes $(-1)^{(n+k)}S(n, k)$.

Let $S_1(n, k)$ be the Stirling number of the first kind, then we have:

$$\sum_{k=0}^n S_1(n, k) x^k = x(x-1)\dots(x-n+1)$$

Examples **Example 1**

Let us have a look what's the result of $x(x-1)(x-2)(x-3)(x-4)(x-5)$ written as a sum.

```
expand(x*(x-1)*(x-2)*(x-3)*(x-4)*(x-5))
```

$$x^6 - 15x^5 + 85x^4 - 225x^3 + 274x^2 - 120x$$

Now let us “prove” the formula mentioned in the “Details” section by calculating the proper Stirling numbers:

```
combinat::stirling1(6,1);
combinat::stirling1(6,2);
combinat::stirling1(6,3);
combinat::stirling1(6,4);
combinat::stirling1(6,5);
combinat::stirling1(6,6)
```

```
- 120
```

combinat::stirling1

274

-225

85

-15

1

Example 2

```
combinat::stirling1(3, -1)
```

```
Error: Nonnegative integers are expected. [combinat::stirling1]
```

Parameters

n, k

Nonnegative integers

Return Values

Integer.

References

J.J. Rotman, An Introduction to the Theory of Groups, 3rd Edition, Wm. C. Brown Publishers, Dubuque, 1988

Purpose Stirling numbers of the second kind

Syntax `combinat::stirling2(n, k)`

Description `combinat::stirling2(n, k)` computes the number of ways of partitioning a set of n elements into k non-empty subsets.

`combinat::stirling2(n, k)` is calculated using the formula

$$\text{stirling2}(n, k) = \frac{1}{k!} \left(\sum_{j=0}^k (-1)^{k-j} \binom{k}{j} j^n \right)$$

Examples

Example 1

One can partition the set $\{1, 2, 3\}$ into $\{1, 2, 3\} = \{1, 2\} \cup \{3\} = \{1, 3\} \cup \{2\} = \{2, 3\} \cup \{1\}$

```
combinat::stirling2(3,2)
```

```
3
```

Example 2

```
combinat::stirling2(3)
```

```
Error: Two arguments are expected. [combinat::stirling2]
```

Parameters

n, k

Nonnegative integers

Return Values

Nonnegative integer.

combinat::subwords

Purpose Subwords of a word

Syntax `combinat::subwords(w)`

Description The function `combinat::subwords(w)` returns a list of all subwords (sublists) of the list `w`.

A subword of a word w is a word obtained by deleting the letters at some of the positions in w . A subword is generated as many times as it appears in the word.

To obtain each subword only once, `combinat::powerset` should be used.

Examples **Example 1**

There are 8 subwords of the word `[a, b, c]`:

```
combinat::subwords([a, b, c])
```

```
[[], [a], [b], [a, b], [c], [a, c], [b, c], [a, b, c]]
```

Parameters **w**

Purpose	(symbolic, multidimensional) arrays
Description	<p>DOM_ARRAY is a multidimensional container type, storing arbitrary MuPAD objects at integer indices.</p> <p>Arrays are a fundamental data type in many programming languages: For a fixed number of indices (“dimensions”), for each index an integer from a fixed range, an array provides space to store an arbitrary piece of data at this combination.</p>
Function Calls	<p>Using an array as a function symbol creates the list obtained by using each array entry as a function symbol for the operands used, i.e., <code>array(1..2, [f, g])(x, y)</code> results in <code>array(1..2, [f(x, y), g(x, y)])</code>.</p>
Operations	<p>As with any container, the most important operation on an array is reading and writing its entries, which is performed by indexed access, as in <code>A[1, 2]</code> or <code>B[1, 3, 2] := exp(x)</code>. Trying to access an element outside the boundaries of an array raises an error.</p> <p>The function <code>map</code> applies some function or transformation to each element of an array, returning an array of the same format as its input, with the results of the calls as its entries.</p> <p>If <code>A</code> is an array, <code>nops(A)</code> returns the number of elements in <code>A</code>.</p>
Operands	<p>If <code>A</code> is an array, the 0th operand of <code>A</code>, <code>op(A, 0)</code>, will be the sequence starting with the number of dimensions (an integer n) followed by n ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.</p> <p>For $1 \leq i \leq nops(A)$, the ith operand of <code>A</code> is the ith entry of <code>A</code>, in the lexicographic order of indices.</p> <p>Uninitialized entries of arrays will be displayed symbolically while still in the array. When being accessed by <code>op</code> or indexed access, <code>NIL</code> is returned.</p>
Output	<p>One-dimensional arrays are displayed as row vectors, two-dimensional arrays as matrices. Higher-dimensional arrays are written in functional form, using the <code>index = value</code> notation, and do not have a typesetting</p>

DOM_ARRAY

version. This also causes typesetting to be disabled for any surrounding expression in the same output.

Element Creation

The primary way of creating arrays is the function `array`. Beside that, obviously, `coerce` can convert a number of data types, such as matrices into arrays and a number of MuPAD functions, especially in the `numeric` library, return arrays.

MuPAD Domains

`DOM_HFARRAY` | `DOM_LIST` | `DOM_TABLE`

MuPAD Functions

`array` | `matrix`

Purpose	Boolean constants
Description	DOM_BOOL is the data type of the truth values TRUE, FALSE, and UNKNOWN. MuPAD uses a three-valued logic system, with these values (constants) TRUE, FALSE, and UNKNOWN.
Function Calls	Using a Boolean constant as a function returns that constant unchanged. The arguments of the call are <i>not</i> evaluated.
Operations	The most important operations on Boolean values are the logical operators and, not, or, xor, ==>, <=>, and using them in conditions of if or piecewise.
Operands	Boolean constants are atomic.
Output	TRUE is displayed as <i>TRUE</i> , FALSE is displayed as <i>FALSE</i> , and UNKNOWN is shown as <i>UNKNOWN</i> .
Element Creation	The three constants can be types in as shown above. Additionally, many MuPAD functions returns Boolean values, the most generic/prominent two being bool and is.
See Also	
MuPAD Functions	bool if is

DOM_COMPLEX

Purpose	(Simple) Complex Numbers
Description	<p>DOM_COMPLEX is the type of complex numbers with integer, rational, or floating-point components.</p> <p>Complex numbers of type DOM_COMPLEX have two operands, their real and imaginary part. These are objects of type DOM_FLOAT, DOM_INT, or DOM_RAT. Complex numbers with other components (such as $\sqrt{2} + i\pi$) are not of domain type DOM_COMPLEX, but DOM_EXPR.</p>
Function Calls	Calling a complex number as a function returns that number unchanged. The arguments of the call are <i>not</i> evaluated.
Operations	Most MuPAD functions operate on complex numbers. Use Re and Im to access the real and imaginary part, respectively.
Operands	Every object of type DOM_COMPLEX has two operands, the real and the imaginary part.
Output	Objects of type DOM_COMPLEX are essentially written as expressions in rectangular form. The imaginary unit is displayed as <i>I</i> .
Element Creation	Complex numbers can be constructed by typing in the corresponding expression, such as 3+4*I. The keyword for typing the imaginary unit <i>I</i> is I (a capital letter i).

MuPAD Domains	DOM_FLOAT DOM_INT DOM_RAT

Purpose

Data type of data types

Description

DOM_DOMAIN is the data type of datatypes.

Each MuPAD object has a unique data type. Since a data type is a MuPAD object, too, it must itself have a data type; the data type comprising all data types (including itself) is DOM_DOMAIN.

There are two kinds of elements of DOM_DOMAIN: data types of the kernel, and data types defined in the library or by the user (*domains*). Objects that have a data type of the latter kind are called *domain elements*.

A data type has the same internal structure as a table; its entries are called slots. One particular slot is the *key*; no two different data types can have the same key. Most of the other slots determine how arguments of that data type are handled by functions.

Once a user-defined domain has been constructed, it cannot be destroyed.

Examples**Example 1**

Our first example stems from ethnology: some languages in Polynesia do not have words for numbers greater than three; every integer greater than three is denoted by the word “many”. Hence two plus two does not equal four but “many”. We are going to implement a domain for this kind of integers; in other words, we are going to implement a data type for the finite set $\{1, 2, 3, \text{many}\}$.

```
S := newDomain("Polynesian integer")
```

Polynesian integer

At this point, we have defined a new data type: a MuPAD object can be a Polynesian integer now. No operations are available yet; the domain consists of its key only:

```
op(S)
```

```
"key" = "Polynesian integer"
```

Even though there are no methods for input and output of domain elements yet, Polynesian integers can be entered and displayed right now. You have to use the function `new` for defining domain elements:

```
x := new(S, 5)
```

```
new(Polynesian integer, 5)
```

Now, `x` is a Polynesian integer:

```
type(x)
```

```
Polynesian integer
```

Of course, MuPAD cannot know what meaning a Polynesian integer has and what its internal structure should be. The arguments of the call to the function `new` are just stored as the zeroth, first, etc. operand of the domain element, without checking them. You may call `new` with as many arguments as you want:

```
new(S, 1, 2, 3, 4); op(%)
```

```
new(Polynesian integer, 1, 2, 3, 4)
```

```
1, 2, 3, 4
```

`new` cannot know that Polynesian integers should have exactly one operand and that we want `5` to be replaced by many. To achieve this, we implement our own method `"new"`; this also allows us to check the argument. We have one more problem: domain methods should refer to the domain; but they should not depend on the fact that the domain

is currently stored in `S`. For this purpose, MuPAD has a special local variable `dom` that always refers to the domain a procedure belongs to:

```
S::new :=
proc(i : Type::PosInt)
begin
  if args(0) <> 1 then
    error("There must be exactly one argument")
  end_if;
  if i > 3 then
    new(dom, hold(many))
  else
    new(dom, i)
  end_if
end_proc:
```

A function call to the domain such as `S(5)` now implicitly calls the "new" method:

```
S(5)
new(Polynesian integer, many)
```

```
S("nonsense")
```

```
Error: The type of argument number 1 must be 'Type::PosInt'. The
Evaluating: S::new
```

In the next step, we define our own output method. A Polynesian integer `i`, say, shall not be printed as `new(Polynesian integer, i)`, only its internal value 1, 2, 3, or many shall appear on the screen. Note that this value is the first operand of the data structure:

```
S::print :=
```

DOM_DOMAIN

```
proc(x)
begin
  op(x, 1)
end_proc:
S(1), S(2), S(3), S(4), S(5)
```

1, 2, 3, many, many

By now, the input and output of elements of S have been defined. It remains to define how the functions and operators of MuPAD should react to Polynesian integers. This is done by *overloading* them. However, it is not necessary to overload each of the thousands of functions of MuPAD; for some of them, the default behavior is acceptable. For example, expression manipulation functions leave domain elements unaltered:

```
x := S(5): expand(x), simplify(x), combine(x); delete x:
```

many, many, many

Arithmetical operations handle domain elements like identifiers; they automatically apply the associative and commutative law for addition and multiplication:

```
(S(3) + S(2)) + S(4)
```

2 + 3 + many

In our case, this is not what we want. So we have to overload the operator $+$. Operators are overloaded by overloading the corresponding “underline-functions”; hence, we have to write a method “_plus”:

```
S::_plus :=
proc()
local argv;
```

```

begin
  argv := map([args()], op, 1);
  if has(argv, hold(many)) then
    new(dom, hold(many))
  else
    dom(_plus(op(argv)))
  end_if
end_proc:

```

Now, the sum of Polynesian integers calls this slot:

```
S(1) + S(2), S(2) + S(3) + S(7)
```

```
3, many
```

Deleting the identifier `S` does not destroy our domain. It can still be reconstructed using `newDomain`.

```

delete S:
op(newDomain("Polynesian integer"))

```

```

"key" = "Polynesian integer", "new" = proc S::new(i) ... end, "print" = proc S::print(x) ... end,
  "_plus" = proc S::_plus() ... end

```

Example 2

We could now give a similar example for more advanced Polynesian mathematics with numbers up to ten, say. This leads to the question whether it is necessary to enter all the code again and again whenever we decide to count a bit farther. It is not; this is one of the advantages of *domain constructors*. A domain constructor may be regarded as a function that returns a domain depending on some input parameters. It has several additional features. Firstly, the additional keywords `category` and `axiom` are available for specifying the mathematical structure of the domain; in our case, we have the structure of a

DOM_DOMAIN

commutative semigroup where different domain elements have different mathematical meanings (we call this a domain with a canonical representation). Secondly, an initialization part may be defined that is executed exactly once for every domain returned by the constructor; it should at least check the parameters passed to the constructor. Each domain created in such a way may inherit methods from other domains, and it must at least inherit the methods of `Dom::BaseDomain`.

```
domain CountingUpTo(n : Type::PosInt)
  inherits Dom::BaseDomain;
  category Cat::AbelianSemiGroup;
  axiom Ax::canonicalRep;

  new := proc(x : Type::PosInt)
  begin
    if args(0) <> 1 then
      error("There must be exactly one argument")
    end_if;
    if x > n then
      new(dom, hold(many))
    else
      new(dom, x)
    end_if
  end_proc;

  print := proc(x) begin op(x, 1) end_proc;

  _plus := proc() local argv;
  begin
    argv:= map([args()], op, 1);
    if has(argv, hold(many)) then
      new(dom, hold(many))
    else
      dom(_plus(op(argv)))
    end_if
  end_proc;
```

```
// initialization part
begin
  if args(0) <> 1 then
    error("Wrong number of arguments")
  end_if;
end:
```

Now, `CountingUpTo` is a domain constructor:

```
type(CountingUpTo)
```

```
DomainConstructor
```

We have defined the domain constructor `CountingUpTo`, but we have not created a domain yet. This is done by calling the constructor:

```
CountingUpToNine := CountingUpTo(9);
CountingUpToTen := CountingUpTo(10)
```

```
CountingUpTo(9)
```

```
CountingUpTo(10)
```

We are now able to create, output, and manipulate domain elements as in the previous example:

```
x := CountingUpToNine(3): y := CountingUpToNine(7):
x, x + x, y, x + y, y + y
```

```
3, 6, 7, many, many
```

```
x := CountingUpToTen(3): y := CountingUpToTen(7):
x, x + x, y, x + y, y + y
```

3, 6, 7, 10, many

```
delete CountingUpToNine, CountingUpToTen, CountingUpTo, x, y:
```

No domain constructor with the same name may be used again during the same session.

Example 3

Suppose that your domain does not really depend on a parameter, but that you need some of the other features of domain constructors. Then you may define a domain constructor `dc`, say, that is called without parameters. From such a domain constructor, you can construct exactly one domain `dc()`. Instead of defining the constructor via `domain dc() ... end` first and then using `d := dc()` to construct the domain `d`, say, you may directly enter `domain d ... end`, thereby saving some work.

Continuing the previous examples, suppose that we want to count up to three, knowing that we never want to count farther. However, we want to declare our domain to be an Abelian semigroup with a canonical representation of the elements. This is not possible with a construction of the domain using `newDomain` as in “Example 1” on page 6-7: we have to use the keyword `domain`. You will notice at once that the following source code is almost identical to the one in the previous example—we just removed the dependence on the parameter `n`.

```
domain CountingUpToThree

inherits Dom::BaseDomain;
category Cat::AbelianSemiGroup;
axiom Ax::canonicalRep;

new := proc(x : Type::PosInt)
begin
  if args(0) <> 1 then
    error("There must be exactly one argument")
  end_if;
  if x > 3 then
```

```

        new(dom, hold(many))
    else
        new(dom, x)
    end_if
end_proc;

print := proc(x) begin op(x, 1) end_proc;

_plus := proc() local argv;
begin
    argv:= map([args()], op, 1);
    if has(argv, hold(many)) then
        new(dom, hold(many))
    else
        dom(_plus(op(argv)))
    end_if
end_proc;

end:

```

Now, `CountingUpToThree` is a domain and not a domain constructor:

```
type(CountingUpToThree)
```

`DOM_DOMAIN`

You may use this domain in the same way as `CountingUpTo(3)` in “Example 2” on page 6-11.

Function Calls

When called as a function, the data type creates a new object of this data type out of the arguments of the call. E.g., the call `DOM_LIST(1, 2, x)` generates the list `[1, 2, x]` of domain type `DOM_LIST` (although, in this case, you probably prefer to type in `[1, 2, x]` directly which results in the same object). It depends on the particular type which arguments are admitted here.

In the case of a domain, the "new" method of that domain is called.

DOM_DOMAIN

Operations

You can obtain the slots of a domain using `slot`. The function `slot` can also be used on the left hand side of an assignment to define new slots, or to re-define existing slots. Use `delete` to delete slots.

Operands

A data type consists of an arbitrary number of equations (objects of type "equal"). If $a = b$ is among these equations, we say that the *slot* of the data type equals b . By convention, a is usually a string. Each domain has at least one slot indexed by "key".

Element Creation

The names of the data types provided by the MuPAD kernel are of the form `DOM_XXX`, such as `DOM_ARRAY`, `DOM_HFARRAY`, `DOM_IDENT`, `DOM_INT`, `DOM_LIST`, `DOM_TABLE` etc.

You can create further data types using the function `newDomain` (cf. "Example 1" on page 6-7) or via the keyword `domain` (cf. "Example 3" on page 6-14).

You can also create new data types by calling a *domain constructor*. Various pre-defined domain constructors can be found in the library `Dom`. You can also define your own domain constructors using the keyword `domain`. Cf. "Example 2" on page 6-11.

The domain type (data type) of any MuPAD object can be queried by the function `domtype`.

Algorithms

Only one domain with a given key may exist. If it is stored in two variables S and T , say, assigning or deleting a slot `slot(S, a)` implicitly also changes `slot(T, a)` (reference effect). This also holds if $a = \text{"key"}$.

Note You get no warning even if T is protected.

Purpose	Kernel functions
Description	<p>Objects of type <code>DOM_EXEC</code> represent kernel functions implemented in C++.</p> <p>Unlike functions defined at the library level (which are stored in objects of type <code>DOM_PROC</code>), functions defined in C++ in the MuPAD kernel are represented by objects of type <code>DOM_EXEC</code>.</p> <p>Users normally need not care about <code>DOM_EXEC</code>s except for the cases where explicitly testing the <code>domtype</code> of arguments; in those cases, <code>DOM_EXEC</code> should often be treated identically to <code>DOM_PROC</code>.</p> <p>Most kernel functions are actually stored inside function environments of type <code>DOM_FUNC_ENV</code>, and therefore, you can see <code>DOM_EXEC</code> only when explicitly accessing the first or second operand of those function environments.</p>
Function Calls	An object of type <code>DOM_EXEC</code> essentially represents a function; using it in this way calls the corresponding function.
Operands	The operands of a <code>DOM_EXEC</code> are used internally, may change at any time and remain undocumented.

MuPAD Domains	<code>DOM_FUNC_ENV</code> <code>DOM_PROC</code>

DOM_EXPR

Purpose

Type of “general expressions”

Description

DOM_EXPR is the data type of symbolic function calls. This includes expressions such as $a + b$ which is internally stored as `_plus(a, b)`.

In MuPAD, non-atomic symbolic expressions which are not elements of special domains have type DOM_EXPR.

Objects of type DOM_EXPR have a 0th operand which contains the functor (the function symbol, the f in $f(x)$). This operand is not counted in the result of `nops`. The subsequent operands can be of arbitrary type (although most functions will limit the number and type of operands when evaluated).

The 0th operand of a DOM_EXPR will be a procedure or function environment only in exceptional circumstances. In usual circumstances, expressions only have expressions, domain elements, or identifiers as their 0th operands.

Examples

Example 1

Function calls are of type DOM_EXPR:

```
domtype(sin(x))
```

```
DOM_EXPR
```

The 0th operand of a function call is the function symbol:

```
op(sin(x), 0)
```

```
sin
```

This operand is taken into account neither by `nops` nor by `op` if called with one argument:

```
nops(sin(x)), op(sin(x))
```

1, x

Function Calls

The effect of using an expression of type DOM_EXPR as a function to call depends on the 0th operand of the expression. For many system functions, the result is that of using all operands of the expression as functions, passing the *unevaluated* arguments. (These functions may in turn evaluate their arguments.)

Operations

Most MuPAD functions (documented as accepting “arithmetical expressions”) are built to work on elements of type DOM_EXPR.

Often, the operands of an expression will be expressions themselves. This creates a so-called “expression tree” which can be visualized using `prog::expmtree`.

Operands

All expressions are internally represented as function calls. The 0th operand is the function symbol of this call.

Evaluation

Evaluating an expression results in calling the 0th operand as a function. For library functions without option `hold`, the operands are evaluated first.

MuPAD Functions

`prog::expmtree`

DOM_FLOAT

Purpose	Real Floating Point Numbers
Description	<p>DOM_FLOAT is the type of (arbitrary precision) real floating-point numbers.</p> <p>Apart from exact symbolic calculations, MuPAD can also compute numerical approximations with arbitrary precision.</p> <p>MuPAD uses the values RD_INF and RD_NINF for real positive and negative infinities in floating-point intervals.</p> <p>MuPAD uses the value RD_NAN to indicate undefined values in floating-point intervals. If you use typeset mode, MuPAD displays this value as NaN in output regions.</p>
Function Calls	Calling a floating-point number as a function returns the number unchanged. The arguments of the call are <i>not</i> evaluated.
Operations	Just about any arithmetical operation can be performed with floating-point numbers.
Operands	DOM_FLOATs are atomic.
Output	The output format of DOM_FLOAT depends on the setting of Pref::floatFormat and is documented there.
Element Creation	<p>Floating point numbers are typed in with an optional sign (an arbitrary number of + and - signs), an optional integer part (consisting of digits), a decimal point (irrespective of locale settings of the operating system, MuPAD always expects a decimal point), a fractional part (one or more decimal digits) and optionally a decimal shift, written as the letter e followed by an optionally signed integer.</p> <p>The decimal shift is interpreted as a power of ten, i.e., 6.022e23 is the Avogadro number 6.02210^{23}.</p> <p>Additionally, the function float and most calls to functions of the numeric library create floating-point numbers as well.</p>

DIGITS | float

DOM_FUNC_ENV

Purpose Data type of function environments

Description DOM_FUNC_ENV is the data type of function environments.

MuPAD uses function environments (domain type DOM_FUNC_ENV) to integrate functions into the system. All MuPAD library functions and most kernel functions are implemented as function environments.

A function environment stores special function attributes (slots) in an internal table. When an overloadable system function, such as `diff`, `expand`, or `float`, encounters an object of type DOM_FUNC_ENV, it searches the function environment for a corresponding slot.

Operands A function environment consists of three operands. The first operand is a procedure that computes the return value of a function call. The second operand is a procedure for printing a symbolic function call on the screen. The third operand is a table that specifies how the system functions handle symbolic function calls.

Element Creation `funcenv` and `fp::unapply` (or its equivalent `-->`) create function environments of type DOM_FUNC_ENV.

MuPAD Functions `funcenv` | `fp::unapply`

Purpose	Hardware floating-point arrays
Description	<p>DOM_HFARRAY is a multidimensional container type, storing hardware floating-point numbers at integer indices.</p> <p>Unlike generic arrays, objects of type DOM_HFARRAY are containers of hardware floating-point numbers, real or complex. They take up considerably less space than the corresponding arrays of software floats (DOM_FLOAT) would, but the range of hardware floating-point numbers is much more limited.</p>
Function Calls	Using an hf-array as the symbol of a function call returns that hf-array unchanged. The arguments of the call are not evaluated.
Operations	<p>Read and write access to an hf-array is performed using indexed access, as in <code>A[1]</code>, which automatically converts between hardware and software floats. Trying to write a value which cannot be converted into a hardware float into an hf-array causes an error to be raised, as does accessing an element out of bounds.</p> <p>The function <code>map</code> applies some function or transformation to each element of an hf-array, returning an hf-array of the same format as its input, with the results of the calls as its entries. If a result cannot be converted to a hardware float, an error is raised.</p> <p>If <code>A</code> is an hf-array, <code>nops(A)</code> returns the number of elements in <code>A</code>.</p> <p>Basic arithmetic works on hf-arrays: Addition and subtraction of hf-arrays of identical format combines the containers element-wise, addition and subtraction of constants is applied to the main diagonal. For two-dimensional hf-arrays, multiplication performs matrix multiplication. Division is possible for completeness, but should be avoided, as it numerically inverts the dividend first, and this is hardly ever the algorithmically “right” way to handle a numerical problem.</p>
Operands	If <code>A</code> is an hf-array, the 0th operand of <code>A</code> , <code>op(A, 0)</code> , will be the sequence starting with the number of dimensions (an integer n) followed by n

DOM_HFARRAY

ranges of integers, which denote the acceptable ranges of indices for each dimension, including both numbers listed in the range.

For $1 \leq i \leq \text{nops}(A)$, the i th operand of A is the i th entry of A , in the lexicographic order of indices.

Output

One-dimensional hf-arrays are displayed as row vectors, two-dimensional hf-arrays as matrices. Higher-dimensional hf-arrays are written in functional form, writing the entries as a flat list, and do not have a typesetting version. This also causes typesetting to be disabled for any surrounding expression in the same output.

Element Creation

The primary way of creating hf-arrays is the function `hfarray`. Other important functions (optionally) returning hardware float arrays include several functions of the `numeric` library and `import::readbitmap`.

MuPAD Functions

`hfarray` | `float`

Purpose	Symbolic Identifiers
Description	<p>DOM_IDENT is the data type of symbolic identifiers, used for example for indeterminates.</p> <p>To perform symbolic computations, it is often necessary to represent indeterminates, which may or may not carry assumptions. These indeterminates (which in some contexts may also be bound identifiers and which may also be assigned specific values) are called “identifiers” in MuPAD and have the domain type DOM_IDENT.</p>
Function Calls	Calling a DOM_IDENT as a function creates a DOM_EXPR. If the identifier has a value, the evaluation of that DOM_EXPR may result in an arbitrary value.
Operations	<p>Identifiers are valid arithmetical expressions, so most MuPAD functions happily accept identifiers.</p> <p>To get and analyze the name of an identifier, you can use <code>coerce(identifier, DOM_STRING)</code> and look at the resulting string. (The call <code>" ".identifier</code> returns the same string and is shorter to type.)</p>
Operands	Identifiers are atomic.
Output	<p>Identifiers are displayed with their names, with the following special cases in typesetting:</p> <ul style="list-style-type: none">• Underscores (<code>_</code>) in the middle of identifiers cause subscripting: <code>x_2</code> is displayed as x_2.• Certain constructs of the form <code>`&...;`</code> in identifiers are replaced by special typeset characters. For example, <code>`&alpha;&rarr;`</code> is displayed as $\vec{\alpha}$. To generate these identifiers, we suggest using the Symbol library, which would use <code>Symbol::accentRightArrow(Symbol::alpha)</code> for the example above.

DOM_IDENT

Element Creation

A sequence of characters, underscores and digits which does not start with a digit is considered an identifier. Examples: `x`, `x0`, `t_0`.

Additionally, an arbitrary string of characters enclosed in 'backticks' `` is also an identifier. Examples: ``x+y``, ``a plus 1``. If the string of characters between the back ticks is a valid identifier already, this input form creates the same identifier as the one without the backticks.

MuPAD Functions

`genident` | `indets`

Purpose	Integers
Description	DOM_INT is the domain of integer constants such as 42 or -56412564156717653. The size of integers is limited to $2^{2^31} - 1$ in absolute value.
Function Calls	Calling an integer as a function returns that integer unchanged. The arguments are <i>not</i> evaluated.
Operations	<p>Integers are arithmetical expressions and thus accepted by almost every MuPAD function.</p> <p>To represent an integer in a basis different from 10, please use <code>int2text</code>.</p>
Operands	Integers are atomic.
Element Creation	Integers are given by an optional sign (an arbitrarily long string of + and - signs) and a sequence of decimal digits. Apart from this direct input method, many MuPAD commands such as <code>text2int</code> return integers.

MuPAD Domains	DOM_FLOAT DOM_RAT

DOM_INTERVAL

Purpose Floating point intervals

Description Object of type `DOM_INTERVAL` represents an interval of complex numbers. Either border may be *infinity* or $-\infty$. The borders are represented by floating point numbers (`DOM_FLOAT`).

Objects of type `DOM_INTERVAL` represent numerical enclosures of rectangles in the complex plane or finite unions thereof. Numerical enclosures of real intervals are an important special case.

Because an element of type `DOM_INTERVAL` contains floating-point numbers of type `DOM_FLOAT`, its exact value depends on the value of the environment variable `DIGITS` at the time of creation.

The result of all arithmetical operations on elements of type `DOM_INTERVAL` is rounded outwards, that is, the resulting (union of) rectangle(s) is *guaranteed* to contain the exact result. If the result interval is purely real, the lower bound of the result is guaranteed to be no larger than the exact value of the exact result, while the upper value of the result is guaranteed to be no smaller than the exact value. The exact values may not be representable as floating-point numbers. In this case, the result of a single operation such as `+` or `*` is the smallest representable interval containing the exact result. In other words, operations on `DOM_INTERVAL` are locally optimal.

Note that the representation of an element of `DOM_INTERVAL` on the screen is generated with outward rounding, too. This may lead to “apparent overestimation,” as you can see in “Example 1” on page 6-28.

For generating matrix or polynomial rings over floating-point intervals, use the façade domain `Dom::FloatIV`.

Examples **Example 1**

An interval of type `DOM_INTERVAL` can only hold floating-point numbers, which are internally stored as binary numbers. For this reason, it cannot hold symbolic expressions as its operands:

```
iv := hull(PI)
```

```
3.141592653 ... 3.141592654
```

This interval certainly does contain π . However, the value printed on the screen does not accurately describe the interval generated, as you can see when you print the same interval with a larger value of DIGITS:

```
DIGITS := 15: iv; delete DIGITS:
```

```
3.14159265358979 ... 3.1415926535898
```

In the first output, it looked as if the difference between the two borders (the width of the interval) was 10^{-8} , while in the latter output we can see that it is at most 10^{-13} . Actually, the difference is even smaller:

```
op(iv,2) - op(iv,1)
```

```
6.938893904 10-18
```

This rounding does not take place for symbolic values which can be represented exactly in both the internal (binary) and the on-screen (decimal) format:

```
iv := hull(1); op(iv,2) - op(iv,1)
```

```
1.0 ... 1.0
```

```
0.0
```

However, floating-point values in the input are assumed to be approximations up to the current computing precision:

```
iv := hull(1.0); op(iv,2) - op(iv,1)
```

```
0.9999999999 ... 1.000000001
```

```
5.204170428 10-18
```

Example 2

If you convert infinity or -infinity into an interval of type DOM_INTERVAL, the resulting interval will contain the corresponding floating-point infinity, which are displayed as RD_INF or RD_NINF, respectively:

```
hull(infinity), hull(-infinity)
```

```
2.098578716 10323228496 ... RD_INF, RD_NINF ... -2.098578716 10323228496
```

Since the range of floating-point numbers is limited, also conversion of finite values may generate floating-point infinities. The exact limit of floating-point numbers may change from one MuPAD version to the next. Currently, the following command exceeds the representable range::

```
hull(exp(109))
```

```
2.098578716 10323228496 ... RD_INF
```

As for calculating with intervals with infinities as their borders, note that any multiplication where one factor is exactly zero and the other factor contains either infinity results in the interval encompassing the whole real axis:

```
(0...0) * (1e30...infinity)
```

```
RD_NINF ... RD_INF
```

Example 3

Objects of type DOM_INTERVAL represent rectangular subsets of the complex plane with the sides parallel to the coordinate axes or unions of such rectangles. In the following example, the exact result would be a rotated rectangle. Interval arithmetics returns the smallest non-rotated rectangle enclosing the precise result:

$$(1 \dots 2 + I) * (1 + I)$$

$$0.0 \dots 2.0 + 1.0 \dots 3.0 i$$
Example 4

When computing with floating-point numbers, you can easily run into cancellation and round-off errors without noticing:

$$(1 + 1e-18) - 1.0$$

$$0.0$$

$$\sin(1e42)$$

$$0.4587729978$$

The fundamental problem of numerical computations is that there is no indication to these errors. Of course, you can get around most problems of this type by increasing the number of significant digits, if you know that problems are lurking:

```
DIGITS:=50:
(1+1e-18) - 1.0,
sin(1e42)
```

As of version 2.5, MuPAD implements the following operations on elements of type `DOM_INTERVAL`:

- The basic arithmetical operations: `+`, `-`, `*`, `/`, `^`, `sqrt`.
- The trigonometric functions and their inverses: `sin`, `cos`, `tan`, `sec`, `csc`, `cot`, `arcsin`, `arccos`, `arctan`, `arccsc`, `arccot`.
- The exponential function and the logarithm.
- The hyperbolic functions and their inverses: `sinh`, `cosh`, `tanh`, `sech`, `csch`, `coth`, `arcsinh`, `arccosh`, `arctanh`, `arccsch`, `arccoth`.
- The functions `Re`, `Im` (real- and imaginary part), `abs`, `sign` and `arg` (the ‘argument’ = polar angle of a complex number).
- For real intervals, `gamma` and `beta`.
- `ceil`, `floor`, `trunc`, `round`.

For legal combinations of arguments, all computations are carried out in interval arithmetics, see “Example 4” on page 6-31.

Operands

The operands of an interval depend on its value:

- An interval of type `DOM_INTERVAL` may be a union of rectangles in the complex plane. In this case, the 0th operand is the identifier `union`, while the remaining operands are the corresponding rectangles, which are of type `DOM_INTERVAL`.
- Rectangles with non-zero imaginary part, which are not unions, have two operands of type `DOM_INTERVAL`: Their real and imaginary parts, both of which are real intervals.
- Real intervals, i.e., non-union rectangles with vanishing imaginary part, have two operands, their left and right borders.

Output

A real interval is displayed in the form “left . . . right”, where “left” and “right” are the borders of the interval, printed as floating-point numbers.

DOM_INTERVAL

A complex interval is displayed as “(real part) + (imaginary part) * I”, with the real and imaginary part displayed as real intervals.

A union of rectangles is displayed as “interval union interval”, with the intervals inside written as specified above.

The output of an interval depends on the environment variable DIGITS as well as on the preference settings `Pref::floatFormat` and `Pref::trailingZeroes`.

Note that the borders are rounded outwards for printing. “Example 1” on page 6-28 shows how this effects the output.

Element Creation

Elements of type `DOM_INTERVAL` can be constructed in the following ways:

- With the function `hull`:

```
hull(PI, -3, 1/2), hull(1/3)
```

```
-3.0 ... 3.141592654, 0.3333333333 ... 0.3333333334
```

- With the operator `...` (which in turn calls `hull`):

```
1 ... 4+I
```

```
1.0 ... 4.0+0.0 ... 1.0i
```

- The function `interval` creates elements of type `DOM_INTERVAL` as well, but may return expressions:

```
interval(x^2+sin(1))
```

```
x2 + 0.8414709848 ... 0.8414709849
```

Note that floating-point values in the input of `hull` or `interval` are considered to be approximations, even if the value displayed in the decimal system can be represented exactly in the internal binary format. This is because `hull` cannot decide whether, for example, `0.25` has actually been typed in as such or if it should have been some `0.25 + .` If you want zero-width intervals, use a rational number as input which can be represented exactly in binary:

Algorithms

Intervals of type `DOM_INTERVAL` are always interpreted as *closed* intervals, i.e., the endpoints belong to the set. It is reasonable not to have open intervals included, since most operations will enlarge the resulting interval anyway (although only marginally so).

DOM_LIST

Purpose Lists of Objects

Description Lists (of domain type DOM_LIST) are ordered collections of an arbitrary number of arbitrary MuPAD objects, except for sequences and the null object.

In MuPAD, the mathematical construct of an n -tuple is implemented as the data type DOM_LIST. Lists consist of an arbitrary (finite) number of arbitrary objects, with the exception of expression sequences, which are split into their operands when placed into a list.

Unlike sets, lists can contain multiple copies of the same element. The order of elements in a list is preserved.

Lists can be empty.

Examples **Example 1**

To create a list for our first example, we use the operator \$:

```
L := [x_.i $ i=1..10]
```

```
[x1, x2, x3, x4, x5, x6, x7, x8, x9, x10]
```

This list contains 10 elements:

```
nops(L)
```

```
10
```

The fifth element of the list is x_5 and the list of elements from x_3 through x_6 can also be accessed very easily:

```
L[5], L[3..6]
```

```
x5, [x3, x4, x5, x6]
```

To change an element of the list, we use the indexed form on the left hand side of an assignment:

$L[5] := 5$

5

L

$[x_1, x_2, x_3, x_4, 5, x_6, x_7, x_8, x_9, x_{10}]$

Note that this assignment only changes L, not x_5 :

x_5

x_5

Likewise, we can change a sublist by assigning another list to it. This may change the length of the list:

$L[3..6] := [1, 2]$

$[1, 2]$

$nops(L), L$

8, $[x_1, x_2, 1, 2, x_7, x_8, x_9, x_{10}]$

Function Calls

Using a list as a function symbol creates the list obtained by using each list element as a function symbol for the operands used, i.e., $[f, g](x, y)$ results in $[f(x, y), g(x, y)]$.

Operations

Assuming that L is a list, the number of elements in L can be determined by calling `nops(L)`.

Individual elements of the list are accessed in the form $L[1]$, $L[2]$ etc. when counting from the beginning or $L[-1]$, $L[-2]$ etc. when counting from the end. Trying to access an element “outside” the list or $L[0]$ raises an error.

Continuous sub-lists can be extracted by using a range in an indexed access: $L[2..4]$ returns the list $[L[2], L[3], L[4]]$; $L[2..-2]$ returns the list L without its first and last element.

Both forms of indexed access can also be used as the left hand side of an assignment, cf. “Example 1” on page 6-36.

Lists can be concatenated with the dot operator, as in $L1 . L2$ or its functional form, `_concat`.

The function `contains` finds the first occurrence of a given MuPAD object in a list. `select` and `split` can be used to extract those elements from a list fulfilling an arbitrary predicate.

Lists can be sorted with `sort` or `prog::sort`.

The function `map` applies a function to all elements of a list, returning the list of results. To combine two lists element-wise with some function, use `zip`.

Assigning a list to a list of identifiers is possible and results in a simultaneous assignment, cf. `?_assign`.

Operands

The operands of a list are its elements.

Element Creation

The most direct way of creating a list is to place a sequence of MuPAD objects (separated by commas) between rectangular brackets, as in $[1, 2, 3]$.

DOM_PROC

Purpose

Data type of procedures

Description

DOM_PROC is the data type of procedures.

MuPAD procedures belong to the kernel domain DOM_PROC.

You can enclose procedures of type DOM_PROC into function environments of type DOM_FUNC_ENV.

Element Creation

proc and its equivalent -> create procedures of type DOM_PROC.

See Also**MuPAD Domains**

DOM_PROC_ENV

MuPAD Functions

proc | funcenv

Purpose

Data type of procedure environments

Description

Procedure environments are mostly ephemeral objects and are only rarely seen by the user (and even more rarely useful to examine). A procedure environment represents a procedure that is currently being executed: formal parameters and local variables have values.

Procedure environments do rarely become visible, and you do not need to manipulate them directly. They serve only one purpose: if a procedure is generated inside another procedure, variable names in the body of the inner procedure that are not declared local there refer to names in the outer procedure, provided they are declared local in the outer procedure. (See the Programming Manual for more information on the scoping rules for MuPAD.) Consequently, the inner procedure must contain information on the current values of local variables of the outer procedure. Hence, the status of the outer procedure is encoded into an object of type `DOM_PROC_ENV`, and that object is stored in the returned procedure as its twelfth operand.

You never need to generate objects of this type. There are no operations available.

Examples

Example 1

The only occasion on which you should come across a procedure environment is the following: an outer procedure returns an inner procedure depending on formal parameters or local variables of the outer procedure:

```
outer :=  
proc(x)  
option escape;  
begin  
  /* inner procedure to return : */  
  y -> x + y  
end_proc:  
add5 := outer(5)
```

```
y → x + y
```

In spite of the (slightly confusing) output, `x` has a special meaning here: it points to the parameter `x` of `outer`. That parameter currently has the value `5` and won't be changed any more. To be able to access that value, the particular instance of `outer` in the status of being executed has to be stored in `add5`:

```
expr2text(op(add5, 12))
```

```
"DOM_PROC_ENV(0x1f9d904)"
```

Operands

The number of operands of a procedure environment depends on the number of local and saved variables of the outer procedure. Details about the operands remain undocumented.

Algorithms

The integers appearing in the output of objects of type `DOM_PROC_ENV` have no mathematical meaning; they denote positions in memory.

Purpose	Rational Numbers
Description	DOM_RAT is the data type of rational numbers.
Examples	<p>Example 1</p> <p>The operands of a rational number are its numerator and denominator:</p> <p><code>op(2/3)</code></p> <p><code>2, 3</code></p> <p>When substituting an operand, the resulting DOM_RAT is again normalized:</p> <p><code>subsop(2/3, 2=6)</code></p> <p>$\frac{1}{3}$</p>
Function Calls	Using a rational number as a function returns that number unchanged. The function arguments are <i>not</i> evaluated.
Operations	<p>Rational numbers are arithmetical expressions and therefore valid inputs to most MuPAD functions.</p> <p>The numerator and denominator of a rational number can be accessed using <code>num</code> and <code>denom</code> or by using <code>op</code> directly.</p> <p>Elements of DOM_RAT are always normalized, cf. “Example 1” on page 6-43.</p>
Operands	A rational number has two operands, which are integers: Its numerator and its denominator.

DOM_RAT

Element Creation

The division of two integers results in an integer or a rational number.

MuPAD Domains

`DOM_COMPLEX` | `DOM_INT` | `DOM_FLOAT` | `Dom::Rational`

Purpose	Sets of Objects
Description	<p>Set of type DOM_SET can store an arbitrary finite number of arbitrary MuPAD objects, except for sequences and the null object.</p> <p>In MuPAD, finite sets are implemented with the data type DOM_SET. Sets are unordered collections of arbitrary objects, with identical objects appearing only once. Sequences (objects separated by commas) are “flattened” when put into a set, i.e., instead of the sequence, its elements are placed into the set. The null object is treated as the empty sequence, i.e., it does not result in an element in the set.</p> <p>Sets can be empty. The empty set is displayed as \emptyset.</p>
Function Calls	<p>Using a set as a function symbol creates the set obtained by using each element as a function symbol for the operands used, i.e., $\{f, g\}(x, y)$ results in $\{f(x, y), g(x, y)\}$.</p>
Operations	<p>Assuming that S is a set, the number of elements in S can be obtained by calling <code>nops(S)</code>.</p> <p>Individual elements of the set can be obtained in two subtly different ways:</p> <ol style="list-style-type: none">1 Using an indexed access, as in $S[2]$, returns the n-th element of the set, counted in the order as the set appears on the screen. This is a potentially slow operation, since it requires determining that order for each access, i.e., sorting the set. <p>Negative indices are accepted, counting from the end of the sequence of elements. Trying to access an element “outside” the set or $S[0]$ raises an error.</p> <ol style="list-style-type: none">2 Using <code>op</code>, as in <code>op(S, 2)</code>, returns the n-th element of the set, counted in the internal order. This is a fast operation ($O(n)$ to get the n-th element, irrespective of the size of S), but the internal order of two mathematically identical sets can be completely different and almost

any operation changing a set can completely change its internal order, so no assumptions should be made.

Both of these ways also accept ranges as indices. `S[2..4]` returns the set `{S[2], S[3], S[4]}`, while `op(S, 2..4)` returns the sequence `op(S, 2), op(S, 3), op(S, 4)`.

To iterate over all elements of a set in no particular order, using `map` or the `$` operator is highly superior to using a `for`-loop with either of the above element access methods. If a `for`-loop is required, you should use the form `for s in S`, which has linear complexity as well.

The usual set operations are provided as infix operations: `union`, `minus`, `intersect`.

To change an element of a set, the preferred method is to remove it using `minus` and adding a new one using `union`. It is also possible to replace an element with `subsop`; replacing an element with `null()` deletes it from the set. (Note that `subsop` does not do a side-effect assignment.)

The function `contains` checks for occurrence of a given MuPAD object in a set; see also the `in` operator for the same purpose, but with different evaluation semantics. `select` and `split` can be used to extract those elements from a set fulfilling an arbitrary predicate.

To get a list of the elements of a set, use `coerce`. To get such a list with the elements ordered in the same way as printed on the screen, use `DOM_SET::sort(S)`.

Operands

The operands of a set are its elements, in the internal order. (See above for details.)

Output

Sets are ordered for the output.

Element Creation

The most direct way of creating a set is to place a sequence of MuPAD objects (separated by commas) between curly brackets, as in `{1, 2, 3}`.

DOM_LIST | Dom::ImageSet | Dom::Multiset

DOM_STRING

Purpose Texts (character strings)

Description Texts (which are not really “mathematical objects”, but useful to the programmer) in MuPAD are of domain type DOM_STRING.

MuPAD can manipulate texts (strings of characters). These are primarily used for output and data input.

Examples **Example 1**

As far as `op` is concerned, a string cannot be dissected:

```
s := "this is a string":  
op(s, 1), op(s, 2)
```

```
"this is a string", FAIL
```

To access individual characters or substrings, use indexed access:

```
s[1], s[6..7]
```

```
"t", "is"
```

Assigning to a substring may change the length of a string:

```
s[6..7] := "changes";  
s
```

```
"changes"
```

```
"this changes a string"
```

Function Calls

Using a string as a function returns the string unchanged. The arguments are *not* evaluated.

Operations

Strings can be concatenated using the dot operator or its functional equivalent, `_concat`.

The length of a string can be obtained using `length`.

Substrings and individual characters (which are strings of length 1) can be accessed using `substring` or indexed access, with indices starting at 1 and negative indices counting from the end of the string: `s[1]`, `s[3..-2]`. It is also possible to perform an indexed assignment to a string, cf. “Example 1” on page 6-48.

To convert a string into the MuPAD expression that would be obtained by using the string as an input, use `text2expr`. For simple MuPAD expressions, it is possible to get a string that evaluates to that expression using `expr2text`. Expressions that are not convertible in this way include all expressions containing local variables set with `option escape`. Also, expressions involving floating point numbers usually will change when being converted to strings and back.

Operands

Strings are atomic, i.e., they have exactly one operand, the string itself.

Output

The output form of strings is very similar to their input form. When typesetting, spaces at the beginning and the end of strings are ignored and multiple adjacent blanks as well as newlines are collapsed to a single space.

Element Creation

A string is created by enclosing characters in a pair of typewriter quotes: `"this is a string"`. The following special sequences are supported (but see below for the typeset output; these are useful only for non-typeset output):

- `"\n"` denotes an end-of-line character.
- `"\b"` is almost identical to `"\n"`, except that for “pretty-printing” it encodes the baseline of the current object.
- `"\t"` is a tabulator.
- `"\""` encodes a backslash.

DOM_STRING

See the documentation of `print` for details.

Purpose	Local Variables in Procedures
Description	<p>Local variables (variables in the programming sense, with “lexical scoping”) are of domain type <code>DOM_VAR</code>.</p> <p>When writing MuPAD functions, often intermediate results need to be stored and retrieved. Like most programming languages, MuPAD offers “local variables” for this purpose. These local variables do not conflict with global identifiers of the same name nor with other local variables of the same name used at other places.</p> <p>Local variables use “lexical scoping”, i.e., they can be used in all program code that is written inside the body of the procedure declaring the local variable. Note that returning anything with a reference to a local variable requires the use of <code>option escape</code> in the procedure definition.</p>
Operations	Local variables can be assigned values and these values can later be retrieved.
Element Creation	Local variables are created by using either the special names <code>dom</code> or <code>procname</code> or one of the names declared with the keyword <code>local</code> inside a procedure definition.

Dom::AlgebraicExtension

Purpose Simple algebraic field extensions

Syntax

Domain Creation

```
Dom::AlgebraicExtension(F, f)
Dom::AlgebraicExtension(F, f, x)
Dom::AlgebraicExtension(F, f1 = f2)
Dom::AlgebraicExtension(F, f1 = f2, x)
```

Element Creation

```
Dom::AlgebraicExtension(F, f)(g)
Dom::AlgebraicExtension(F, f)(rat)
```

Description **Domain Creation**

For a given field F and a polynomial $f \in F[x]$,
`Dom::AlgebraicExtension(F, f, x)` creates the residue class field $F[x]/\langle f \rangle$.

`Dom::AlgebraicExtension(F, f1=f2, x)` does the same for $f = f_1 - f_2$.

`Dom::AlgebraicExtension(F, f, x)` creates the field $F[x]/\langle f \rangle$ of residue classes of polynomials modulo f . This field can also be written as $F[x]/\langle f \rangle$, the field of residue classes of rational functions modulo f .

The parameter x may be omitted if f is a univariate polynomial or a polynomial expression that contains exactly one indeterminate; it is then taken to be the indeterminate occurring in f .

The field F must have normal representation.

f must not be a constant polynomial.

f must be irreducible; this is *not* checked.

f may be a polynomial over a coefficient ring different from F , or multivariate; however, it must be possible to convert it to a univariate polynomial over F . See “Example 2” on page 6-54.

Element Creation

`Dom::AlgebraicExtension(F, f)(g)` creates the residue class of g modulo f .

If `rat` has numerator and denominator `p` and `q`, respectively, then `Dom::AlgebraicExtension(F,f)(rat)` equals `Dom::AlgebraicExtension(F,f)(p)` divided by `Dom::AlgebraicExtension(F,f)(q)`.

Superdomain `Dom::BaseDomain`

Axioms If `F` has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories `Cat::Field`, `Cat::Algebra(F)`, `Cat::VectorSpace(F)`
If `F` is a `Cat::DifferentialRing`, then `Cat::DifferentialRing`.
If `F` is a `Cat::PartialDifferentialRing`, then `Cat::PartialDifferentialRing`.

Examples **Example 1**

We adjoin a cubic root `alpha` of 2 to the rationals.

```
G := Dom::AlgebraicExtension(Dom::Rational, alpha^3 = 2)
```

```
Dom::AlgebraicExtension(Dom::Rational, alpha^3 - 2 = 0, alpha)
```

The third power of a cubic root of 2 equals 2, of course.

```
G(alpha)^3
```

```
2
```

The trace of `a` is zero:

```
G::conjTrace(G(alpha))
```

```
0
```

Dom::AlgebraicExtension

You can also create random elements:

```
G := random()
```

```
2 - 814 alpha^2 - 65 alpha + 824
```

Example 2

The ground field may be an algebraic extension itself. In this way, it is possible to construct a tower of fields. In the following example, an algebraic extension is defined using a primitive element `alpha`, and the primitive element `beta` of a further extension is defined in terms of `alpha`. In such cases, when a minimal equation contains more than one identifier, a third argument to `Dom::AlgebraicExtension` must be explicitly given.

```
F := Dom::AlgebraicExtension(Dom::Rational, alpha^2 = 2):  
G := Dom::AlgebraicExtension(F, bet^2 + bet = alpha, bet)
```

```
Dom::AlgebraicExtension(Dom::AlgebraicExtension(Dom::Rational, alpha^2 - 2 =  
0, alpha), - alpha + bet + bet^2 = 0, bet)
```

Example 3

We want to define an extension of the field of fractions of the ring of bivariate polynomials over the rationals.

```
P := Dom::DistributedPolynomial([x, y], Dom::Rational):  
F := Dom::Fraction(P):  
K := Dom::AlgebraicExtension(F, alpha^2 = x, alpha)
```

```
Dom::AlgebraicExtension(Dom::Fraction(Dom::DistributedPolynomial([x,  
y], Dom::Rational, LexOrder)), -x + alpha^2 = 0, alpha)
```

Now $K = \mathcal{Q}[\sqrt{x}, y]$. Of course, the square root function has the usual derivative; note that $\frac{1}{\sqrt{x}}$ can be expressed as $\frac{\alpha}{x}$:

```
diff(K(alpha), x)
```

$$\frac{\alpha}{2x}$$

On the other hand, the derivative of \sqrt{x} with respect to y is zero, of course:

```
diff(K(alpha), y)
```

0

We must not use D here. This works only if we start our construction with a ring of univariate polynomials:

```
P:= Dom::DistributedPolynomial([x], Dom::Rational):
```

```
F:= Dom::Fraction(P):
```

```
K:= Dom::AlgebraicExtension(F, alpha^2 = x, alpha):
```

```
D(K(alpha))
```

$$\frac{\alpha}{2x}$$

Parameters

F

The ground field: a domain of category `Cat::Field`

f, f1, f2

Polynomials or polynomial expressions

x

Dom::AlgebraicExtension

Identifier

g

Element of the residue class to be defined: polynomial over F in the variable x , or any object convertible to such.

rat

Rational function that belongs to the residue class to be defined: expression whose numerator and denominator can be converted to polynomials over F in the variable x . The denominator must not be a multiple of f .

Entries

"zero"	the zero element of the field extension
"one"	the unit element of the field extension
"groundField"	the ground field of the extension
"minpoly"	the minimal polynomial f
"deg"	the degree of the extension, i.e., of f
"variable"	the unknown of the minimal polynomial f

"characteristic"

the characteristic, which always equals the characteristic of the ground field. This entry only exists if the characteristic of the ground field is known.

"degreeOverPrimeField"

the dimension of the field when viewed as a vector space over the prime field. This entry only exists if the ground field is a prime field, or its degree over its prime field is known.

Methods

Mathematical Methods

plus - Sum of field elements

`_plus(a,)`

This method overloads the function `_plus` of the system kernel.

mult - Product of field elements

`_mult(a,)`

This method overloads the function `_mult` of the system kernel.

power - Raise to the nth power

Inherited from `Cat::Monoid`.

negate - Negate a field element

`_negate(a)`

This method overloads the function `_negate` of the system kernel.

subtract - Difference of field elements

`_subtract(a, b)`

This method overloads the function `_subtract` of the system kernel.

Dom::AlgebraicExtension

equal - Test for mathematical equality

Inherited from Dom::BaseDomain.

equiv - Test for equivalence

Inherited from Cat::BaseCategory.

iszero - Test whether a field element is zero.

iszero(a)

This method overloads the function iszero.

isone - Test if element is one

Inherited from Cat::Monoid.

isUnit - Test if element is an unit

Inherited from Cat::Field.

intmult - Multiply a field element by an integer

intmult(a, b)

This method is more efficient than "_mult" in this special case.

invert - Inverse of a field element

invert(a)

This method overloads the function invert.

divide - Exact division

Inherited from Cat::Field.

divide - Division with remainder

Inherited from Cat::Field.

quo - Return Euclidean quotient

Inherited from Cat::Field.

rem - Return Euclidean remainder

Inherited from Cat::Field.

euclideanDegree - Return Euclidean degree

Inherited from `Cat::Field`.

idealGenerator - Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

divides - Test if division is exact

Inherited from `Cat::Field`.

gcd - Gcd of field elements

`gcd(a,)`

This method overloads the function `gcd`.

gcdex - Extended greatest common divisor

Inherited from `Cat::EuclideanDomain`.

associates - Test for associate elements

Inherited from `Cat::Field`.

unitNormal - Unit normal form

Inherited from `Cat::Field`.

unitNormalRep - Unit normal representation

Inherited from `Cat::Field`.

lcm - Least common multiple

Inherited from `Cat::GcdDomain`.

sqrfree - Square-free factorization

Inherited from `Cat::Field`.

irreducible - Test if element is irreducible

Inherited from `Cat::Field`.

factor - Unique factorization

Inherited from `Cat::Field`.

conjNorm - Norm of an element

`conjNorm(a)`

conjTrace - Trace of an element

`conjTrace(a)`

minimalPolynomial - Minimal polynomial of an element

`minimalPolynomial(a)`

D - Differential operator

`D(a)`

This method overloads the function `D`.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 6-54.

diff - Partial differentiation

`diff(a, x1,)`

Differentiation is defined to be the continuation of differentiation of the ground field; this method exists only if the ground field has a method “diff”, too.

Differentiation is not possible in inseparable extensions.

This method overloads the function `diff`.

This method must not be called for inseparable extensions; note that MuPAD cannot check whether an extension is separable.

See “Example 3” on page 6-54.

random - Random element of the field

`random()`

The `random` method of the ground field is used to generate coefficients of a random polynomial of the ground field; the residue class of that polynomial is the return value. Hence the

probability distribution of the elements returned depends on that of the random method of the ground field.

Conversion Methods

convert - Convert into a field element

`convert(x)`

If the conversion fails, then FAIL is returned.

convert_to - Convert a field element into another type

`convert_to(a, T)`

Field elements can be converted to polynomials or expressions. Field elements represented by constant polynomials can also be converted to the same types as the elements of the ground field; in particular, they can be converted to elements of the ground field.

coerce - Coerce into this domain

Inherited from `Cat::BaseCategory`.

new - Create element of this domain

Inherited from `Cat::BaseCategory`.

expr - Convert an element of the field into an expression

`expr(a)`

This method overloads the function `expr`.

subs - Avoid substitution

Inherited from `Dom::BaseDomain`.

subsex - Avoid extended substitution

Inherited from `Dom::BaseDomain`.

testtype - Test type of object

Inherited from `Cat::BaseCategory`.

print - Return expression to print an element

Dom::AlgebraicExtension

Inherited from `Cat::BaseCategory`.

printMethods - Print out methods

Inherited from `Dom::BaseDomain`.

TeX - Generate TeX output

Inherited from `Dom::BaseDomain`.

hasProp - Test for a certain property

Inherited from `Dom::BaseDomain`.

whichEntry - Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

allEntries - Return the names of all entries

Inherited from `Dom::BaseDomain`.

undefinedEntries - Return missing entries

Inherited from `Dom::BaseDomain`.

getAxioms - Return axioms stated in the constructor

Inherited from `Dom::BaseDomain`.

getSuperDomain - Return super-domain stated in the constructor

Inherited from `Dom::BaseDomain`.

allSuperDomains - Return all super-domains

Inherited from `Dom::BaseDomain`.

getCategories - Return categories stated in the constructor

Inherited from `Dom::BaseDomain`.

allAxioms - Return all axioms

Inherited from `Dom::BaseDomain`.

allCategories - Return all categories

Inherited from Dom::BaseDomain.

MuPAD Domains

Dom::GaloisField

Dom::ArithmeticalExpression

Purpose	Domains of arithmetical expressions
Syntax	Dom::ArithmeticalExpression(x)
Description	<p>Dom::ArithmeticalExpression is a façade domain of arithmetical expressions built up by the system functions and operators like + and *.</p> <p>This domain has almost no algebraic structure because unqualified expressions have no normal form. (For example, there are rational expressions for zero which are not normalized to 0.) The main purpose of Dom::ArithmeticalExpression is to provide implementations for methods used by façade sub-domains like Dom::Integer which are represented by a subset of the arithmetical expressions.</p> <p>Elements of Dom::ArithmeticalExpression are usually not created explicitly. However, if one creates elements using the usual syntax, the input is converted to an expression using <code>expr</code>, then it is checked whether the result is an arithmetical expression.</p>
Superdomain	Dom::Expression
Axioms	Ax::systemRep
Categories	Cat::BaseCategory
Examples	<p>Example 1</p> <p>For brevity, we will use AE as a shorthand notation for Dom::ArithmeticalExpression:</p> <pre>AE := Dom::ArithmeticalExpression</pre> <pre>Dom::ArithmeticalExpression</pre> <p>An element of this domain can <i>not</i> be created as follows:</p> <pre>e := AE(2*sin(x) + f(x)/y)</pre>

$$2 \sin(x) + \frac{f(x)}{y}$$

Since `Dom::ArithmeticalExpression` is a façade domain, `e` is not a domain element, but an expression:

```
domtype(e)
```

```
DOM_EXPR
```

The fact that no error was returned yields the information that `e` is an arithmetical expression. This can also be checked as follows:

```
testtype(e,AE)
```

```
TRUE
```

In contrast to its super-domain `Dom::Expression`, this domain only allows elements which are valid arguments for the arithmetical functions, thus the following yields an error:

```
AE([a, b])
```

```
Error: The arguments are invalid. [Dom::ArithmeticalExpression::
```

Parameters

x

An arithmetical expression

Dom::ArithmeticalExpression

Entries

"key"	The name of this domain.
"one"	The neutral element w.r.t. "_mult": the constant 1.
"zero"	The neutral element w.r.t. "_plus": the constant 0.

Methods

Mathematical Methods

divide - Divide arithmetical expressions

`_divide(f, g)`

This method overloads the function `_divide`.

For details, please see `_divide`.

invert - Invert an arithmetical expression

`_invert(f)`

This method overloads the function `_invert`.

For details, please see `_invert`.

mult - Multiplie arithmetical expressions

`_mult(<f, g, >)`

This method overloads the function `_mult`.

For details, please see `_mult`.

negate - Negate an arithmetical expression

`_negate(f)`

This method overloads the function `_negate`.

For details, please see `_negate`.

plus - Add arithmetical expressions

`_plus(<f, g, >)`

This method overloads the function `_plus`.

For details, please see `_plus`.

`_power` - Power operator

`_power(f, g)`

This method overloads the function `_power`.

For details, please see `_power`.

`_subtract` - Subtract an arithmetical expression

`_subtract(f, g)`

For details, please see `_subtract`.

D - Differential operator for functions

`D(f)`

`D([c1, ...], f)`

This method overloads the function `D`.

For details, please see `D`.

`diff` - Differentiate an arithmetical expression

`diff(f, <x, >)`

This method overloads the function `diff`.

For details, please see `diff`.

`equiv` - Test for equivalence

Inherited from `Cat::BaseCategory`.

`intmult` - Multiply an arithmetical expression with an integer

`intmult(f, n)`

This method overloads the function `_mult`.

For details, please see `_mult`.

`iszero` - Test for zero

Dom::ArithmeticalExpression

`iszero(f)`

This method overloads the function `iszero`.

For details, please see `iszero`.

max - Maximum of numbers

`max(x, <y, >)`

All numerical arguments must be real.

This method overloads the function `max`.

For details, please see `max`.

min - Minimum of numbers

`min(x, <y, >)`

All numerical arguments must be real.

This method overloads the function `min`.

For details, please see `min`.

norm - Norm of an arithmetical expression

`norm(f)`

This method overloads the function `abs`.

For details, please see `abs`.

random - Create random expression

Inherited from `Dom::Expression`.

Access Methods

subs - Substitution

Inherited from `Dom::Expression`.

subsex - Extended substitution

Inherited from `Dom::Expression`.

Conversion Methods

coerce - Coerce into this domain

Inherited from `Cat::BaseCategory`.

convert - Check for being an arithmetical expression

`convert(x)`

convert_to - Conversion to other domains

Inherited from `Dom::Expression`.

expr - Just return the argument

Inherited from `Dom::Expression`.

float - Convert numbers to floats

Inherited from `Dom::Expression`.

Technical Methods

allAxioms - Return all axioms

Inherited from `Dom::BaseDomain`.

allCategories - Return all categories

Inherited from `Dom::BaseDomain`.

allEntries - Return the names of all entries

Inherited from `Dom::BaseDomain`.

allSuperDomains - Return all super-domains

Inherited from `Dom::BaseDomain`.

testtype - Test type of object

Inherited from `Cat::BaseCategory`.

undefinedEntries - Return missing entries

Inherited from `Dom::BaseDomain`.

Dom::ArithmeticalExpression

whichEntry - Return the domain or category implementing an entry

Inherited from Dom::BaseDomain.

getAxioms - Return axioms stated in the constructor

Inherited from Dom::BaseDomain.

getCategories - Return categories stated in the constructor

Inherited from Dom::BaseDomain.

getSuperDomain - Return super-domain stated in the constructor

Inherited from Dom::BaseDomain.

hasProp - Test for a certain property

Inherited from Dom::BaseDomain.

info - Print short information about this domain

Inherited from Dom::BaseDomain.

new - Create element of this domain

Inherited from Cat::BaseCategory.

print - Return expression to print an element

Inherited from Cat::BaseCategory.

printMethods - Print out methods

Inherited from Dom::BaseDomain.

testtype - Test whether its argument is an expression

Inherited from Dom::Expression.

undefinedEntries - Return missing entries

Inherited from Dom::BaseDomain.

whichEntry - Return the domain or category implementing an entry

Inherited from Dom::BaseDomain.

MuPAD Domains

Dom::Expression

Dom::BaseDomain

Purpose	Root of the domain hierarchy
Description	<p>Dom::BaseDomain is the root of the domain hierarchy as defined by the Dom package. Every domain of the package inherits from it.</p> <p>The only purpose of Dom::BaseDomain is to supply all domains of the package with some basic methods like "hasProp". Elements of Dom::BaseDomain cannot be created.</p> <p>Unlike other super-domains this domain does not impose any restrictions on the representation of the elements of its sub-domains. Thus it may be a super-domain for any domain created by a domain constructor.</p>
Categories	Cat::BaseCategory
Entries	<p>"create_dom"</p> <p>This domain entry is used to revive the domain when it is read from a binary MCode stream.</p> <p>If this entry is present it is written to the MCode stream instead of the contents of the domain. When the stream is read it is used to create the domain.</p> <p>If this entry does not exist all entries of the domain are written to the stream and read in later to create the domain.</p> <p>Dom::BaseDomain defines "create_dom" to have the same value as the key of the domain, as stored in the entry "key". All domains of the Dom package inherit this entry, thus they must be created by the reader of the MCode stream by evaluating the expression stored in the key.</p>

Methods

Mathematical Methods

equal - Test for mathematical equality

`equal(x, y)`

If this domain has the axiom `Ax::canonicalRep`, which implies that two domain elements are mathematically equal if and only if they are structurally equal, the kernel function `_equal` is used to decide the equality. In this case `UNKNOWN` is never returned.

If the axiom `Ax::canonicalRep` does not hold the method will return `TRUE` if `x` and `y` are structurally equal (in the sense of the function `_equal`) and `UNKNOWN` otherwise.

Conversion Methods

convert_to - Convert element

`convert_to(x, T)`

The implementation provided here can convert `x` to an element of this domain (the trivial case) or to an element of `Dom::Expression` (by using the method `"expr"`, see `Cat::BaseCategory`).

TeX - Generate TeX output

`TeX(x)`

The default implementation provided here converts `x` into an expression using the method `"expr"` and then uses the function `generate::TeX` to convert the expression.

Access Methods

allAxioms - Return all axioms

`allAxioms()`

allCategories - Return all categories

`allCategories()`

allEntries - Return the names of all entries

Dom::BaseDomain

allEntries()

allSuperDomains - Return all super-domains

allSuperDomains()

The last, most general, super-domain of all domains of the Dom package is Dom::BaseDomain.

getAxioms - Return axioms stated in the constructor

getAxioms()

getCategories - Return categories stated in the constructor

getCategories()

getSuperDomain - Return super-domain stated in the constructor

getSuperDomain()

hasProp - Test for a certain property

hasProp(d)

hasProp(dc)

hasProp(a)

hasProp(ac)

hasProp(c)

hasProp(cc)

hasProp(dc) tests if this domain or a super-domain of it was defined by the domain constructor dc.

hasProp(a) tests if this domain has the axiom a.

hasProp(ac) tests if an axiom of this domain was defined by the axiom constructor ac.

hasProp(c) tests if this domain has the category c.

hasProp(cc) tests if a category of this domain was defined by the category constructor cc.

info - Print short information about this domain

```
info()
```

It prints out the super-domains, categories, axioms and entry names of this domain.

If an entry "info_str", which must be a string, is defined for this domain it is used to print the header line.

printMethods - Print out methods

```
printMethods(<sort>, <Table>)
```

```
printMethods(<sort>, Tree)
```

If no sorting function is given, `sort` is used as default.

Similar as above, using `Tree` provides only that the names of the entries are inserted into a tree, an element of the domain `adt::Tree`. The tree is both printed out and returned by the method.

Using neither `Table` nor `Tree` the function does the same as `dom::printMethods(sort, Table)`.

subs - Avoid substitution

```
subs(x, , )
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

subsex - Avoid extended substitution

```
subsex(x, , )
```

Sub-domains should provide a new implementation of this method with sensible semantics if possible.

undefinedEntries - Return missing entries

```
undefinedEntries()
```

An entry is missing if it should have a definition according to a category of the domain, but the definition is not present.

Dom::BaseDomain

whichEntry - Return the domain or category implementing an entry

`whichEntry(e)`

FAIL is returned if no entry with the given name is defined for this domain.

Purpose	Field of complex numbers
Syntax	<code>Dom::Complex(x)</code>
Description	<p><code>Dom::Complex</code> is the domain of complex constants represented by expressions of type <code>DOM_INT</code>, <code>DOM_RAT</code>, <code>DOM_FLOAT</code> or <code>DOM_COMPLEX</code>. An expression of type <code>DOM_EXPR</code> is considered a complex number if it is of type <code>Type::Arithmetical</code> and if it contains only indeterminates which are of type <code>Type::ConstantIdents</code> or if it contains no indeterminates, cf. “Example 2” on page 6-78.</p> <p><code>Dom::Complex</code> is of category <code>Cat::Field</code> due to pragmatism. This domain actually is not a field because <code>bool(1.0 = float(3) / float(3))</code> returns <code>FALSE</code>, for example.</p> <p>Elements of <code>Dom::Complex</code> are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means <code>Dom::Complex</code> is a facade domain which creates elements of domain type <code>DOM_INT</code>, <code>DOM_RAT</code>, <code>DOM_FLOAT</code>, <code>DOM_COMPLEX</code> or <code>DOM_EXPR</code>.</p> <p><code>Dom::Complex</code> has no normal representation, because 0 and 0.0 both represent the zero.</p> <p>Viewed as a differential ring, <code>Dom::Complex</code> is trivial. It only contains constants.</p> <p><code>Dom::Complex</code> has the domain <code>Dom::BaseDomain</code> as its super domain, i.e., it inherits each method which is defined by <code>Dom::BaseDomain</code> and not re-implemented by <code>Dom::Complex</code>. Methods described below are re-implemented by <code>Dom::Complex</code>.</p>
Superdomain	<code>Dom::ArithmeticalExpression</code>
Axioms	<code>Ax::systemRep</code> , <code>Ax::efficientOperation("_divide")</code> , <code>Ax::efficientOperation("_mult")</code> , <code>Ax::efficientOperation("_invert")</code>
Categories	<code>Cat::DifferentialRing</code> , <code>Cat::Field</code>

Dom::Complex

Examples

Example 1

Creating some complex numbers using `Dom::Complex`:

```
Dom::Complex(2/3)
```

$$\frac{2}{3}$$

```
Dom::Complex(2/3 + 4*I)
```

$$\frac{2}{3} + 4i$$

Example 2

It's also possible to use expressions or constants for creating an element of `Dom::Complex`:

```
Dom::Complex(PI)
```

$$\pi$$

```
Dom::Complex(sin(2))
```

$$\sin(2)$$

```
Dom::Complex(sin(2/3*I) + 3)
```

$$3 + \sinh\left(\frac{2}{3}\right) i$$

If the expression cannot be converted to an element of `Dom::Complex` we will get an error message:

```
Dom::Complex(sin(x))
```

Error: The arguments are invalid. [Dom::Complex::new]

Parameters

x

An expression of type DOM_INT, DOM_RAT, DOM_FLOAT, DOM_COMPLEX.
An expression of type DOM_EXPR is also possible if it is of type Type::Arithmetical and if it contains only indeterminates which are of type Type::ConstantIdents or if it contains no indeterminates.

Entries

"characteristic"

the characteristic of this field is 0.

"one"

the unit element; it equals 1.

"zero"

The zero element; it equals 0.

Methods

Mathematical Methods

_divide - Divide numbers

`_divide(x, y)`

_invert - Invert numbers

`_invert(x)`

_mult - Multiplie numbers

`_mult(x, y,)`

_negate - Negate numbers

`_negate(x)`

_plus - Add numbers

`_plus(x, y,)`

_power - Power operator

Dom::Complex

`_power(x, y)`

_unequal - Inequalities

`_unequal(x, y)`

conjugate - Conversion to a basic type

`conjugate(x)`

D - Differential operator

`D(x)`

diff - Differentiates

`diff(z, <x, >)`

equal - Equations

`equal(x, y)`

expr - Conversion to a basic type

`expr(x)`

iszero - Zero test

`iszero(x)`

norm - Absolute value of a number

`norm(x)`

random - Random number generation

`random()`

`random(n)`

`random(m .. n)`

`random(n)` returns a random number generator which creates complex random numbers where the real parts and the imaginary parts are positive integers between 0 and $n - 1$.

`random(m..n)` returns a random number generator which creates complex random numbers where the real parts and the imaginary parts are positive integers between m and n .

unequal - Inequalities

`unequal(x, y)`

Conversion Methods

convert - Conversion into this domain

`convert(x)`

An arithmetical expression can be converted if it only contains subexpression of the types just mentioned.

If the conversion fails, FAIL is returned.

convert_to - Conversion to other domains

`convert_to(x, T)`

If the conversion fails, FAIL is returned.

The following domains are allowed for T: DOM_INT, Dom::Integer, DOM_RAT, Dom::Rational, DOM_FLOAT, Dom::Float, Dom::Numerical, DOM_COMPLEX and DOM_EXPR.

normal - Normal form of objects

`normal(x)`

Dom::DenseMatrix(R) (m, n, List, Banded)
Dom::DenseMatrix(R) (1, n, List)
Dom::DenseMatrix(R) (m, 1, List)

Description **Domain Creation**

Dom::DenseMatrix(R) creates domains of matrices over a component domain R of category Cat::Rng (a ring, possibly without unit).

If the optional parameter R is not given, the domain Dom::ExpressionField() is used.

A vector with n entries is either an $n \times 1$ matrix (a column vector), or a $1 \times n$ matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if A and B are two matrices defined by Dom::DenseMatrix(R), A + B computes the sum, and A * B computes the product of the two matrices, provided that the dimensions are correct.

Similarly, A^{-1} or $1/A$ computes the inverse of a square matrix A if it exists, and returns FAIL otherwise. See “Example 1” on page 6-86.

Many system functions have been overloaded for matrices, such as `map`, `subs`, `has`, `zip`, `conjugate` to compute the complex conjugate of a matrix, `norm` to compute matrix norms, or `exp` to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package `linalg` work with matrices. For example, the command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on A to transform A to its reduced row echelon form.

The domain `Dom::DenseMatrix(R)` represents matrices over R of arbitrary size, and it therefore does not have any algebraic structure (other than being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of $n \times n$ matrices over R . The domain `Dom::MatrixGroup(m, n, R)` represents the *Abelian group* of $m \times n$ matrices over R .

We use the following notations for a matrix A (an element of `Dom::DenseMatrix(R)`):

- $nrows(A)$ denotes the number of rows of A .
- $ncols(A)$ denotes the number of columns of A .
- A *row index* is an integer in the range from 1 to $nrows(A)$.
- A *column index* is an integer in the range from 1 to $ncols(A)$.

Note The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

Element Creation

`Dom::DenseMatrix(R)(Array)` and `Dom::DenseMatrix(R)(Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(List)` creates an $m \times 1$ column vector with components taken from the nonempty list, where m is the number of entries of `List`.

`Dom::DenseMatrix(R)(ListOfRows)` creates an $m \times n$ matrix with components taken from the nested list `ListOfRows`, where m is the number of inner lists of `ListOfRows`, and n is the maximal number of elements of an inner list. Each inner list corresponds to a row of the matrix. Both m and n must be non-zero.

If an inner list has less than n entries, then the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::DenseMatrix(R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

The call `Dom::DenseMatrix(R)(m, n)` returns the $m \times n$ zero matrix.

Use the method "identity" to create the $n \times n$ identity matrix.

The call `Dom::DenseMatrix(R)(m, n, Array)` creates an $m \times n$ matrix with components taken from `Array`, which must be an array or an `hfarray`. `Array` must have mn operands. The first m operands define the first row, the next m operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1×6 , or 2×3 , or 3×2 , or 6×1 .

The call `Dom::DenseMatrix(R)(m, n, List)` creates an $m \times n$ matrix with components taken from the list `List` with mn elements. The first m elements of the list define the first row, the next m elements of the list define the second row, etc.

The call `Dom::DenseMatrix(R)(m, n, ListOfRows)` creates an $m \times n$ matrix with components taken from the list `ListOfRows`.

If $m \geq 2$ and $n \geq 2$, then `ListOfRows` must consist of at most m inner lists, each having at most n entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than n entries, then the remaining components of the corresponding row of the matrix are set to zero. If there are less than m inner lists, then the remaining lower rows of the matrix are filled with zeroes.

`Dom::DenseMatrix(R)(m, n, f)` returns the matrix whose (i, j) th component is the value of the function call `f(i, j)`. The row index i ranges from 1 to m and the column index j from 1 to n .

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(1, n, List)` returns the $1 \times n$ row vector with components taken from `List`. The list `List` must have at most n entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, 1, List)` returns the $m \times 1$ column vector with components taken from `List`. The list `List` must have at most m entries. If there are fewer entries, then the remaining vector components are set to zero.

The entries of the list are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Superdomain `Dom::BaseDomain`

Dom::DenseMatrix

Axioms If R has Ax::canonicalRep, then Ax::canonicalRep.

Categories Cat::Matrix(R).

Examples **Example 1**

First we create the domain of matrices over the field of rational numbers:

```
MatQ := Dom::DenseMatrix(Dom::Rational)
```

```
Dom::DenseMatrix(Dom::Rational)
```

We assigned this domain to the identifier MatQ. Next we define the 2×2 matrix

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

by a list of two rows, where each row is a list of two elements:

```
A := MatQ([[1, 5], [2, 3]])
```

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way we define the following 2×3 matrix:

```
B := MatQ([[-1, 5/2, 3], [1/3, 0, 2/5]])
```

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{1}{3} & 0 & \frac{2}{5} \end{pmatrix}$$

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product AB , the 4th power of A as well as the scalar multiplication of A times $\frac{1}{3}$:

`A * B, A ^ 4, 1/3 * A`

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices A and B have different dimensions, and therefore the sum of A and B is not defined. MuPAD issues an error message:

`A + B`

Error: The dimensions do not match. [(Dom::DenseMatrix(Dom::Rati

To compute the inverse of A , just enter:

`1/A`

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, FAIL is the result of this operation. For example, the matrix:

`C := densmatrix(2, 2, [[2]])`

Dom::DenseMatrix

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:

```
C^(-1)
```

```
FAIL
```

Example 2

We create the domain of matrices over the reals:

```
MatR := Dom::DenseMatrix(Dom::Real)
```

```
Dom::DenseMatrix(Dom::Real)
```

Beside standard matrix arithmetic, the library `linalg` offers a lot of functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use `linalg::rank`:

```
A := MatR([[1, 2], [2, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

```
linalg::rank(A)
```

```
1
```

Use `linalg::eigenvectors` to compute eigenvalues and eigenvectors of the matrix A :

```
linalg::eigenvectors(A)
```

$$\left[\left[0, 1, \left[\begin{pmatrix} -2 \\ 1 \end{pmatrix} \right] \right], \left[5, 1, \left[\begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix} \right] \right] \right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library `linalg`.

Some of the functions in the `linalg` package simply serve as “interface” functions for methods of a matrix domain described above. For example, `linalg::transpose` uses the method “`transpose`” to get the transposed matrix. The function `linalg::gaussElim` applies Gaussian elimination to a matrix, such as:

```
linalg::gaussElim(A)
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

The computation is performed by the method “`gaussElim`” as described above. Such functions of the `linalg` packages, in contrast to the corresponding methods of the domain `Dom::DenseMatrix(R)`, check their incoming parameters, and some of them offer extended functionalities.

Example 3

In this example, we use the default matrix domain which is created by `Dom::DenseMatrix()`. This domain represents matrices whose components can be arbitrary arithmetical expressions (i.e., the component ring is the domain `Dom::ExpressionField()`).

This domain is already known to MuPAD by the name `matrix`:

```
A := densematrix(
  [[1, 2, 3, 4], [2, 0, 4, 1], [-1, 0, 5, 2]]
)
```

Dom::DenseMatrix

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

`domtype(A)`

`Dom::DenseMatrix()`

Matrix components can be extracted by the index operator []:

`A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]`

`7`

If one of the indices is not in its valid range, an error message is issued. Assignments to matrix components are performed similarly:

`delete a:`

`A[1, 2] := a^2: A`

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of A which consists of the rows 2 to 3 and columns 1 to 3 of A :

`A[2..3, 1..3]`

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function `linalg::substitute`.

Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field \mathbb{F}_{19} , i.e., the field of integers modulo 19. This component ring can be created with the domain constructor `Dom::IntegerMod`.

We start by giving a list of rows, where each row is a list of row entries:

```
MatZ19 := Dom::DenseMatrix(Dom::IntegerMod(19)):
MatZ19([[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted into elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e., $m = 2$. The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:

```
MatZ19(4, 4, [[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

Dom::DenseMatrix

An error message is issued if one of the given entries cannot be converted into an element over \mathbb{Z}_{19} :

```
MatZ19([[2, 3], [-1, I]])
```

```
Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom::De
```

Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2×2 Hilbert matrix (see also the functions `linalg::hilbert` and `linalg::invhilbert`):

```
densematrix(2, 2, (i, j) -> 1/(i + j - 1))
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

```
delete x:  
densematrix(2, 2, x), densematrix(2, 2, (i, j) -> x)
```

$$\begin{pmatrix} x(1, 1) & x(1, 2) \\ x(2, 1) & x(2, 2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
MatC := Dom::DenseMatrix(Dom::Complex):  
MatC(3, 4, [1, 2, 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the $n \times n$ identity matrix, you can enter:

```
MatC(3, 3, [1 $ 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or even call:

```
MatC(3, 3, x -> 1, Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method "identity":

```
MatC::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

Example 7

Toeplitz matrices can be defined with the option `Banded`. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component -1 on the first subdiagonals:

```
densematrix(4, 4, [-1, 2, -1], Banded)
```

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Example 8

Some system functions can be applied to matrices, such as `norm`, `expand`, `diff`, `conjugate`, or `exp`.

For example, to expand the components of the matrix:

```
delete a, b:  
A := densematrix(  
  [[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]]  
)
```

$$\begin{pmatrix} (a-b)^2 & a^2 + b^2 \\ a^2 + b^2 & (a+b)(a-b) \end{pmatrix}$$

enter:

```
expand(A)
```

$$\begin{pmatrix} a^2 - 2ab + b^2 & a^2 + b^2 \\ a^2 + b^2 & a^2 - b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:

```
diff(A, a)
```

$$\begin{pmatrix} 2a - 2b & 2a \\ 2a & 2a \end{pmatrix}$$

To substitute matrix components by some values, enter:

```
subs(A, a = 1, b = -1)
```

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function `zip` can also be applied to matrices. The following call combines two matrices A and B by dividing each component of A by the corresponding component of B :

```
A := densematrix([[4, 2], [9, 3]]):
B := densematrix([[2, 1], [3, -1]]):
zip(A, B, `/`)
```

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character ``/`` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function `map`. For example, to simplify the components of the matrix:

```
C := densematrix(
  [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)],
   [(a^2 - b^2)/(a + b), 1]]
```

)

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & \cos(x) \tan(x) \\ \frac{a^2 - b^2}{a + b} & 1 \end{pmatrix}$$

call:

```
map(C, Simplify)
```

$$\begin{pmatrix} 1 & \sin(x) \\ a - b & 1 \end{pmatrix}$$

Example 9

However, there may appear some unexpected results using the function `diff` in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:

```
diff(f(densematrix([[a*x^2, b], [c, d]])), x)
```

$$\begin{pmatrix} 2ax f' \left(\begin{pmatrix} ax^2 & b \\ c & d \end{pmatrix} \right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components `a*x^2`, `b`, `c` and `d`. Its derivative is computed by simply applying `diff` to each component of the matrix:

```
diff(densematrix([[a*x^2, b], [c, d]]), x)
```

$$\begin{pmatrix} 2 & a & x & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function f is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

Example 10

A column vector is represented as a 2×1 matrix:

```
MatR := Dom::DenseMatrix(Dom::Real):
v := MatR(2, 1, [1, 2])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
MatR::matdim(v)
```

$$[2, 1]$$

Use `linalg::vecdim`, or even call `nops(v)` to get the length of a vector:

```
linalg::vecdim(v)
```

$$2$$

The i th component of this vector can be extracted in two ways: either by `v[i, 1]` or by `v[i]`:

```
v[1], v[2]
```

$$1, 2$$

Dom::DenseMatrix

We get the 2-norm of v by the following call:

```
norm(v, 2)
```

$\sqrt{5}$

Parameters

R

A ring, i.e., a domain of category `Cat::Rng`; default is `Dom::ExpressionField()`

Array

A one- or two-dimensional array or `hfarray`

Matrix

A matrix, i.e., an element of a domain of category `Cat::Matrix`

m, n

Matrix dimension (positive integers)

List

A list of matrix components

ListOfRows

A list of at most m rows; each row given as a list of at most n matrix components

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::DenseMatrix(R)(m, n, List, Diagonal)` creates the $m \times n$ diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most $\min(m, n)$ entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::DenseMatrix(R)(m, n, g, Diagonal)` returns the matrix whose i th diagonal element is `g(i, i)`, where the index i runs from 1 to $\min(m, n)$.

The function values are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a banded Toeplitz matrix

`Dom::DenseMatrix(R)(m, n, List, Banded)` creates an $m \times n$ banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed n . The resulting matrix has bandwidth at most $2h + 1$.

A Toeplitz matrix is a matrix where the elements of each band are identical. See also “Example 7” on page 6-94.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the i th subdiagonal are initialized with the $(h + 1 - i)$ th element of `List`. All elements of the i th superdiagonal are initialized with the $(h + 1 + i)$ th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

Dom::DenseMatrix

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"isSparse"

is always `FALSE`, as elements of `Dom::DenseMatrix(R)` use a dense representation of their matrix components.

"randomDimen"

is set to `[10,10]`. See the method "random" below for details.

Methods

Mathematical Methods

`_divide` - Divide matrices

`_divide(A, B)`

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if `R` is a commutative ring with a unit, i.e., a domain of category `Cat::Ring`.

This method overloads the function `_divide` for matrices, i.e., one may use it in the form `A / B`, or in functional notation: `_divide(A, B)`.

`_invert` - Compute the inverse of a matrix

`_invert(A, Normal = b)`

If the component ring `R` is the domain `Dom::Float`, a floating-point approximation of the inverse matrix is computed by the function `numeric::inverse`.

This method only exists if `R` is a domain of category `Cat::Ring`.

This method overloads the function `_invert` for matrices, i.e., one may use it in the form `1/A` or `A^(-1)`, or in functional notation: `_invert(A)`.

If `Normal = TRUE`, then the matrix inverse is always returned in a normalized form. For details about normalization, see `normal`. If `Normal = FALSE`, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default `Normal = TRUE`.

`Normal` affects the results only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

`_mod` - Map the modulo operator to a matrix

```
_mod(A, n)
```

`n` must be non-zero, and a `mod n` must be defined for every entry `a` of `A`.

This method overloads the function `mod` for matrices; one may use it in the form `A mod n`, or in functional notation: `_mod(A, n)`.

`_mult` - Multiplie matrices by matrices, vectors and scalars

```
_mult(x, y)
```

```
_mult(x, y)
```

If `y` is of the domain type `R` or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, `y` is converted into a matrix of the domain type of `x`. If this conversion fails, then this method calls the method "`_mult`" of the domain of `y` giving all arguments in the same order.

If `x` is a matrix of the same domain type as `y`, then the matrix product `xy` is computed. An error message is issued if the dimensions of the matrices do not match.

If `x` is of the domain type `R` or can be converted into such an element, the corresponding scalar multiplication is computed.

Otherwise, `x` is converted into a matrix of the domain type of `y`. If this conversion fails, then `FAIL` is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of

all arguments. Then the product of these two results is computed with the system function `_mult`.

This method overloads the function `_mult` for matrices, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

`_negate` - Negate a matrix

`_negate(A)`

This method overloads the function `_negate` for matrices, i.e., one may use it in the form `-A`, or in functional notation: `_negate(A)`.

`_plus` - Add matrices

`_plus(A, B, ...)`

The arguments `A, B, ...` are converted into matrices of the domain type `Dom::DenseMatrix(R)`. `FAIL` is returned if one of these conversions fails.

This method overloads the function `_plus` for matrices, i.e., one may use it in the form `A + B`, or in functional notation: `_plus(A, B)`.

`_power` - Integer power of a matrix

`_power(A, n)`

If the power `n` is a negative integer then `A` must be nonsingular and `R` must be a domain of category `Cat::IntegralDomain`. Otherwise `FAIL` is returned.

If `n` is zero and the component ring `R` is a ring with no unit (i.e., of category `Cat::Rng`, but not of category `Cat::Ring`), `FAIL` is returned.

This method overloads the function `_power` for matrices, i.e., one may use it in the form `A^n`, or in functional notation: `_power(A, n)`.

`conjugate` - Complex conjugate of a matrix

`conjugate(A)`

This method only exists if R implements the method "conjugate", which computes the complex conjugate of an element of the domain R .

This method overloads the function `conjugate` for matrices, i.e., one may use it in the form `conjugate(A)`.

cos - Cosine of a matrix

`cos(A)`

If A is not square, an error message is issued. If the component domain of A does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, FAIL is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of A if A is defined over the domain `Dom::Float`.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of A . In this case FAIL is returned.

This method only exists if R is a domain of category `Cat::Field`.

This method overloads the function `cos` for matrices, i.e., one may use it in the form `cos(A)`.

diff - Differentiation of matrix components

`diff(A,)`

This method only exists if R implements the method "diff".

This method overloads the function `diff` for matrices, i.e., one may use it in the form `diff(A, ...)`. See "Example 8" on page 6-94 and "Example 9" on page 6-96.

equal - Equality test of matrices

`equal(A, B)`

Note that if `R` has the axiom `Ax::systemRep` then `normal` is used to simplify the components of `A` and `B` before testing their equality.

exp - Exponential of a matrix

`exp(A, <t>)`

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A` is defined over the domain `Dom::Float` and if $t = 1$.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case the function `linalg::jordanForm` is called, which may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned.

This method only exists if `R` is a domain of category `Cat::Field`.

This method overloads the function `exp` for matrices, i.e., one may use it in the form `exp(A, ...)`.

expand - Expand matrix components

`expand(A)`

This method only exists if `R` implements the method "expand", or if `R` has the axiom `Ax::systemRep` (in this case, the system function `expand` is used).

This method overloads the function `expand` for matrices, i.e., one may use it in the form `expand(A)`.

factor - Scalar-matrix factorization

`factor(A)`

The factor s is the gcd of all components of the matrix A . Hence, this method only exists if R is of category `Cat::GcdDomain`.

This method overloads the function `factor` for matrices, i.e., one may use it in the form `factor(A)`.

float - Floating-point approximation of the matrix components

`float(A)`

This method only exists if R implements the method `"float"`.

Note Usually the floating-point approximations are not elements of R ! For example, `Dom::Integer` implements such a method, but the floating-point approximation of an integer cannot be re-converted into an integer.

This method checks whether the resulting matrix can be converted into the domain type of A only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible to its component ring.

gaussElim - Gaussian elimination

`gaussElim(A)`

If the matrix is not square, i.e., the determinant of A is not defined, then the third entry of the list returned is the value `FAIL`.

This method only exists if the component ring R is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If R has the method `"pivotSize"`, then the pivot element of smallest size is chosen at every pivoting step, whereby `pivotSize` must return a positive integer representing the "size" of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to A .

If R has the axiom $Ax::\text{efficientOperation}(\text{"_invert"})$ and is of category $Cat::\text{Field}$, then ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on A .

If R implements the method "normal", it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom $Ax::\text{systemRep}$, the system function `normal` is used instead.

identity - Identity matrix

```
identity(n)
```

This method only exists if the component ring R is of category $Cat::\text{Ring}$, i.e., a ring with unit.

int - Integration of matrix components

```
int(A, )
```

This method only exists if R implements the method "int".

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.

iszero - Test for zero matrices

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if R does not have $Ax::\text{canonicalRep}$.

If R implements the method "normal", it is used to simplify the components of A for the zero-test.

Note that if R does not implement such a method, but the elements of R are represented by kernel domains, i.e., R has the axiom $Ax::\text{systemRep}$, the system function `normal` is used instead.

This method overloads the function `iszero` for matrices, i.e., one may use it in the form `iszero(A)`.

matdim - Matrix dimension

`matdim(A)`

norm - Norm of matrices and vectors

`norm(A, Infinity)`

`norm(A, Maximum)`

`norm(v, Infinity)`

`norm(v, Maximum)`

`norm(A, Frobenius)`

`norm(A, 1)`

`norm(v, Euclidean)`

`norm(v, k)`

`norm(A, Maximum)` computes the maximum norm of the matrix `A`, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Infinity)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

Using `norm(v, Maximum)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods `"max"` and `"norm"`, `FAIL` is returned.

`norm(A, Frobenius)` computes the Frobenius norm of A , which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain R , or if R does not implement the method "norm", FAIL is returned.

`norm(A, 1)` computes the 1-norm of the matrix A , which is the maximum sum of the norms of the elements of each column. If R does not implement the methods "max" and "norm", FAIL is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector v , which is defined to be the square root of the sum of the norms of the elements of v raised to the square.

FAIL is returned if the result is no longer an element of the domain R . The function `linalg::scalarProduct` is used to compute the Euclidean norm of the vector v .

If R does not implement the method "norm", FAIL is returned.

`norm(v, k)` computes the k -norm of the vector v , which is defined to be the k th root of the sum of the norms of the elements of v raised to the k th power.

FAIL is returned if the result is no longer an element of the domain R . For $k = 2$, the function `linalg::scalarProduct` is used to compute the 2-norm of v .

If R does not implement the method "norm", FAIL is returned.

The method `norm` overloads the function `norm` for matrices, i.e., one may use it in the form `norm(A k)`, where k is either `Infinity`, `Frobenius`, or a positive integer. The default value of k is `Infinity`.

normal - Simplification of matrix components

`normal(A)`

If R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom

`Ax::systemRep`, then the system function `normal` is applied to the components of `A`. Otherwise `normal(A)` returns `A` without any changes.

This method overloads the function `normal` for matrices, i.e., one may use it in the form `normal(A)`.

nonZeros - Number of non-zero components of a matrix

```
nonZeros(A)
```

nonZeroes - Number of non-zero components of a matrix

```
nonZeroes(A)
```

nonZeroOperands - Return a sequence of all non-zero operands

```
nonZeroOperands(A)
```

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.

random - Random matrix generation

```
random()
```

This method only exists if `R` implements the method "random".

The dimension of the matrix is also chosen randomly, but it is limited by the values given in "randomDimen" (see "Entries" above).

To change the value of the entry "randomDimen" for a domain `MatR` created with `Dom::DenseMatrix`, one must first unprotect the domain `Dom` (see `unprotect` for details).

sin - Sine of a matrix

```
sin(A)
```

If A is not square, an error message is issued. If the component domain of A does not allow the computation of `sin(elem)` for an arbitrary element `elem` of the component ring, FAIL is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of A if A is defined over the domain `Dom::Float`.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of A . In this case FAIL is returned.

This method only exists if R is a domain of category `Cat::Field`.

This method overloads the function `sin` for matrices, i.e., one may use it in the form `sin(A)`.

sqrt - Square root of a matrix

`sqrt(A, <sqrtfunc>)`

Returned is a matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or FAIL if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying $\text{sqrtfunc}(a)^2 = a$ for every element a of the coefficient ring of A can be given as optional second argument.

For details we refer to the help page of the function `linalg::sqrtMatrix`.

testeq - Testing for equality of two matrices

`testeq(A, B)`

tr - Trace of a square matrix

`tr(A)`

If A is not square, then an error message is issued.

transpose - Transpose of a matrix

`transpose(A)`

Access Methods

`_concat` - Horizontal concatenation of matrices

`_concat(A, B, ...)`

An error message is issued if the given matrices do not have the same number of rows.

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B`, or in functional notation:

`_concat(A, B, ...)`.

`_index` - Matrix indexing

`_index(A, i, j)`

`_index(A, r1 .. r2, c1 .. c2)`

`_index(v, i)`

`_index(v, i1 .. i2)`

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(A, r1 .. r2, c1 .. c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

`_index(v, i)` returns the `i`th entry of the vector `v`.

An error message is issued if v is not a vector.

If i is not an integer, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if i is less than one or greater than the dimension of v .

Note Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(v, i1..i2)` returns the subvector of v , formed by the entries with index $i1$ to $i2$. See also the method "`op`".

An error message is issued if v is not a vector.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

concatMatrix - Horizontal concatenation of matrices

```
concatMatrix(A, B, )
```

col - Extracting a column

```
col(A, c)
```

An error message is issued if c is less than one or greater than the number of columns of A .

delCol - Deleting a column

```
delCol(A, c)
```

NIL is returned if A consists of only one column.

An error message is issued if c is less than one or greater than the number of columns of A .

delRow - Deleting a row

`delRow(A, r)`

NIL is returned if A consists of only one row.

An error message is issued if r is less than one or greater than the number of rows of A.

evalp - Evaluating matrices of polynomials at a certain point

`evalp(A, x = a,)`

This method is only defined if R is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

length - Length of a matrix

`length(A)`

This method overloads the function `length` for matrices, i.e., one may use it in the form `length(A)`.

map - Apply a function to matrix components

`map(A, func, <expr, >)`

Note Note that the function values are converted into elements of the domain R only if `testargs` returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns FALSE, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain R!

This method overloads the function `map` for matrices, i.e., one may use it in the form `map(A, func, ...)`.

mapNonZeroes - Apply a function to the non-zero components of a matrix

```
mapNonZeroes(A, f, <p1, p2, >)
```

nops - Number of components of a matrix

```
nops(A)
```

This method overloads the function nops for matrices, i.e., one may use it in the form nops(A).

op - Component of a matrix

```
op(A, i)
```

```
op(A)
```

This method returns an expression sequence of all components of A.

See also the method "_index".

This method overloads the function op for matrices, i.e., one may use it in the form op(A, i) and op(A), respectively.

row - Extracting a row

```
row(A, r)
```

An error message is issued if r is less than one or greater than the number of rows of A.

setCol - Replacing a column

```
setCol(A, c, v)
```

An error message is issued if c is less than one or greater than the number of rows of A.

setRow - Replacing a row

```
setRow(A, r, v)
```

An error message is issued if r is less than one or greater than the number of rows of A.

stackMatrix - Vertical concatenation of matrices

```
stackMatrix(A, B, ...)
```

An error message is issued if the given matrices do not have the same number of columns.

subs - Substitution of matrix components

```
subs(A, ...)
```

Note Note that the function values are converted into elements of the domain R only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the function calls return elements of the domain type R , otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain R !

This method overloads the function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

subsex - Extended substitution of matrix components

```
subsex(A, ...)
```

Note Note that the results of the substitutions are converted into elements of the domain R only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then one must guarantee that the results of the substitutions are of the domain type R , otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain R !

This method overloads the function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

subsop - Operand substitution of matrix components

`subsop(A, i = x, ...)`

Note Note that `x` is converted into the domain `R` only if `testargs` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns `FALSE`, then `x` must be an element of `R`, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain `R`!

See also the method "`set_index`".

This method overloads the function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

swapCol - Swapping matrix columns

`swapCol(A, c1, c2)`

`swapCol(A, c1, c2, r1 .. r2)`

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`.

`swapCol(A, c1, c2, r1 .. r2)` swaps the column with index `c1` and the column with index `c2` of `A`, but by taking only those column components which lie in the rows with indices `r1` to `r2`.

An error message is issued if one of the column indices is less than one or greater than the number of columns of `A`, or if one of the row indices is less than one or greater than the number of rows of `A`.

swapRow - Swapping matrix rows

```
swapRow(A, r1, r2)
```

```
swapRow(A, r1, r2, c1 .. c2)
```

An error message is issued if one of the row indices is less than one or greater than the number of rows of A.

`swapCol(A, r1, r2, c1 .. c2)` swaps the row with index `r1` and the row with index `r2` of A, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of A, or if one of the column indices is less than one or greater than the number of columns of A.

set_index - Setting matrix components

```
set_index(A, i, j, x)
```

```
set_index(v, i, x)
```

Note Note that `x` is converted into an element of the domain `R` only if `testargs` returns `TRUE` and `i` and `j` are integers (e.g., if one calls this method from the interactive level of MuPAD). If `x` is a matrix of the same type as `A` or can be converted into a matrix of the same type as `A` and the indices `i` or `j` are ranges corresponding to a submatrix of `A`, then `x` replaces the corresponding submatrix in `A`.

Otherwise one has to take care that `x` is of domain type `R`.

See also the method "subsop".

`set_index(v, i, x)` replaces the i th entry of the vector `v` by `x`.

`set_index` on vectors overloads the function `set_index` for matrices, i.e., one may use it in the form `A[i, j] := x` and `v[i] := x`, respectively, or in functional notation: `A := set_index(A, i, j, x)` or `v := set_index(v, i, x)`.

zip - Combine matrices component-wise

`zip(A, B, func, <expr, >)`

The row number of the matrix returned is the minimum of the row numbers of A and B, and its column number is the minimum of the column numbers of A and B.

Note Note that the function values are converted into elements of the domain R only if `testargs` returns TRUE (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs` returns FALSE, then one must guarantee that the function calls return elements of the domain type R, otherwise the resulting matrix, which is of domain type `Dom::DenseMatrix(R)`, would have components which are not elements of the domain R!

This method overloads the function `zip` for matrices, i.e., one may use it in the form `zip(A, B, ...)`.

Conversion Methods

convert - Conversion to a matrix

`convert(x)`

FAIL is returned if the conversion fails.

x may either be an array, a matrix, or a list (of sublists, see the parameter `ListOfRows` in “Creating Elements” above). Their entries must then be convertible into elements of the domain R.

convert_to - Matrix conversion

`convert_to(A, T)`

T may either be `DOM_ARRAY`, `DOM_LIST`, or a domain constructed by `Dom::DenseMatrix` or `Dom::SquareMatrix`. The elements of A must be convertible into elements of the domain R.

Use the function `expr` to convert `A` into an object of a kernel domain (see below).

create - Defining matrices without component conversions

```
create(x, )
```

This method works more efficient than if one creates matrices by calling the method "new" of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

If `x` is a list of sublists, it might be a good idea first to create a two-dimensional array from that list before calling this method. This is due to the fact that creating a matrix from an array is the fastest way one can achieve.

Please note that when creating a two-dimensional array from a list of sublists, the sublists must have the same number of elements.

expr - Matrix conversion into an object of a kernel domain

```
expr(A)
```

The result is an array representing the matrix `A` where each entry is an object of a kernel domain.

This method overloads the function `expr` for matrices, i.e., one may use it in the form `expr(A)`.

expr2text - Matrix conversion to a string

```
expr2text(A)
```

This method overloads the function `expr2text` for matrices, i.e., one may use it in the form `expr2text(A)`.

TeX - TeX formatting of a matrix

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function "doprint".

The method "TeX" of the component ring R is used to get the TeX-representation of each component of A.

This method is used by the function `generate::TeX`.

Technical Methods

assignElements - Multiple assignment to matrices

```
assignElements(A, )
```

The assigned components must have the domain type R, an implicit conversion of the components into elements of domain type R is not performed.

This method overloads the function `assignElements` for matrices, i.e., one may use it in the form `assignElements(A, ...)`.

mkDense - Conversion of a matrix to an array

```
mkDense(Array)
```

```
mkDense(List)
```

```
mkDense(r, c, List)
```

`mkDense(List)` tries to convert the list `List` into an array `a`. The result is either FAIL if this is not possible, or the list `[r, c, a]`, where the positive integers `r` and `c` give the dimension of `a`. See the parameters `List` and `ListOfRows` in "Creating Elements" above for admissible formats of `List`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain R.

`mkDense(r,c,List)` tries to convert the list `List` into an array `a` of the dimension `r` times `c`.

The result is either FAIL if this is not possible, or the list `[r, c, a]`.

The array `a` has dimension one if `r` or `c` is equal to one. The entries of `a` have been converted into elements of the domain R.

print - Printing matrices

```
print(A)
```

Note Note that in general it is not useful to print very large matrices. Hence, a warning message is displayed if the size of the matrix oversteps a certain dimension – printing such matrices can be done by using the function "doprint".

doprint - Printing very large matrices

```
doprint(A)
```

unapply - Create a procedure from a matrix

```
unapply(A, <x, >)
```

This method overloads the function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

See Also

MuPAD Domains

`Dom::Matrix` | `Dom::MatrixGroup` | `Dom::SquareMatrix`

Dom::DihedralGroup

Purpose Dihedral groups

Syntax **Domain Creation**
Dom::DihedralGroup(n)

Element Creation
Dom::DihedralGroupn(1)

Description **Domain Creation**

Dom::DihedralGroup(n) creates the dihedral group of size n , i.e., the group of symmetries of a regular polygon with n edges.

Dom::DihedralGroup(n) creates the group of all congruent mappings of the plane that induce a bijective mapping of the set of corners of a regular n -angle to itself.

Element Creation

Dom::DihedralGroup(n)([a,b]) represents the group element " t^a carried out after r^b ", where r is a rotation that maps each corner to its left neighbor, and t is a reflection w.r.t. some fixed central diagonal.

Superdomain Dom::BaseDomain

Axioms Ax::canonicalRep

Categories Cat::Group

Examples **Example 1**

Define the group D_6 , i.e., the group of congruence mappings of the hexagon:

```
G := Dom::DihedralGroup(6)
```

```
Dom::DihedralGroup(6)
```

Then elements may be created as follows:

```
a := G([7, 19]);
```

```
[1, 1]
```

This means that 19 rotations—mapping each corner to its left neighbor—and 7 reflections have the same effect as one operation of either type.

Parameters

n

Positive integer

l

List or array of two integers

Entries

"size"

the number of elements, which equals $2n$.

"one"

the mapping leaving each point fixed.

Methods

Mathematical Methods

_mult - Functional composition of elements

```
_mult(a, )
```

This method overloads the kernel function `_mult`.

_invert - Inverse of an element

```
_invert(a)
```

This method overloads the kernel function `_invert`.

_power - Power of an element

Dom::DihedralGroup

`_power(a, n)`

It overloads the kernel function `_power`.

order - Order of a group element

`order(a)`

random - Random element

`random()`

Conversion Methods

expr - Convert group element to list

`expr(a)`

TeX - TeX output of a group element

`TeX(a)`

equiv - Test for equivalence

Inherited from `Cat::BaseCategory`.

new - Create element of this domain

Inherited from `Cat::BaseCategory`.

coerce - Coerce into this domain

Inherited from `Cat::BaseCategory`.

hasProp - Test for a certain property

Inherited from `Dom::BaseDomain`.

whichEntry - Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

isone - Test if element is one

Inherited from `Cat::Monoid`.

printMethods - Print out methods

Inherited from Dom::BaseDomain.

info - Print short information about this domain

Inherited from Dom::BaseDomain.

_divide - Return quotient

Inherited from Cat::Group.

getAxioms - Return axioms stated in the constructor

Inherited from Dom::BaseDomain.

getCategories - Return categories stated in the constructor

Inherited from Dom::BaseDomain.

equal - Test for mathematical equality

Inherited from Dom::BaseDomain.

allAxioms - Return all axioms

Inherited from Dom::BaseDomain.

undefinedEntries - Return missing entries

Inherited from Dom::BaseDomain.

allCategories - Return all categories

Inherited from Dom::BaseDomain.

testtype - Test type of object

Inherited from Cat::BaseCategory.

allEntries - Return the names of all entries

Inherited from Dom::BaseDomain.

getSuperDomain - Return super-domain stated in the constructor

Inherited from Dom::BaseDomain.

subs - Avoid substitution

Inherited from Dom::BaseDomain.

Dom::DihedralGroup

allSuperDomains - Return all super-domains

Inherited from Dom::BaseDomain.

subsex - Avoid extended substitution

Inherited from Dom::BaseDomain.

Purpose

Domains of distributed polynomials

Syntax

Domain Creation

```
Dom::DistributedPolynomial(<Vars, <R, <Order>>>)
```

Element Creation

```
Dom::DistributedPolynomial(Vars, R, Order)(p)
```

```
Dom::DistributedPolynomial(Vars, R, Order)(lm)
```

```
Dom::DistributedPolynomial(Vars, R, Order)(lm, v)
```

Description

`Dom::DistributedPolynomial(Vars, R, ..)` creates the domain of polynomials in the variables of the list `Vars` over the commutative ring `R` in distributed representation.

`Dom::DistributedPolynomial(Vars, R, Order)` creates a domain of polynomials in the variables of the list `Vars` over a domain of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::DistributedPolynomial` is called without any argument, a polynomial domain in arbitrarily many indeterminates over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

If `Dom::DistributedPolynomial` is called only with the variable list `Vars` as argument, the polynomial domain in the variable list `Vars` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note Only commutative coefficient rings of type `DOM_DOMAIN` are allowed which inherit from `Dom::BaseDomain`. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

`Dom::DistributedPolynomial` accepts expressions as indeterminates, similar to the kernel domain `DOM_POLY`. Hence, for example, `[x, cos(x)]` is a valid variable list.

Dom::DistributedPolynomial

If the variable list `Vars` is the empty list (`[]`), a polynomial domain in arbitrarily many indeterminates is created. In this case, when creating new elements from polynomials or polynomial expressions, the system function `indets` is first called to get the variables and then the polynomial is created with respect to these variables. Hence, in this case only identifiers can be valid indeterminates, because `indets` returns only identifiers.

It is not allowed to create polynomial domains in arbitrarily many indeterminates over another polynomial domain of category `Cat::Polynomial`, but it is possible to create multivariate polynomial domains with a given list of variables over any polynomial domain.

`Dom::DistributedPolynomial` represents polynomials over arbitrary commutative rings. It is intended as a basic domain for distributed polynomials from which it is easy to create new distributed polynomial domains.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation.

Note It is highly recommended to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods.

Superdomain `Dom::BaseDomain`

Axioms If `R` has `Ax::normalRep`, then `Ax::normalRep`.

If `R` has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories If Vars has exactly one variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

Examples **Example 1**

The following call creates a polynomial domain in x , y and z .

```
DP := Dom::DistributedPolynomial([x, y, z])
```

```
Dom::DistributedPolynomial([x, y, z], Dom::ExpressionField(normal, iszero ◦ normal), LexOrder)
```

Since neither the coefficient ring nor the monomial ordering was specified, this domain is created with the default values for these parameters.

It is rather easy to create elements of this domain, as e.g.

```
a := DP(x + 2*y*z + 3)
```

$$x + 2yz + 3$$

```
b := DP(z^4 - 2*y^2*x^2)
```

$$-2x^2y^2 + z^4$$

In contrast to expressions all elements of this domain have a representation which is fixed by the chosen Order, the representation of the coefficient ring R and the way of representing monomials.

With these elements one can now perform usual arithmetic operations as, e.g., (scalar) multiplication, multiplication with integers and adding polynomials and ring elements:

```
4*b^2 + a/3 + 1/2
```

Dom::DistributedPolynomial

$$16x^4y^4 - 16x^2y^2z^4 + \frac{x}{3} + \frac{2yz}{3} + 4z^8 + \frac{3}{2}$$

There are a lot of methods for manipulating polynomials and to get access to all parts of a polynomial. For example one has access to the leading monomial of a as follows:

`lmonomial(a)`

$$x$$

The leading monomial of a polynomial depends on the monomial ordering, so with respect to the degree order one gets a different result:

`lmonomial(a, DegreeOrder)`

$$2yz$$

To get a minus its leading monomial one may call:

`DP::reductum(a)`

$$2yz + 3$$

Obviously the following identity holds:

`a - lmonomial(a) - DP::reductum(a)`

$$0$$

There are also methods for converting elements of this domain into other domains, like a basic polynomial domain or the domain of arbitrary expressions:

`poly(a), domtype(poly(a))`

`poly(x + 2 y z + 3, [x, y, z], Dom::ExpressionField(normal, iszero ◦ normal)), DOM_POLY`

`expr(b), domtype(expr(b))`

`z4 - 2 x2 y2, DOM_EXPR`

Parameters

Vars

A list of indeterminates. Default is [] (the empty list, indicating “arbitrary indeterminates”).

R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default is `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or any object of type `Dom::MonomOrdering`. Default is `LexOrder`.

P

A polynomial or a polynomial expression.

lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

v

List of indeterminates. This parameter is only valid for `Vars = []`.

Dom::DistributedPolynomial

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter R.
"key"	The name of the created domain.
"one"	The neutral element w.r.t. "_mult".
"ordering"	The monomial order as defined by the parameter Order.
"variables"	The list of variables as defined by the parameter Vars.
"zero"	The neutral element w.r.t. "_plus".

Methods

Mathematical Methods

`_divide` - Exact polynomial division

```
_divide(a, b)
```

```
_divide(a, b)
```

```
_divide(a, b)
```

It overloads the function `_divide` for polynomials, i.e., one may use it either in the form a / b , or in functional form `_divide(a, b)`.

Note This method only exists if R is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

`_invert` - Inverse of an element

```
_invert(a)
```

`_mult` - Multiplie polynomials and coefficient ring elements

`_mult(<a, b, >)`

This method overloads the function `_mult` for polynomials, i.e., one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.

`_negate` - Negate a polynomial

`_negate(a)`

This method overloads the function `_negate` for polynomials, i.e., one may use it either in the form `-a` or in functional notation `_negate(a)`.

`_plus` - Add polynomials and coefficient ring elements

`_plus(<a, b, >)`

This method overloads the function `_plus` for polynomials, i.e., one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.

`_power` - Nth power of a polynomial

`_power(a, n)`

This method overloads the function `_power` for polynomials, i.e., one may use it either in the form `a^n` or in functional notation `_power(a,n)`.

`_subtract` - Subtract a polynomial or a coefficient ring element

`_subtract(a, b)`

This method overloads the function `_subtract` for polynomials, i.e., one may use it either in the form `a - b` or in functional notation `_subtract(a, b)`.

`associates` - Test if elements are associates

Inherited from `Cat::IntegralDomain`.

`content` - Content of a polynomial

Dom::DistributedPolynomial

`content(a)`

Note This method only exists if R is a domain of category `Cat::GcdDomain`.

D - Differential operator for polynomials

`D(a)`

`D(l, a)`

Dpoly - Differential operator for polynomials

`Dpoly(a)`

`Dpoly(l, a)`

`Dpoly(l, a)` computes the partial derivative of `a` with respect to `l`.
For details see `polylib::Dpoly`.

This method overloads the function `polylib::Dpoly` for polynomials.

decompose - Functional decomposition of a polynomial

`decompose(a, <var>)`

If `a` is a polynomial in only one variable, the second argument is not necessary.

This method overloads the function `polylib::decompose` for polynomials.

diff - Differentiate a polynomial

`diff(a, varseq)`

If `varseq` is an empty sequence, `a` is returned unchanged.

If in `varseq` an expression occurs which is not a variable of `a`, the zero polynomial is returned.

This method overloads the function `diff` for polynomials.

dimension - Dimension of affine variety

```
dimension(ais, <ord>)
```

```
dimension(ais, <ord>)
```

This method is merely an interface for the function `groebner::dimension`.

Note This method only exists if R is a field, i.e., a domain of category `Cat::Field` and `Vars` is not the empty list.

divide - Divide polynomials

```
divide(a, b, <Quo | Rem | Exact>)
```

```
divide(a, b, var, <Quo | Rem | Exact>)
```

If no option is given, the quotient s and the remainder r are computed such that $a = s*b + r$ and the degree of r in the relevant indeterminate is smaller than that of b . The sequence consisting of s , r is returned, otherwise FAIL.

If the option `Quo` is given, only the quotient s is returned.

If the option `Rem` is given, only the remainder r is returned.

If the option `Exact` is given, only the quotient s is returned, in case the remainder is zero, otherwise FAIL.

`divide(a,b,Exact)` divides the multivariate polynomial a by b . If a cannot be divided by b , the method returns FAIL.

This method overloads the function `divide` for polynomials.

Dom::DistributedPolynomial

Note This method only exists if R is a field, i.e., a domain of category `Cat::Field` and either this domain is of category `Cat::UnivariatePolynomial(R)` or R has characteristic zero (`R::characteristic = 0`). If the first pair of conditions is true then the first call is valid otherwise the second one.

divides - Test if elements divides another

Inherited from `Cat::IntegralDomain`.

equal - Test for mathematical equality

Inherited from `Dom::BaseDomain`.

equiv - Test for equivalence

Inherited from `Cat::BaseCategory`.

evalp - Evaluate a polynomial

```
evalp(a, var = e)
```

This method overloads the function `evalp` for polynomials.

factor - Factor a polynomial

```
factor(a)
```

This method overloads the function `factor` for polynomials.

Note This method only exists if R is a domain of category `Cat::Field` or if R is the domain `Dom::Integer`.

func_call - Apply expressions to a polynomial

```
func_call(a, e1, , en, <Expr>)
```

```
func_call(a, e1, , en, <Expr>)
```

```
func_call(a, e1, , en, <Expr>)
```

$a(e_1, \dots, e_n)$ applies the sequence e_1, \dots, e_n of either elements of this domain or elements of R with respect to $Vars$ (where n is the number of variables) to the polynomial a . An element of this domain or an element of the coefficient ring respectively is returned.

$a(e_1, \dots, e_n, Expr)$ applies the sequence of expressions or of elements of this domain or of elements of R to the polynomial a . With this call a is first converted into an expression. Afterwards e_1, \dots, e_n is substituted into this expression with respect to $Vars$. The return value may be any object.

The number of variables must be equal to the number of applied expressions.

Note This method only exists if $Vars$ has at least one indeterminate.

gcd - Greatest common divisor of polynomials

$gcd(a, b, \dots)$

This method overloads the function `gcd` for polynomials.

Note This method only exists if R is a domain of category `Cat::GcdDomain`.

gcdex - Extended Euclidean algorithm for polynomials

$gcdex(a, b)$

This method overloads the function `gcdex` for polynomials. Especially, it only works for coefficient rings described there.

Dom::DistributedPolynomial

Note This method only exists if R is a domain of category `Cat::GcdDomain`.

groebner - Reduced Gröbner basis

```
groebner(ais, <ord>, <Reorder>)
```

```
groebner(ais, <ord>, <Reorder>)
```

If the option `Reorder` is given, the lexicographical order of variables may change to another one that is likely to decrease the running time.

Note Note that this may also cause a change of the returned list, which may now have polynomials over the same coefficient ring R but with a possibly re-ordered variable list. Thus, it may contain elements *not* belonging to this domain.

This method is merely an interface for the function `groebner::gbasis`.

Note This method only exists if R is a field, i.e., a domain of category `Cat::Field`, and `Vars` is not the empty list.

idealGenerator - Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

int - Definite and indefinite integration of a polynomial

```
int(a, <x>)
```

```
int(a, <x = x0 .. x1>)
```

`int(a, x=x0..x1)` returns the definite integral $\int_{x_0}^{x_1} a \, dx$ or FAIL, if the result is not an element of this domain or an element of a polynomial domain over `Dom::Fraction(R)`.

This method overloads the function `int` for polynomials.

intmult - Multiply a polynomial with an integer

`intmult(a, z)`

This method is more efficient than using polynomial multiplication and is, e.g., necessary for the method "Dpoly".

irreducible - Test if element is irreducible

Inherited from `Cat::FactorialDomain`.

isUnit - Test if element is a unit

Inherited from `Cat::Polynomial`.

isone - Test for one

`isone(a)`

Note The result can only be valid if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, `R` should have at least `Ax::normalRep`.

iszero - Test for zero

`iszero(a)`

Note The result can only be valid, if the coefficients of `a` are in normal form (i.e., if zero has a unique representation in `R`). Thus, the coefficient ring `R` should have at least `Ax::normalRep`.

lcm - Least common multiple of polynomials

Dom::DistributedPolynomial

`lcm(a, b,)`

This method overloads the function `lcm` for polynomials.

Note This method only exists if `R` is a domain of category `Cat::GcdDomain`.

makeIntegral - Make the coefficients fraction free

`makeIntegral(a)`

Note This method only exists if `R` is a domain of category `Cat::GcdDomain` and `R` has the method "denom".

monic - Normalize a polynomial

`monic(a)`

The zero polynomial returns itself.

Note This method only exists if `R` is a field, i.e., a domain of category `Cat::Field`.

normalForm - Complete reduction modulo an ideal

`normalForm(a, ais, <ord>)`

`normalForm(a, ais, <ord>)`

This method is merely an interface for the function `groebner::normalf`.

Note This method only exists if R is a field, i.e., a domain of category `Cat::Field`, and `Vars` is not the empty list.

pdioe - Solve polynomial Diophantine equations

`pdioe(a, b, c)`

This method overloads the function `solveLib::pdioe`.

Note This method only exists if R is a field, i.e., a domain of category `Cat::Field` and `Vars` consists of a single variable.

pdivide - Pseudo-division of polynomials

`pdivide(a, b, <Quo | Rem>)`

If the option `Quo` is given, only the pseudo-quotient q is returned.

If the option `Rem` is given, only the pseudo-remainder r is returned.

This method overloads the function `pdivide` for polynomials.

Note This method only exists if `Vars` consists of a single variable.

pquo - Pseudo-quotient of polynomials

`pquo(a, b)`

Note This method only exists if `Vars` consists of a single variable.

prem - Pseudo-remainder of polynomials

`prem(a, b)`

Dom::DistributedPolynomial

Note This method only exists if Vars consists of a single variable.

primpart - Return primitive part

Inherited from `Cat::Polynomial`.

quo - Euclidean quotient

Inherited from `Cat::EuclideanDomain`.

random - Create a random polynomial

`random()`

With every call the global variable `SEED` is changed by a call of `random()`. Thus it is hard to create the same random sequence twice, see `random`.

If the parameter `Vars` is the empty list, first a list of 1 to 4 variables is generated randomly and the random polynomial is generated in these indeterminates afterwards.

This method overloads the function `polylib::randpoly` for polynomials.

rem - Euclidean remainder

Inherited from `Cat::EuclideanDomain`.

resultant - Resultant of two polynomials

`resultant(a, b, <var>)`

`resultant(a, b, var)` returns the resultant of `a` and `b` with respect to the variable `var`.

The value returned is a polynomial of this domain or `FAIL`.

This method overloads the function `polylib::resultant` for polynomials.

Note This method only exists if R has the method "_divide".

ringmult - Multiplie a polynomial with a coefficient ring element

ringmult(a, c)

solve - Zero of polynomials

solve(a, <var>, <options>)

solve(a, <vars>, <options>)

solve(ais, <var>, <options>)

solve(ais, <vars>, <options>)

solve(ais, ..) tries to find the zeros of the polynomial system ais. The exact behavior depends on further arguments.

For a detailed description of possible return values and options see function solve.

This method overloads the function solve.

SPolynomial - Compute the S-polynomial of two polynomials

SPolynomial(a, b, <ord>)

This method is merely an interface for the function groebner::spoly.

Note This method only exists if R is a field, i.e., a domain of category Cat::Field, and Vars is not the empty list.

sqrfree - Square-free factorization of polynomials

sqrfree(a)

The ai are primitive and pairwise different square-free divisors of a and represented as elements of this domain. u is a unit of the

Dom::DistributedPolynomial

coefficient ring and represented as an element of this domain. The e_i are integers.

This method overloads the function `polylib::sqrfree` for polynomials.

Note This method only exists if R is a field, i.e., a domain of category `Cat::Field`, or if R is `Dom::Integer`.

unitNormal - Return unit normal

Inherited from `Cat::Polynomial`.

unitNormalRep - Return unit normal representation

Inherited from `Cat::Polynomial`.

Access Methods

coeff - Coefficient of a polynomial

`coeff(a)`

`coeff(a, var, n)`

`coeff(a, n)`

`coeff(a, var, n)` returns the coefficient of the term var^n —as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring R if it is of `Cat::UnivariatePolynomial(R)`, where a is considered as a univariate polynomial in a valid variable `var`.

`coeff(a, n)` returns the coefficient of the term var^n —as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring R if it is of `Cat::UnivariatePolynomial(R)`, where a is considered as a univariate polynomial in `var` and `var` is the main variable of a , i.e., the variable returned by `dom::mainvar(a)`.

This method overloads the function `coeff` for polynomials.

degree - Degree of a polynomial

`degree(a)`

`degree(a, var)`

`degree(a, var)` returns the degree of `a` with respect to `var`.

The degree of the zero polynomial is defined as zero.

This method overloads the function `degree` for polynomials.

degreevec - Vector of exponents of the leading term of a polynomial

`degreevec(a, <ord>)`

The degree vector of the zero polynomial is defined as a list of zeros.

This method overloads the function `degreevec` for polynomials.

euclideanDegree - Euclidean degree function

`euclideanDegree(a)`

Note This method only exists if `Vars` consists of a single variable.

ground - Ground term of a polynomial

`ground(a)`

This method overloads the function `ground` for polynomials.

has - Existence of an object in a polynomial

`has(a, obj)`

This method overloads the function `has`.

indets - Indeterminate of a polynomial

`indets(<a>)`

In case `Vars` is not the empty list, `indets` can be called without argument.

Since this domain allows expressions as indeterminates, the returned set may contain expressions, too.

This method overloads the function `indets` for polynomials.

lcoeff - Leading coefficient of a polynomial

`lcoeff(a)`

`lcoeff(a, <vars>, <ord>)`

`lcoeff(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of the coefficient ring `R`.

`lcoeff(a, vars, ord)` returns the leading coefficient of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain if it is of category `Cat::Polynomial(R)`, or as an element of the coefficient ring `R` if it is of `Cat::UnivariatePolynomial(R)`.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

This method overloads the function `lcoeff` for polynomials.

ldegree - Lowest degree of a polynomial

`ldegree(a)`

`ldegree(a, x)`

`ldegree(a, x)` returns the lowest degree of the variable `x` in `a`.

This method overloads the function `ldegree` for polynomials.

lmonomial - Leading monomial of a polynomial

`lmonomial(a, <ord>)`

`lmonomial(a, <vars>, <ord>, <Rem>)`

`lmonomial(a, vars, ord)` returns the leading monomial of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

`lmonomial(a, vars, ord, Rem)` returns the list consisting of the leading monomial and the reductum of `a` with respect to the variable list `vars` and the monomial ordering `ord` as a list of elements of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

Note In MuPAD a monomial denotes a coefficient together with a power product as, e.g., $3x^2$.

This method overloads the function `lmonomial` for polynomials.

lterm - Leading term of a polynomial

`lterm(a)`

`lterm(a, <vars>, <ord>)`

Dom::DistributedPolynomial

`lterm(a, ord)` returns the leading coefficient of `a` with respect to the monomial ordering `ord` as an element of this domain.

`lterm(a, vars, ord)` returns the leading term of `a` with respect to the variable list `vars` and the monomial ordering `ord` as an element of this domain.

- If `ord` is not explicitly given, the lexicographical order `LexOrder` will be used instead.
- It tries to convert `a` into a polynomial in the specified list of indeterminates `vars` over the coefficient ring `R` and returns `FAIL` if this conversions fails.

Note In MuPAD a term denotes a power product without a coefficient as, e.g., x^2y^3z .

This method overloads the function `lterm` for polynomials.

mainvar - Main variable of a polynomial

`mainvar(<a>)`

If `Vars` is not the empty list, `mainvar` can be called without argument.

mapcoeffs - Apply a function to the coefficients of a polynomial

`mapcoeffs(a, f, <e1, >)`

This method overloads the function `mapcoeffs` for polynomials.

multcoeffs - Multiply the coefficients of a polynomial with a factor

`multcoeffs(a, c)`

This method overloads the function `multcoeffs` for polynomials.

nterms - Number of terms of a polynomial

`nterms(a)`

This method overloads the function `nterms` for polynomials.

nthcoeff - N-th coefficient of a polynomial

`nthcoeff(a, n, <ord>)`

If `n` is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. `nthcoeff` returns FAIL when invoked on the zero polynomial.

This method overloads the function `nthcoeff` for polynomials.

nthmonomial - N-th monomial of a polynomial

`nthmonomial(a, n, <ord>)`

If `n` is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. `nthmonomial` returns FAIL for the zero polynomial.

This method overloads the function `nthmonomial` for polynomials.

nthterm - N-th term of a polynomial

`nthterm(a, n, <ord>)`

If `n` is larger than the number of monomials of the polynomial then the function returns FAIL.

The zero polynomial has no monomials. `nthterm` returns FAIL when called with the zero polynomial.

This method overloads the function `nthterm` for polynomials.

orderedVariableList - Ordered list of indeterminates of a polynomial

`orderedVariableList(<a>)`

Dom::DistributedPolynomial

In case Vars is not the empty list, orderedVariableList can be called without an argument.

pivotSize - Size of a pivot element

`pivotSize(a)`

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

reductum - Reductum of a polynomial

`reductum(a, <ord>)`

subs - Avoid substitution

Inherited from Dom::BaseDomain.

subsex - Avoid extended substitution

Inherited from Dom::BaseDomain.

tcoeff - Lowest coefficient of a polynomial

`tcoeff(a, <ord>)`

This method overloads the function tcoeff for polynomials.

Conversion Methods

coerce - Coerce into this domain

Inherited from Cat::BaseCategory.

convert - Conversion to a polynomial

`convert(p)`

convert_to - Convert element

Inherited from Dom::BaseDomain.

expr - Conversion to a basic type

`expr(a)`

This method overloads the function expr.

poly - Convert to a basic polynomial domain

`poly(a)`

This method overloads the function `poly`.

TeX - TeX formatting of a polynomial

`TeX(a)`

TeXCoeff - TeX formatting of a polynomial coefficient

`TeXCoeff(c)`

TeXIdent - TeX formatting of a polynomial indeterminate

`TeXIdent(var)`

TeXTerm - TeX formatting of a polynomial term

`TeXTerm(t)`

Technical Methods

adaptIndets - Convert polynomials to common indeterminates

`adaptIndets(<a, b, >)`

Note This method only exists if the parameter `Vars` is the empty list `[]`.

allAxioms - Return all axioms

Inherited from `Dom::BaseDomain`.

allCategories - Return all categories

Inherited from `Dom::BaseDomain`.

allEntries - Return the names of all entries

Inherited from `Dom::BaseDomain`.

allSuperDomains - Return all super-domains

Dom::DistributedPolynomial

Inherited from Dom::BaseDomain.

getAxioms - Return axioms stated in the constructor

Inherited from Dom::BaseDomain.

getCategories - Return categories stated in the constructor

Inherited from Dom::BaseDomain.

getSuperDomain - Return super-domain stated in the constructor

Inherited from Dom::BaseDomain.

hasProp - Test for a certain property

Inherited from Dom::BaseDomain.

info - Print short information about this domain

Inherited from Dom::BaseDomain.

isNeg - Test on leading output token

isNeg(a)

mult - Multiplie polynomials

mult(a, b,)

new - Create a new element

new(p)

new(lm)

new(lm, v)

dom(p) creates an element of this domain from a polynomial or a polynomial expression p and returns that element. If this is not possible, an error message is given.

If Vars is chosen as the empty list ([]) then in creating new elements from a polynomial or polynomial expression the function indets is first called to get the identifiers. Afterwards the element is created with this list of identifiers. For creating an element from a constant the dummy variable _dummy is introduced. The

drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by the dummy variable.

`dom(lm)` creates, if `Vars` is not the empty list `[]`, a polynomial from the list `lm` of the form `[[c1, [e11,... e1n]],... [cm,[em1,... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `Vars`. For a univariate polynomial this list can be simplified to `[[c1,e1],... [cm,em]]`.

`dom(lm,v)` creates, if `Vars = []`, a polynomial from the list `lm` of the form `[[c1, [e11,... e1n]],... [cm,[em1,... emn]]]` where the `ci` are coefficients and the `eij` are the exponents with respect to `v`. For a univariate polynomial this list can be simplified to `[[c1,e1],... [cm,em]]`. The list of indeterminates `v` must contain valid indeterminates.

plus - Add polynomials

```
plus(a, b, )
```

print - Print polynomials

```
print(a)
```

This method overloads the function `print`.

printMethods - Print out methods

Inherited from `Dom::BaseDomain`.

printMonomial - Print a monomial in defined order

```
printMonomial(c, d, v)
```

printTerm - Print a term in defined order

```
printTerm(d)
```

```
printTerm(d, v)
```

`printTerm(d,v)` returns an ordered sequence of the indeterminates together with their powers as given in the variable list `v` and the degree vector `d` respectively.

Dom::DistributedPolynomial

Note that this call is only valid if $\text{nops}(v) = \text{nops}(d)$.

Rep - Data representation of a polynomial

Rep(a)

sign - Leading sign of a polynomial

sign(a)

Note: this method does not have the meaning of a mathematical sign function!

testtype - Test type of object

Inherited from `Cat::BaseCategory`.

undefinedEntries - Return missing entries

Inherited from `Dom::BaseDomain`.

whichEntry - Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

MuPAD Domains

`Dom::Polynomial` | `Dom::MultivariatePolynomial` |
`Dom::UnivariatePolynomial`

Purpose	Domain of all objects of basic type
Syntax	<code>Dom::Expression(x)</code>
Description	<p><code>Dom::Expression</code> comprises all objects only consisting of operands of built-in types.</p> <p><code>Dom::Expression</code> is a façade domain: it has no domain elements, but uses system representation.</p> <p>Unlike <code>Dom::ExpressionField</code>, <code>Dom::Expression</code> does not belong to any arithmetical category, and its elements need not be arithmetical expressions.</p> <p><code>Dom::Expression</code> mainly serves as a super-domain to <code>Dom::ArithmeticalExpression</code>; it rarely makes sense to use it directly.</p>
Superdomain	<code>Dom::BaseDomain</code>
Axioms	<code>Ax::systemRep</code> , <code>Ax::efficientOperation("_divide")</code> , <code>Ax::efficientOperation("_mult")</code> , <code>Ax::efficientOperation("_invert")</code>
Categories	<code>Cat::BaseCategory</code>
Examples	<p>Example 1</p> <p>Almost every MuPAD object can be converted to an expression. Objects of basic type <i>are</i> expressions.</p> <pre>Dom::Expression([3, array(1..2), rectform(exp(I))])</pre> <pre>[3, (NIL NIL), cos(1) + sin(1) i]</pre> <p>The <code>convert</code> method flattens its argument: hence expression sequences are <i>not</i> allowed.</p>

Dom::Expression

```
Dom::Expression((3, x))
```

```
Error: The number of arguments is incorrect. [expr]  
Evaluating: Dom::Expression::new
```

Parameters

x

An object of basic type consisting only of operands of built-in types, or any other object convertible to such using `expr`.

Entries

"randomIdent"

an identifier used for creating random elements

Methods

Conversion Methods

convert - Conversion of objects

```
convert(x)
```

convert_to - Conversion to other domains

```
convert_to(x, T)
```

expr - Just return the argument

```
expr(x)
```

testtype - Test whether its argument is an expression

```
testtype(x, Dom::Expression)
```

This method overloads `testtype`; since `Dom::Expression` has no domain elements, the overloading can only be caused by the second argument.

float - Convert numbers to floats

```
float(x)
```

Technical Methods

subs - Substitution

`subs(x, s,)`

subsex - Extended substitution

`subsex(x, s,)`

random - Create random expression

`random()`

MuPAD Domains

`Dom::ExpressionField`

Dom::ExpressionField

Purpose Domains of expressions forming a field

Syntax **Domain Creation**
Dom::ExpressionField(<Normal, <IsZero>>)

Element Creation
Dom::ExpressionField(Normal, IsZero)(e)

Description **Domain Creation**

Dom::ExpressionField(Normal, IsZero) creates a domain of expressions forming a field, where the functions Normal and IsZero are used to normalize expressions and test for zero.

The function Normal is used to normalize the expressions representing the elements, the function IsZero is used to test the expressions for zero. It is assumed that the field has characteristic 0.

The domain cannot decide if the element expressions—given the normalizing function and zero test—actually form a field. It is up to the user to choose correct functions for normalizing and zero test and to enter only valid expressions as domains elements.

One should view this domain constructor as a pragmatic way to create a field of characteristic 0 in an ad-hoc fashion. Note that the default of using id and iszero does not yield a field really, but it is often convenient and sensible to use the resulting structure as a field.

Normal must be a function which takes an expression representing a domain element and returns the normalized expression. Normal should return FAIL if the expression is not valid.

If Normal is not given, then the system function id is used, i.e., only the kernel simplifier is used to normalize expressions.

If a normalizing function other than id is given, it is assumed that this functions returns a normal form where the zero element is uniquely represented by the constant 0.

IsZero must be a function which takes an expression representing a domain element and returns TRUE if the expression represents zero and FALSE otherwise.

If IsZero is not given, then iszero @ Normal is used for zero testing. If Normal is equal to id this functional expression is simplified to iszero.

If Normal is equal to id and IsZero is equal to iszero, a façade domain is created, i.e., the domain elements are simply expressions and are not explicitly created by new.

Otherwise the elements of the domain are explicitly created by new. Each such element has one operand, which is the expression representing the domain element. The element expressions are normalized after each operation using the function Normal.

Element Creation

Dom::ExpressionField(Normal, IsZero)(e) creates a field element represented by the expression e. The expression is normalized using the function Normal.

If Normal returns FAIL, it is assumed that the expression does not represent a valid field element. If this test is not fully implemented the domain cannot decide if the expression represents a valid field element. In this case it is up to the user to enter only valid expressions as field elements.

If Normal is equal to id and IsZero is equal to iszero, the domain is only a façade domain. In this case the expression e is returned after being simplified by the built-in kernel simplifier.

Superdomain

If Normal = id and IsZero = iszero, then
Dom::ArithmeticalExpression, else Dom::BaseDomain.

Axioms

Ax::indetElements

If Normal = id and IsZero = iszero, then Ax::efficientOperation
("_divide"), Ax::efficientOperation("_mult"),
Ax::efficientOperation("_invert"), else Ax::normalRep.

Dom::ExpressionField

If `Normal = id` and `IsZero = iszero` and `IsZero = iszero`, then
`Ax::systemRep`.

Categories

`Cat::Field`, `Cat::DifferentialRing`

Examples

Example 1

`Dom::ExpressionField(normal)` creates a field of rational expressions over the rationals. The expressions representing the field elements are always normalized by `normal`:

```
Fn := Dom::ExpressionField(normal):  
a := Fn((x^2 - 1)/(x - 1))
```

$x + 1$

The field elements are explicit elements of the domain:

```
domtype(a)
```

`Dom::ExpressionField(normal, iszero ◦ normal)`

Example 2

In the domain `Dom::ExpressionField(id, iszero@normal)` the expressions representing the elements are normalized by the kernel simplifier only:

```
Fi := Dom::ExpressionField(id, iszero@normal):  
a := Fi((x^2 - 1)/(x - 1))
```

$\frac{x^2 - 1}{x - 1}$

The elements of this domain are not normalized (when viewed as rational expressions over the rationals), thus the domain does not have the axiom `Ax::normalRep`:

```
b := a/Fi(x + 1) - Fi(1)
```

$$\frac{x^2 - 1}{(x - 1)(x + 1)} - 1$$

But nevertheless this domain also represents the field of rational expressions over the rationals, because zero is detected correctly by the function `iszero @ normal`:

```
iszero(b)
```

```
TRUE
```

Parameters

Normal

A function used to normalize the expressions of the domain; default is `id`.

IsZero

A function used to test the expressions of the domain for zero; default is `iszero @ Normal`.

e

An expression representing a field element.

Dom::ExpressionField

Entries

"characteristic"	The characteristic of the fields created by this constructor is assumed to be 0.
"one"	The element represented by the expression 1 is assumed to be a neutral element w.r.t. "_mult".
"zero"	The element represented by the expression 0 is assumed to be a neutral element w.r.t. "_plus".

Methods

Mathematical Methods

abs - Absolute value

`abs(x)`

Overloads the function `abs`, thus may be called via `abs(x)`.

combine - Combine terms of the same algebraic structure

`combine(x, <a>)`

Overloads the function `combine`, thus may be called via `combine(x, ...)`.

conjugate - Complex conjugate

`conjugate(x)`

Overloads the function `conjugate`, thus may be called via `conjugate(x)`.

D - Differential operator

`D(<l>, x)`

Overloads the function `D`, thus may be called via `D(x)` or `D(l, x)`.

denom - Denominator

`denom(x)`

Overloads the function `denom`, thus may be called via `denom(x)`.

diff - Differentiate an element

`diff(x, <v, , >)`

Overloads the function `diff`, thus may be called via `diff(x, ...)`.

_divide - Divide elements

`_divide(x, y)`

Overloads the function `_divide`, thus may be called via `x/y` or `_divide(x, y)`.

equal - Test for mathematical equality

`equal(x, y)`

expand - Expand an element

`expand(x)`

Overloads the function `expand`, thus may be called via `expand(x)`.

factor - Factorize an element

`factor(x)`

Overloads the function `factor`, thus may be called via `factor(x)`.

float - Floating-point approximation

`float(x)`

Overloads the function `float`, thus may be called via `float(x)`.

gcd - Greatest common divisor

`gcd(x,)`

Overloads the function `gcd`, thus may be called via `gcd(x, ...)`.

Im - Imaginary part of an element

`Im(x)`

Overloads the function `Im`, thus may be called via `Im(x)`.

int - Definite and indefinite integration

`int(x, <v>)`

Overloads the function `int`, thus may be called via `int(x, ...)`.

intmult - Integer multiple

`intmult(x, n)`

_invert - Invert an element

`_invert(x)`

Overloads the function `_invert`, thus may be called via `1/x` or `_invert(x)`.

iszero - Test for zero

`iszero(x)`

Overloads the function `iszero`, thus may be called via `iszero(x)`.

lcm - Least common multiple

`lcm(x,)`

Overloads the function `lcm`, thus may be called via `lcm(x, ...)`.

_leequal - Test if less or equal

`_leequal(x, y)`

Please note that the function `_leequal` can only test numbers (in a syntactical sense), but not constant expressions like `PI` or `sqrt(2)`.

Overloads the function `_leequal`, thus may be called via `x <= y`, `y >= x` or `_leequal(x, y)`.

_less - Test if element is less

`_less(x, y)`

Please note that the function `_less` can only test numbers (in a syntactical sense), but not constant expressions like `PI` or `sqrt(2)`.

Overloads the function `_less`, thus may be called via `x < y`, `y > x` or `_less(x, y)`.

limit - Limit computation

`limit(x, <v, >)`

Overloads the function `limit`, thus may be called via `limit(x, ...)`.

max - Maximum of arguments

`max(x,)`

Overloads the function `max`, thus may be called via `max(x, ...)`.

min - Minimum of arguments

`min(x,)`

Overloads the function `min`, thus may be called via `min(x, ...)`.

_mult - Multiplie elements

`_mult(x,)`

If all arguments are of this domain or can be coerced to this domain (using the method `coerce`), the product of the expressions representing the arguments is calculated using the function `_mult`.

If one of the arguments cannot be coerced, the arguments up to the offending one are multiplied and then the method `"_mult"` of the domain of the offending argument is called to multiply the remaining arguments.

Overloads the function `_mult`, thus may be called via `x*...` or `_mult(x, ...)`.

_negate - Negate an element

`_negate(x)`

Overloads the function `_negate`, thus may be called via `-x` or `_negate(x)`.

norm - Norm of an element

`norm(x)`

Overloads the function `norm`, thus may be called via `norm(x)`.

Please note that the system function `norm`, applied to an expression, computes the norm of that expression interpreted as a polynomial expression and *not* the absolute value of the expression. This may be regarded as an inconsistency.

normal - Normal form

`normal(x)`

Overloads the function `normal`, thus may be called via `normal(x)`.

numer - Numerator

`numer(x)`

Overloads the function `numer`, thus may be called via `numer(x)`.

_plus - Add elements

`_plus(x,)`

If all arguments are of this domain or can be coerced to this domain (using the method `coerce`) the sum of the expressions representing the arguments is calculated using the function `_plus`.

If one of the arguments cannot be coerced the arguments up to the offending one are added and then the method "`_plus`" of the domain of the offending argument is called to add the remaining arguments.

Overloads the function `_plus`, thus may be called via `x+...` or `_plus(x,...)`.

_power - Exponentiate arguments

`_power(x, y)`

`_power(x, y)`

If both arguments are of this domain the power is calculated by mapping the function `_power` to the expressions representing the arguments.

If one of the arguments is not of this domain it is coerced to this domain, then the power is computed. If the coercion fails an error is raised.

Note that it is assumed that at least one of the arguments is of this domain.

Overloads the function `_power`, thus may be called via `x^y` or `_power(x, y)`.

radsimp - Simplifie radicals

`radsimp(x)`

Overloads the function `radsimp`, thus may be called via `radsimp(x)`.

random - Create a random element

`random()`

See `polylib::randpoly` for details about creating random polynomials.

Re - Real part of an element

`Re(x)`

Overloads the function `Re`, thus may be called via `Re(x)`.

sign - Sign of an element

`sign(x)`

Overloads the function `sign`, thus may be called via `sign(x)`.

simplify - General simplification of an element

`simplify(x, <a>)`

Overloads the function `simplify`, thus may be called via `simplify(x, ...)`.

Dom::ExpressionField

solve - Solve an equation

`solve(x, <a, >)`

Note that this method will never return an element of this domain. See `solve` for details about results and optional additional arguments.

Overloads the function `solve`, thus may be called via `solve(x, ...)`.

sqrfree - Square-free factorization

`sqrfree(x)`

Overloads the function `polylib::sqrfree`, thus may be called via `polylib::sqrfree(x)`.

_subtract - Subtract elements

`_subtract(x, y)`

Overloads the function `_subtract`, thus may be called via `x - y` or `_subtract(x, y)`.

Conversion Methods

convert - Convert to this domain

`convert(x)`

convert_to - Convert to other domain

`convert_to(x, T)`

expr - Convert to basic type

`expr(x)`

This method is called by the function `expr` if a subexpression of the argument is an element of this domain.

new - Creating an element

`new(x)`

Overloads the function call operator for this domain, thus may be called via $F(x)$ where F is this domain.

Access Methods

nops - Number of operands

`nops(x)`

Overloads the function `nops`, thus may be called via `nops(x)`.

op - Get operands

`op(x)`

`op(x, i)`

Returns the operand with index i of the expression representing x . If i is 0 then the operator of the expression is returned, which usually is not an element of this domain. The other operands are converted to elements of this domain.

This method is called by the function `op` when an element of this domain is contained, as a subexpression, in the first argument of `op`. Operand ranges and paths are handled by `op` and need not be handled by this method. See `op` for details.

subs - Substitute subexpressions

`subs(x, e,)`

Maps `subs` to the expression representing x . The resulting expression is converted to an element of this domain.

This method is called by the function `subs` when an element of this domain is contained, as a subexpression, in the first argument of `subs`. See `subs` for details.

subsex - Extended substitution

`subsex(x, e, ,)`

Maps `subsex` to the expression representing x . The resulting expression is converted to an element of this domain.

Dom::ExpressionField

This method is called by the function `subsex` when an element of this domain is contained, as a subexpression, in the first argument of `subsex`. See `subsex` for details.

subsop - Substitute operand

`subsop(x, e, ,)`

This method is called by the function `subsop` when an element of this domain is contained, as a subexpression, in the first argument of `subsop`. Operand ranges and paths are handled by `subsop` and need not be handled by this method. See `subsop` for details.

Technical Methods

indets - Identifier of an element

`indets(x, <optionName>)`

Overloads the function `indets`, thus may be called via `indets(x)` and `indets(x, optionName)`, respectively.

length - Size of an element

`length(x)`

Overloads the function `length`, thus may be called via `length(x)`.

map - Apply function to operands

`map(x, f, <a, >)`

Overloads the function `map`, thus may be called via `map(x, f, ...)`.

rationalize - Approximate floating-point numbers by rationals

`rationalize(x, <a, >)`

Note that this method does *not* overload the function `rationalize` from the standard library package, but the function `numeric::rationalize` from the `numeric` package instead. Thus the method may be called via `numeric::rationalize(x, ...)`.

pivotSize - Pivot size

`pivotSize(x)`

Dom::Float

Purpose	Real floating-point numbers
Syntax	<code>Dom::Float(x)</code>
Description	<p><code>Dom::Float</code> is the set of real floating-point numbers represented by elements of the domain <code>DOM_FLOAT</code>.</p> <p><code>Dom::Float</code> is the domain of real floating point numbers represented by expressions of type <code>DOM_FLOAT</code>.</p> <p><code>Dom::Float</code> has category <code>Cat::Field</code> out of pragmatism. This domain actually is not a field because <code>bool(1.0 = float(3) / float(3))</code> returns <code>FALSE</code> for example.</p> <p>Elements of <code>Dom::Float</code> are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression may be converted to a floating point number. This means <code>Dom::Float</code> is a facade domain which creates elements of domain type <code>DOM_FLOAT</code>.</p> <p>Viewed as a differential ring <code>Dom::Float</code> is trivial, it contains constants only.</p> <p><code>Dom::Float</code> has the domain <code>Dom::Numerical</code> as its super domain, i.e., it inherits each method which is defined by <code>Dom::Numerical</code> and not implemented by <code>Dom::Float</code>. Methods described below are re-implemented by <code>Dom::Float</code>.</p>
Superdomain	<code>Dom::Numerical</code>
Axioms	<code>Ax::canonicalRep</code> , <code>Ax::systemRep</code> , <code>Ax::canonicalOrder</code> , <code>Ax::efficientOperation("_divide")</code> , <code>Ax::efficientOperation("_mult")</code> , <code>Ax::efficientOperation("_invert")</code>
Categories	<code>Cat::DifferentialRing</code> , <code>Cat::Field</code> , <code>Cat::OrderedSet</code>

Examples

Example 1

Creating some floating-point numbers using `Dom::Float`. This example also shows that `Dom::Float` is a facade domain.

```
Dom::Float(2.3); domtype(%)
```

```
2.3
```

```
DOM_FLOAT
```

```
Dom::Float(sin(2/3*PI) + 3)
```

```
3.866025404
```

```
Dom::Float(sin(x))
```

```
Error: The arguments are invalid. [Dom::Float::new]
```

Example 2

By tracing the method `Dom::Float::testtypeDom` we can see the interaction between `testtype` and `Dom::Float::testtypeDom`.

```
prog::trace(Dom::Float::testtypeDom):  
delete x:  
testtype(x, Dom::Float);  
testtype(3.4, Dom::Float);  
prog::untrace(Dom::Float::testtypeDom):
```

```
enter Dom::Float::testtypeDom(x, Dom::Float)  
computed FAIL
```

Dom::Float

FALSE

```
enter Dom::Float::testtypeDom(3.4, Dom::Float)
computed TRUE
```

TRUE

Parameters

x

An expression which can be converted to a DOM_FLOAT by the function float.

Entries

"one"

the unit element; it equals 1.0.

"zero"

The zero element; it equals 0.0.

Methods

Mathematical Methods

pivotSize - Size of a pivot element

`pivotSize(x)`

This method is called if this domain is used as the component ring of a matrix domain to perform Gaussian elimination.

random - Random number generation

`random()`

Conversion Methods

convert - Conversion of objects

`convert(x)`

In general, if `float(x)` evaluates to a real floating-point number of type `DOM_FLOAT`, this number is the result of the conversion.

convert_to - Conversion to other domains

`convert_to(x, T)`

The following domains are allowed for `T`: `DOM_FLOAT`, `Dom::Float` and `Dom::Numerical`.

testtype - Type checking

`testtype(x, T)`

In general this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-173 demonstrates this behavior.

`Dom::Numerical` | `Dom::Rational` | `Dom::Real`

Purpose Field of fractions of an integral domain

Syntax **Domain Creation**

Dom::Fraction(R)

Element Creation

Dom::Fraction(R)(r)

Description **Domain Creation**

Dom::Fraction(R) creates a domain which represents the field of

fractions $F = \left\{ \frac{x}{y} \mid x \in R, y \in R \setminus \{0\} \right\}$ of the integral domain R .

An element of the domain Dom::Fraction(R) has two operands, the numerator and denominator.

If Dom::Fraction(R) has the axiom Ax::canonicalRep (see below), the denominators have unit normal form and the gcds of numerators and denominators cancel.

The domain Dom::Fraction(Dom::Integer) represents the field of rational numbers. But the created domain is not the domain Dom::Rational, because it uses a different representation of its elements. Arithmetic in Dom::Rational is much more efficient than it is in Dom::Fraction(Dom::Integer).

Element Creation

If r is a rational expression, then an element of the field of fractions Dom::Fraction(R) is created by going through the operands of r and converting each operand into an element of R . The result of this

process is r in the form $\frac{x}{y}$, where x and y are elements of R . If R has Cat::GcdDomain, then x and y are coprime.

If one of the operands can not be converted into the domain R , an error message is issued.

Superdomain Dom::BaseDomain

Dom::Fraction

Axioms Ax::normalRep

Categories Cat::QuotientField(R)

Examples **Example 1**

We define the field of rational functions over the rationals:

```
F := Dom::Fraction(Dom::Polynomial(Dom::Rational))
```

```
Dom::Fraction(Dom::Polynomial(Dom::Rational, LexOrder))
```

and create an element of F:

```
a := F(y/(x - 1) + 1/(x + 1))
```

$$\frac{x+y+xy-1}{x^2-1}$$

To calculate with such elements use the standard arithmetical operators:

```
2*a, 1/a, a*a
```

$$\frac{2x+2y+2xy-2}{x^2-1}, \frac{x^2-1}{x+y+xy-1}, \frac{x^2y^2+2x^2y+x^2+2xy^2-2x+y^2-2y+1}{x^4-2x^2+1}$$

Some system functions are overloaded for elements of domains generated by Dom::Fraction, such as diff, numer or denom (see the description of the corresponding methods "diff", "numer" and "denom" above).

For example, to differentiate the fraction a with respect to x enter:

```
diff(a, x)
```

$$\frac{-y - 2x + 2xy + x^2y + x^2 + 1}{x^4 - 2x^2 + 1}$$

If one knows the variables in advance, then using the domain `Dom::DistributedPolynomial` yields a more efficient arithmetic of rational functions:

```
Fxy := Dom::Fraction(
  Dom::DistributedPolynomial([x, y], Dom::Rational)
)
```

```
Dom::Fraction(Dom::DistributedPolynomial([x, y], Dom::Rational, LexOrder))
```

```
b := Fxy(y/(x - 1) + 1/(x + 1)):
b^3
```

$$(x^3 y^3 + 3 x^3 y^2 + 3 x^3 y + x^3 + 3 x^2 y^3 + 3 x^2 y^2 - 3 x^2 y - 3 x^2 + 3 x y^3 - 3 x y^2 - 3 x y + 3 x + y^3 - 3 y^2 + 3 y - 1)/(x^6 - 3 x^4 + 3 x^2 - 1)$$

Example 2

We create the field of rational numbers as the field of fractions of the integers, i.e., $\mathbb{Q} = \left\{ \frac{x}{y} \mid x \in \mathbb{Z}, y \in \mathbb{Z} \setminus \{0\} \right\}$:

```
Q := Dom::Fraction(Dom::Integer):
Q(1/3)
```

$$\frac{1}{3}$$

```
domtype(%)
```

```
Dom::Fraction(Dom::Integer)
```

Dom::Fraction

Another representation of in MuPAD is the domain `Dom::Rational` where the rationals are of the kernel domains `DOM_INT` and `DOM_RAT`. Therefore it is much more efficient to work with `Dom::Rational` than with `Dom::Fraction(Dom::Integer)`.

Parameters

R

An integral domain, i.e., a domain of category `Cat::IntegralDomain`

r

A rational expression, or an element of R

Entries

"characteristic"	is the characteristic of R.
"coeffRing"	is the integral domain R.
"one"	is the one of the field of fractions of R, i.e., the fraction 1.
"zero"	is the zero of the field of fractions of R, i.e., the fraction 0.

Methods

Mathematical Methods

divide - Divide two fractions

`_divide(x, y)`

This method overloads the function `_divide` for fractions, i.e., one may use it in the form `x / y` or in functional notation: `_divide(x, y)`.

invert - Invert a fraction

`_invert(r)`

This method overloads the function `_invert` for fractions, i.e., one may use it in the form `1/r` or `r^(-1)`, or in functional notation: `_invert(r)`.

`_less` - Less-than relation

`_less(q, r)`

An implementation is provided only if R is an ordered set, i.e., a domain of category `Cat::OrderedSet`.

This method overloads the function `_less` for fractions, i.e., one may use it in the form $q < r$, or in functional notation: `_less(q, r)`.

`_mult` - Multiplie fractions by fractions or rational expressions

`_mult(q, r)`

If q is not of the domain type `Dom::Fraction(R)`, it is considered as a rational expression which is converted into a fraction over R and multiplied with q . If the conversion fails, `FAIL` is returned.

The same applies to r .

This method also handles more than two arguments. In this case, the argument list is splitted into two parts of the same length which both are multiplied with the function `_mult`. The two results are multiplied again with `_mult` whose result then is returned.

This method overloads the function `_mult` for fractions, i.e., one may use it in the form $q * r$ or in functional notation: `_mult(q, r)`.

`_negate` - Negate a fraction

`_negate(r)`

This method overloads the function `_negate` for fractions, i.e., one may use it in the form $-r$ or in functional notation: `_negate(r)`.

`_power` - Integer power of a fraction

`_power(r, n)`

This method overloads the function `_power` for fractions, i.e., one may use it in the form r^n or in functional notation: `_power(r, n)`.

`_plus` - Add fractions

`_plus(q, r,)`

If one of the arguments is not of the domain type `Dom::Fraction(R)`, then FAIL is returned.

This method overloads the function `_plus` for fractions, i.e., one may use it in the form $q + r$ or in functional notation: `_plus(q, r)`.

D - Differential operator

`D(r)`

An implementation is provided only if R is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

This method overloads the operator D for fractions, i.e., one may use it in the form $D(r)$.

denom - Denominator of a fraction

`denom(r)`

This method overloads the function `denom` for fractions, i.e., one may use it in the form `denom(r)`.

diff - Differentiation of fractions

`diff(r, u)`

This method overloads the function `diff` for fractions, i.e., one may use it in the form `diff(r, u)`.

An implementation is provided only if R is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

equal - Test on equality of fractions

`equal(q, r)`

factor - Factorize the numerator and denominator of a fraction

`factor(r)`

The factors u, r_1, \dots, r_n are fractions of type `Dom::Fraction(R)`, the exponents e_1, \dots, e_n are integers.

The system function `factor` is used to perform the factorization of the numerator and denominator of r .

This method overloads the function `factor` for fractions, i.e., one may use it in the form `factor(r)`.

intmult - Integer multiple of a fraction

`intmult(r, n)`

iszero - Test for zero

`iszero(r)`

An element of the field `Dom::Fraction(R)` is zero if its numerator is the zero element of R . Note that there may be more than one representation of the zero element if R does not have `Ax::canonicalRep`.

This method overloads the function `iszero` for fractions, i.e., one may use it in the form `iszero(r)`.

numer - Numerator of a fraction

`numer(r)`

This method overloads the function `numer` for fractions, i.e., one may use it in the form `numer(r)`.

random - Random fraction generation

`random()`

The returning fraction is normalized (see the methods "`normalize`" and "`normalizePrime`").

Conversion Methods

convert_to - Fraction conversion

`convert_to(r, T)`

If the conversion fails, FAIL is returned.

The conversion succeeds if T is one of the following domains:
Dom::Expression or Dom::ArithmeticalExpression.

Use the function `expr` to convert `r` into an object of a kernel domain (see below).

expr - Convert a fraction into an object of a kernel domain

`expr(r)`

The result is an object of a kernel domain (e.g., DOM_RAT or DOM_EXPR).

This method overloads the function `expr` for fractions, i.e., one may use it in the form `expr(r)`.

TeX - TeX formatting of a fraction

`TeX(r)`

The method `TeX` of the component ring `R` is used to get the TeX-representations of the numerator and denominator of `r`, respectively.

retract - Retraction to base domain

`retract(r)`

Technical Methods

normalize - Normalizing fractions

`normalize(x, y)`

Normalization means to remove the gcd of `x` and `y`. Hence, `R` needs to be of category `Cat::GcdDomain`. Otherwise, normalization

cannot be performed and the result of this method is the fraction

$$\frac{x}{y}$$

normalizePrime - Normalizing fractions over integral domains with a gcd

`normalizePrime(x, y)`

In rings of category `Cat::GcdDomain`, elements are assumed to be relatively prime. Hence, there is no need to normalize the

fraction $\frac{x}{y}$.

In rings not of category `Cat::GcdDomain`, normalization of elements can not be performed and the result of this method is

the fraction $\frac{x}{y}$.

`Dom::Rational`

Dom::GaloisField

Purpose Finite fields

Syntax

Domain Creation

```
Dom::GaloisField(q)
Dom::GaloisField(p, n)
Dom::GaloisField(p, n, f)
Dom::GaloisField(F, n)
Dom::GaloisField(F, n, f)
```

Element Creation

```
Dom::GaloisField(p, n, f)(g)
```

Description **Domain Creation**

`Dom::GaloisField(p, n, f)` creates the residue class field $\mathbb{Z}[X]/\langle f \rangle$, a finite field with p^n elements. If `f` is not given, it is chosen at random among all irreducible polynomials of degree n .

`Dom::GaloisField(q)` (where $q = p^n$) is equivalent to `Dom::GaloisField(p, n)`.

`Dom::GaloisField(F, n, f)` creates the residue class field $F[X]/\langle f \rangle$, a finite field with $|F|^n$ elements.

If `f` is not given, a random irreducible polynomial of appropriate degree is used; some free identifier is chosen as its variable, and this one must also be used when creating domain elements.

Although $n = 1$ is allowed, `Dom::IntegerMod` should be used for representing prime fields.

If `F` is of type `Dom::GaloisField`, consisting of residue classes of polynomials, the variable of these polynomials must be distinct from the variable of `f`. If a tower several of Galois fields is constructed, the variable used in the uppermost Galois field must not equal any of those used in the tower. A special entry "VariablesInUse" serves to keep track of all variables appearing somewhere in the tower.

Element Creation

Dom::GaloisField(p,n,f)(g) (or, respectively, Dom::GaloisField(F,n,f)(g)) creates the residue class of g modulo f. It is represented by the unique polynomial in that class that has smaller degree than f.

Superdomain Dom::AlgebraicExtension(Dom::IntegerMod(p), f)

Axioms Ax::canonicalRep

Categories Cat::Field, Cat::Algebra(F), Cat::VectorSpace(F)

Examples **Example 1**

We define L to be the field with 4 elements. Then $a^4 = a$ for every $a \in L$, by a well-known theorem.

```
L:=Dom::GaloisField(2, 2, u^2+u+1): L(u+1)^4
```

```
u+1
```

Parameters

q

Prime power

p

Prime

n

Positive integer

f

Univariate irreducible polynomial over Dom::IntegerMod(p) or F, or polynomial expression convertible to such

F

Dom::GaloisField

Finite field of type `Dom::IntegerMod` or `Dom::GaloisField`.

g

Univariate polynomial over the ground field in the same variable as `f`, or polynomial expression convertible to such

Entries

"zero"	the zero element of the field
"one"	the unit element of the field
"characteristic"	the characteristic of the field
"size"	the number of elements of the field
"PrimeField"	the prime field, which equals <code>Dom::IntegerMod(p)</code> .
"Variable"	the variable of the polynomial <code>f</code> .
"VariablesInUse"	a list consisting of "Variable" and the variables used by the ground field.

Methods

Mathematical Methods

iszero - Test for zero

`iszero(a)`

It overloads the function `iszero`.

_power - Integer power of an element

`_power(a, n)`

It overloads `_power`.

frobenius - Frobeniu map

`frobenius(a)`

conjugates - Conjugate of an element

conjugates(a)

order - Order of an element

order(a)

isSquare - Test whether an element is a square

isSquare(a)

ln - Discrete logarithm

ln(a, b)

elementNumber - Enumerate field elements

elementNumber(a)

The inverse of this mapping has not been implemented.

companionMatrix - Companion matrix of the Galois field over its ground field

companionMatrix()

companionPowers - Power of the companion matrix

companionPowers()

matrixRepresentation - Isomorphism to the algebra generated by the companion matrix

matrixRepresentation(a)

If A is the companion matrix, the image of $\sum a_i X^i$ is $\sum a_i A^i$.

randomPrimitive - Choose a primitive element at random

randomPrimitive()

isBasis - Test elements for being a basis over the ground field

isBasis(l)

isNormal - Test whether a given field element is normal

isNormal(a)

Dom::GaloisField

randomNormal - Choose normal element at random

```
randomNormal()
```

isPrimitivePolynomial - Test whether a polynomial over the field is primitive

```
isPrimitivePolynomial(h)
```

Conversion Methods

convert - Conversion from other types

```
convert(a)
```

convert_to - Conversion to other types

```
convert_to(a, T)
```

**MuPAD
Domains**

[Dom::AlgebraicExtension](#) | [Dom::IntegerMod](#)

Purpose Domain of images of sets under mappings

Syntax **Domain Creation**

Dom::ImageSet()

Element Creation

Dom::ImageSet(f, x, S)

Dom::ImageSet(f, [x1, ...], [S1, ...])

Description **Domain Creation**

Dom::ImageSet is the domain of all sets of complex numbers that can be written as the set of all values taken on by some mapping, i.e., sets of the form $\{f(x_1, \dots, x_n) \mid x_i \in S_i\}$ for some function f and some sets S_1, \dots, S_n .

Image sets are mainly used by solve to express sets like $\{k\pi \mid k \in \mathbb{Z}\}$.

Dom::ImageSet belongs to the category Cat::Set—arithmetical and set-theoretic operations are inherited from there.

Element Creation

Dom::ImageSet(f, x, S) represents the set of all values that can be obtained by substituting some element of S for x in the expression f.

Dom::ImageSet(f, [x1, ...], [S1, ...]) represents the set of all values that can be obtained by substituting, for each i , the identifier x_i by some element of S_i in the expression f.

Dom::ImageSet(f, x, S) represents the set $\{f \mid x \in S\}$.

Dom::ImageSet(f, [x1, ..., xn], [S1, ..., Sn]) represents the set $\{f \mid x_i \in S_i, i = 1 \dots n\}$.

f need not contain x; on the other hand, it may contain other identifiers (free variables).

If a list of several identifiers is given, the identifiers must be distinct.

Dom::ImageSet

S must be a set; see `solve` for an overview of the different kinds of sets in MuPAD.

`Dom::ImageSet` carries out some automatical simplifications that may produce a result of a type different from `Dom::ImageSet`.

`Dom::ImageSet` renames the variables x_1, \dots, x_n , in order to avoid naming conflicts as well as producing a nicer output.

Superdomain `Dom::BaseDomain`

Categories `Cat::Set`

Examples **Example 1**

We define S to be the set of all integer multiples of π .

```
S := Dom::ImageSet(ugly*PI, ugly, Z_)
```

```
{ $\pi k \mid k \in \mathbb{Z}$ }
```

Our ugly variable name has been replaced by a nicer one which suggests that it represents an integer.

We may now apply the usual set-theoretic operations.

```
S intersect Dom::Interval(3..7)
```

```
{ $\pi, 2\pi$ }
```

Example 2

An element of an image set may be obtained by substituting all parameters by some values:

```
S := Dom::ImageSet(a^7 + b^3 + C, [a, b], [Z_, Z_])
```

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

On calling the `evalParam` method, we have to take care that the variable names have been replaced.

```
Dom::ImageSet::evalParam(S, k = 3, l = 5)
```

$$C + 2312$$

The same may be achieved using the index operator:

```
S[3, 5]
```

$$C + 2312$$

Substituting only for one parameter, we obtain an image set in the other parameter:

```
Dom::ImageSet::evalParam(S, k = 3)
```

$$\{l^3 + C + 2187 \mid l \in \mathbb{Z}\}$$

A parameter may be substituted by itself, meaning that it becomes a free variable:

```
Dom::ImageSet::evalParam(S, k = k)
```

$$\{k^7 + l^3 + C \mid l \in \mathbb{Z}\}$$

The `evalParam` method cannot be used to substitute a free variable:

```
Dom::ImageSet::evalParam(S, C = 3)
```

Dom::ImageSet

$$\{k^7 + l^3 + C \mid k \in \mathbb{Z}, l \in \mathbb{Z}\}$$

delete S:

Parameters

f

Arithmetical expression

x

Identifier or indexed identifier

S

Set of any type

Methods

Mathematical Methods

changevar - Change the name of a variable

changevar(A, oldvar, newvar)

The new variable newvar must not equal any element of the list of variables; this is not checked!

setvar - Set the name of the variable

setvar(A, newvar)

setvar(A, newvar)

For an argument A that is not an image set, the method "setvar" is applied to all image sets contained in the expression A. A might be, for example, a union, intersection, etc. of image sets and other sets.

homogpointwise - Define an n-ary pointwise operator for image sets

homogpointwise(Op)

Op must accept arithmetical expressions as arguments.

isEmpty - Test whether a set is empty

```
isEmpty(A)
```

substituteBySet - Substitute an ImageSet for a variable

```
substituteBySet(a, x, A)
```

freeIndets - Free parameters of a set

```
freeIndets(A)
```

If $A = \{f(x_1, \dots, x_n, y_1, \dots, y_k) \mid x_i \in S_i\}$, the x_i are called bound and the y_i are called free parameters.

Use the slot "variables" to obtain the bound parameters.

evalParam - Insert values for bound parameters

```
evalParam(A(x = value, ))
```

If x is not a parameter, but a free variable of A, it is not substituted by value.

value may be an identifier or contain identifiers; in particular, it may contain x and/or some of the remaining parameters. This may be used to convert parameters into free variables.

Several parameters may be replaced in a single call.

See "Example 2" on page 6-196.

_index - Extract element by inserting values for bound parameters

```
_index(A, value1, )
```

The number of values passed must match the number of variables of A.

It is not checked whether for each i , the value for the i th parameter belongs to the i th set.

See "Example 2" on page 6-196.

Dom::ImageSet

Access Methods

expr - Defining mapping as an expression

expr(A)

This method overloads the function expr.

variables - List of variables

variables(A)

The free parameters (identifiers appearing in f other than the x_i) can be obtained using the "freeIndets" slot.

nvars - Number of variables

nvars(A)

sets - List of sets

sets(A)

Technical Methods

print - Print image set

print(A)

Purpose	Ring of integer numbers
Syntax	<code>Dom::Integer(x)</code>
Description	<p><code>Dom::Integer</code> is the ring of integer numbers represented by elements of the domain <code>DOM_INT</code>.</p> <p>Elements of <code>Dom::Integer</code> are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is an integer number. This means that <code>Dom::Integer</code> is a façade domain which creates elements of domain type <code>DOM_INT</code>.</p> <p>Viewed as a differential ring <code>Dom::Integer</code> is trivial, it contains constants only.</p> <p><code>Dom::Integer</code> has the domain <code>Dom::Numerical</code> as its super domain, i.e., it inherits each method which is defined by <code>Dom::Numerical</code> and not re-implemented by <code>Dom::Integer</code>. Methods described below are those implemented by <code>Dom::Integer</code>.</p>
Superdomain	<code>Dom::Numerical</code>
Axioms	<code>Ax::canonicalRep</code> , <code>Ax::systemRep</code> , <code>Ax::canonicalOrder</code> , <code>Ax::canonicalUnitNormal</code> , <code>Ax::closedUnitNormals</code> , <code>Ax::efficientOperation("_divide")</code> , <code>Ax::efficientOperation("_mult")</code>
Categories	<code>Cat::EuclideanDomain</code> , <code>Cat::FactorialDomain</code> , <code>Cat::DifferentialRing</code> , <code>Cat::OrderedSet</code>
Examples	Example 1 <p>Creating some integer numbers using <code>Dom::Integer</code>. This example also shows that <code>Dom::Integer</code> is a façade domain.</p> <pre>Dom::Integer(2); domtype(%)</pre>

Dom::Integer

2

DOM_INT

Dom::Integer(2/3)

Error: The arguments are invalid. [Dom::Integer::new]

Example 2

By tracing the method `Dom::Integer::testtypeDom` we can see the interaction between `testtype` and `Dom::Integer::testtypeDom`.

```
prog::trace(Dom::Integer::testtypeDom):  
delete x:  
testtype(x, Dom::Integer);  
testtype(3, Dom::Integer);  
prog::untrace(Dom::Integer::testtypeDom):
```

```
enter Dom::Integer::testtypeDom(x, Dom::Integer)  
computed FALSE
```

FALSE

```
enter Dom::Integer::testtypeDom(3, Dom::Integer)  
computed TRUE
```

TRUE

Parameters

x

An integer

Methods

Mathematical Methods

associates - Associate elements

`associates(x, y)`

_divide - Division of two objects

`_divide(x, y)`

_divides - Decide if a number divides another one

`_divides(x, y)`

euclideanDegree - Euclidean degree

`euclideanDegree(x)`

factor - Factorization

`factor(x)`

gcd - Gcd computation

`gcd(x1, x2,)`

gcdex - Applie the extended Euclidean algorithm

`gcdex(x, y)`

_invert - Inverse of an element

`_invert(x)`

irreducible - Prime number test

`irreducible(x)`

isUnit - Test if an element is a unit

`isUnit(x)`

lcm - Compute the lcm

Dom::Integer

lcm(x1, x2, ...)

quo - Compute the euclidean quotient

quo(x, y)

random - Random number generation

random()

random(n)

random(m .. n)

This methods returns a random number between 0 and $n - 1$.

This methods returns a random number between m and n .

rem - Compute the Euclidean remainder

rem(x, y)

unitNormal - Unit normal part

unitNormal(x)

unitNormalRep - Unit normal representation

unitNormalRep(x)

Conversion Methods

convert - Conversion of objects

convert(x)

convert_to - Conversion to other domains

convert_to(x, T)

The following domains are allowed for T: DOM_INT, Dom::Integer, Dom::Rational, DOM_FLOAT, Dom::Float and Dom::Numerical.

testtype - Type checking

testtype(x, T)

Usually, this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-202 demonstrates this behavior.

MuPAD Domains

`Dom::Complex` | `Dom::Float` | `Dom::Numerical` | `Dom::Rational` |
`Dom::Real`

Dom::IntegerMod

Purpose Residue class rings modulo integers

Syntax **Domain Creation**
`Dom::IntegerMod(n)`

Element Creation
`Dom::IntegerMod(n)(a)`

Description **Domain Creation**
`Dom::IntegerMod(n)` creates the residue class ring of integers modulo n .

`Dom::IntegerMod(n)` creates the integer residue class rings $\mathbb{Z}/n\mathbb{Z}$.

Element Creation
`Dom::IntegerMod(n)(a)` creates the residue class of a modulo n .

Superdomain `Dom::BaseDomain`

Axioms `Ax::normalRep`, `Ax::canonicalRep`, `Ax::noZeroDivisors`,
`Ax::closedUnitNormals`, `Ax::canonicalUnitNormal`,
`Ax::efficientOperation("_invert")`,
`Ax::efficientOperation("_divide")`,
`Ax::efficientOperation("_mult")`

Categories If n is prime, then `Cat::Field`, else `Cat::CommutativeRing`.

Examples **Example 1**

We define the residue class ring of the integers mod 7:

```
Z7:= Dom::IntegerMod(7)
```

```
Dom::IntegerMod(7)
```

Next, we create some elements:

```
a:= Z7(1); b:= Z7(2); c:= Z7(3)
```

```
1 mod 7
```

```
2 mod 7
```

```
3 mod 7
```

We may use infix notation for arithmetical operations since the operators have been overloaded:

```
a + b, a*b*c, 1/c, b/c/a/c
```

```
3 mod 7, 6 mod 7, 5 mod 7, 1 mod 7
```

a and b are squares while c is not:

```
Z7::isSquare(a), Z7::isSquare(b), Z7::isSquare(c)
```

```
TRUE, TRUE, FALSE
```

Indeed, c is a generator of the group of units:

```
Z7::order(a), Z7::order(b), Z7::order(c)
```

```
1, 3, 6
```

Parameters

n

Positive integer greater than 1

a

Dom::IntegerMod

Any integer or a rational number whose denominator is coprime to n

Entries

"characteristic"	the characteristic of the residue class ring, n
"one"	the unit element, $1 \bmod n$
"zero"	the zero element, $0 \bmod n$

Methods

Mathematical Methods

`_divide` - Division of two elements

`_divide(element1, element2)`

`_invert` - Invert elements

`_invert(element)`

`_mult` - Multiply elements

`_mult(element,)`

`_negate` - Negate elements

`_negate(element)`

`_plus` - Add elements

`_plus(element,)`

`_power` - Power of elements

`_power(element, power)`

`_subtract` - Subtraction of two elements

`_subtract(element1, element2)`

D - Return derivative

Inherited from `Cat::CommutativeRing`.

`associates` - Test for associate elements

Inherited from `Cat::Field`.

coerce - Coerce into this domain

Inherited from `Cat::BaseCategory`.

diff - Differentiate element

Inherited from `Cat::CommutativeRing`.

divide - Division with remainder

Inherited from `Cat::Field`.

divides - Test if division is exact

Inherited from `Cat::Field`.

equal - Test for mathematical equality

Inherited from `Dom::BaseDomain`.

equiv - Test for equivalence

Inherited from `Cat::BaseCategory`.

euclideanDegree - Return Euclidean degree

Inherited from `Cat::Field`.

factor - Unique factorization

Inherited from `Cat::Field`.

gcd - Greatest common divisor

Inherited from `Cat::Field`.

gcdex - Extended greatest common divisor

Inherited from `Cat::EuclideanDomain`.

idealGenerator - Generator of finitely generated ideal

Inherited from `Cat::EuclideanDomain`.

irreducible - Test if element is irreducible

Inherited from `Cat::Field`.

Dom::IntegerMod

isUnit - Test if element is an unit

Inherited from `Cat::Field`.

isone - Test if element is one

Inherited from `Cat::Monoid`.

lcm - Least common multiple

Inherited from `Cat::GcdDomain`.

quo - Return Euclidean quotient

Inherited from `Cat::Field`.

rem - Return Euclidean remainder

Inherited from `Cat::Field`.

sqrfree - Square-free factorization

Inherited from `Cat::Field`.

testtype - Test type of object

Inherited from `Cat::BaseCategory`.

isSquare - Test for being a square

`isSquare(element)`

iszero - Zero test

`iszero(element)`

ln - Discrete logarithm

`ln(element, base)`

The result is infinity if `element` is not in the subgroup generated by `base`.

The result is FAIL if `base` is not a unit.

order - Order

`order(element)`

The result is FAIL if element is not a unit.

Access Methods

subs - Avoid substitution

Inherited from Dom::BaseDomain.

subsex - Avoid extended substitution

Inherited from Dom::BaseDomain.

Conversion Methods

TeX - TeX output

TeX(element)

convert - Conversion

convert(number)

The conversion fails if the denominator of number and the modulus n are not relatively prime.

convert_to - Conversion

convert_to(element, d)

expr - Convert an element to an expression

expr(element)

Technical Methods

allAxioms - Return all axioms

Inherited from Dom::BaseDomain.

allCategories - Return all categories

Inherited from Dom::BaseDomain.

allEntries - Return the names of all entries

Inherited from Dom::BaseDomain.

Dom::IntegerMod

allSuperDomains - Return all super-domains

Inherited from Dom::BaseDomain.

getAxioms - Return axioms stated in the constructor

Inherited from Dom::BaseDomain.

getCategories - Return categories stated in the constructor

Inherited from Dom::BaseDomain.

getSuperDomain - Return super-domain stated in the constructor

Inherited from Dom::BaseDomain.

hasProp - Test for a certain property

Inherited from Dom::BaseDomain.

info - Print short information about this domain

Inherited from Dom::BaseDomain.

new - Create element of this domain

Inherited from Cat::BaseCategory.

print - Printing elements

```
print(element)
```

printMethods - Print out methods

Inherited from Dom::BaseDomain.

random - Random element

```
random()
```

undefinedEntries - Return missing entries

Inherited from Dom::BaseDomain.

unitNormal - Unit normal form

Inherited from Cat::Field.

unitNormalRep - Unit normal representation

Inherited from `Cat::Field`.

whichEntry - Return the domain or category implementing an entry

Inherited from `Dom::BaseDomain`.

MuPAD Domains

`Dom::Integer` | `Dom::GaloisField`

Dom::Interval

Purpose Intervals of real numbers

Syntax Dom::Interval(l, r)
Dom::Interval([l], r)
Dom::Interval(l, [r])
Dom::Interval([l], [r])
Dom::Interval([l, r])

Description Dom::Interval represents the set of all intervals of real numbers.

Dom::Interval(l, r) creates the interval of all real numbers between l and r. If a border is given as a list with l or r as the sole element, this border will be regarded as a closed border, otherwise the interval does not contain l and r.

A border can be any arithmetical expression that could represent a real number, e.g., sqrt(2*x) and a + I. Properties are ignored.

The domain Dom::Interval provides fundamental operations to combine intervals with intervals and other mathematical objects.

The return value can be either an interval of type Dom::Interval or the empty set of type DOM_SET, if the interval is empty.

Most mathematical operations are overloaded to work with intervals (such as sin). If f is a function of n real variables, its extension to intervals is defined to be $f(J_1, \dots, J_n) = \{f(j_1, \dots, j_n) \mid j_i \in J_i\}$. The return value of such an operation is in most cases an interval, a union of intervals, a Dom::ImageSet or a set. For example, the sine of an interval $[a, b]$ is the interval $\{\sin(x), x \text{ in } [a, b]\}$ that contains all sine values of the given interval. In general, you should expect the return value to be an interval larger than strictly necessary. Also note that, when using the same interval twice in one formula, the uses are regarded as independent, so interval1/interval1 does not return the interval $[1, 1]$ as you might expect.

The functions overloaded in this way are:

- `_mult`, `_divide`, `_invert`, `_power`

- `_plus`, `_negate`, `_subtract`
- `abs`
- `cos`, `arccos`, `cosh`, `arccosh`, `cot`, `arccot`, `coth`, `arccoth`, `csc`, `arccsc`, `csch`, `arccsch`, `sec`, `arcsec`, `sech`, `arcsech`, `sin`, `arcsin`, `sinh`, `arcsinh`, `tan`, `arctan`, `tanh`, `arctanh`
- `dirac`, `heaviside`
- `exp`, `ln`
- `sign`

Furthermore, an interval is a special type of set. This is reflected by `Dom::Interval` having the category `Cat::Set`. Among the methods inherited from `Cat::Set`, the following are especially important: `intersect`, `minus` and `union`.

An interval can be open or closed. If one border is given as a list with one element `[x]`, then this element `x` is taken as border and the interval will be created as closed at this side. If the interval should be closed at both sides, one list with the both borders as arguments can be given.

Superdomain `Dom::BaseDomain`

Categories `Cat::Set`, `Cat::AbelianMonoid`

Examples **Example 1**

First create a closed interval between 0 and 1.

```
A:= Dom::Interval([0], [1])
```

```
[0, 1]
```

Now another open interval between -1 and 1.

```
B:= Dom::Interval(-1, 1)
```

Dom::Interval

```
(-1, 1)
```

Intervals can be handled like other objects.

```
A + B, A - B, A*B, A/B
```

```
(-1, 2), (-1, 2), (-1, 1), ℝ
```

```
2*A, 1 - A, (A - 1)^2
```

```
[0, 2], [0, 1], [0, 1]
```

Example 2

Standard functions are overloaded to work with intervals.

```
sin(B), float(sin(B))
```

```
(-sin(1), sin(1)), (-0.8414709848, 0.8414709848)
```

Example 3

The next examples show some technical methods to access and manipulate intervals.

Get the borders and open/closed information about intervals.

```
A:= Dom::Interval([0], [1]):  
Dom::Interval::left(A), Dom::Interval::leftB(A)
```

```
0, [0]
```

```
Dom::Interval::isleftopen(A), Dom::Interval::subleft(A, -1)
```

```
FALSE, [-1, 1]
```

Parameters

l

The left border. If given as a list of one element (the left border), the interval will be created as left closed.

r

The right border. If given as a list of one element (the right border), the interval will be created as right closed.

Entries

"one"

the unit element; it equals the one-point interval [1, 1].

"zero"

the zero element; it equals the one-point interval [0, 0].

Methods

Mathematical Methods

Im - Imaginary part of an interval (this always equals zero)

`Im(interval)`

Re - Real part of an interval (this is the interval)

`Re(interval)`

divide - Divide intervals

`_divide(interval1, interval2)`

intersect - Intersection of sets

Inherited from `Cat::Set`.

invert - Invert intervals

`_invert(interval)`

minus - Set of subtractions

Inherited from `Cat::Set`.

mult - Set of product of set elements

Dom::Interval

Inherited from `Cat::Set`.

_negate - Negate intervals

`_negate(interval)`

_plus - Set of sums of set elements

Inherited from `Cat::Set`.

_power - Pointwise power

Inherited from `Cat::Set`.

_union - Union of sets

Inherited from `Cat::Set`.

abs - Absolute value of intervals

`abs(interval)`

arccos - Inverse cosine of intervals

`arccos(interval)`

arccosh - Area cosine of intervals

`arccosh(interval)`

arccot - Inverse cotangent of intervals

`arccot(interval)`

arccoth - Area cotangent of intervals

`arccoth(interval)`

arcsin - Inverse sine of intervals

`arcsin(interval)`

arcsinh - Area sine of intervals

`arcsinh(interval)`

arctan - Inverse tangent of intervals

`arctan(interval)`

arctanh - Area tangent of intervals

arctanh(interval)

coerce - Coerce into this domain

Inherited from `Cat::BaseCategory`.

contains - Containing an element

contains(interval, element)

cos - Cosinu of intervals

cos(interval)

cosh - Hyperbolic cosinus of intervals

cosh(interval)

cot - Cotangent of intervals

cot(interval)

coth - Hyperbolic cotangent of intervals

coth(interval)

dirac - Dirac distribution of an interval

dirac(interval)

equiv - Test for equivalence

Inherited from `Cat::BaseCategory`.

exp - Exponential function of an interval

exp(interval)

heaviside - Heaviside function

heaviside(interval)

intmult - Return integer multiple

Inherited from `Cat::AbelianMonoid`.

ln - Natural logarithm of an interval

Dom::Interval

`ln(interval)`

max - Maximum of an interval

`max(interval,)`

The maximum of intervals is the set of all possible results of the function `max` when applied to a sequence of arguments consisting of exactly one element of each interval.

min - Minimum of an interval

`min(interval,)`

The minimum of intervals is defined analogously to their maximum.

new - Create an interval

`new(left, right)`

`new([left], right)`

`new(left, [right])`

`new([left], [right])`

sign - Signum of an interval

`sign(interval)`

sin - Sine of intervals

`sin(interval)`

sinh - Hyperbolic sine of intervals

`sinh(interval)`

tan - Tangent of intervals

`tan(interval)`

tanh - Hyperbolic tangent of intervals

`tanh(interval)`

Access Methods

borders - Border of an interval

borders(interval)

left - Left border of an interval

left(interval)

leftB - Left border of an interval

leftB(interval)

isleftopen - Left open interval

isleftopen(interval)

isrightopen - Right open interval

isrightopen(interval)

iszero - Null interval

iszero(interval)

op - Operand (borders) of an interval

op(interval)

subs - Substitution in intervals

subs(Interval, equation,)

subsex - Avoid extended substitution

Inherited from Dom::BaseDomain.

subsleft - Substitute left border

subsleft(interval, left)

subsright - Substitute right border

subsright(interval, right)

subsvals - Substitute both borders

subsvals(interval, left, right)

Dom::Interval

Conversion Methods

convert - Converting objects to intervals

`convert(object)`

If the conversion fails, FAIL is returned.

convert_to - Convert element

Inherited from `Dom::BaseDomain`.

float - Convert to floating-point interval

`float(interval)`

getElement - One element of an interval

`getElement(interval)`

simplify - Simplify intervals

`simplify(interval)`

testtype - Test type of object

Inherited from `Cat::BaseCategory`.

TeX - Generate TeX output

Inherited from `Dom::BaseDomain`.

Technical Methods

allAxioms - Return all axioms

Inherited from `Dom::BaseDomain`.

allCategories - Return all categories

Inherited from `Dom::BaseDomain`.

allEntries - Return the names of all entries

Inherited from `Dom::BaseDomain`.

allSuperDomains - Return all super-domains

Inherited from Dom::BaseDomain.

emptycheck - Check intervals

emptycheck(interval)

equal - Comparison of intervals

equal(interval, interval)

getAxioms - Return axioms stated in the constructor

Inherited from Dom::BaseDomain.

getCategories - Return categories stated in the constructor

Inherited from Dom::BaseDomain.

getSuperDomain - Return super-domain stated in the constructor

Inherited from Dom::BaseDomain.

hasProp - Test for a certain property

Inherited from Dom::BaseDomain.

info - Print short information about this domain

Inherited from Dom::BaseDomain.

map - Apply functions to intervals

map(interval, function, <argument, >)

mapBorders - Apply functions to the borders of an interval

mapBorders(interval, function, <argument, >)

print - Printing intervals

print(interval)

printMethods - Print out methods

Inherited from Dom::BaseDomain.

random - Random interval

random()

Dom::Interval

undefinedEntries - Return missing entries

Inherited from Dom::BaseDomain.

whichEntry - Return the domain or category implementing an entry

Inherited from Dom::BaseDomain.

zip - Combine intervals

zip(interval, interval, function)

Algorithms

The operand of an object of Dom::Interval is an object of the domain property::IVnat, which realizes the basic interval arithmetic. This domain is not documented.

MuPAD Functions

Type::Interval

Dom::LinearOrdinaryDifferentialOperator

Purpose

Domain of linear ordinary differential operators

Syntax

Domain Creation

Dom::LinearOrdinaryDifferentialOperator(<Var,
<DVar, <Ring>>>)

Element Creation

Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(p)
Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)(l)
Dom::LinearOrdinaryDifferentialOperator(Var,
DVar, Ring)(eq, yx)

Description

Dom::LinearOrdinaryDifferentialOperator(Var, DVar, Ring)
creates the domain of linear ordinary differential operators with
coefficients in the differential ring Ring and with derivation Var
where DVar is the differential indeterminate. Elements of this
domain are also called Ore polynomials and the multiplication
of two elements is completely determined by the prescribed

rule $\text{Var } r = r \text{ Var} + \frac{\partial}{\partial \text{DVar}} r$ for every element r in Ring. And so
Dom::LinearOrdinaryDifferentialOperator is a noncommutative
ring.

Note Nevertheless, for some reasons, for every element r in Ring,
 $\text{Var} * r$ is automatically rewritten as $r * \text{Var}$. See “Example 1” on page
6-226.

If Dom::LinearOrdinaryDifferentialOperator is called
without any argument, a domain with coefficients in
Dom::ExpressionField(normal) with derivation Df and differential
indeterminate x is created.

Dom::LinearOrdinaryDifferentialOperator

Note Only commutative differential rings of type `DOM_DOMAIN` are allowed which inherit from `Dom::BaseDomain`. If `Ring` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it can happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Examples

Example 1

First we create the domain of linear ordinary differential operators:

```
lodo := Dom::LinearOrdinaryDifferentialOperator()
```

```
Dom::LinearOrdinaryDifferentialOperator(Df, x, Dom::ExpressionField(normal, iszero ◦ normal))
```

by default the above domain has coefficients in the field `Dom::ExpressionField(normal)` with derivation `Df` and differential indeterminate `x`.

We can create elements of `lodo` in 3 ways: polynomials in `Df`, list of elements of `Dom::ExpressionField` and with a linear ordinary homogeneous differential equation:

```
lodo(Df^2 + (x + 1)*Df + 2*x), lodo([2*x, x + 1, 1]),  
lodo(diff(y(x),x,x) + (x + 1)*diff(y(x),x) + 2*x*y(x), y(x)))
```

```
Df2 + (x + 1) Df + 2 x, Df2 + (x + 1) Df + 2 x, Df2 + (x + 1) Df + 2 x
```

It's easy to obtain the linear differential equation associated to a linear differential operator:

Dom::LinearOrdinaryDifferentialOperator

```
L := lodo((x + x^3)*Df^3 + (6*x^2 + 3)*Df^2 - 12):
L(y(x))
```

$$6x^2 \frac{\partial^2}{\partial x^2} y(x) - 12 y(x) + x \frac{\partial^3}{\partial x^3} y(x) + x^3 \frac{\partial^3}{\partial x^3} y(x) + 3 \frac{\partial^2}{\partial x^2} y(x)$$

and one can also evaluates a differential operator at an expression:

```
L(2*x^2 + 1), L(ln(x)), L(ln(x), Unsimplified)
```

$$0, -\frac{12x^2 \ln(x) + 4x^2 + 1}{x^2}, \frac{2(x^3 + x)}{x^3} - \frac{6x^2 + 3}{x^2} - 12 \ln(x)$$

Multiplication of elements of lodo is noncommutative but for every element r of the coefficients ring one has $Df * r = r * Df$:

```
lodo(x^2*Df), lodo(Df*x^2), lodo(Df)*lodo(x^2)
```

$$x^2 Df, x^2 Df, x^2 Df + 2x$$

Example 2

Dom::LinearOrdinaryDifferentialOperator is a domain where the Euclidean division exists but one has to precise if the multiplication of 2 elements of this domain is made on the right or on the left side:

```
L1 := lodo(x*Df^3 + (x^2 - 3)*Df^2 + 4*x*Df + 2):
lodo::leftDivide(L1, lodo(x*Df + 1))
```

quotient	$Df^2 + \frac{Df(x^2 - 4)}{x} + 2$
remainder	0

```
lodo(x*Df + 1) * %[quotient] = L1
```

Dom::LinearOrdinaryDifferentialOperator

$$x Df^3 + (x^2 - 3) Df^2 + (4x) Df + 2 = x Df^3 + (x^2 - 3) Df^2 + (4x) Df + 2$$

Hence one has the notions of greatest common divisor, least common multiple on the right and on the left, and a modified version of the extended Euclidean algorithm:

```
L2 := lodo(x*Df + 1):  
ree := lodo::rightExtendedEuclid(L1,L2)
```

$$\left[\left[-\frac{12}{x^2}, 1, -Df^2 - \frac{x^2 - 6}{x} Df - \frac{2(x^2 + 6)}{x^2} \right], \right. \\ \left. \left[\frac{x^3}{12} Df + \frac{x^2}{4}, -\frac{x^3}{12} Df^3 + \left(\frac{x^2}{4} - \frac{x^4}{12} \right) Df^2 - \frac{x^3}{2} Df - \frac{x^2}{2} \right] \right]$$

The right greatest common divisor and the left least common multiple can be read from the above list:

```
iszero(lodo::rightGcd(L1,L2) - ree[1][1]),  
iszero(ree[1][1] - (ree[1][2]*L1 + ree[1][3]*L2)),  
iszero(lodo::leftLcm(L1,L2) - (-ree[2][1]*L1)),  
iszero(-ree[2][1]*L1 - ree[2][2]*L2)
```

TRUE, TRUE, TRUE, TRUE

Example 3

One can compute polynomial, rational and exponential zeros of linear differential operators of any degree provided the ring Ring is the field of rational functions of x

```
L3 := lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12):  
lodo::rationalZeros(L3), lodo::exponentialZeros(L3)
```

Dom::LinearOrdinaryDifferentialOperator

$$\left\{x^2 + \frac{1}{2}\right\}, \left\{x^2 + \frac{1}{2}, x \sqrt{x^2 + 1}\right\}$$

even when the operator contains some parameters rationally:

```
lodo::exponentialZeros(
lodo(Df^4 + (b*1 - 2*a^2 - a*1*x)*Df^2 + a^4-a^2*b*1 + a^3*1*x))
```

$$\{e^{ax}, e^{-ax}\}$$

Example 4

One can factorize linear differential operators into irreducible factors when the ring Ring is the field of rational functions of x . Nevertheless, the algorithm is complete only for operators of degree at most 3; for higher degree only left and right factors of degree 1 are found:

```
factor(lodo((x^2 + 1)*x*Df^3 + 3*(2*x^2 + 1)*Df^2 - 12)),
factor(lodo(Df^3 + a*x*Df + a + b^3 + a*b*x))
```

$$\left((x(x^2 + 1)) Df + 5x^2 + 3\right) \left(Df + \frac{x(6x^2 + 5)}{(x^2 + 1)(2x^2 + 1)}\right) \left(Df - \frac{4x}{2x^2 + 1}\right),$$

$$(Df + b) (Df^2 - b Df + ax + b^2)$$

Here the operator factors into two factors of degree 2 which cannot be found by MuPAD:

```
factor(lodo(Df^2 + x^3 + 1/x^3) * lodo(Df^2 + x^2 - 1/x^3))
```

$$Df^4 + (x^2 + x^3) Df^2 + \frac{2(2x^5 + 3)}{x^4} Df + \frac{-12x + x^5 + x^6 + x^{11} - 1}{x^6}$$

Dom::LinearOrdinaryDifferentialOperator

Example 5

Solving linear differential operators using the command `solve` is also possible:

```
solve(lodo(Df^2 + (3 - x)/(16*x^2)))
```

$$\left\{ x^{1/4} e^{-\frac{\sqrt{x}}{2}}, x^{1/4} e^{\frac{\sqrt{x}}{2}} \right\}$$

For certain cases, where the groups associated to the differential operators are finite primitive groups of degree 2, a polynomial is returned corresponding to the minimal polynomial of all zeros of the differential operator (they are algebraic over the base field):

```
solve(lodo(Df^2 + (-27*x + 32*x^2 + 27)/(144*x^2 - 288*x^3 + 144*x^4)))
```

$$\left\{ \text{RootOf}\left(Y^{124} + (-4320 x^2 (x-1)^3) Y^{16} + ((51840 \sqrt{3} i) x^3 (x-2) (x-1)^4) Y^{12} \right. \right. \\ \left. \left. + (-2799360 x^4 (x-1)^6) Y^8 + ((4478976 \sqrt{3} i) x^5 (x-2) (x-1)^7) Y^4 \right. \right. \\ \left. \left. + 2985984 x^8 (x-1)^8, Y \right) \right\}$$

For linear differential operators of degree greater than 3 only exponential zeros will be found:

```
solve(lodo(x*Df^4 + (-x + 4)*Df^3 - 3*Df^2 - x^2*Df - x + x^2))
```

$$\left\{ \frac{e^x}{x} \right\}$$

Dom::LinearOrdinaryDifferentialOperator

Certain second degree linear differential operator can be solved in terms of some special functions (nonliouvillian functions) such as `airyAi`, `besseli` and `whittakerM`:

```
solve(lodo(Df^2 - (x + 1)/(x - 1)^5))
```

```
{airyAi(σ1, 0) (x - 1), airyBi(σ1, 0) (x - 1)}
```

where

$$\sigma_1 = -\frac{2^{2/3} \sqrt{3} i + 2^{2/3} x + 2^{2/3} + 2^{2/3} \sqrt{3} x i}{8x - 8}$$

```
solve(lodo(Df^2 - (243 + 4*x^8 + 162*x^2 + 19*x^4)/
          36/x^2/(x^2 + 3)^2))
```

$$\left\{ \frac{M_{\frac{1}{2}, -\frac{2}{3}}\left(\frac{x^2}{3} + 1\right)}{\sqrt{x}}, \frac{W_{\frac{1}{2}, -\frac{2}{3}}\left(\frac{x^2}{3} + 1\right)}{\sqrt{x}} \right\}$$

Parameters

Var

An indeterminate of type `DOM_IDENT`. Default is `Df`.

DVar

A differential indeterminate of type `DOM_IDENT`. Default is `x`.

Ring

An arbitrary commutative differential ring of characteristic zero. Default is `Dom::ExpressionField(normal)`.

P

A polynomial expression in `Var`.

I

Dom::LinearOrdinaryDifferentialOperator

A list corresponding to the coefficients of the differential operator. If n is the length of l then the result returned is $l[1] + l[2]*\text{Var} + \dots + l[n]*\text{Var}^{(n-1)}$.

eq

A linear homogeneous differential equation.

yx

A function of DVar representing the dependent variable of the above linear differential equation.

Methods

Mathematical Methods

`_mult` - Multiplie linear differential operators

`_mult(<a, b, >)`

This method overloads the function `_mult` of the system kernel, i.e. one may use it either in the form `a * b * ...` or in functional notation `_mult(a, b, ...)`.

`_negate` - Negate a linear differential operator

`_negate(a)`

This method overloads the function `_negate` of the system kernel, i.e. one may use it either in the form `-a` or in functional notation `_negate(a)`.

`_plus` - Add linear differential operators and coefficient ring elements

`_plus(<a, b, >)`

This method overloads the function `_plus` of the system kernel, i.e. one may use it either in the form `a + b + ...` or in functional notation `_plus(a, b, ...)`.

`_power` - Nth power of a linear differential operator

`_power(a, n)`

Dom::LinearOrdinaryDifferentialOperator

This method overloads the function `_power` of the system kernel, i.e., one may use it either in the form a^n or in functional notation `_power(a, n)`.

`_subtract` - Subtract a linear differential operator

`_subtract(a, b)`

This method overloads the function `_subtract` of the system kernel, i.e. one may use it either in the form $a - b$ or in functional notation `_subtract(a, b)`.

`adjoint` - Adjoint of a linear differential operator

`adjoint(a)`

`companionSystem` - Companion matrix of a linear differential operator

`companionSystem(a)`

If a is not of positive degree, an error message is issued.

`D` - Derivative of a linear differential operator

`D(<l>, a)`

`Dpoly` - Derivative of a linear differential operator

`Dpoly(<l>, a)`

`Dpoly(l, a)` computes the partial derivative of a with respect to l . If $l = [1, \dots, 1]$ with $\text{length}(l) = n$ then the method computes the n -th derivative a . If $l = []$ then the result returned is a .

`evalLODO` - Apply an expression to a linear differential operator

`evalLODO(a, f)`

This method may be used either in the form $a(f)$ or in functional notation `evalLODO(a, f)`.

`exponentialZeros` - Exponential zeros of a linear differential operator

`exponentialZeros(a)`

Dom::LinearOrdinaryDifferentialOperator

Note This method only works when Ring is the field of rational functions in DVar.

factor - Factor a linear differential operator

factor(a)

Note This method is only available when the base field Ring is the field of rational functions in DVar. If a is of degree greater than or equal to 4 then only left and right factors of degree 1 of a will be found. Otherwise, a complete factorization is returned.

This method overloads the function factor of the system kernel.

factors - List of irreducible factors of a linear differential operator

factors(a)

func_call - Apply an expression to a linear differential operator

func_call(a, f, <Unsimpified>)

This method may be used either in the form a(f) or in functional notation func_call(a,f).

leftDivide - Left division of 2 linear differential operators

leftDivide(a, b)

leftExtendedEuclid - Left extended Euclidean algorithm for linear differential operators

leftExtendedEuclid(a, b)

leftExtendedGcd - Coefficient in the left extended Euclidean algorithm

leftExtendedGcd(a, b)

Dom::LinearOrdinaryDifferentialOperator

leftGcd - Left greatest common divisor of linear differential operators

```
leftGcd(a, b)
```

leftLcm - Left least common multiple of linear differential operators

```
leftLcm(a, b)
```

leftQuotient - Left quotient of linear differential operators

```
leftQuotient(a, b)
```

leftRemainder - Left remainder of linear differential operators

```
leftRemainder(a, b)
```

makeIntegral - Integral form of a linear differential operator

```
makeIntegral(a)
```

monic - Normalize a linear differential operator

```
monic(a)
```

polynomialZeros - Polynomial zeros of a linear differential operator

```
polynomialZeros(a)
```

Note This method only works when Ring is the field of rational functions in DVar.

rationalZeros - Rational zeros of a linear differential operator

```
rationalZeros(a)
```

Note This method only works when Ring is the field of rational functions in DVar.

Dom::LinearOrdinaryDifferentialOperator

rightDivide - Right division of 2 linear differential operators

rightDivide(a, b)

rightExtendedEuclid - Right extended Euclidean algorithm for linear differential operators

rightExtendedEuclid(a, b)

rightExtendedGcd - Coefficient in the right extended Euclidean algorithm

rightExtendedGcd(a, b)

rightGcd - Right greatest common divisor of linear differential operators

rightGcd(a, b)

rightLcm - Right least common multiple of linear differential operators

rightLcm(a, b)

rightQuotient - Right quotient of linear differential operators

rightQuotient(a, b)

rightRemainder - Right remainder of linear differential operators

rightRemainder(a, b)

solve - Zero of a linear differential operator

solve(a, <Transform>, <Irreducible>)

The algorithm for finding liouvillian solutions is complete for operators of degree at most 2 and enables to solve partially operators of higher degree (i.e. it finds all exponential solutions). The algorithm for finding solutions in terms of special functions (nonliouvillian solutions) is not complete even for the degree 2.

When option Transform is given the unimodular transformation is performed unconditionally and when option Irreducible is given, a is assumed to be irreducible.

Note This method only works when Ring is the field of rational functions in DVar.

This method overloads the function solve of the system kernel.

symmetricPower - Symmetric power of a linear differential operator

symmetricPower(a, m)

unimodular - Unimodular transformation of a linear differential operator

unimodular(a, <Transform>)

If the option Transform is given then a is transformed unconditionally even if a has yet a unimodular Galois group.

Access Methods

coeff - Coefficient of a linear differential operator

coeff(a)

coeff(a, Var, n)

coeff(a, n)

coeff(a, Var, n) returns the coefficient of the term Var^n as an element of the coefficient ring Ring, where a is a linear differential operator in the variable Var.

coeff(a, n) returns the coefficient of the term Var^n as an element of the coefficient ring Ring, where a is a linear differential operator in the variable Var.

This method overloads the function coeff of the system kernel.

degree - Degree of a linear differential operator

degree(a)

Dom::LinearOrdinaryDifferentialOperator

The degree of the zero polynomial is defined as zero.

This method overloads the function degree for polynomials.

vectorize - List of coefficients of a linear differential operator

`vectorize(a)`

Conversion Methods

convert - Conversion to a linear differential operator

`convert(a)`

FAIL is returned if the conversion fails.

expr - Conversion into an object of a kernel domain

`expr(a)`

This method overloads the function `expr` of the system kernel.

TeX - TeX formatting of a linear differential operator

`TeX(a)`

This method is used by the function `generate::TeX`.

Description **Domain Creation**

Dom::Matrix(R) creates domains of matrices over a component domain R of category Cat::Rng (a ring, possibly without unit).

If the optional parameter R is not given, Dom::ExpressionField() is used as component domain. Matrices of this type accept arbitrary

MuPAD expressions (numbers, symbols etc.) as entries. The name `matrix` is an alias for this default matrix domain `Dom::Matrix()`.

A vector with n entries is either an $n \times 1$ matrix (a column vector), or a $1 \times n$ matrix (a row vector).

Arithmetical operations with matrices can be performed by using the standard arithmetical operators of MuPAD.

E.g., if A and B are two matrices defined by `Dom::Matrix(R)`, $A + B$ computes the sum, and $A * B$ computes the product of the two matrices, provided that the dimensions are appropriate.

Similarly, A^{-1} or $1/A$ computes the inverse of a square matrix A if it exists. Otherwise, FAIL is returned. See “Example 1” on page 6-245.

Many system functions are overloaded for matrices, such as `map`, `subs`, `has`, `zip`. E.g., use `conjugate` to compute the complex conjugate of a matrix, `norm` to compute matrix norms, or `exp` to compute the exponential of a matrix.

Most of the functions in the MuPAD linear algebra package `linalg` work with matrices. For example, the command `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on A to transform A to its reduced row echelon form.

See the documentation of `linalg` for a list of available functions of this package.

The domain `Dom::Matrix(R)` represents matrices over R of arbitrary size. Therefore, it does not have any algebraic structure (other than being a *set* of matrices).

In this help page, we use the following notations for a matrix A (an element of `Dom::Matrix(R)`):

- $nrows(A)$ denotes the number of rows of A .
- $ncols(A)$ denotes the number of columns of A .
- A *row index* is an integer in the range from 1 to $nrows(A)$.
- A *column index* is an integer in the range from 1 to $ncols(A)$.

Note The number of rows and columns, respectively, of a matrix must be less than 2^{31} .

Note The components of a matrix are no longer evaluated after the creation of the matrix, i.e., if they contain free identifiers they will not be replaced by their values.

Element Creation

`Dom::Matrix(R) (Array)` and `Dom::Matrix(R) (Matrix)` create a new matrix with the dimension and the components of `Array` and `Matrix`, respectively.

The components of `Array` or `Matrix` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

The creation of (sparse) matrices via arrays is useful for matrices of moderate size. Note that indexed assignments to arrays are much faster than the corresponding indexed assignments to matrices. However, since all elements of the array (including the zeroes) need to be filled in before conversion to a (sparse) matrix, memory is wasted for very large and very sparse matrices. In such a situation, one should define a table containing only the non-zero elements and convert the table to a matrix (see below).

`Dom::Matrix(R) (List)` creates an $m \times 1$ column vector with components taken from the nonempty list, where m is the number of entries of `List`.

One may also use a list of equations to create an object of `Dom::Matrix`. In this case the entries of the list must be of the form $(i, j) = \text{value}$, where i and j denote the row and column index and `value` the coefficient of the matrix. i and j need to be positive integers.

`Dom::Matrix(R) (ListOfRows)` creates an $m \times n$ matrix with components taken from the nested list `ListOfRows`, where m is the number of inner lists of `ListOfRows`, and n is the maximal number of elements of an

inner list. Each inner list corresponds to a row of the matrix. Both m and n must be non-zero.

If an inner list has less than n entries, the remaining components in the corresponding row of the matrix are set to zero.

The entries of the inner lists are converted to elements of the domain R . An error message is issued if one of these conversions fails.

The call `Dom::Matrix(R)(m, n)` returns the $m \times n$ zero matrix.

Use the method "identity" to create the $n \times n$ identity matrix.

The call `Dom::Matrix(R)(m, n, Array)` creates an $m \times n$ matrix with components taken from `Array`, which must be an array or an `hfarray`. `Array` must have mn operands. The first m operands define the first row, the next m operands define the second row, etc. The formatting of the array is irrelevant. E.g., any array with 6 elements can be used to create a matrix of dimension 1×6 , or 2×3 , or 3×2 , or 6×1 .

`Dom::Matrix(R)(m, n, List)` creates an $m \times n$ matrix with components taken row after row from the non-empty list. The list must contain mn entries.

`Dom::Matrix(R)(m, n, ListOfRows)` creates an $m \times n$ matrix with components taken from the list `ListOfRows`.

If $m \geq 2$ and $n \geq 2$, then `ListOfRows` must consist of at most m inner lists, each having at most n entries. The inner lists correspond to the rows of the returned matrix.

If an inner list has less than n entries, the remaining components of the corresponding row of the matrix are set to zero. If there are less than m inner lists, the remaining lower rows of the matrix are filled with zeroes.

`Dom::Matrix(R)(m, n, Table)` creates an $m \times n$ matrix with components taken from the table `Table`.

By defining the entries of the table first, one can easily create large and sparse matrices. The entry `Table[i, j]` of the table will be the entry in the i -th row and the j -th column of the matrix. Therefore, the table needs to be indexed by positive integers i and j .

Dom::Matrix

`Dom::Matrix(R)(m, n, [(i1, j1) = value1, (i2, j2) = value2, ...])` is a further way to create a matrix specifying only the non-zero entries $A[i1, j1] = \text{value1}$, $A[i2, j2] = \text{value2}$ etc. The ordering of the entries in the input list is irrelevant.

`Dom::Matrix(R)(m, n, f)` returns the matrix whose (i, j) -th component is the value of the function call $f(i, j)$. The row index i ranges from 1 to m and the column index j from 1 to n .

The function values are converted to elements of the domain R . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Array)` returns the $1 \times n$ row vector with components taken from `Array`. The array or `hfarray` `Array` must have n entries.

The entries of the array are converted to elements of the domain R . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, List)` returns the $1 \times n$ row vector with components taken from `List`. The list `List` must have at most n entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain R . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(1, n, Table)` returns the $1 \times n$ row vector with components taken from `Table`. The table `Table` must not have more than n entries. If there are fewer entries, the remaining vector components are regarded as zero.

`Dom::Matrix(R)(m, 1, Array)` returns the $m \times 1$ column vector with components taken from `Array`. The array or `hfarray` `Array` must have m entries.

The entries of the array are converted to elements of the domain R . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, List)` returns the $m \times 1$ column vector with components taken from `List`. The list `List` must have at most m

entries. If there are fewer entries, the remaining vector components are set to zero.

The entries of the list are converted to elements of the domain R . An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, 1, Table)` returns the $m \times 1$ column vector with components taken from `Table`. The table `Table` must have no more than m entries. If there are fewer entries, the remaining vector components are regarded as zero.

Superdomain `Dom::BaseDomain`

Axioms If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories `Cat::Matrix(R)`

Examples **Example 1**

Whenever possible, one should use `Dom::ExpressionField()` as the coefficient domain of matrices – therefore `Dom::ExpressionField()` is the default coefficient domain of matrices.

The components of matrices over `Dom::ExpressionField()` can be arbitrary arithmetical expressions. Consider

```
Mat := Dom::Matrix()
```

```
Dom::Matrix()
```

We assigned the domain to the identifier `Mat` and now we can define a matrix A of two rows, where each row is a list of two elements by the following line:

```
A := Mat([[1, 5], [2, 3]])
```

Dom::Matrix

$$\begin{pmatrix} 1 & 5 \\ 2 & 3 \end{pmatrix}$$

In the same way, we define the following 2×3 matrix:

```
B := Mat([[ -1, 5/2, 3], [1/3, 0, 2/5]])
```

$$\begin{pmatrix} -1 & \frac{5}{2} & 3 \\ \frac{1}{3} & 0 & \frac{2}{5} \end{pmatrix}$$

and perform matrix arithmetic using the standard arithmetical operators of MuPAD, e.g., the matrix product AB , the fourth power of A as well as the scalar multiplication of A times $\frac{1}{3}$:

```
A * B, A ^ 4, 1/3 * A
```

$$\begin{pmatrix} \frac{2}{3} & \frac{5}{2} & 5 \\ -1 & 5 & \frac{36}{5} \end{pmatrix}, \begin{pmatrix} 281 & 600 \\ 240 & 521 \end{pmatrix}, \begin{pmatrix} \frac{1}{3} & \frac{5}{3} \\ \frac{2}{3} & 1 \end{pmatrix}$$

The matrices A and B have different dimensions, and therefore the sum of A and B is not defined. MuPAD issues an error message:

```
A + B
```

```
Error: The dimensions do not match. [(Dom::Matrix(Dom::ExpressionFi
```

To compute the inverse of A , just enter:

```
1/A
```

$$\begin{pmatrix} -\frac{3}{7} & \frac{5}{7} \\ \frac{2}{7} & -\frac{1}{7} \end{pmatrix}$$

If a matrix is not invertible, FAIL is the result of this operation. For example, the matrix:

```
C := Mat(2, 2, [[2]])
```

$$\begin{pmatrix} 2 & 0 \\ 0 & 0 \end{pmatrix}$$

is not invertible, hence:

```
C^(-1)
```

```
FAIL
```

```
delete A, B, C:
```

Example 2

We create the domain of matrices over the coefficient ring
Dom::ExpressionField():

```
Mat := Dom::Matrix()
```

```
Dom::Matrix()
```

Beside standard matrix arithmetic, the library linalg offers many functions dealing with matrices. For example, if one wants to compute the rank of a matrix, use linalg::rank:

```
A := Mat([[1, 2], [2, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix}$$

```
linalg::rank(A)
```

```
1
```

Use `linalg::eigenvectors` to compute eigenvalues and eigenvectors of the matrix A :

```
linalg::eigenvectors(A)
```

$$\left[\left[0, 1, \left[\begin{pmatrix} -2 \\ 1 \end{pmatrix} \right] \right], \left[5, 1, \left[\begin{pmatrix} \frac{1}{2} \\ 1 \end{pmatrix} \right] \right] \right]$$

Try `info(linalg)` for a list of available functions, or enter `help(linalg)` for details about the library `linalg`.

Some of the functions in the `linalg` package simply serve as “interface” functions for methods of a matrix domain described above. For example, `linalg::transpose` uses the method “`transpose`” to get the transposed matrix. The function `linalg::gaussElim` applies Gaussian elimination to a matrix by calling the method “`gaussElim`”:

```
linalg::gaussElim(A) = A::dom::gaussElim(A)[1]
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

In contrast to the methods of the domain `Dom::Matrix(R)`, the corresponding functions of the `linalg` packages do extended checking of their input parameters. Note that there might be minor differences in the functionality of the `linalg` functions and the matrix methods. E.g., the option `ColumnElimination` is not available in `linalg::gaussElim`, but only in the “`gaussElim`” method of the matrix domain:

```
A::dom::gaussElim(A, ColumnElimination)
```

$$\left[\begin{pmatrix} 1 & 0 \\ 2 & 0 \end{pmatrix}, 1, 0, \{1\} \right]$$

```
delete A:
```

Example 3

We create the default matrix domain `Dom::Matrix()`. As a shortcut, this domain can also be created via `matrix`:

```
A := matrix([[ 1, 2, 3, 4],
             [ 2, 0, 4, 1],
             [-1, 0, 5, 2]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

```
domtype(A)
```

```
Dom::Matrix()
```

Matrix components can be extracted by the index operator `[]`:

```
A[2, 1] * A[1, 2] - A[3, 1] * A[1, 3]
```

```
7
```

If one of the indices is not in its valid range, an error message is issued. Assignments to matrix components are performed similarly:

```
delete a:
A[1, 2] := a^2: A
```

$$\begin{pmatrix} 1 & a^2 & 3 & 4 \\ 2 & 0 & 4 & 1 \\ -1 & 0 & 5 & 2 \end{pmatrix}$$

Beside the usual indexing of matrix components, it is also possible to extract submatrices from a given matrix. The following call creates the submatrix of A which consists of the rows 2 to 3 and columns 1 to 3 of A :

`A[2..3, 1..3]`

$$\begin{pmatrix} 2 & 0 & 4 \\ -1 & 0 & 5 \end{pmatrix}$$

The index operator does not allow to insert submatrices into a given matrix. This is implemented by the function `linalg::substitute`.

`delete A:`

Example 4

In the following examples, we demonstrate the different ways of creating matrices. We work with matrices defined over the field \mathbb{F}_{19} , i.e., the field of integers modulo 19. This component ring can be created with the domain constructor `Dom::IntegerMod`.

We start by giving a list of rows, where each row is a list of row entries:

```
MatZ19 := Dom::Matrix(Dom::IntegerMod(19)):
MatZ19([[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

The elements of the two inner lists, the row entries, were converted to elements of the domain `Dom::IntegerMod(19)`.

The number of rows is the number of sublists of the argument, i.e., $m = 2$. The number of columns is determined by the length of the inner list with the most entries, which is the first inner list with two entries. Missing entries in the other inner lists are treated as zero components. The call:

```
MatZ19(4, 4, [[1, 2], [2]])
```

$$\begin{pmatrix} 1 \bmod 19 & 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 2 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \\ 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 & 0 \bmod 19 \end{pmatrix}$$

fixes the dimension of the matrix. Missing entries and inner lists are treated as zero components and zero rows, respectively.

An error message is issued if one of the given entries cannot be converted to an element over $_{19}$:

```
MatZ19([[2, 3], [-1, I]])
```

```
Error: Cannot define a matrix over 'Dom::IntegerMod(19)'. [(Dom:
```

```
delete MatZ19:
```

Example 5

This example illustrates how to create a matrix with components given as values of an index function. First we create the 2×2 Hilbert matrix (see also the functions `linalg::hilbert` and `linalg::invhilbert`):

```
Dom::Matrix()(2, 2, (i, j) -> 1/(i + j - 1))
```

Dom::Matrix

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

Note the difference when working with expressions and functions. If you give an expression it is treated as a function in the row and column indices:

`delete x:`

```
Dom::Matrix()(2, 2, x), Dom::Matrix()(2, 2, (i, j) -> x)
```

$$\begin{pmatrix} x(1, 1) & x(1, 2) \\ x(2, 1) & x(2, 2) \end{pmatrix}, \begin{pmatrix} x & x \\ x & x \end{pmatrix}$$

Example 6

Diagonal matrices can be created with the option `Diagonal` and a list of diagonal components:

```
Mat := Dom::Matrix():  
Mat(3, 4, [1, 2, 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 \end{pmatrix}$$

Hence, to define the $n \times n$ identity matrix, you can enter:

```
Mat(3, 3, [1 $ 3], Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

or call:

```
Mat(3, 3, x -> 1, Diagonal)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

The easiest way to create the identity matrix, however, is to use the method "identity":

```
Mat::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

```
delete Mat:
```

Example 7

Toeplitz matrices can be defined with the option Banded. The following call defines a three-banded matrix with the component 2 on the main diagonal and the component - 1 on the first subdiagonal and superdiagonal:

```
Dom::Matrix()(4, 4, [-1, 2, -1], Banded)
```

$$\begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Example 8

Some system functions can be applied to matrices, such as norm, expand, diff, conjugate, or exp.

For example, to expand the components of the matrix:

Dom::Matrix

```
delete a, b:  
A := Dom::Matrix(  
  [[(a - b)^2, a^2 + b^2], [a^2 + b^2, (a - b)*(a + b)]]  
)
```

$$\begin{pmatrix} (a-b)^2 & a^2+b^2 \\ a^2+b^2 & (a+b)(a-b) \end{pmatrix}$$

enter:

```
expand(A)
```

$$\begin{pmatrix} a^2-2ab+b^2 & a^2+b^2 \\ a^2+b^2 & a^2-b^2 \end{pmatrix}$$

If you want to differentiate the matrix components, then call for example:

```
diff(A, a)
```

$$\begin{pmatrix} 2a-2b & 2a \\ 2a & 2a \end{pmatrix}$$

To substitute matrix components by some values, enter:

```
subs(A, a = 1, b = -1)
```

$$\begin{pmatrix} 4 & 2 \\ 2 & 0 \end{pmatrix}$$

The function `zip` can also be applied to matrices. The following call combines two matrices A and B by dividing each component of A by the corresponding component of B :

```
A := Dom::Matrix()([[4, 2], [9, 3]]):
B := Dom::Matrix()([[2, 1], [3, -1]]):
zip(A, B, `/`)
```

$$\begin{pmatrix} 2 & 2 \\ 3 & -3 \end{pmatrix}$$

The quoted character `/` is another notation for the function `_divide`, the functional form of the division operator `/`.

If one needs to apply a function to the components of a matrix, then use the function `map`. For example, to simplify the components of the matrix:

```
C := Dom::Matrix()(
  [[sin(x)^2 + cos(x)^2, cos(x)*tan(x)],
   [(a^2 - b^2)/(a + b), 1]]
)
```

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & \cos(x) \tan(x) \\ \frac{a^2 - b^2}{a + b} & 1 \end{pmatrix}$$

call:

```
map(C, Simplify)
```

$$\begin{pmatrix} 1 & \sin(x) \\ a - b & 1 \end{pmatrix}$$

```
delete A, B, C:
```

Example 9

However, there may appear some unexpected results using the function `diff` in the context of matrices. The derivative of the following unspecified function `f` of a matrix is computed due to the chain rule:

```
diff(f(matrix([[a*x^2, b], [c, d]])), x)
```

$$\begin{pmatrix} 2ax f' \left(\begin{pmatrix} ax^2 & b \\ c & d \end{pmatrix} \right) & 0 \\ 0 & 0 \end{pmatrix}$$

Usually, the function `f` would implicitly be assumed to be scalar. Hence, the derivative of `f` should be scalar as well. In the above situation the chain rule is applied for differentiation: the inner function is the matrix containing the symbolic components `a*x^2`, `b`, `c` and `d`. Its derivative is computed by simply applying `diff` to each component of the matrix:

```
diff(matrix([[a*x^2, b], [c, d]]), x)
```

$$\begin{pmatrix} 2ax & 0 \\ 0 & 0 \end{pmatrix}$$

Finally, the exterior unspecified function `f` is implicitly assumed to be scalar, such that each component of the derivative of the inner function is multiplied by the exterior differentiation.

Example 10

A column vector is represented by a 2×1 matrix:

```
Mat := Dom::Matrix():  
v := Mat(2, 1, [1, 2])
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

The dimension of this vector is:

```
Mat::matdim(v)
```

$$[2, 1]$$

The length of a vector may also be queried by `linalg::vecdim` or `nops(v)`:

```
linalg::vecdim(v)
```

$$2$$

The i th component of this vector can be extracted in two ways: either by `v[i, 1]` or by `v[i]`:

```
v[1], v[2]
```

$$1, 2$$

We compute the 2-norm of v by the following call:

```
norm(v, 2)
```

$$\sqrt{5}$$

```
delete Mat, v:
```

Example 11

We create random matrices over the field of the rational numbers. Consider a random matrix $A1$ with 3 rows and 3 columns:

Dom::Matrix

```
Mat := Dom::Matrix(Dom::Rational):  
A1 := Mat::random(3, 3)
```

$$\begin{pmatrix} -\frac{65}{824} & \frac{221}{72} & -\frac{245}{597} \\ \frac{741}{814} & \frac{229}{220} & \frac{747}{79} \\ \frac{764}{979} & -\frac{535}{617} & -\frac{535}{477} \end{pmatrix}$$

A second matrix A2 should contain at most 2 non-zero entries. We can create such a matrix by using 2 as the third argument for random:

```
A2 := Mat::random(3, 3, 2)
```

$$\begin{pmatrix} 0 & 0 & \frac{905}{906} \\ 0 & 0 & 0 \\ 0 & \frac{4}{133} & 0 \end{pmatrix}$$

The product of these matrices is given by

```
C := A1 * A2
```

$$\begin{pmatrix} 0 & -\frac{140}{11343} & -\frac{58825}{746544} \\ 0 & \frac{2988}{10507} & \frac{223535}{245828} \\ 0 & -\frac{2140}{63441} & \frac{345710}{443487} \end{pmatrix}$$

By default, matrices are displayed like 'dense' arrays with zeroes in the empty places. For sparse matrices of large column and/or row dimension, such a 'dense' print mode is not appropriate: formatting of the print output would be very time consuming. Further, a 'dense' print output is not very informative for sparse matrices. For this reason,

the "doprint" method provides a sparse output mode printing only the non-zero entries:

```
C::dom::doprint(C)
```

```
Dom::Matrix(Dom::Rational)(3, 3, [(1, 2) = -140/11343, (1, 3) = -58825/746544, (2, 2) = 2988/1050\
7, (2, 3) = 223535/245828, (3, 2) = -2140/63441, (3, 3) = 345710/443487])
```

With this method, one can also print large sparse matrices. We create a random sparse matrix with 100 rows, 200 columns and at most 6 non-zero entries:

```
X := Mat::random(100, 200, 6): print(X)
```

```
Warning: This matrix is too large for display. To see all nonzero
```

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

```
Warning: This matrix is too large for display.
If you want to see all nonzero entries of a matrix, say A, then
'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print]
```

```
Warning: This matrix is too large for display.
If you want to see all nonzero entries of a matrix, say A, then
'A::dom::doprint(A)'. [(Dom::Matrix(Dom::Rational))::print]
```

```
Dom::Matrix(Dom::Rational)(100, 200, ["..."])
```

The warning speaks for itself. X is regarded as 'too large for display' since, with the default 'dense' output mode, the sparse matrix would be printed as a huge array-like structure of dimension 100×200 with (integer) zeroes in the empty places. The sparse print mode should be used:

Dom::Matrix

```
X::dom::doprint(X)
```

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, \  
(46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])
```

For convenience, there is a function `doprint` that calls this method by just entering:

```
doprint(X)
```

```
Dom::Matrix(Dom::Rational)(100, 200, [(16, 64) = 448/765, (19, 4) = -61/702, (27, 126) = 343/304, \  
(46, 42) = 433/49, (68, 176) = 451/483, (100, 97) = -235/174])
```

```
delete Mat, A1, A2, C, X:
```

Parameters

R

A ring, i.e., a domain of category `Cat::Rng`. The default ring is `Dom::ExpressionField()`.

Array

A one- or two-dimensional array or `hfarray`

Matrix

A matrix, i.e., an element of a domain of category `Cat::Matrix`

m, n

Matrix dimension (positive integers)

List

A list of matrix components

ListOfRows

A list of at most `m` rows; each row given as a list of at most `n` matrix components

Table

A table of coefficients of the matrix for sparse input

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options**Diagonal**

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function or a functional expression.

`Dom::Matrix(R)(m, n, List, Diagonal)` creates the $m \times n$ diagonal matrix, whose diagonal elements are the entries of `List`.

`List` must have at most $\min(m, n)$ entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::Matrix(R)(m, n, g, Diagonal)` returns the sparse matrix whose i th diagonal element is `g(i, i)`, where the index i runs from 1 to $\min(m, n)$.

The function values are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a Toeplitz matrix

`Dom::Matrix(R)(m, n, List, Banded)` creates an $m \times n$ Toeplitz matrix with the elements of `List` as entries. The number of

entries of `List` must be odd, say $2h + 1$, and must not exceed $2\min(m, n) - 1$. The bandwidth of the resulting matrix is at most $2h + 1$.

A Toeplitz matrix is a matrix where the elements of each band are identical. See also “Example 7” on page 6-253.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the i -th subdiagonal are initialized with the $(h + 1 - i)$ -th element of `List`. All elements of the i -th superdiagonal are initialized with the $(h + 1 + i)$ -th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted to elements of the domain `R`. An error message is issued if one of these conversions fails.

Entries

"isSparse"	is always TRUE.
"randomDimen"	is set to [10, 10]. See the method "random" below for details.

Methods

Mathematical Methods

`_divide` - Divide matrices

`_divide(A, B)`

An error message is issued if the dimensions of `A` and `B` do not match.

This method only exists if `R` is a commutative ring with a unit, i.e., a domain of category `Cat::Ring`.

This method overloads the system function `_divide` for matrices, i.e., one may use it in the form `A / B`, or in functional notation: `_divide(A, B)`.

`_invert` - Compute the inverse of a matrix

```
_invert(A, Normal = b)
```

This method only exists if R is a domain of category `Cat::Ring`.

This method overloads the system function `_invert` for matrices, i.e., one may use it in the form $1/A$ or A^{-1} , or in functional notation: `_invert(A)`.

If `Normal = TRUE`, then the matrix inverse is always returned in a normalized form. For details about normalization, see `normal`. If `Normal = FALSE`, then the matrix inverse can appear in a normalized form, but normalization is not guaranteed. By default `Normal = TRUE`.

`Normal` affects the results only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

`_mod` - Map the modulo operator to the elements of a matrix

```
_mod(A, n)
```

n must be non-zero, and `a mod n` must be defined for every entry a of A .

This method overloads the function `_mod` for matrices; one may use it in the form `A mod n`, or in functional notation: `_mod(A, n)`.

`_mult` - Multiplie matrices by matrices, vectors and scalars

```
_mult(x, y)
```

```
_mult(x, y)
```

If y is of the domain type R or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, y is converted to a matrix of the domain type of x . If this conversion fails, this method calls the method `"_mult"` of the domain of y giving all arguments in the same order.

If x is a matrix of the same domain type as y , the matrix product xy is computed. An error message is issued if the dimensions of the matrices do not match.

If x is of the domain type R or can be converted to such an element, the corresponding scalar multiplication is computed.

Otherwise, x is converted to a matrix of the domain type of y . If this conversion fails, FAIL is returned.

This method handles more than two arguments by calling itself recursively with the first half of all arguments and the last half of all arguments. Then the product of these two results is computed with the system function `_mult`.

This method overloads the system function `_mult` for matrices, i.e., one may use it in the form $x * y$, or in functional notation: `_mult(x, y)`.

`_negate` - Negate a matrix

`_negate(A)`

This method overloads the system function `_negate` for matrices, i.e., one may use it in the form $-A$, or in functional notation: `_negate(A)`.

`_plus` - Add matrices

`_plus(A, B, ...)`

The arguments A, B, \dots are converted to matrices of the domain type `Dom::Matrix(R)`. FAIL is returned if one of these conversions fails.

This method overloads the system function `_plus` for matrices, i.e., one may use it in the form $A + B$, or in functional notation: `_plus(A, B)`.

`_power` - Integer power of a matrix

`_power(A, n)`

If the power n is a negative integer then A must be nonsingular and R must be a domain of category `Cat::IntegralDomain`. Otherwise FAIL is returned.

If n is zero and the component ring R is a ring with no unit (i.e., of category `Cat::Rng`, but not of category `Cat::Ring`), `FAIL` is returned.

This method overloads the system function `_power` for matrices, i.e., one may use it in the form A^n , or in functional notation: `_power(A, n)`.

conjugate - Complex conjugate of a matrix

`conjugate(A)`

This method only exists if R implements the method "conjugate", which computes the complex conjugate of an element of the domain R .

This method overloads the system function `conjugate` for matrices, i.e., one may use it in the form `conjugate(A)`.

cos - Cosine of a matrix

`cos(A)`

If A is not square, an error message is issued. If the component domain of A does not allow the computation of `cos(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of A if A is defined over the domain `Dom::Float`.

If some eigenvalues of A do not exist in R or cannot be computed, then `FAIL` is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of A . In this case `FAIL` is returned.

This method only exists if R is a domain of category `Cat::Field`.

This method overloads the function `cos` for matrices, i.e., one may use it in the form `cos(A)`.

diff - Differentiation of matrix components

`diff(A,)`

This method only exists if `R` implements the method "diff".

This method overloads the system function `diff` for matrices, i.e., one may use it in the form `diff(A, ...)`. See "Example 8" on page 6-253 and "Example 9" on page 6-256.

equal - Equality test of matrices

`equal(A, B)`

Note that if `R` has the axiom `Ax::systemRep` then `normal` is used to simplify the components of `A` and `B` before testing their equality.

exp - Exponential of a matrix

`exp(A, <t>)`

If `A` is not square, an error message is issued. If the component domain of `A` does not allow the computation of `exp(elem)` for an arbitrary element `elem` of the component ring, `FAIL` is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of `A` if `A*t` contains at least one floating-point number and all entries can be converted to floating-point numbers.

If some eigenvalues of `A` do not exist in `R` or cannot be computed, then `FAIL` is returned.

In the symbolic case, the function `linalg::jordanForm` is called, which may not be able to compute the Jordan form of `A`. In this case `FAIL` is returned.

This method only exists if `R` is a domain of category `Cat::Field`.

This method overloads the system function `exp` for matrices, i.e., one may use it in the form `exp(A, ...)`.

expand - Expand matrix components

`expand(A)`

This method only exists if R implements the method "expand", or if R has the axiom $Ax::\text{systemRep}$ (in this case, the system function `expand` is used).

This method overloads the system function `expand` for matrices, i.e., one may use it in the form `expand(A)`.

factor - Scalar-matrix factorization

`factor(A)`

The factor s is the gcd of all components of the matrix A . Hence, this method only exists if R is of category $Cat::\text{GcdDomain}$.

This method overloads the system function `factor` for matrices, i.e., one may use it in the form `factor(A)`.

float - Floating-point approximation of the matrix components

`float(A)`

This method only exists if R implements the method "float".

Note Usually the floating-point approximations are not elements of R ! For example, $Dom::\text{Integer}$ implements such a method, but the floating-point approximation of an integer cannot be re-converted to an integer.

This method checks whether the resulting matrix can be converted to the domain type of A only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

Otherwise, one has to take care that the matrix returned is compatible with its component ring.

fourier - Fourier transform of the matrix components

`fourier(A, t, s)`

This method overloads the function `fourier` for matrices.

gaussElim - Gaussian elimination for matrices

`gaussElim(A, <ColumnElimination>)`

With the option `ColumnElimination`, the matrix A is reduced to a lower triangular echelon form via elementary *column* operations (without `ColumnElimination`, the Gauss algorithm uses elementary *row* operations to obtain the upper echelon form). The following relation holds: `transpose(gaussElim(A, ColumnElimination)[1]) = gaussElim(transpose(A))[1]`. With `ColumnElimination`, the last entry of the returned list is the set of characteristic *column* indices of A .

For very large $m \times n$ matrices A with m much greater n , the column elimination is faster than the row elimination.

If the matrix is not square, i.e., the determinant of A is not defined, then the third entry of the returned list is the value `FAIL`.

This method only exists if the component ring R is an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If R has the method `"pivotSize"`, the pivot element of smallest size is chosen at every pivoting step, whereby `pivotSize` must return a positive integer representing the "size" of an element.

If no such method is defined, Gaussian elimination without a pivot strategy is applied to A .

If R has the axiom `Ax::efficientOperation("_invert")` and is of category `Cat::Field`, ordinary Gaussian elimination is used. Otherwise, fraction-free elimination is performed on A .

If R implements the method `"normal"`, it is used to simplify subsequent computations of the Gaussian elimination process.

Note that if R does not implement the method `"normal"`, but the elements of R are represented by kernel domains, i.e., R has the axiom `Ax::systemRep`, the system function `normal` is used instead.

identity - Identity matrix

```
identity(n)
```

This method only exists if the component ring R is of category $\text{Cat}::\text{Ring}$, i.e., a ring with unit.

int - Integration of matrix components

```
int(A, )
```

This method only exists if R implements the method "int".

This method overloads the system function `int` for matrices, i.e., one may use it in the form `int(A, ...)`.

ifourier - Inverse Fourier transform of the matrix components

```
ifourier(A, s, t)
```

This method overloads the function `ifourier` for matrices.

ilaplace - Inverse Laplace transform of the matrix components

```
ilaplace(A, s, t)
```

This method overloads the function `ilaplace` for matrices.

iszero - Test for zero matrices

```
iszero(A)
```

Note that there may exist more than one representation of the zero matrix of a given dimension if R does not have $\text{Ax}::\text{canonicalRep}$.

If R implements the method "normal", it is used to simplify the components of A for the zero-test.

Note that if R does not implement such a method, but the elements of R are represented by kernel domains, i.e., R has the axiom $\text{Ax}::\text{systemRep}$, the system function `normal` is used instead.

This method overloads the system function `iszero` for matrices, i.e., one may use it in the form `iszero(A)`.

laplace - Laplace transform of the matrix components

```
laplace(A, t, s)
```

This method overloads the function `laplace` for matrices.

matdim - Matrix dimension

`matdim(A)`

norm - Norm of matrices and vectors

`norm(A, Infinity)`

`norm(A, Maximum)`

`norm(v, Infinity)`

`norm(v, Maximum)`

`norm(A, Frobenius)`

`norm(A, 1)`

`norm(v, Euclidean)`

`norm(v, k)`

`norm(A, Maximum)` computes the maximum norm of the matrix `A`, which is the maximum row sum (the row sum is the sum of norms of each component in a row).

If the domain `R` does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Infinity)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods "max" and "norm", FAIL is returned.

Using `norm(v, Maximum)` for a vector `v` the maximum norm of all elements is returned.

If the domain `R` does not implement the methods "max" and "norm", FAIL is returned.

`norm(A, Frobenius)` computes the Frobenius norm of `A`, which is the square root of the sum of the squares of the norms of each component.

If the result is no longer an element of the domain R, or if R does not implement the method "norm", FAIL is returned.

`norm(A, 1)` computes the 1-norm of the matrix A, which is the maximum sum of the norms of the elements of each column. If R does not implement the methods "max" and "norm", FAIL is returned.

`norm(v, Euclidean)` computes the Euclidean norm (2-norm) of the vector v, which is defined to be the square root of the sum of the norms of the elements of v raised to the square.

FAIL is returned if the result is no longer an element of the domain R. The function `linalg::scalarProduct` is used to compute the Euclidean norm of the vector v.

If R does not implement the method "norm", FAIL is returned.

`norm(v, k)` computes the *k*-norm of the vector v, which is defined to be the *k*th root of the sum of the norms of the elements of v raised to the *k*th power.

FAIL is returned if the result is no longer an element of the domain R. For *k* = 2, the function `linalg::scalarProduct` is used to compute the 2-norm of v.

If R does not implement the method "norm", FAIL is returned.

The method `norm` overloads the function `norm` for matrices, i.e., one may use it in the form `norm(A k)`, where *k* is either `Infinity`, `Frobenius`, or a positive integer. The default value of *k* is `Infinity`.

normal - Simplification of matrix components

`normal(A)`

If R does not implement the method "normal", but the elements of R are represented by kernel domains, i.e., R has the axiom `Ax::systemRep`, the system function `normal` is applied to the components of A. Otherwise `normal(A)` returns A without any changes.

This method overloads the system function `normal` for matrices, i.e., one may use it in the form `normal(A)`.

nonZeros - Number of non-zero components of a matrix

`nonZeros(A)`

nonZeroes - Number of non-zero components of a matrix

`nonZeroes(A)`

nonZeroOperands - Return a sequence of all non-zero operands

`nonZeroOperands(A)`

This method is useful for retrieving information on the non-zero entries. For example, to find out the types of the entries in the matrix, one should not consider all operands `op(A)`, because this would also involve the zero entries. For large matrices with few entries, it is much more efficient to use this method to extract the entries.

random - Random matrix generation

`random()`

`random(g)`

`random(m, n)`

`random(m, n, g)`

`random(m, n, p)`

`random(m, n, p, g)`

The dimension of the matrix is also chosen randomly. The matrix size is limited by the values "randomDimen" (see "Entries" above). To change the value of the entry "randomDimen", one must first unprotect the domain Dom (see `unprotect` for details).

When calling the "random" method with one parameter `g`, this parameter is regarded as a random generator. The matrix entries are created by the calls `g()` which must return elements of the coefficient ring `R`.

The dimension of the matrix is chosen randomly as above.

When calling the "random" method with two positive integers m and n , a random matrix with m rows and n columns is created. Its elements are generated by the method "random" of the component ring R . If $R::\text{random}$ does not exist, FAIL is returned.

$\text{random}(m, n, g)$ creates a matrix with m rows and n columns. The third parameter g is regarded as a random generator. The matrix entries are created by the calls $g()$ which must return elements of the coefficient ring R .

When calling the "random" method with positive integers m , n and a nonnegative integer p , a sparse matrix with m rows, n columns and at most p non-zero entries is created. These entries are generated by the function "random" of the component ring R . If $R::\text{random}$ does not exist, FAIL is returned.

The integer p must satisfy $0 \leq p \leq mn$.

When calling the "random" method with four parameters, a sparse matrix with m rows, n columns and at most p non-zero entries is created. The fourth parameter g is regarded as a random generator. The matrix entries are created by the calls $g()$ which must return elements of the coefficient ring R .

The integer p must satisfy $0 \leq p \leq mn$.

sin - Sine of a matrix

$\text{sin}(A)$

If A is not square, an error message is issued. If the component domain of A does not allow the computation of $\text{sin}(\text{elem})$ for an arbitrary element elem of the component ring, FAIL is returned.

This method uses the function `numeric::expMatrix` for a floating-point approximation of the exponential of A if A is defined over the domain `Dom::Float`.

If some eigenvalues of A do not exist in R or cannot be computed, then FAIL is returned.

In the symbolic case the functions `exp` and `linalg::jordanForm` are called. The latter may not be able to compute the Jordan form of A . In this case `FAIL` is returned.

This method only exists if R is a domain of category `Cat::Field`.

This method overloads the function `sin` for matrices, i.e., one may use it in the form `sin(A)`.

sqrt - Square root of a matrix

`sqrt(A, <sqrtfunc>)`

Returned is a matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or `FAIL` if the square root of the matrix does not exist. For computing the square roots of the eigenvalues a function satisfying $\text{sqrtfunc}(a)^2 = a$ for every element a of the coefficient ring of A can be given as optional second argument.

For details we refer to the help page of the function `linalg::sqrtMatrix`.

testeq - Testing for equality of two matrices

`testeq(A, B)`

tr - Trace of a square matrix

`tr(A)`

If A is not square, an error message is issued.

transpose - Transpose of a matrix

`transpose(A)`

Access Methods

`_concat` - Horizontal concatenation of matrices

`_concat(A, B,)`

This method overloads the system function `_concat` for matrices, i.e., one may use it in the form `A . B`, or in functional notation: `_concat(A, B, ...)`.

`_index` - Matrix indexing

`_index(A, i, j)`

`_index(A, r1 .. r2, c1 .. c2)`

`_index(v, i)`

`_index(v, i1 .. i2)`

If `i` and `j` are not integers, the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(A, r1 .. r2, c1 .. c2)` returns the submatrix of `A` created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

This method returns the i th entry of the vector `v`.

An error message is issued if `v` is not a vector.

If `i` is not an integer, the call of `_index(v, i)` returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` is less than one or greater than the dimension of `v`.

Note Note that this method uses the system function `context` to evaluate the entry in the context of the calling environment.

`_index(v, i1..i2)` returns the subvector of `v`, formed by the entries with index `i1` to `i2`. See also the method "`op`".

An error message is issued if `v` is not a vector.

`_index` overloads the system function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `v[i]` and `v[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

addCol - Addition of a multiple of one column to the multiple of another column

```
addCol(A, i, j, f, <g>)
```

`i` and `j` must be positive integers smaller than or equal to the number of columns of the matrix `A`.

If `f` and `g` are not elements of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

addRow - Addition of a multiple of one row to the multiple of another row

```
addRow(A, i, j, f, g)
```

`i` and `j` must be positive integers smaller than or equal to the number of rows of the matrix `A`.

If `f` and `g` are not elements of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

concatMatrix - Horizontal concatenation of matrices

```
concatMatrix(A, B, )
```

col - Extracting a column of a matrix

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

delCol - Deleting a column of a matrix

```
delCol(A, c)
```

NIL is returned if `A` consists of only one column.

An error message is issued if `c` is less than one or greater than the number of columns of `A`.

delRow - Deleting a row of a matrix

```
delRow(A, r)
```

NIL is returned if `A` consists of only one row.

An error message is issued if `r` is less than one or greater than the number of rows of `A`.

evalp - Evaluating matrices of polynomials at a certain point

```
evalp(A, x = a, )
```

This method is only defined if `R` is a polynomial ring of category `Cat::Polynomial`.

This method overloads the system function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

length - Length of a matrix

```
length(A)
```

This method overloads the system function `length` for matrices, i.e., one may use it in the form `length(A)`.

map - Apply a function to matrix components

```
map(A, f, <p1, p2, >)
```

Note Note that values returned by `f` are converted to elements of the domain `R` only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that `f` returns elements of the domain type `R`. Otherwise, the resulting matrix will have components which are not elements of the component ring `R`!

Note If the function `f` does not map the zero element of the component ring to the zero element, a sparse matrix will change into a dense matrix. This may lead to memory problems when dealing with very large (sparse) matrices.

Note that there is the method "`mapNonZeroes`" which maps a function to the non-zero entries of the matrix only.

This method overloads the system function `map` for matrices, i.e., one may use it in the form `map(A, f p1 , p2 , ,)`.

mapNonZeroes - Apply a function to the non-zero components of a (sparse) matrix

```
mapNonZeroes(A, f, <p1, p2, >)
```

multCol - Multiplication of one column by a scalar factor

```
multCol(A, i, f)
```

`i` must be a positive integer smaller than or equal to the number of columns of the matrix `A`.

If `f` is not an element of the coefficient domain `R` of the matrix `A` and cannot be converted to `R`, `FAIL` is returned.

multRow - Multiplication of one row by a scalar factor

```
multRow(A, i, f)
```

i must be a positive integer smaller than or equal to the number of rows of the matrix *A*.

If *f* is not an element of the coefficient domain *R* of the matrix *A* and cannot be converted to *R*, FAIL is returned.

nops - Number of components of a matrix

```
nops(A)
```

This method overloads the system function `nops` for matrices, i.e., one may use it in the form `nops(A)`.

op - Component of a matrix

```
op(A, i)
```

```
op(A)
```

This method returns an expression sequence of all components of *A*.

See also the method "`_index`".

This method overloads the system function `op` for matrices, i.e., one may use it in the form `op(A, i)` and `op(A)`, respectively.

row - Extracting a row from a matrix

```
row(A, r)
```

An error message is issued if *r* is less than one or greater than the number of rows of *A*.

setCol - Replacing a column of a matrix

```
setCol(A, c, v)
```

An error message is issued if *c* is less than one or greater than the number of rows of *A*.

setRow - Replacing a row of a matrix

```
setRow(A, r, v)
```

An error message is issued if r is less than one or greater than the number of rows of A .

stackMatrix - Vertical concatenation of matrices

```
stackMatrix(A, B, ...)
```

An error message is issued if the given matrices do not have the same number of columns.

subs - Substitution of matrix components

```
subs(A, ...)
```

Note Note that the function values are converted to elements of the domain R only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that f returns elements of the domain type R . Otherwise, the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain R !

This method overloads the system function `subs` for matrices, i.e., one may use it in the form `subs(A, ...)`.

subsex - Extended substitution of matrix components

```
subsex(A, ...)
```

Note Note that the results of the substitutions are converted to elements of the domain R only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that the results of the substitutions are of the domain type R , otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain R !

This method overloads the system function `subsex` for matrices, i.e., one may use it in the form `subsex(A, ...)`.

subsop - Operand substitution of matrix components

```
subsop(A, i = x, )
```

Note Note that x is converted to the domain R only if `testargs()` returns `TRUE` (e.g., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, x must be an element of R , otherwise the resulting matrix, which is of domain type `Dom::Matrix(R)`, would have components which are not elements of the domain R !

See also the method "`set_index`".

This method overloads the system function `subsop` for matrices, i.e., one may use it in the form `subsop(A, ...)`.

swapCol - Swapping matrix columns

```
swapCol(A, c1, c2)
```

```
swapCol(A, c1, c2, r1 .. r2)
```

An error message is issued if one of the column indices is less than one or greater than the number of columns of A.

`swapCol(A, c1, c2, r1..r2)` swaps the column with index `c1` and the column with index `c2` of A, but by taking only those column components which lie in the rows with indices `r1` to `r2`.

An error message is issued if one of the column indices is less than one or greater than the number of columns of A, or if one of the row indices is less than one or greater than the number of rows of A.

swapRow - Swapping matrix rows

`swapRow(A, r1, r2)`

`swapRow(A, r1, r2, c1 .. c2)`

An error message is issued if one of the row indices is less than one or greater than the number of rows of A.

`swapCol(A, r1, r2, c1..c2)` swaps the row with index `r1` and the row with index `r2` of A, but by taking only those row components which lie in the columns with indices `c1` to `c2`.

An error message is issued if one of the row indices is less than one or greater than the number of rows of A, or if one of the column indices is less than one or greater than the number of columns of A.

set_index - Setting matrix components

`set_index(A, i, j, x)`

`set_index(v, i, x)`

Note Note that x is converted into an element of the domain R only if `testargs` returns `TRUE` and i and j are integers (e.g., if one calls this method from the interactive level of MuPAD). If x is a matrix of the same type as A or can be converted into a matrix of the same type as A and the indices i or j are ranges corresponding to a submatrix of A , then x replaces the corresponding submatrix in A .

Otherwise one has to take care that x is of domain type R .

See also the method "subsop".

`set_index(v, i, x)` replaces the i th entry of the vector v by x .

`set_index` on vectors overloads the function `set_index` for matrices, i.e., one may use it in the form `A[i, j] := x` and `v[i] := x`, respectively, or in functional notation: `A := set_index(A, i, j, x)` or `v := set_index(v, i, x)`.

zip - Combine matrices component-wise

`zip(A, B, f, <p1, p2, >)`

The row number of the matrix returned is the minimum of the row numbers of A and B . Its column number is the minimum of the column numbers of A and B .

Note Note that the values returned by f are converted to elements of the domain R only if `testargs()` returns `TRUE` (i.e., if one calls this method from the interactive level of MuPAD).

If `testargs()` returns `FALSE`, one must guarantee that f returns elements of the domain type R . Otherwise, the resulting matrix will have components which are not elements of the component ring R !

This method overloads the system function `zip` for matrices, i.e., one may use it in the form `zip(A, B, f p1 , p2 , ,)`.

Conversion Methods

convert - Conversion to a matrix

`convert(x)`

FAIL is returned if the conversion fails.

`x` may either be an array, a matrix, or a list (of sublists, see the parameter `ListOfRows` in “Creating Elements” above). Their entries must then be convertible into elements of the domain `R`.

convert_to - Matrix conversion

`convert_to(A, T)`

`T` may either be `DOM_ARRAY`, `DOM_LIST`, or a domain constructed by `Dom::Matrix` or `Dom::SquareMatrix`. The elements of `A` must be convertible into elements of the domain `R`.

Use the function `expr` to convert `A` into an object of a kernel domain (see below).

create - Defining matrices without component conversions

`create(x,)`

This method works more efficiently than if one creates matrices by calling the method "new" of the domain, because it avoids any conversion of the components. One must guarantee that the components have the correct domain type, otherwise run-time errors can be caused.

expr - Conversion of a matrix to an object of a kernel domain

`expr(A)`

The result is an array representing the matrix `A` where each entry is an object of a kernel domain.

This method overloads the system function `expr` for matrices, i.e., one may use it in the form `expr(A)`.

expr2text - Conversion of a matrix to a string

```
expr2text(A)
```

This method overloads the system function `expr2text` for matrices, i.e., one may use it in the form `expr2text(A)`.

TeX - TeX formatting of a matrix

```
TeX(A)
```

Note that in the case of very large matrices the output will not be useful. For printing large matrices use the function `"doprint"` to obtain a sparse matrix output displaying all non-zero entries. Alternatively, use the matrix slot `"setPrintMaxSize"` to set the maximal size of matrices that will be printed like "dense" arrays with zero entries displayed as the integer 0.

The method `"TeX"` of the component ring `R` is used to get the TeX-representation of each component of `A`.

This method is used by the function `generate::TeX`.

Technical Methods

assignElements - Multiple assignment to matrices

```
assignElements(A, ...)
```

The assigned components must have the domain type `R`, an implicit conversion of the components into elements of domain type `R` is not performed.

This method overloads the system function `assignElements` for matrices, i.e., one may use it in the form `assignElements(A, ...)`.

mkSparse - Conversion of an array or a list of lists to a sparse structure

```
mkSparse(Array)
```

`mkSparse(List)`

`mkSparse(r, c, List)`

The 'sparse structure' `s` is a list of `c` univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

`mkSparse(List)` tries to convert the list `List` into a sparse structure. The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`, where the positive integers `r` and `c` are the dimension of the corresponding matrix. The 'sparse structure' `s` is a list of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

See the parameters `List` and `ListOfRows` in "Creating Elements" above for admissible formats of `List`.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. `T`

`mkSparse(r,c,List)` tries to convert the list `List` into a sparse structure representing a matrix of dimension `r` times `c`.

The result is either `FAIL` if this is not possible, or the list `[s, [r, c]]`. The 'sparse structure' `s` is a list of univariate polynomials that is used to store the non-trivial elements of the columns of matrices.

The matrix is regarded as a column or a row vector, if `r` or `c` is equal to one. `T`

print - Printing matrices

`print(A)`

Note Note that it will not be useful to print very large sparse matrices with lots of zero coefficients in this way – printing such matrices can be done by using the function "`doprint`".

Use the matrix slot "setPrintMaxSize" to set the maximal size of matrices that will be printed like "dense" arrays with zero entries displayed as the integer 0.

doprint - Printing large sparse matrices

```
doprint(A)
```

setPrintMaxSize - Set the maximal size of matrices that will be printed like "dense" arrays

```
setPrintMaxSize(printMaxSize)
```

The value of the parameter `printMaxSize` may also be infinity. In this case, matrices of arbitrary size are printed like "dense" arrays.

This method returns the previous value of `printMaxSize`.

The default value is `printMaxSize = 500`.

unapply - Create a procedure from a matrix

```
unapply(A, <x, >)
```

This method overloads the system function `fp::unapply` for matrices, i.e., one may use it in the form `fp::unapply(A)`.

Dom::MatrixGroup

Purpose The Abelian group of matrices

Syntax **Domain Creation**
`Dom::MatrixGroup(m, n, <R>)`

Element Creation

`Dom::MatrixGroup(m, n, R)(Array)`
`Dom::MatrixGroup(m, n, R)(Matrix)`
`Dom::MatrixGroup(m, n, R)(<m, n>)`
`Dom::MatrixGroup(m, n, R)(<m, n>, List)`
`Dom::MatrixGroup(m, n, R)(<m, n>, ListOfRows)`
`Dom::MatrixGroup(m, n, R)(<m, n>, f)`
`Dom::MatrixGroup(m, n, R)(<m, n>, List, <Diagonal>)`
`Dom::MatrixGroup(m, n, R)(<m, n>, g, <Diagonal>)`
`Dom::MatrixGroup(m, n, R)(<m, n>, List, <Banded>)`

Description **Domain Creation**

`Dom::MatrixGroup(m, n, R)` creates a domain which represents the Abelian group of $m \times n$ matrices over the component ring R , i.e., it is a domain of category `Cat::AbelianGroup`.

The domain `Dom::ExpressionField()` is used as the component ring for the matrices if the optional parameter R is not given.

For matrices of a domain created by `Dom::MatrixGroup(m, n, R)`, matrix arithmetic is implemented by overloading the standard arithmetical operators $+$, $-$, $*$, $/$ and $^$. All functions of the `linalg` package dealing with matrices can be applied.

`Dom::MatrixGroup(m, n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::MatrixGroup(m, n, R)`.

Methods described below are implemented by `Dom::MatrixGroup`.

The domain `Dom::Matrix(R)` represents matrices over R of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::SquareMatrix(n, R)` represents the *ring* of $n \times n$ matrices over R .

Element Creation

`Dom::MatrixGroup(m, n, R)(Array)` and `Dom::MatrixGroup(m, n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain R . An error message is issued if one of these conversions fails.

The call `Dom::MatrixGroup(m, n, R)(m , n)` returns the $m \times n$ zero matrix. Note that the $m \times n$ zero matrix can also be found in the entry "zero" (see below).

`Dom::MatrixGroup(m, n, R)(m , n List)` creates an $m \times n$ matrix with components taken from the list `List`.

This call is only allowed for $m \times 1$ or $1 \times n$ matrices, i.e., if either m or n is equal to one.

If the list has too few entries, the remaining components of the matrix are set to zero.

The entries of the list are converted into elements of the domain R . An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)(m , n ListOfRows)` creates an $m \times n$ matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than n entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than m inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are coerced into elements of the domain R . An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::MatrixGroup(m, n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one

Dom::MatrixGroup

can achieve. However, in this case the sublists must have the same number of elements.

`Dom::MatrixGroup(m, n, R)(m , n f)` returns the matrix whose (i, j) th component is the value of the function call `f(i, j)`. The row index i ranges from 1 to m and the column index j from 1 to n .

The function values are coerced into elements of the domain R . An error message is issued if one of these conversions fails.

Superdomain `Dom::Matrix(R)`

Axioms If R has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories `Cat::Matrix(R)`, `Cat::AbelianGroup`

Examples **Example 1**

A lot of examples can be found on the help page of the domain constructor `Dom::Matrix`, and most of them are also examples for working with domains created by `Dom::MatrixGroup`. This example only highlights some differences with respect to working with matrices of the domain `Dom::Matrix(R)`.

The following command defines the abelian group of 3×4 matrices over the rationals:

```
MatGQ := Dom::MatrixGroup(3, 4, Dom::Rational)
```

```
Dom::MatrixGroup(3, 4, Dom::Rational)
```

```
MatGQ::hasProp(Cat::AbelianGroup), MatGQ::hasProp(Cat::Ring)
```

```
TRUE, FALSE
```

`MatGQ` is a commutative group with respect to the addition of matrices. The unit of this group is the 3×4 zero matrix:

`MatGQ::zero`

$$\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Note that some operations defined by the domain `MatGQ` return matrices which are no longer elements of the matrix group. They return matrices of the domain `Dom::Matrix(Dom::Rational)`, the super-domain of `MatGQ`.

For example, if we define the matrix:

`A := MatGQ([[1, 2, 1, 2], [-5, 3], [2, 1/3, 0, 1]])`

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ -5 & 3 & 0 & 0 \\ 2 & \frac{1}{3} & 0 & 1 \end{pmatrix}$$

and delete its third column, we get the matrix:

`MatGQ::delCol(A, 3)`

$$\begin{pmatrix} 1 & 2 & 2 \\ -5 & 3 & 0 \\ 2 & \frac{1}{3} & 1 \end{pmatrix}$$

which is of the domain type:

`domtype(%)`

`Dom::Matrix(Dom::Rational)`

Dom::MatrixGroup

As another example we create the 3×3 identity matrix using the method "identity" of our domain:

```
E3 := MatGQ::identity(3)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

This is also a matrix of the domain Dom::Matrix(Dom::Rational):

```
domtype(E3)
```

```
Dom::Matrix(Dom::Rational)
```

If we concatenate E3 to the right of the matrix A defined above, we get the 3 ×7 matrix:

```
B := A . E3
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 & 1 & 0 & 0 \\ -5 & 3 & 0 & 0 & 0 & 1 & 0 \\ 2 & \frac{1}{3} & 0 & 1 & 0 & 0 & 1 \end{pmatrix}$$

which is of the domain type Dom::Matrix(Dom::Rational):

```
domtype(B)
```

```
Dom::Matrix(Dom::Rational)
```

Example 2

We can convert a matrix from a domain created with Dom::MatrixGroup into or from another matrix domain, as shown next:

```
MatGR := Dom::MatrixGroup(2, 3, Dom::Real):  
MatC := Dom::Matrix(Dom::Complex):
```

```
A := MatGR((i, j) -> i*j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

To convert A into a matrix of the domain MatC, enter:

```
coerce(A, MatC)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 4 & 6 \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix(Dom::Complex)
```

The conversion is done component-wise. For example, we define the following matrix:

```
B := MatC([[0, 1, 0], [exp(I), 0, 1]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ e^i & 0 & 1 \end{pmatrix}$$

The matrix B has one complex component and therefore cannot be converted into the domain MatGR:

```
coerce(B, MatGR)
```

```
FAIL
```

Dom::MatrixGroup

Note: The system function `coerce` uses the methods "convert" and "convert_to" implemented by any domain created with `Dom::MatrixGroup` and `Dom::Matrix`.

Parameters

m, n

Positive integers (matrix dimension)

R

A commutative ring, i.e., a domain of category

`Cat::CommutativeRing`; the default is `Dom::ExpressionField()`

Array

An $m \times n$ array

Matrix

An $m \times n$ matrix, i.e., an element of a domain of category

`Cat::Matrix`

List

A list of matrix components

ListOfRows

A list of at most m rows; each row is a list of at most n matrix components

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::MatrixGroup(m, n, R)(m , n List, Diagonal)` creates the $m \times n$ diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most $\min(m, n)$ entries. If it has fewer elements, then the remaining diagonal elements are set to zero.

The entries of `List` are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::MatrixGroup(m, n, R)(m , n g, Diagonal)` returns the matrix whose i th diagonal element is $g(i, i)$, where the index i runs from 1 to $\min(m, n)$.

The function values are coerced into elements of the domain `R`. An error message is issued if one of these conversions fails.

Banded

Create a banded Toeplitz matrix

With the option `Banded`, banded matrices can be created.

A *banded matrix* has all entries zero outside the main diagonal and some of the adjacent sub- and superdiagonals.

`Dom::MatrixGroup(m, n, R)(m , n List, Banded)` creates an $m \times n$ banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed n . The resulting matrix has bandwidth at most $2h + 1$.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the i th subdiagonal are initialized with the $(h + 1 - i)$ th element of `List`. All elements of the i th superdiagonal are initialized with the $(h + 1 + i)$ th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

Dom::MatrixGroup

Entries

"one"	is only defined if m is equal to n ; in that case it defines the $n \times n$ identity matrix.
"randomDimen"	is set to $[m, n]$.
"zero"	is the $m \times n$ zero matrix.

Methods

Mathematical Methods

evalp - Evaluating matrices of polynomials at a certain point

`evalp(A, x = a,)`

This method is only defined if R is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

identity - Identity matrix

`identity(k)`

Note The matrix returned is of the domain `Dom::Matrix(R)`, if $m \neq n$ or if $k \neq n$.

matdim - Matrix dimension

`matdim(A)`

random - Random matrix generation

`random()`

The components of the random matrix are randomly generated with the method "random" of the component ring R .

Access Methods

_concat - Horizontally concatenation of matrices

`_concat(A, B, ...)`

An error message is issued if the given matrices do not have the same number of rows.

Note The returned matrix is of the domain `Dom::Matrix(R)`.

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B`, or in functional notation: `_concat(A, B, ...)`.

_index - Matrix indexing

`_index(A, i, j)`

`_index(A, r1 .. r2, c1 .. c2)`

`_index(A, i)`

`_index(A, i1 .. i2)`

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]` or in functional notation: `_index(A, i, j)`.

Returns the submatrix of A , created by the rows of A with indices from $r1$ to $r2$ and the columns of A with indices from $c1$ to $c2$.

Note The submatrix is of the domain `Dom::Matrix(R)`.

This method returns the i th entry of A .

If i is not an integer, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if i is less than one or greater than the dimension of v .

This call is only allowed for $1 \times n$ or $m \times 1$ matrices, i.e., either m or n must be equal to one. Otherwise an error message is issued.

Note Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

This method returns the subvector of A , formed by the entries with index $i1$ to $i2$ (see also the method "`op`").

This call is only allowed for $1 \times n$ or $m \times 1$ matrices, i.e., either m or n must be equal to one. Otherwise an error message is issued.

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]`, `A[r1..r2, c1..c2]`, `A[i]` or `A[i1..i2]`, respectively, or in functional notation: `_index(A, ...)`.

concatMatrix - Horizontally concatenation of matrices

```
concatMatrix(A, B, )
```

col - Extracting a column

```
col(A, c)
```

An error message is issued if c is less than one or greater than n .

delCol - Deleting a column

`delCol(A, c)`

NIL is returned if A only consists of one column.

Note The returned matrix is of the domain `Dom::Matrix(R)`.

An error message is issued if c is less than one or greater than n .

delRow - Deleting a row

`delRow(A, r)`

NIL is returned if A only consists of one row.

Note The returned matrix is of the domain `Dom::Matrix(R)`.

An error message is issued if r is less than one or greater than m .

row - Extracting a row

`row(A, r)`

An error message is issued if r is less than one or greater than m .

stackMatrix - Concatenating of matrices vertically

`stackMatrix(A, B,)`

An error message is issued if the given matrices do not have the same number of columns.

Note The matrix returned is of the domain `Dom::Matrix(R)`.

Conversion Methods

convert - Conversion into a matrix

`convert(x)`

FAIL is returned if the conversion fails.

x may either be an $m \times n$ array, or an $m \times n$ matrix of category `Cat::Matrix`.

x can also be a list. See the parameter `List` and `ListOfRows` in “Creating Elements” above for admissible values of x .

The entries of x must be convertible into elements of the domain R , otherwise FAIL is returned.

Dom::MonomOrdering(Block(o1, ...))
Dom::MonomOrdering(Matrix(params))
```

Description

Dom::MonomOrdering represents the set of all possible monomial orderings. A monomial ordering is a well-ordering of the set of all k -tuples of nonnegative integers for some k .

In MuPAD, a monomial ordering is implemented as a function that, when applied to two lists of nonnegative integers, returns -1, 0, or 1 if the first list is respectively smaller than, equal to, or greater than the second list. Each ordering can only compare lists of one fixed length, called its *order length*. Since the lists under consideration will be exponent vectors in most cases, their length is also referred to as the number of indeterminates.

Monomial orderings are used in algebraic geometry for comparing

terms $\prod_{i=1}^n X_i^{\alpha_i}$ and $\prod_{i=1}^n X_i^{\beta_i}$ in a polynomial ring. Since Dom::MonomOrdering works on the exponent vectors $[\alpha_1, \dots, \alpha_n]$ and $[\beta_1, \dots, \beta_n]$, degreevec must be applied to the terms to be compared before applying Dom::MonomOrdering.

Elements of Dom::MonomOrdering can be used as arguments for lcoeff, lmonomial, lterm, and tcoeff as well as for the functions of the groebner package in order to specify the monomial ordering to be considered.

Dom::MonomOrdering

Monomial orderings are created by calling `Dom::MonomOrdering(someIdentifier(parameters))`, where `someIdentifier` is one of a certain set of predefined identifiers, as stated below. Converting `someIdentifier` into a string gives the *order type* of the monomial ordering.

`Dom::MonomOrdering(Lex(n))` creates the lexicographical order on n indeterminates.

`Dom::MonomOrdering(RevLex(n))` creates the reverse lexicographical order on n indeterminates, i.e.,

`Dom::MonomOrdering(RevLex(n))([a1, ..., an]) =`

`Dom::MonomOrdering(Lex(n))([an, ..., a1]).`

`Dom::MonomOrdering(DegLex(n))` creates the degree order on n indeterminates with the lexicographical order used for tie-break.

`Dom::MonomOrdering(DegRevLex(n))` creates the degree order on n indeterminates with the reverse lexicographical order used for tie-break

.

`Dom::MonomOrdering(DegInvLex(n))` creates the degree order on n indeterminates, with the tie break being the opposite to the lexicographical order.

`Dom::MonomOrdering(Weighted... (w1, ..., wn))` returns a weighted degree order with weights w_1 through w_n . The word following the word `Weighted` specifies the tie-break used. Note that MuPAD uses the ordinary degree order as the first tie-break.

`Dom::MonomOrdering(Matrix(params))` creates a matrix order, with the order matrix defined by `Dom::Matrix()(params)`.

`Dom::MonomOrdering(Block(o1, ..., on))` or, equivalently, `Dom::MonomOrdering([o1, ..., on])`, creates a block order such that `Dom::MonomOrdering(o1)` is used on the first indeterminates, then `Dom::MonomOrdering(o2)` is used as a tie-break on the following indeterminates etc.

Block orders may be nested, i.e., the blocks may be block orders, too.

Weight vectors with negative entries and order matrices do not define well-orderings in general. You may enter such orderings, but it may cause trouble, e.g., to use them with the groebner package.

Superdomain Dom::BaseDomain

Categories Cat::BaseCategory

Examples **Example 1**

We define ORD by prescribing that lists $[a, b, c]$ are ordered according to their weighted degrees $5a + 2b + \pi c$. For lists with equal weighted degree, the non-weighted degree $a + b + c$ is used as a tie-break. Finally, the lexicographical order decides (in fact, this last step is not necessary because π is irrational).

```
ORD:=Dom::MonomOrdering(WeightedDegLex(5, 2, PI))
```

```
WeightedDegLex(5, 2,  $\pi$ )
```

With respect to ORD, $[1, 6, 1]$ is smaller than $[2, 1, 3]$:

```
ORD([1,6,1], [2,1,3])
```

```
-1
```

Parameters

n

Positive integer

w₁, ...

Numerical expressions

o₁, ...

Valid arguments to Dom::MonomOrdering

Dom::MonomOrdering

params

A sequence valid as the sequence of arguments to `Dom::Matrix()`.

Methods

Mathematical Methods

func_call - Compare two lists of integers

```
func_call(o, l1, l2)
```

The lengths of `l1` and `l2` must not exceed the order length of `o`. If `l1` or `l2` is too short, the necessary number of zeroes is appended.

Access Methods

ordertype - Return the type of an order

```
ordertype(o)
```

If `o` equals `Dom::MonomOrdering(someIdentifier(params))`, then converting `someIdentifier` into a string gives the order type of `o`.

orderlength - Return the length of an order

```
orderlength(o)
```

nops - Number of blocks

```
nops(o)
```

block - Get a particular block

```
block(o, i)
```

blocktype - Get the order type of a particular block

```
blocktype(o, i)
```

blocklength - Get the order length of a particular block

```
blocklength(o, i)
```

Conversion Methods

expr - Return an expression from which the order can be restored

`expr(o)`

MuPAD Functions

`groebner::gbasis`

Dom::Multiset

Purpose Multisets

Syntax `Dom::Multiset(<s1, s2, >)`

Description `Dom::Multiset` is the domain of multisets, i.e., sets with possibly multiple identical elements.

A multiset is represented by a set of lists of the form $[s, m]$, where s is an element of the multiset and m its multiplicity.

Multisets can be returned by the system solver `solve`. For example, the input `solve(x^3 - 4*x^2 + 5*x - 2, x, Multiple)` gives all roots of the polynomial $x^3 - 4x^2 + 5x - 2$ in form of the multiset $\{[1, 2], [2, 1]\}$.

The standard set operations such as union, intersection and subtraction of sets have been extended to deal with multisets.

These operations can handle different types of sets, such as sets of type `DOM_SET` and multisets. One may, for example, compute the union of the multiset $\{[a, 2], [b, 1]\}$ and the set $\{c\}$, which results in the multiset $\{[a, 2], [b, 1], [c, 1]\}$.

The elements of the multiset are sorted at the time where the multiset is created. The system function `sort` is used in order to guarantee that exactly one representation exists for a multiset, independent of the sequence in which the arguments appear.

`Dom::Multiset(s1, s2, ...)` creates the multiset consisting of the elements $s1, s2, \dots$

Multiple identical elements in $s1, s2, \dots$ are collected. For example, the call `Dom::Multiset(a, b, a, c)` creates a multiset with the elements a, b, c . The element a has multiplicity two, the other two elements b and c both have multiplicity one.

Superdomain `Dom::BaseDomain`

Categories `Cat::Set`

Examples

Example 1

The multiset $\{a, a, b\}$ consists of the two different elements a and b , where a has multiplicity two and b has multiplicity one:

```
delete a, b, c:  
set1 := Dom::Multiset(a, a, b)
```

```
{[a, 2], [b, 1]}
```

We create another multiset:

```
set2 := Dom::Multiset(a, c, c)
```

```
{[a, 1], [c, 2]}
```

Standard set operations such as disjoint union, intersection or subtraction are implemented for multisets and can be performed using the standard set operators of MuPAD:

```
set1 union set2
```

```
{[a, 3], [b, 1], [c, 2]}
```

```
set1 intersect set2
```

```
{[a, 1]}
```

```
contains(set1, a), contains(set1, d)
```

```
TRUE, FALSE
```

Example 2

Some system functions were overloaded for multisets, such as `expand`, `normal` or `split`.

If we apply `expand` to a multiset, for example, we get an expression sequence of all elements of the multiset (appearing in correspondence to their multiplicity):

```
delete a, b, c, d, e:  
set := Dom::Multiset(a, b, c, a, c, d, c, e, c)
```

```
{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]}
```

```
expand(set)
```

```
a, a, b, c, c, c, c, d, e
```

If you want to convert a multiset into an ordinary set of the domain type `DOM_SET`, use `coerce`:

```
coerce(set, DOM_SET)
```

```
{a, b, c, d, e}
```

Note: The system function `coerce` uses the methods "convert" and "convert_to" of the domain `Dom::Multiset`.

Compare the last result with the return value of the function `expr`, when it is applied for multisets:

```
expr(set)
```

```
{[a, 2], [b, 1], [c, 4], [d, 1], [e, 1]}
```

The result is a set of the domain type `DOM_SET`, consisting of lists of the domain type `DOM_LIST` with two entries, an element of the multiset and the corresponding multiplicity of that element.

Parameters

s1, s2, ...

Objects of any type

Entries

"isFinite"

is TRUE because `Dom::Multiset` represents finite sets.

"inhomog_intersect"

a table of the form `T = Proc(multiset, setoftypeT)`. This entry is used internally by the implementation, and thus should not be touched.

"inhomog_union"

a table of the form `T = Proc(multiset, setoftypeT)`. This entry is used internally by the implementation, and thus should not be touched.

Methods

Mathematical Methods

normal - Normalization of multisets

`normal(set)`

This method overloads the function `normal` for multisets, i.e., one may use it in the form `normal(set)`.

powerset - Power set of a multiset

`powerset(set)`

The power set of `set` is returned as a set of multisets.

random - Random multiset generation

`random()`

The number of elements created, including their multiplicities, is restricted to 20.

Access Methods

_index - Multiset indexing

`_index(set, i)`

See the method "op".

This method overloads the function `_index` for multisets, i.e., one may use it in the form `set[i]`, or in functional notation:

`_index(set, i)`.

contains - Check on existence of set elements

`contains(set, s)`

This method overloads the function `contains` for multisets, i.e., one may use it in the form `contains(set, s)`.

equal - Test on equality of multisets

`equal(set1, set2)`

The system function `_equal` is used for the test.

expand - Expand a multiset to a sequence of its elements

`expand(set)`

This method overloads the function `expand` for multisets, i.e., one may use it in the form `expand(set)`.

getElement - Extract one element from a multiset

`getElement(set)`

Note that the elements of the multiset are sorted with the use of the system function `sort`, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function `solveLib::getElement`, i.e., one may use it in the form `solveLib::getElement(set)`.

has - Check on existence of (sub-)expressions

```
has(set, expr)
```

To check whether `expr` is contained as an element of `set` and not as a subexpression of the elements of `set`, the function `contains` must be used.

This method overloads the function `has` for multisets, i.e., one may use it in the form `has(set, expr)`.

map - Apply a function to multiset elements

```
map(set, func, <expr, >)
```

It overloads the function `map` for multisets, i.e., one may use it in the form `map(set, func, ...)`.

multiplicity - Multiplicity of an element

```
multiplicity(set, s)
```

Elements which are not contained in `set` have multiplicity zero.

card - Number of elements in a multiset

```
card(set)
```

This method overloads the function `card`.

nops - Number of different elements in a multiset

```
nops(set)
```

This method overloads the function `nops` for multisets, i.e., one may use it in the form `nops(set)`.

op - Element of a multiset

```
op(set)
```

```
op(set, i)
```

Returns the i -th element s of the multiset `set` and its multiplicity m in form of the list `[s, m]`.

See also the method `"_index"`.

Note that the elements of the multiset are sorted with the use of the system function `sort`, and thus the order of a multiset depends on the sorting criteria specified by this function.

This method overloads the function `op` for multisets, i.e., one may use it in the form `op(s, i)`.

select - Selecting of multiset elements

```
select(set, func, <expr, >)
```

This method overloads the function `select` for multisets, i.e., one may use it in the form `select(set, func, ...)`. See `select` for details.

split - Splitting a multiset

```
split(set, func, <expr, >)
```

This method overloads the function `split` for multisets, i.e., one may use it in the form `split(set, func, ...)`. See `split` for details.

subs - Substitution of elements in multisets

```
subs(set, )
```

This method overloads the function `subs` for multisets, i.e., one may use it in the form `subs(set, ...)`.

Conversion Methods

convert - Conversion into a multiset

```
convert(x)
```

FAIL is returned if the conversion fails.

Currently only sets of type `DOM_SET` can be converted into multisets.

convert_to - Multiset conversion

```
convert_to(set, T)
```

FAIL is returned if the conversion fails.

Currently T may either be DOM_SET to convert the multiset set into a set (loosing the multiplicities and the order of the elements of set), or DOM_EXPR or "_exprseq" to convert set into an expression sequence (see the method "expand" for details).

See also the method "expr".

expr - Multiset conversion into an object of a kernel domain

```
expr(set)
```

This method overloads the function expr for multisets, i.e., one may use it in the form expr(set).

sort - Sorting of multisets

```
sort(set)
```

This method overloads the function sort for multisets, i.e., one may use it in the form sort(set).

Technical Methods

bin_intersect - Intersection of two multisets

```
bin_intersect(set1, set2)
```

This method is called from routines defined in the category Cat::Set, which implements among others the overloading of the function intersect for multisets. One may intersect two multisets directly by set1 intersect set2, or in functional notation by _intersect(set1, set2).

bin_minus - Subtraction of two multisets

```
bin_minus(set1, set2)
```

This method is called from routines defined in the category Cat::Set, which implements among others the overloading of the function minus for multisets. One may subtract two multisets directly by set1 minus set2, or in functional notation by _minus(set1, set2).

homog_union - Union of multisets

`homog_union(set,)`

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `union` for multisets. One may compute the union of two multisets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

nested_union - Union of nested sets

`nested_union(setofsets)`

This method is called from routines defined in the category `Cat::Set`, which implements among others the overloading of the function `union` for multisets and sets. One may compute the union of multisets and sets directly by `set1 union set2`, or in functional notation by `_union(set1, set2)`.

MuPAD Domains

`DOM_SET` | `Dom::ImageSet`

Purpose

Domains of multivariate polynomials

Syntax

Domain Creation

`Dom::MultivariatePolynomial(<Vars, <R, <Order>>>)`

Element Creation

`Dom::MultivariatePolynomial(Vars, R, Order)(p)`

`Dom::MultivariatePolynomial(Vars, R, Order)(lm)`

Description

`Dom::MultivariatePolynomial(Vars, R, ..)` creates the domain of multivariate polynomials in the variable list `Vars` over the commutative ring `R` in distributed representation.

`Dom::MultivariatePolynomial` represents multivariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computation and some classical construction tools used in invariant theory.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

`Dom::MultivariatePolynomial(Vars, R, Order)` creates a domain of multivariate polynomials in the variable list `Vars` over a domain `R` of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

`Dom::MultivariatePolynomial()` creates a polynomial domain in the variable list `[x,y,z]` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering.

`Dom::MultivariatePolynomial(Vars)` generates the polynomial domain in the variable list `Vars` over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Dom::MultivariatePolynomial

Note Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

In contrast to the domain `Dom::DistributedPolynomial`, `Dom::MultivariatePolynomial` accepts only identifiers (`DOM_IDENT`) as indeterminates. This restriction enables some further methods described below.

Please note: For reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. This may cause strange error messages.

Superdomain `Dom::DistributedPolynomial`

Axioms If `R` has `Ax::normalRep`, then `Ax::normalRep`.

If `R` has `Ax::canonicalRep`, then `Ax::canonicalRep`.

Categories If `Vars` has a single variable, then `Cat::UnivariatePolynomial(R)`, else `Cat::Polynomial(R)`.

Examples **Example 1**

To create the ring of multivariate polynomials in `x`, `y` and `z` over the rationals one may define

```
MP := Dom::MultivariatePolynomial([x, y, z], Dom::Rational)
```

```
Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder)
```

The elementary symmetric polynomials of this domain are

```
s1 := MP(x + y + z)
```

```
x + y + z
```

```
s2 := MP(x*y + x*z + y*z)
```

```
x y + x z + y z
```

```
s3 := MP(x*y*z)
```

```
x y z
```

A polynomial is called symmetric if it remains unchanged under every possible permutation of variables as, e.g.:

```
s3 = s3(MP(y), MP(z), MP(x))
```

```
x y z = x y z
```

These polynomials arise naturally in studying the roots of a polynomial. To show this, we first have to create an univariate polynomial, e.g., in U over MP , and generate a polynomial in U with roots in x , y and z .

```
UP := Dom::UnivariatePolynomial(U, MP)
```

```
Dom::UnivariatePolynomial(U, Dom::MultivariatePolynomial([x, y, z], Dom::Rational, LexOrder), LexOrder)
```

```
f := UP((U - x)*(U - y)*(U - z))
```

```
U3 + (-x - y - z) U2 + (x y + x z + y z) U - x y z
```

```
UP(U3) - s1*UP(U2) + s2*UP(U) + (-1)3*s3
```

Dom::MultivariatePolynomial

$$U^3 + (-x - y - z) U^2 + (x y + x z + y z) U - x y z$$

This exemplifies that the coefficients of f are (elementary) symmetric polynomials in its roots.

From the fundamental theorem of symmetric polynomials we know that every symmetric polynomial can be written uniquely as a polynomial in the elementary symmetric polynomials. Thus we can rewrite the following symmetric polynomial s in the elementary symmetric polynomials s_1 , s_2 and s_3 ,

$$s := \text{MP}(x^3 y + x^3 z + x y^3 + x z^3 + y^3 z + y z^3)$$

$$x^3 y + x^3 z + x y^3 + x z^3 + y^3 z + y z^3$$

$$S := \text{MP}::\text{rewritePoly}(s, [s_1=S_1, s_2=S_2, s_3=S_3])$$

$$S_1^2 S_2 - S_1 S_3 - 2 S_2^2$$

where these polynomials are represented by the three new variables S_1 , S_2 and S_3 respectively. To see that this new polynomial S in the new variables indeed represents the old original polynomial s , we simply have to plug in the three elementary symmetric polynomials into S :

$$\text{poly}(S, \text{Expr})(s_1, s_2, s_3)$$

$$x^3 y + x^3 z + x y^3 + x z^3 + y^3 z + y z^3$$

When one has a given list of polynomials, e.g., like:

$$l := [3*s_1, 2*s_1, s_1, s_3]$$

$$[3x + 3y + 3z, 2x + 2y + 2z, x + y + z, xy z]$$

and one wants to sort them in an appropriate order, one may use one of the following two methods.

```
MP::sortList(l, Dom::MonomOrdering(DegLex(3)))
```

```
[x y z, 2 x + 2 y + 2 z, x + y + z, 3 x + 3 y + 3 z]
```

```
MP::stableSort(l, Dom::MonomOrdering(DegLex(3)))
```

```
[x y z, 3 x + 3 y + 3 z, 2 x + 2 y + 2 z, x + y + z]
```

In the first sorted list the order of the three polynomials of the same degree has changed, while with the second method this order remains stable.

Example 2

Let $G \subset GL(n, k)$ be a finite (matrix) subgroup of the general linear group. Then a polynomial $f \in k[x_1, \dots, x_n]$ is called *invariant under G*, if for all $A \in G$

$$f(x) = f(Ax)$$

where $x = (x_1 \dots x_n)$. The symmetric polynomials s_1, s_2 and s_3 from the previous example are invariants under the symmetric group S_3 . In fact, these three fundamental invariants yet generate the whole ring of invariants of S_3 .

Now let us examine the invariants of the famous icosahedral group. One may find a representation of this group on page 73 of H. F. Blichfeldt: Finite collineation groups, University of Chicago Press, 1917.

$$S' = \begin{pmatrix} \varepsilon^3 & 0 \\ 0 & \varepsilon^2 \end{pmatrix}, U' = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, T' = \begin{pmatrix} \alpha & \beta \\ \beta & -\alpha \end{pmatrix}, \varepsilon^5 = 1, \alpha = \frac{\varepsilon^4 - \varepsilon}{\sqrt{5}}, \beta = \frac{\varepsilon^2 - \varepsilon^3}{\sqrt{5}}$$

Dom::MultivariatePolynomial

The group is generated from these three matrices, has 120 elements and is thus a finite subgroup, even of the special linear group $SL(2, (\epsilon))$. It is also well known that

$$i_1 = x_1 x_2^{11} - x_1^6 x_2^6 - x_1^{11} x_2$$

is a fundamental invariant of degree 12 of this group. To declare i_1 in MuPAD one has first to define the polynomial domain.

```
MP:=Dom::MultivariatePolynomial([x1,x2],Dom::Rational)
```

```
Dom::MultivariatePolynomial([x1,x2],Dom::Rational,LexOrder)
```

```
i1:=MP(x1*x2^(11)-11*x1^6*x2^6-x1^(11)*x2)
```

$$-x_1^{11} x_2 - 11 x_1^6 x_2^6 + x_1 x_2^{11}$$

From the invariant i_1 one can compute a further fundamental invariant i_2 with

```
i2:=MP::hessianDet(i1)
```

$$-121 x_1^{20} + 27588 x_1^{15} x_2^5 - 59774 x_1^{10} x_2^{10} - 27588 x_1^5 x_2^{15} - 121 x_2^{20}$$

But to get more simple coefficients we choose i_2 as

```
i2:=-1/121*MP::hessianDet(i1)
```

$$x_1^{20} - 228 x_1^{15} x_2^5 + 494 x_1^{10} x_2^{10} + 228 x_1^5 x_2^{15} + x_2^{20}$$

instead. Similar we obtain a third fundamental invariant i_3 with

```
i3:=1/20*MP::jacobianDet([i1,i2])
```

$$x_1^{30} + 522 x_1^{25} x_2^5 - 10005 x_1^{20} x_2^{10} - 10005 x_1^{10} x_2^{20} - 522 x_1^5 x_2^{25} + x_2^{30}$$

In contrast to the symmetric groups, where all invariants can be uniquely represented by the fundamental invariants, the fundamental invariants of this group have an algebraic relation, a so-called syzygy between them. It is possible to represent i_3^2 in two ways:

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3])
```

$$-1728 I_1^5 + I_2^3$$

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted)
```

$$I_3^2$$

And hence we get the syzygy:

```
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3],Unsorted) -  
MP::rewritePoly(i3^2,[i1=I1,i2=I2,i3=I3]) = 0
```

$$1728 I_1^5 - I_2^3 + I_3^2 = 0$$

Parameters

Vars

A list of indeterminates. Default: [x,y,z].

R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default: `Dom::ExpressionField(normal)`.

Order

Dom::MultivariatePolynomial

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or any object of type `Dom::MonomOrdering`. Default: `LexOrder`.

P

A polynomial or a polynomial expression.

Im

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter <code>R</code> .
"key"	The name of the domain created.
"one"	The neutral element w.r.t. " <code>_mult</code> ".
"ordering"	The monomial ordering defined by the parameter <code>Order</code> .
"variables"	The list of variables defined by the parameter <code>Vars</code> .
"zero"	The neutral element w.r.t. " <code>_plus</code> ".

Methods

Mathematical Methods

D - Differential operator for polynomials

Inherited from `Dom::DistributedPolynomial`.

Dpoly - Differential operator for polynomials

Inherited from `Dom::DistributedPolynomial`.

SPolynomial - Compute the S-polynomial of two polynomials

Inherited from Dom::DistributedPolynomial.

divide - Exact polynomial division

Inherited from Dom::DistributedPolynomial.

invert - Inverse of an element

Inherited from Dom::DistributedPolynomial.

mult - Multiplie polynomials and coefficient ring elements

Inherited from Dom::DistributedPolynomial.

negate - Negate a polynomial

Inherited from Dom::DistributedPolynomial.

plus - Add polynomials and coefficient ring elements

Inherited from Dom::DistributedPolynomial.

power - Nth power of a polynomial

Inherited from Dom::DistributedPolynomial.

subtract - Subtract a polynomial or a coefficient ring element

Inherited from Dom::DistributedPolynomial.

associates - Test if elements are associates

Inherited from Cat::IntegralDomain.

borderedHessianDet - Bordered Hessian determinant of a polynomial

borderedHessianDet(a, b, <v>)

borderedHessianMat - Bordered Hessian matrix of a polynomial

borderedHessianMat(a, b, <v>)

content - Content of a polynomial

Inherited from Dom::DistributedPolynomial.

decompose - Functional decomposition of a polynomial

Dom::MultivariatePolynomial

Inherited from Dom::DistributedPolynomial.

degLex - Compare two polynomials w.r.t. the graded lexicographical order

degLex(a, b)

degRevLex - Compare two polynomials w.r.t. the graded reverse lexicographical order

degRevLex(a, b)

diff - Differentiate a polynomial

Inherited from Dom::DistributedPolynomial.

dimension - Dimension of affine variety

Inherited from Dom::DistributedPolynomial.

divide - Divide polynomials

Inherited from Dom::DistributedPolynomial.

divides - Test if elements divides another

Inherited from Cat::IntegralDomain.

equal - Test for mathematical equality

Inherited from Dom::BaseDomain.

equiv - Test for equivalence

Inherited from Cat::BaseCategory.

evalp - Evaluate a polynomial

Inherited from Dom::DistributedPolynomial.

factor - Factor a polynomial

Inherited from Dom::DistributedPolynomial.

func_call - Apply expressions to a polynomial

Inherited from Dom::DistributedPolynomial.

gcd - Greatest common divisor of polynomials

Inherited from Dom::DistributedPolynomial.

gcdex - Extended Euclidean algorithm for polynomials

Inherited from Dom::DistributedPolynomial.

groebner - Reduced Gröbner basis

Inherited from Dom::DistributedPolynomial.

hessianDet - Hessian determinant of a polynomial

hessianDet(a, <v>)

hessianMat - Hessian matrix of a polynomial

hessianMat(a, <v>)

homogeneousComponents - List of homogeneous components of a polynomial

homogeneousComponents(a)

idealGenerator - Generator of finitely generated ideal

Inherited from Cat::EuclideanDomain.

int - Definite and indefinite integration of a polynomial

Inherited from Dom::DistributedPolynomial.

intmult - Multiply a polynomial with an integer

Inherited from Dom::DistributedPolynomial.

irreducible - Test if element is irreducible

Inherited from Cat::FactorialDomain.

isHomogeneous - Test if a polynomial is homogeneous

isHomogeneous(a)

isUnit - Test if element is a unit

Inherited from Cat::Polynomial.

Dom::MultivariatePolynomial

isone - Test for one

Inherited from Dom::DistributedPolynomial.

iszero - Test for zero

Inherited from Dom::DistributedPolynomial.

jacobianDet - Jacobian determinant of a polynomial

`jacobianDet(ais, <v>)`

jacobianMat - Jacobian matrix of a polynomial

`jacobianMat(ais, <v>)`

lcm - Least common multiple of polynomials

Inherited from Dom::DistributedPolynomial.

makeIntegral - Make the coefficients fraction free

Inherited from Dom::DistributedPolynomial.

monic - Normalize a polynomial

Inherited from Dom::DistributedPolynomial.

normalForm - Complete reduction modulo an ideal

Inherited from Dom::DistributedPolynomial.

pdioe - Solve polynomial Diophantine equations

Inherited from Dom::DistributedPolynomial.

pddivide - Pseudo-division of polynomials

Inherited from Dom::DistributedPolynomial.

pquo - Pseudo-quotient of polynomials

Inherited from Dom::DistributedPolynomial.

prem - Pseudo-remainder of polynomials

Inherited from Dom::DistributedPolynomial.

primpart - Return primitive part

Inherited from `Cat::Polynomial`.

quo - Euclidean quotient

Inherited from `Cat::EuclideanDomain`.

random - Create a random polynomial

Inherited from `Dom::DistributedPolynomial`.

rem - Euclidean remainder

Inherited from `Cat::EuclideanDomain`.

resultant - Resultant of two polynomials

Inherited from `Dom::DistributedPolynomial`.

rewriteHomPoly - Rewrite a polynomial in terms of other polynomials

```
rewriteHomPoly(a, ais, v)
```

All the polynomials `a` and `ais` must be homogeneous.

The variables of `v` should be new variables.

rewritePoly - Rewrite a polynomial in terms of other polynomials

```
rewritePoly(a, [ai = vi], <Unsorted>)
```

This method can be used for representing a polynomial with respect to a given polynomial basis.

When option `Unsorted` is given, the list `[ai=vi]` is not sorted. Otherwise, in a precomputation step this list will be sorted in the `ai`'s w.r.t. the graded lexicographical order ("`degLex`").

Please note: the algorithm depends on the order of `Vars` and `ais`.

All the polynomials `ai` must be homogeneous.

The variables of `vi` should be new variables.

ringmult - Multiplie a polynomial with a coefficient ring element

Inherited from `Dom::DistributedPolynomial`.

Dom::MultivariatePolynomial

solve - Zero of polynomials

Inherited from Dom::DistributedPolynomial.

sqrfree - Square-free factorization of polynomials

Inherited from Dom::DistributedPolynomial.

unitNormal - Return unit normal

Inherited from Cat::Polynomial.

unitNormalRep - Return unit normal representation

Inherited from Cat::Polynomial.

Access Methods

coeff - Coefficient of a polynomial

Inherited from Dom::DistributedPolynomial.

degree - Degree of a polynomial

Inherited from Dom::DistributedPolynomial.

degreevec - Vector of exponents of the leading term of a polynomial

Inherited from Dom::DistributedPolynomial.

euclideanDegree - Euclidean degree function

Inherited from Dom::DistributedPolynomial.

ground - Ground term of a polynomial

Inherited from Dom::DistributedPolynomial.

has - Existence of an object in a polynomial

Inherited from Dom::DistributedPolynomial.

indets - Indeterminate of a polynomial

Inherited from Dom::DistributedPolynomial.

lcoeff - Leading coefficient of a polynomial

Inherited from Dom::DistributedPolynomial.

ldegree - Lowest degree of a polynomial

Inherited from Dom::DistributedPolynomial.

lmonomial - Leading monomial of a polynomial

Inherited from Dom::DistributedPolynomial.

lterm - Leading term of a polynomial

Inherited from Dom::DistributedPolynomial.

mainvar - Main variable of a polynomial

Inherited from Dom::DistributedPolynomial.

mapcoeffs - Apply a function to the coefficients of a polynomial

Inherited from Dom::DistributedPolynomial.

multcoeffs - Multiply the coefficients of a polynomial with a factor

Inherited from Dom::DistributedPolynomial.

nterms - Number of terms of a polynomial

Inherited from Dom::DistributedPolynomial.

nthcoeff - N-th coefficient of a polynomial

Inherited from Dom::DistributedPolynomial.

nthmonomial - N-th monomial of a polynomial

Inherited from Dom::DistributedPolynomial.

nthterm - N-th term of a polynomial

Inherited from Dom::DistributedPolynomial.

order - Compare two polynomials w.r.t. a given order

order(a, b, o)

Dom::MultivariatePolynomial

orderedVariableList - Ordered list of indeterminates of a polynomial

Inherited from Dom::DistributedPolynomial.

pivotSize - Size of a pivot element

Inherited from Dom::DistributedPolynomial.

reductum - Reductum of a polynomial

Inherited from Dom::DistributedPolynomial.

sortList - Sort a list of polynomials w.r.t. a given order

```
sortList(ais, o)
```

This sorting method may be not stable if o is not a total order.

stableSort - Sort a list of polynomials w.r.t. a given order

```
stableSort(ais, o)
```

This sorting method is stable, even if o is not a total order.

subs - Avoid substitution

Inherited from Dom::BaseDomain.

subsex - Avoid extended substitution

Inherited from Dom::BaseDomain.

tcoeff - Lowest coefficient of a polynomial

Inherited from Dom::DistributedPolynomial.

MuPAD Domains

Dom::Complex | Dom::Float | Dom::Numerical | Dom::Rational |
Dom::Integer

Dom::Numerical

Purpose Field of numbers

Syntax `Dom::Numerical(x)`

Description `Dom::Numerical` is the field of numbers.

`Dom::Numerical` is the domain of numbers represented by one of the kernel domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_COMPLEX`.

`Dom::Numerical` is of category `Cat::Field` due to pragmatism. This domain actually is not a field because `bool(1.0 = float(3) / float(3))` returns `FALSE`, for example.

Elements of `Dom::Numerical` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted into a number (see below).

This means that `Dom::Numerical` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`. Every system function dealing with numbers can be applied, and computations in this domain are performed efficiently.

`Dom::Numerical` has no normal representation, because 0 and 0.0 both represent zero.

Viewed as a differential ring, `Dom::Numerical` is trivial. It only contains constants.

If `x` is a constant arithmetical expression such as `sin(2)` or `PI + 2`, the system function `float` is applied to convert `x` into a floating-point approximation.

An error message is issued if the result of this conversion is not of domain type `DOM_FLOAT` or `DOM_COMPLEX`.

Superdomain `Dom::ArithmeticalExpression`

Axioms `Ax::canonicalRep`, `Ax::systemRep`,
`Ax::efficientOperation("_divide")`,

```
Ax::efficientOperation("_mult"),  
Ax::efficientOperation("_invert")
```

Categories

```
Cat::DifferentialRing, Cat::Field
```

Examples

Example 1

Dom::Numerical contains numbers of the domains DOM_INT, DOM_RAT, DOM_FLOAT and DOM_COMPLEX:

```
Dom::Numerical(2), Dom::Numerical(2/3),  
Dom::Numerical(3.141), Dom::Numerical(2 + 3*I)
```

```
2,  $\frac{2}{3}$ , 3.141, 2 + 3i
```

Constant arithmetical expressions are converted into a real and complex floating-point number, respectively, i.e., into an element of the domain DOM_FLOAT or DOM_COMPLEX (see the function float for details):

```
Dom::Numerical(exp(5)), Dom::Numerical(sin(2/3*I) + 3)
```

```
148.4131591, 3.0 + 0.717158461i
```

Note that the elements of this domain are elements of kernel domains, there are no elements of the domain type Dom::Numerical!

An error message is issued for non-constant arithmetical expressions:

```
Dom::Numerical(sin(x))
```

```
Error: The arguments are invalid. [Dom::Numerical::new]
```

Example 2

Dom::Numerical is regarded as a field, and it therefore can be used as a coefficient ring of polynomials or as a component ring of matrices, for example.

We create the domain of matrices of arbitrary size (see Dom::Matrix) with numerical components:

```
MatN := Dom::Matrix(Dom::Numerical)
```

```
Dom::Matrix(Dom::Numerical)
```

Next we create a banded matrix, such as:

```
A := MatN(4, 4, [-PI, 0, PI], Banded)
```

```
( 0      3.141592654  0      0
 -3.141592654  0      3.141592654  0
  0      -3.141592654  0      3.141592654
  0      0      -3.141592654  0 )
```

and a row vector with four components as a 1 × 4 matrix:

```
v := MatN([[2, 3, -1, 0]])
```

```
( 2 3 -1 0 )
```

Vector-matrix multiplication can be performed with the standard operator * for multiplication:

```
v * A
```

```
( -9.424777961 9.424777961 9.424777961 -3.141592654 )
```

Finally we compute the determinant of the matrix A, using the function `det`:

`det(A)`

`97.40909103`

Parameters

x

An arithmetical expression

Entries

"characteristic"

is zero.

Methods

Mathematical Methods

D - Differential operator for numbers

`D(a)`

See the function `D` for details and further calling sequences.

diff - Differentiation of numbers

`diff(a, x)`

See the function `diff` for details and further calling sequences.

norm - Absolute value of numbers

`norm(a)`

random - Random number generation

`random()`

Conversion Methods

convert - Conversion of objects into numbers

`convert(x)`

Dom::Numerical

If x is of the domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT` or `DOM_COMPLEX`, x is returned.

Otherwise `float(x)` is computed and the result is returned, if it is of the domain type `DOM_FLOAT` or `DOM_COMPLEX`. If it is not, `FAIL` is returned.

convert_to - Conversion into other domains

```
convert_to(a, T)
```

If the conversion fails, `FAIL` is returned.

It currently handles the following domains for `T`: `DOM_INT`, `Dom::Integer`, `DOM_RAT`, `Dom::Rational`, `DOM_FLOAT`, `Dom::Float` and `DOM_COMPLEX`.

testtype - Type checking

```
testtype(a, T)
```

This method is called from the function `testtype`.

`Dom::Real`

Purpose

Domains of polynomials in arbitrarily many indeterminates

Syntax**Domain Creation**

`Dom::Polynomial(<R, <Order>>)`

Element Creation

`Dom::PolynomialRorder(p)`

`Dom::PolynomialRorder(lm, v)`

Description

`Dom::Polynomial(R, ..)` creates the domain of polynomials in arbitrarily many indeterminates over the commutative ring `R` in distributed representation.

`Dom::Polynomial` represents polynomials in arbitrarily many indeterminates over arbitrary commutative rings.

It is simply a front end to the domain

`Dom::DistributedPolynomial([],R,Order)` and thus all usual algebraic and arithmetical polynomial operations are implemented. Please see the documentation for `Dom::DistributedPolynomial` for a list of methods.

`Dom::Polynomial(R, Order)` creates a domain of polynomials in arbitrarily many indeterminates over a domain of category `Cat::CommutativeRing` in sparse distributed representation with respect to the monomial ordering `Order`.

If `Dom::Polynomial` is called without any argument, a polynomial domain over the domain `Dom::ExpressionField(normal)` with respect to the lexicographic monomial ordering is created.

Note Only commutative coefficient rings of type `DOM_DOMAIN` which inherit from `Dom::BaseDomain` are allowed. If `R` is of type `DOM_DOMAIN` but does not inherit from `Dom::BaseDomain`, the domain `Dom::ExpressionField(normal)` will be used instead.

Dom::Polynomial

Only identifiers should be used as polynomial indeterminates, since when creating a new element from a polynomial or a polynomial expression the function `indet`s is first called to get the identifiers and then the polynomial is created with respect to these identifiers.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular, this is true for many access methods, converting methods and technical methods. Thus, improper use of these methods may result in confusing error messages.

Superdomain `Dom::DistributedPolynomial`

Axioms `Ax::indetElements`

Categories `Cat::Polynomial(R)`

Examples **Example 1**

The following call creates the polynomial domain over the rationals.

```
PR:=Dom::Polynomial(Dom::Rational)
```

```
Dom::Polynomial(Dom::Rational, LexOrder)
```

Since the monomial ordering was not specified, this domain is created with the default value for this parameter.

It is rather easy to create elements of this domain, as, e.g.,

```
a := PR(x*(2*x + y^3) - 7/2)
```

$$2x^2 + xy^3 - \frac{7}{2}$$

b := PR(x*(2*t + z^3) - 6)

$$2tx + xz^3 - 6$$

c := a^2 - b/3 + 3

$$-\frac{2tx}{3} + 4x^4 + 4x^3y^3 + x^2y^6 - 14x^2 - 7xy^3 - \frac{xz^3}{3} + \frac{69}{4}$$

Parameters

R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`. Default: `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e., one of the predefined orderings `LexOrder`, `DegreeOrder`, or `DegInvLexOrder` or an element of the domain `Dom::MonomOrdering`. Default: `LexOrder`.

P

A polynomial or a polynomial expression.

lm

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

v

List of indeterminates.

Dom::Polynomial

Entries

"characteristic"	The characteristic of this domain, which is the characteristic of R.
"coeffRing"	The coefficient ring of this domain as defined by the parameter R.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. " <code>_mult</code> ", which is <code>R::one</code> .
"ordering"	The monomial order as defined by the parameter <code>Order</code> .
"zero"	The neutral element w.r.t. " <code>_plus</code> ", which is <code>R::zero</code> .

Algorithms

To create polynomials from expressions with no suitable indeterminates the dummy variable `_dummy` is introduced. With this variable it is possible to create elements from constants which otherwise would fail. The drawback of this approach is that two mathematically equal polynomials may have variable lists which differ by this dummy variable.

MuPAD Domains

`Dom::DistributedPolynomial` | `Dom::MultivariatePolynomial` | `Dom::UnivariatePolynomial`

Purpose Homogeneous direct products

Syntax **Domain Creation**
Dom::Product(Set, <n>)
Dom::ProductSetn(e1, e2, ..., en)
Dom::ProductSetn(List)

Description Dom::Product(Set, n) is an n-fold direct product of the domain *Set*.
Dom::Product(Set, n)(e1, e2, ..., en) creates the n-tuple (e_1, e_2, \dots, e_n) .
The objects e1, e2, ..., en must be convertible into elements of the domain *Set*, otherwise an error message is issued.
Dom::Product(Set, n)(List) creates the n-tuple (l_1, l_2, \dots, l_n) .
The n elements l_i of List must be convertible into elements of the domain *Set*, otherwise an error message is issued.
The list must consist of exactly n elements, otherwise an error message is issued.
Following to the definition of a direct product many of the methods such as "D" and "_negate" just map the operation to all the components of the tuple.
Most n-ary methods like "_plus" and "_mult" apply the operation component-wise to the tuples.

Superdomain Dom::BaseDomain

Axioms If Set has Ax::canonicalRep, then Ax::canonicalRep.
If Set has Cat::AbelianMonoid, then Ax::normalRep.

Categories Cat::HomogeneousFiniteProduct(Set)

Dom::Product

Examples

Example 1

Define the 3-fold direct product of the rational numbers:

```
P3 := Dom::Product(Dom::Rational, 3)
```

```
Dom::Product(Dom::Rational, 3)
```

and create elements:

```
a := P3([1, 2/3, 0])
```

```
[1, 2/3, 0]
```

```
b := P3(2/3, 4, 1/2)
```

```
[2/3, 4, 1/2]
```

We use the standard arithmetical operators to calculate with such tuples:

```
a + b, a*b, 2*a
```

```
[5/3, 14/3, 1/2], [2/3, 8/3, 0], [2, 4/3, 0]
```

Some system functions were overloaded for such elements, such as `diff`, `map` or `zip` (see the description of the corresponding methods "diff", "map" and "zip" above).

For example, to divide each component of `a` by 2 we enter:

```
map(a, `/`, 2)
```

$$\left[\frac{1}{2}, \frac{1}{3}, 0\right]$$

The quoted character ``/`` is another notation for the function `_divide`, the functional form of the division operator `/`.

Be careful that the mapping function returns elements of the domain the product is defined over. This is not checked by the function `map` (for efficiency reasons) and may lead to “invalid” tuples. For example:

```
b := map(a, sin); domtype(b)
```

$$\left[\sin(1), \sin\left(\frac{2}{3}\right), 0\right]$$

```
Dom::Product(Dom::Rational, 3)
```

But the components of `b` are no longer rational numbers!

Parameters

Set

An arbitrary domain of elements, i.e., a domain of category
`Cat::BaseCategory`

n

The dimension of the product (a positive integer); default is 1

e1e2, en, ...

Elements of `Set` or objects convertible into such

List

A list of `n` elements of `Set` or objects convertible into such

Dom::Product

Entries

"dimen"	is the dimension of <code>Dom::Product(Set, n)</code> , which is equal to <code>n</code> .
"coeffRing"	is the domain <code>S</code> .
"one"	is the <code>n</code> -tuple <code>(Set::one, Set::one, ..., Set::one)</code> . This entry only exists if <code>Set</code> is a monoid, i.e., a domain of category <code>Cat::Monoid</code> .
"zero"	is the <code>n</code> -tuple <code>(Set::zero, Set::zero, ..., Set::zero)</code> . This entry only exists if <code>Set</code> is an Abelian group, i.e., a domain of category <code>Cat::AbelianGroup</code> .

Methods

Mathematical Methods

_divide - Divide tuples

`_divide(x, y)`

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category `Cat::Group`.

This method overloads the function `_divide` for `n`-tuples, i.e., one may use it in the form `x / y`, or in functional notation:

`_divide(x, y)`.

_invert - Compute the inverse of a tuple

`_invert(x)`

This method only exists if `Set` is a (multiplicative) group, i.e., a domain of category `Cat::Group`.

This method overloads the function `_invert` for `n`-tuples, i.e., one may use it in the form `1/x` or `x^(-1)`, or in functional notation:

`_inverse(x)`.

_less - Less-than relation

`_less(x, y)`

An implementation is provided only if `Set` is an ordered set, i.e., a domain of category `Cat::OrderedSet`.

This method overloads the function `_less` for n-tuples, i.e., one may use it in the form `x < y`, or in functional notation: `_less(x, y)`.

_mult - Multiplie tuples by tuples and scalars

`_mult(x, y,)`

If `x` is not of the type `Dom::Product(Set, n)`, it is considered as a scalar which is multiplied to each component of the n-tuple `y` (and vice versa).

This method only exists if `Set` is a semigroup, i.e., a domain of category `Cat::SemiGroup`.

This method also handles more than two arguments. In this case, the argument list is split into two parts of the same length which both are multiplied with the function `_mult`. These two result are multiplied again with `_mult` whose result then is returned.

This method overloads the function `_mult` for n-tuples, i.e., one may use it in the form `x * y`, or in functional notation: `_mult(x, y)`.

_negate - Negate an n-tuple

`_negate(x)`

This method overloads the function `_negate` for n-tuples, i.e., one may use it in the form `-x`, or in functional notation: `_negate(x)`.

_power - ith power of a tuple

`_power(x, i)`

An implementation is provided only if `Set` is a semigroup, i.e., a domain of category `Cat::SemiGroup`.

This method overloads the function `_power` for n-tuples, i.e., one may use it in the form x^i , or in functional notation: `_power(x, i)`.

`_plus` - Add tuples

`_plus(x, y,)`

The sum of two n-tuples x and y is defined component-wise as $(x_1 + y_1, \dots, x_n + y_n)$.

This method overloads the function `_plus` for n-tuples, i.e., one may use it in the form $x + y$, or in functional notation: `_plus(x, y)`.

D - Differential operator

`D(x)`

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

This method overloads the operator `D` for n-tuples, i.e., one may use it in the form `D(x)`.

diff - Differentiation of n-tuples

`diff(a, x)`

This method overloads the function `diff` for n-tuples, i.e., one may use it in the form `diff(a, x)`.

An implementation is provided only if `Set` is a partial differential ring, i.e., a domain of category `Cat::PartialDifferentialRing`.

equal - Test on equality of n-tuples

`equal(x, y)`

intmult - Multiple of a tuple

`intmult(x, k)`

An implementation is provided only if `Set` is an Abelian semigroup, i.e., a domain of category `Cat::AbelianSemiGroup`.

iszero - Test on zero

```
iszero(x)
```

Note that there may be more than one representation of the zero n-tuple if R does not have $Ax :: \text{canonicalRep}$.

This method overloads the function `iszero` for n-tuples, i.e., one may use it in the form `iszero(x)`.

random - Random tuple generation

```
random()
```

Access Methods

`_index` - Tuple indexing

```
_index(x, i)
```

See also the method "op".

This method overloads the function `_index` for n-tuples, i.e., one may use it in the form `x[i]`, or in functional notation: `_index(x, i)`.

map - Apply a function to tuple components

```
map(x, func, <expr, >)
```

Note Note that the function values will *not* be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain type `Set`.

This method overloads the function `map` for n-tuples, i.e., one may use it in the form `map(x, func, ...)`.

mapCanFail - Apply a function to tuple components

```
mapCanFail(x, func, <expr, >)
```

op - Component of a tuple

`op(x, i)`

`op(x)`

See also the method "`_index`".

This method overloads the function `op` for n-tuples, i.e., one may use it in the form `op(x, i)`.

Returns a sequence of all components of `x`.

set_index - Assigning tuple components

`set_index(x, i, e)`

See also the method "`subsop`".

Note This method does not check whether `e` has the correct type.

This method overloads the indexed assignment `_assign` for n-tuples, i.e., one may use it in the form `x[i] := e`, or in functional notation: `_assign(x[i], e)`.

sort - Sorting the components of a tuple

`sort(x)`

This method overloads function `sort` for tuples, i.e. one may use it in the form `sort(x)`.

subs - Substitution of tuple components

`subs(x,)`

Note The objects obtained by the substitutions will not be implicitly converted into elements of the domain `Set`. One has to take care that the substitutions return elements of the domain `Set`.

This method overloads the function `subs` for n-tuples, i.e., one may use it in the form `subs(x, ...)`. See `subs` for details and calling sequences.

testEach - Check every component for a certain condition

```
testEach(x, func, <expr, >)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

testOne - Check an component for a certain condition

```
testOne(x, func, <expr, >)
```

`func` must return either `TRUE` or `FALSE`, otherwise a runtime error is raised.

zip - Combine tuples component-wise

```
zip(x, y, func, <expr, >)
```

Note The function values will not be implicitly converted into elements of the domain `Set`. One has to take care that the function calls return elements of the domain `Set`.

This method overloads the function `zip` for n-tuples, i.e., one may use it in the form `zip(x, y, func, ...)`.

zipCanFail - Combine tuples component-wise

```
zipCanFail(x, y, func, <expr, >)
```

Conversion Methods

convert - Conversion into an n-tuple

```
convert(List)
```

```
convert(e1, <e2, >)
```

`FAIL` is returned if this conversion fails.

Dom::Product

Tries to convert the arguments into an element of the domain `Dom::Product(Set, n)`. This can be done if exactly `n` arguments are given where each argument can be converted into an element of the domain `Set`.

FAIL is returned if this conversion fails.

expr - Conversion into an object of a kernel domain

`expr(x)`

This method overloads the function `expr` for `n`-tuples, i.e., one may use it in the form `expr(x)`.

Purpose Skew field of quaternions

Syntax Dom::Quaternion(listi)
Dom::Quaternion(ex)
Dom::Quaternion(M)

Description Domain Dom::Quaternion represents the skew field of quaternions. Quaternions are usually defined to be complex 2×2 matrices of the special form

$$\begin{pmatrix} a+bi & -c-di \\ c-di & a-bi \end{pmatrix},$$

where a, b, c, d are real numbers. Another usual notation is $a + bi + cj + dk$; the subfield of those quaternions for which $c = d = 0$ is isomorphic to the field of complex numbers.

The domain Dom::Quaternion regards these fields as being identical, and it allows both notations that have been mentioned, as well as simply $[a, b, c, d]$.

If you enter a quaternion as an arithmetical expression ex , the identifiers i, j , and k are understood in the way mentioned above; I, J , and K may be used alternatively, and you may also mix small and capital letters. Every subexpression of ex not containing one of these must be real and constant.

Note Be sure that you have not assigned a value to one of the identifiers mentioned.

Dom::Quaternion has the domain Dom::BaseDomain as its super domain, i.e., it inherits each method which is defined by Dom::BaseDomain and not re-implemented by Dom::Quaternion. Methods described below are re-implemented by Dom::Quaternion.

Dom::Quaternion

Superdomain Dom::BaseDomain

Axioms Ax::canonicalRep

Categories Cat::SkewField

Examples **Example 1**

Creating some quaternions.

```
Dom::Quaternion([1,2,3,4]),  
Dom::Quaternion(11+12*i+13*j+14*k);  
M := Dom::Matrix(Dom::Complex)([[3+4*I, -6-2*I], [6-2*I, 3-4*I]]):  
M, Dom::Quaternion(M)
```

$1 + 2i + 3j + 4k, 11 + 12i + 13j + 14k$

$\begin{pmatrix} 3+4i & -6-2i \\ 6-2i & 3-4i \end{pmatrix}, 3+4i+6j+2k$

Example 2

Doing some standard arithmetic.

```
a:=Dom::Quaternion([1,2,3,4]):  
b:=Dom::Quaternion([11,2,33.3,2/3]):  
a*b, a+b, a^2/3, b^3;
```

$-95.56666667 - 107.2i + 72.96666667j + 105.26666667k, 12 + 4i + 36.3j + \frac{14k}{3},$

$-\frac{28}{3} + \frac{4i}{3} + 2j + \frac{8k}{3}, -35409.03667 - 1500.668889i - 24986.137j - 500.222963k$

Example 3

More mathematical operations:

```
a:=Dom::Quaternion([1,2,3,4]):
b:=Dom::Quaternion([11,2,33.3,2/3]):
Dom::Quaternion::nthroot(b,3);
abs(a), sign(b)
```

$2.993953193 + 0.07959236197 i + 1.325212827 j + 0.02653078732 k$

$\sqrt{30}, 0.3130950929 + 0.05692638053 i + 0.9478242358 j + 0.01897546018 k$

Example 4

Some miscellaneous operations.

```
a:=Dom::Quaternion([1,2,3,4]):
Dom::Quaternion::matrixform(a);
map(a, sqrt), map(a, _plus, 1);
```

$$\begin{pmatrix} 1+2i & -3-4i \\ 3-4i & 1-2i \end{pmatrix}$$

$1 + \sqrt{2} i + \sqrt{3} j + 2 k, 2 + 3 i + 4 j + 5 k$

Parameters

listi

A list containing four elements of type `Type::Real`

ex

Arithmetical expression

M

A matrix of type `Dom::Matrix(Dom::Complex)`. It has to be of a special form described in the Details section.

Dom::Quaternion

Entries

"characteristic"	the characteristic of this domain is 0
"one"	the unit element; it equals <code>Dom::Quaternion([1,0,0,0])</code> .
"size"	the number of quaternions is infinity.
"zero"	The zero element; it equals <code>Dom::Quaternion([0,0,0,0])</code> .

Methods

Mathematical Methods

`_mult` - Multiply quaternions

`_mult(x, y,)`

`_plus` - Add quaternions

`_plus(x, y,)`

`_power` - n-th power of a quaternion

`_power(x, n)`

`Im` - Return the imaginary (vectorial) part of a quaternion.

`Im(x)`

The result is still a quaternion.

`Re` - Return the real part of a quaternion.

`Re(x)`

The result is of type `Type::Real`.

`abs` - Absolute value of a quaternion

`abs(x)`

The result is of type `Type::Real`.

`conjugate` - Conjugate element

`conjugate(x)`

intpower - Multiplie quaternions

`intpower(x, {DOM_INT})`

The implementation uses “repeated squaring”.

Dom::Quaternion is used by “_power”.

nthroot - N-th root of a quaternion

`nthroot(x, n)`

The implementation uses “repeated squaring”.

Dom::Quaternion is used by “_power”.

norm - Norm of a quaternion

`norm(x)`

The result is of type `Type::Real`.

random - Random number generation

`random()`

scalarmult - Scalar multiplication

`scalarmult(s, x)`

scalarprod - Inner product

`scalarprod(x, y)`

sign - Sign of a quaternion

`sign(x)`

The result is of type `Type::Real`.

Conversion Methods

convert - Conversion of objects

`convert(x)`

convert_to - Conversion to other domains

```
convert_to(x, T)
```

It currently handles the following domains for T: DOM_EXPR, DOM_LIST, Dom::Matrix(Dom::Complex).

expr - Convert a quaternion to an object of a kernel domain

```
expr(x)
```

The result is an object of the kernel domain DOM_EXPR.

This method overloads the function `expr` for quaternions, i.e., you may use it in the form `expr(x)`.

matrixform - Convert a quaternion to a 2 x 2 matrix with complex entries.

```
matrixform(x)
```

The result is an object of the domain Dom::Matrix(Dom::Complex).

Technical Methods

TeX - Generate TeX-formatted string

```
TeX(x)
```

map - Apply a function to all components of a quaternion

```
map(x, f, arg, )
```

If optional arguments are present, then each component `co` of `x` is replaced by `f(co, arg...)`. So for the quaternion $x := a + bi + cj + dk$, `Dom::Quaternion(x, f, arg, ...)` returns the quaternion $f(a, arg, ...) + f(b, arg, ...)i + f(c, arg, ...)j + f(d, arg, ...)k$.

simplify - Simplification of a quaternion

```
simplify(x)
```

MuPAD Domains

Dom::Complex

Dom::Rational

Purpose Field of rational numbers

Syntax `Dom::Rational(x)`

Description `Dom::Rational` is the domain of rational numbers represented by elements of the domains `DOM_INT` or `DOM_RAT`. `Dom::Rational` represents the field of rational numbers.

Elements of `Dom::Rational` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input is of type `DOM_INT` or `DOM_RAT`. This means `Dom::Rational` is a façade domain which creates elements of domain type `DOM_INT` or `DOM_RAT`.

Viewed as a differential ring `Dom::Rational` is trivial, it contains constants only.

`Dom::Rational` has the domain `Dom::Numerical` as its super domain, i.e., it inherits each method which is defined by `Dom::Numerical` and not re-implemented by `Dom::Rational`. Methods described below are re-implemented by `Dom::Rational`.

Superdomain `Dom::Numerical`

Axioms `Ax::canonicalRep`, `Ax::systemRep`, `Ax::canonicalOrder`,
`Ax::efficientOperation("_divide")`,
`Ax::efficientOperation("_mult")`,
`Ax::efficientOperation("_invert")`

Categories `Cat::QuotientField(Dom::Integer)`, `Cat::DifferentialRing`,
`Cat::OrderedSet`

Examples **Example 1**

Creating some rational numbers using `Dom::Rational`. This example also shows that `Dom::Rational` is a façade domain.

```
Dom::Rational(2/3) ; domtype(%)
```

$\frac{2}{3}$

DOM_RAT

Dom::Rational(2.0)

Error: The arguments are invalid. [Dom::Rational::new]

Example 2

By tracing the method `Dom::Rational::testtypeDom` we can see the interaction between `testtype` and `Dom::Rational::testtypeDom`.

```
prog::trace(Dom::Rational::testtypeDom):  
delete x:  
testtype(x, Dom::Rational);  
testtype(3/4, Dom::Rational);  
prog::untrace(Dom::Rational::testtypeDom):
```

```
enter Dom::Rational::testtypeDom(x, Dom::Rational)  
computed FAIL
```

FALSE

```
enter Dom::Rational::testtypeDom(3/4, Dom::Rational)  
computed TRUE
```

TRUE

Dom::Rational

Parameters **x**

An integer or a rational number

Methods

Mathematical Methods

denom - Denominator of a rational number

denom(x)

diff - Differentiates

diff(z, <x, >)

numer - Numerator of the rational number

numer(x)

random - Random number generation

random()

retract - Retract to an integer element

retract(x)

Conversion Methods

convert - Conversion of objects

convert(x)

convert_to - Conversion to other domains

convert_to(x, T)

The following domains are allowed for T: DOM_INT, Dom::Integer, Dom::Rational, DOM_RAT, DOM_FLOAT, Dom::Float and Dom::Numerical.

testtype - Type checking

testtype(x, T)

In general this method is called from the function `testtype` and not directly by the user. “Example 2” on page 6-363 demonstrates this behaviour.

MuPAD Domains

Dom::Complex | Dom::Float | Dom::Numerical | Dom::Rational |
Dom::Real

Dom::Real

Purpose Field of real numbers

Syntax `Dom::Real(x)`

Description `Dom::Real` is the field of real numbers represented by elements of the kernel domains `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, and `DOM_EXPR`.

`Dom::Real` is the domain of real numbers represented by expressions of type `DOM_INT`, `DOM_RAT` or `DOM_FLOAT`. An expression of type `DOM_EXPR` is considered as a real number if it is of type `Type::Arithmetical` and if it contains no indeterminates which are not of type `Type::ConstantIdents` and if it contains no imaginary part. See “Example 2” on page 6-367.

`Dom::Real` has category `Cat::Field` due to practical reasons. This domain actually is not a field because `bool(1.0 = 1e100 + 1.0 - 1e100)` returns `FALSE` for example.

Elements may not have an unique representation, for example `bool(0 = sin(2)^2 + cos(2)^2 - 1)` returns `FALSE`.

Elements of `Dom::Real` are usually not created explicitly. However, if one creates elements using the usual syntax, it is checked whether the input expression can be converted to a number. This means `Dom::Real` is a façade domain which creates elements of domain type `DOM_INT`, `DOM_RAT`, `DOM_FLOAT`, or `DOM_EXPR`.

`Dom::Real` has no normal representation, because 0 and 0.0 both represent zero.

Viewed as a differential ring, `Dom::Real` is trivial, it contains constants only.

`Dom::Real` has the domain `Dom::Complex` as its super domain, i.e., it inherits each method which is defined by `Dom::Complex` and not re-implemented by `Dom::Real`. Methods described below are re-implemented by `Dom::Real`.

Superdomain `Dom::Complex`

Axioms

```
Ax::systemRep, Ax::canonicalOrder,
Ax::efficientOperation("_divide"),
Ax::efficientOperation("_mult"),
Ax::efficientOperation("_invert")
```

Categories

```
Cat::DifferentialRing, Cat::Field, Cat::OrderedSet
```

Examples**Example 1**

The following lines demonstrate how to generate elements of `Dom::Real`. The rational and the floating-point numbers are elements of the real numbers:

```
Dom::Real(2/3)
```

$$\frac{2}{3}$$

```
Dom::Real(0.5666)
```

$$0.5666$$
Example 2

The numbers `PI` and `sin(2)` are real numbers whereas `sin(2/3 * I) + 3` and `sin(x)` for general symbolic `x` are not real numbers. If we try to create the elements `Dom::Real(sin(2/3 * I) + 3)` and `Dom::Real(sin(x))` an error message is produced.

```
Dom::Real(PI)
```

$$\pi$$

```
Dom::Real(sin(2))
```

$$\sin(2)$$

Dom::Real

```
Dom::Real(sin(2/3 * I) + 3)
```

```
Error: The arguments are invalid. [Dom::Real::new]
```

```
Dom::Real(sin(x))
```

```
Error: The arguments are invalid. [Dom::Real::new]
```

Parameters

x

An expression of type DOM_INT, DOM_RAT, or DOM_FLOAT. An expression of type DOM_EXPR is also allowed if it is of type Type::Arithmetical and if it contains no indeterminates which are not of type Type::ConstantIdents and if it contains no imaginary part.

Methods

Mathematical Methods

_less - Boolean operator "less"

```
_less(x, y)
```

_leequal - Boolean operator "less or equal"

```
_leequal(x, y)
```

_power - Power operator

```
_power(z, n)
```

conjugate - Complex conjugate

```
conjugate(x)
```

Im - Imaginary part of a real number

```
Im(x)
```

random - Random number generation`random()``random(n)``random(m .. n)`

This method returns a random number generator which creates positive integer between 0 and $n - 1$.

This method returns a random number generator which creates positive integer between m and n .

Re - Real part of a real number`Re(x)`**Conversion Methods****convert - Conversion of objects**`convert(x)`**convert_to - Conversion to other domains**`convert_to(x, T)`

The following domains are allowed for T: DOM_INT, Dom::Integer, DOM_RAT, Dom::Rational, DOM_FLOAT, Dom::Float, Dom::Numerical, Dom::ArithmeticalExpression, Dom::Complex.

See Also**MuPAD
Domains**

Dom::Complex | Dom::Float | Dom::Integer | Dom::Numerical |
Dom::Rational

Dom::SquareMatrix

Purpose Rings of square matrices

Syntax **Domain Creation**
`Dom::SquareMatrix(n, <R>)`

Element Creation

`Dom::SquareMatrix(n, R)(Array)`
`Dom::SquareMatrix(n, R)(Matrix)`
`Dom::SquareMatrix(n, R)(<n, n>)`
`Dom::SquareMatrix(n, R)(<n, n>, ListOfRows)`
`Dom::SquareMatrix(n, R)(<n, n>, f)`
`Dom::SquareMatrix(n, R)(<n, n>, List, <Diagonal>)`
`Dom::SquareMatrix(n, R)(<n, n>, g, <Diagonal>)`
`Dom::SquareMatrix(n, R)(<n, n>, List, <Banded>)`

Description **Domain Creation**

`Dom::SquareMatrix(n, R)` creates a domain which represents the ring of $n \times n$ matrices over a component domain `R`. The domain `R` must be of category `Cat::Rng` (a ring, possibly without unit).

If the optional parameter `R` is not given, the domain `Dom::ExpressionField()` is used as the component ring for the square matrices.

For matrices of a domain created by `Dom::SquareMatrix(n, R)`, standard matrix arithmetic is implemented by overloading the standard arithmetical operators `+`, `-`, `*`, `/` and `^`. All functions of the `linalg` package dealing with matrices can also be applied.

`Dom::SquareMatrix(n, R)` has the domain `Dom::Matrix(R)` as its super domain, i.e., it inherits each method which is defined by `Dom::Matrix(R)` and not re-implemented by `Dom::SquareMatrix(n, R)`.

Methods described below are re-implemented by `Dom::SquareMatrix`.

The domain `Dom::Matrix(R)` represents matrices over `R` of arbitrary size, and it therefore does not have any algebraic structure (except of being a *set* of matrices).

The domain `Dom::MatrixGroup(m, n, R)` represents the Abelian group of $m \times n$ matrices over R .

Element Creation

`Dom::SquareMatrix(n, R)(Array)` and `Dom::SquareMatrix(n, R)(Matrix)` create a new matrix formed by the entries of `Array` and `Matrix`, respectively.

The components of `Array` and `Matrix`, respectively, are converted into elements of the domain R . An error message is issued if one of these conversions fails.

The call `Dom::SquareMatrix(n, R)(n , n)` returns the $n \times n$ zero matrix. Note that the $n \times n$ zero matrix is also defined by the entry "zero" (see below).

`Dom::SquareMatrix(n, R)(n , n ListOfRows)` creates an $n \times n$ matrix with components taken from the nested list `ListOfRows`. Each inner list corresponds to a row of the matrix.

If an inner list has less than n entries, the remaining components in the corresponding row of the matrix are set to zero. If there are less than n inner lists, the remaining lower rows of the matrix are filled with zeroes.

The entries of the inner lists are converted into elements of the domain R . An error message is issued if one of these conversions fails.

It might be a good idea first to create a two-dimensional array from that list before calling `Dom::SquareMatrix(n, R)`. This is due to the fact that creating a matrix from an array is the fastest way one can achieve. However, in this case the sublists must have the same number of elements.

`Dom::SquareMatrix(n, R)(n , n f)` returns the matrix whose (i, j) th component is the value of the function call `f(i, j)`. The row and column indices i and j range from 1 to n .

The function values are converted into elements of the domain R . An error message is issued if one of these conversions fails.

Superdomain `Dom::Matrix(R)`

Dom::SquareMatrix

Axioms If R has Ax::canonicalRep, then Ax::canonicalRep.

Categories Cat::SquareMatrix(R)

Examples **Example 1**

A lot of examples can be found on the help page of the domain constructor Dom::Matrix, and most of them are also examples for working with domains created by Dom::SquareMatrix.

These examples only concentrate on some differences with respect to working with matrices of the domain Dom::Matrix(R).

The following command defines the ring of two-dimensional matrices over the rationals:

```
SqMatQ := Dom::SquareMatrix(2, Dom::Rational)
```

```
Dom::SquareMatrix(2, Dom::Rational)
```

```
SqMatQ::hasProp(Cat::Ring)
```

```
TRUE
```

The unit is defined by the entry "one", which is the 2×2 identity matrix:

```
SqMatQ::one
```

```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

```

Note that some operations defined by the domain SqMatQ return matrices which are no longer square. They return therefore matrices of the domain Dom::Matrix(Dom::Rational), the super-domain of SqMatQ. For example, if we delete the first row of the matrix:

```
A := SqMatQ([[1, 2], [-5, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -5 & 3 \end{pmatrix}$$

we get the matrix:

```
SqMatQ::delRow(A, 1)
```

$$\begin{pmatrix} -5 & 3 \end{pmatrix}$$

which is of the domain type:

```
domtype(%)
```

```
Dom::Matrix(Dom::Rational)
```

Example 2

We can convert a square matrix into or from another matrix domain, as shown next:

```
SqMatR := Dom::SquareMatrix(3, Dom::Real):
```

```
MatC := Dom::Matrix(Dom::Complex):
```

```
A := SqMatR((i, j) -> sin(i*j))
```

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

To convert A into a matrix of the domain MatC, enter:

```
coerce(A, MatC)
```

Dom::SquareMatrix

$$\begin{pmatrix} \sin(1) & \sin(2) & \sin(3) \\ \sin(2) & \sin(4) & \sin(6) \\ \sin(3) & \sin(6) & \sin(9) \end{pmatrix}$$

`domtype(%)`

`Dom::Matrix(Dom::Complex)`

The conversion is done component-wise, as the following examples shows:

`B := MatC([[0, 1], [exp(I), 0]])`

$$\begin{pmatrix} 0 & 1 \\ e^i & 0 \end{pmatrix}$$

The matrix B is square but has one complex component and therefore cannot be converted into the domain `SqMatR`:

`coerce(B, SqMatR)`

`FAIL`

Parameters

n

A positive integer

R

A ring, i.e., a domain of category `Cat::Rng`; default is `Dom::ExpressionField()`

Array

An $n \times n$ array

Matrix

An $n \times n$ matrix, i.e., an element of a domain of category
Cat::Matrix

List

A list of matrix components

ListOfRows

A list of at most n rows; each row is a list of at most n matrix components

f

A function or a functional expression with two parameters (the row and column index)

g

A function or a functional expression with one parameter (the row index)

Options

Diagonal

Create a diagonal matrix

With the option `Diagonal`, diagonal matrices can be created with diagonal elements taken from a list, or computed by a function.

`Dom::SquareMatrix(n, R)(n , n List, Diagonal)` creates the $n \times n$ diagonal matrix whose diagonal elements are the entries of `List`.

`List` must have at most n entries. If it has fewer elements, the remaining diagonal elements are set to zero.

The entries of `List` are converted into elements of the domain `R`. An error message is issued if one of these conversions fails.

`Dom::SquareMatrix(n, R)(n , n g, Diagonal)` returns the matrix whose i th diagonal element is `g(i)`, where the index i runs from 1 to n .

Dom::SquareMatrix

The function values are converted into elements of the domain R. An error message is issued if one of these conversions fails.

Banded

Create a banded Toeplitz matrix

`Dom::SquareMatrix(n, R)(n , n List, Banded)` creates an $n \times n$ banded Toeplitz matrix with the elements of `List` as entries. The number of entries of `List` must be odd, say $2h + 1$, and must not exceed n . The resulting matrix has bandwidth at most $2h + 1$.

All elements of the main diagonal of the created matrix are initialized with the middle element of `List`. All elements of the i th subdiagonal are initialized with the $(h + 1 - i)$ th element of `List`. All elements of the i th superdiagonal are initialized with the $(h + 1 + i)$ th element of `List`. All entries on the remaining sub- and superdiagonals are set to zero.

The entries of `List` are converted into elements of the domain R. An error message is issued if one of these conversions fails.

Entries

"one"	is the $n \times n$ identity matrix. This entry exists if the component ring R is a domain of category <code>Cat::Ring</code> , i.e., a ring with unit.
"randomDimen"	is set to <code>[n, n]</code> .
"zero"	is the $n \times n$ zero matrix.

Methods

Mathematical Methods

evalp - Evaluating matrices of polynomials at a certain point

`evalp(A, x = a,)`

This method is only defined if R is a polynomial ring of category `Cat::Polynomial`.

This method overloads the function `evalp` for matrices, i.e., one may use it in the form `evalp(A, x = a)`.

identity - Identity matrix

`identity(k)`

Note The matrix returned is of the domain `Dom::Matrix(R)` if $k \neq n$.

This method only exists if the component ring `R` is of category `Cat::Ring`, i.e., a ring with unit.

matdim - Matrix dimension

`matdim(A)`

random - Random matrix generation

`random()`

The components of the random matrix are generated with the method "random" of the component ring `R`.

Access Methods

`_concat` - Horizontal concatenation of matrices

`_concat(A, B, ...)`

An error message is issued if the given matrices do not have the same number of rows.

Note The matrix returned is of the domain `Dom::Matrix(R)`!

This method overloads the function `_concat` for matrices, i.e., one may use it in the form `A . B`, or in functional notation: `_concat(A, B, ...)`.

`_index` - Matrix indexing

```
_index(A, i, j)
```

```
_index(A, r1 .. r2, c1 .. c2)
```

If `i` and `j` are not integers, then the call of this method returns in its symbolic form (of type "`_index`") with evaluated arguments.

Otherwise an error message is given, if `i` and `j` are not valid row and column indices, respectively.

Note Note that the system function `context` is used to evaluate the entry in the context of the calling environment.

Returns the submatrix of `A`, created by the rows of `A` with indices from `r1` to `r2` and the columns of `A` with indices from `c1` to `c2`.

Note The submatrix returned is of the domain `Dom::Matrix(R)!`

This method overloads the function `_index` for matrices, i.e., one may use it in the form `A[i, j]` and `A[r1..r2, c1..c2]`, respectively, or in functional notation: `_index(A, ...)`.

`concatMatrix` - Horizontal concatenation of matrices

```
concatMatrix(A, B, )
```

`col` - Extracting a column

```
col(A, c)
```

An error message is issued if `c` is less than one or greater than `n`.

`delCol` - Deleting a column

```
delCol(A, c)
```

NIL is returned if `A` only consists of one column.

Note The matrix returned is of the domain `Dom::Matrix(R)`.

An error message is issued if `c` is less than one or greater than `n`.

delRow - Deleting a row

`delRow(A, r)`

NIL is returned if `A` only consists of one row.

Note The matrix returned is of the domain `Dom::Matrix(R)`.

An error message is issued if `r` is less than one or greater than `n`.

row - Extracting a row

`row(A, r)`

An error message is issued if `r` is less than one or greater than `n`.

stackMatrix - Vertical concatenation of matrices

`stackMatrix(A, B,)`

An error message is issued if the given matrices do not have the same number of columns.

Note The matrix returned is of the domain `Dom::Matrix(R)`!

Conversion Methods

create - Defining matrices without component conversions

`create(x,)`

This method should be used if the elements of the parameters `x`, ... are elements of the domain type `R`. This is often the case if a

Dom::SquareMatrix

matrix is to be created whose components come from preceding matrix and scalar operations.

6

Parameters

n

Positive integer

l

List or array consisting of the first n integers in some order.

Entries

"one"

the identical mapping of the set $\{1, \dots, n\}$ to itself.

Methods

Mathematical Methods

_mult - Product of permutations

`_mult(a1,)`

This method overloads the function `_mult`.

_invert - Inverse of a permutation

`_invert(a)`

This method overloads the function `_invert`.

func_call - Function value of a permutation at a point

`func_call(a, i)`

It computes the function value of a at i , i.e., the integer that i is mapped to by the permutation a ; i must be an integer between 1 and n .

cycles - Cycle representation of a permutation

`cycles(a)`

order - Order of a permutation

`order(a)`

inversions - Number of inversions

`inversions(a)`

sign - Sign of a permutation

`sign(a)`

random - Random permutation

`random()`

convert_to - Conversion of a permutation into another type

`convert_to(a, T)`

expr - Convert a permutation into a list

`expr(a)`

Dom::UnivariatePolynomial

Purpose Domains of univariate polynomials

Syntax **Domain Creation**
Dom::UnivariatePolynomial(<Var, <R, <Order>>>)

Element Creation
Dom::UnivariatePolynomial(Var, R, Order)(p)
Dom::UnivariatePolynomial(Var, R, Order)(lm)

Description Dom::UnivariatePolynomial(Var, R, ..) creates the domain of univariate polynomials in the variable Var over the commutative ring R.

Dom::UnivariatePolynomial represents univariate polynomials over arbitrary commutative rings.

All usual algebraic and arithmetical polynomial operations are implemented, including Gröbner basis computations.

Dom::UnivariatePolynomial(Var, R, Order) creates a domain of univariate polynomials in the variable Var over a domain of category Cat::CommutativeRing in sparse representation with respect to the monomial ordering Order.

Dom::UnivariatePolynomial() creates the univariate polynomial domain in the variable x over the domain Dom::ExpressionField(normal) with respect to the lexicographic monomial ordering.

Dom::UnivariatePolynomial(Var) creates the univariate polynomial domain in the variable Var over the domain Dom::ExpressionField(normal) with respect to the lexicographic monomial ordering.

Note Only commutative coefficient rings of type DOM_DOMAIN which inherit from Dom::BaseDomain are allowed. If R is of type DOM_DOMAIN but inherits not from Dom::BaseDomain, the domain Dom::ExpressionField(normal) will be used instead.

For this domain only identifiers are valid variables.

Note It is highly recommend to use only coefficient rings with unique zero representation. Otherwise it may happen that, e.g., a polynomial division will not terminate or a wrong degree will be returned.

Please note that for reasons of efficiency not all methods check their arguments, not even at the interactive level. In particular this is true for many access methods, converting methods and technical methods. Therefore, using these methods inappropriately may result in strange error messages.

Superdomain Dom::MultivariatePolynomial

Axioms If R has Ax::normalRep, then Ax::normalRep.
If R has Ax::canonicalRep, then Ax::canonicalRep.

Categories Cat::UnivariatePolynomial(R)

Examples **Example 1**

To create the ring of univariate polynomials in x over the integers one may define

```
UP:=Dom::UnivariatePolynomial(x,Dom::Integer)
```

```
Dom::UnivariatePolynomial(x, Dom::Integer, LexOrder)
```

Now, let us create two univariate polynomials.

```
a:=UP((2*x-1)^2*(3*x+1))
```

```
12x3 - 8x2 - x + 1
```

Dom::UnivariatePolynomial

`b:=UP((2*x-1)*(3*x+1))^2`

$$36x^4 - 12x^3 - 11x^2 + 2x + 1$$

The usual arithmetical operations for polynomials are available:

`a^2+a*b`

$$432x^7 - 288x^6 - 264x^5 + 200x^4 + 35x^3 - 36x^2 - x + 2$$

The leading coefficient, leading term, leading monomial and reductum of a are

`lcoeff(a), lterm(a), lmonomial(a), UP::reductum(a)`

$$12, x^3, 12x^3, -8x^2 - x + 1$$

and a is of degree

`degree(a)`

$$3$$

The method `gcd` computes the greatest common divisor of two polynomials

`gcd(a,b)`

$$12x^3 - 8x^2 - x + 1$$

and `lcm` the least common multiple:

`lcm(a,b)`

$$36x^4 - 12x^3 - 11x^2 + 2x + 1$$

Computing the definite and indefinite integral of a polynomial is also possible,

`int(a)`

$$3x^4 - \frac{8x^3}{3} - \frac{x^2}{2} + x$$

which is in the case of indefinite integration simply the antiderivative of the polynomial.

`D(int(a))`, `domtype(D(int(a)))`

$$12x^3 - 8x^2 - x + 1, \text{Dom::UnivariatePolynomial}(x, \text{Dom::Fraction}(\text{Dom::Integer}), \text{LexOrder})$$

But, since for representing the indefinite integral of a the coefficient ring chosen as the integers is not appropriate, the polynomial ring over its quotient field is used instead.

Furthermore, interpreting the polynomials as polynomial functions is also allowed in applying coefficient ring elements, polynomials of this domain or arbitrary expressions with option `Expr` to them:

`a(5)`

$$1296$$

`a(b)`

$$559872x^{12} - 559872x^{11} - 326592x^{10} + 414720x^9 + 73872x^8 - 123120x^7 - 9924x^6 + 18408x^5 \\ + 1144x^4 - 1364x^3 - 97x^2 + 38x + 4$$

Dom::UnivariatePolynomial

`a(sin(x), Expr)`

`12 sin(x)3 - 8 sin(x)2 - sin(x) + 1`

To get a vector of coefficients of a polynomial, which gives the dense representation of it, one may use the method `vectorize`.

`UP::vectorize(a), UP::vectorize(a,6)`

`[1, -1, -8, 12], [1, -1, -8, 12, 0, 0]`

Parameters

Var

An indeterminate given by an identifier; default is `x`.

R

A commutative ring, i.e. a domain of category `Cat::CommutativeRing`; default is `Dom::ExpressionField(normal)`.

Order

A monomial ordering, i.e. one of the predefined orderings `LexOrder`, `DegreeOrder` or `DegInvLexOrder` or an element of domain `Dom::MonomOrdering`; default is `LexOrder`.

P

A polynomial or a polynomial expression.

Im

List of monomials, which are represented as lists containing the coefficients together with the exponents or exponent vectors.

Entries

"characteristic"	The characteristic of this domain.
"coeffRing"	The coefficient ring of this domain as defined by the parameter R.
"key"	The name of the domain created.
"one"	The neutral element w.r.t. " <code>_mult</code> ".
"ordering"	The monomial order as defined by the parameter Order.
"variables"	The list of the variable as defined by the parameter Var.
"zero"	The neutral element w.r.t. " <code>_plus</code> ".

Methods

Access Methods

coeff - Coefficient of a polynomial

`coeff(a)`

`coeff(a, Var, n)`

`coeff(a, n)`

`coeff(a, Var, n)` returns the coefficient of the term Var^n as an element of R.

`coeff(a, n)` returns the coefficient of the term Var^n as an element of R.

This method overloads the function `coeff` for polynomials.

degree - Degree of a polynomial

Inherited from `Dom::DistributedPolynomial`.

degreevec - Vector of exponents of the leading term of a polynomial

Dom::UnivariatePolynomial

Inherited from Dom::DistributedPolynomial.

euclideanDegree - Euclidean degree function

Inherited from Dom::DistributedPolynomial.

ground - Ground term of a polynomial

Inherited from Dom::DistributedPolynomial.

has - Existence of an object in a polynomial

Inherited from Dom::DistributedPolynomial.

indets - Indeterminate of a polynomial

Inherited from Dom::DistributedPolynomial.

lcoeff - Leading coefficient of a polynomial

Inherited from Dom::DistributedPolynomial.

ldegree - Lowest degree of a polynomial

Inherited from Dom::DistributedPolynomial.

lmonomial - Leading monomial of a polynomial

Inherited from Dom::DistributedPolynomial.

lterm - Leading term of a polynomial

Inherited from Dom::DistributedPolynomial.

mainvar - Main variable of a polynomial

Inherited from Dom::DistributedPolynomial.

mapcoeffs - Apply a function to the coefficients of a polynomial

Inherited from Dom::DistributedPolynomial.

multcoeffs - Multiply the coefficients of a polynomial with a factor

Inherited from Dom::DistributedPolynomial.

nterms - Number of terms of a polynomial

Inherited from Dom::DistributedPolynomial.

nthcoeff - N-th coefficient of a polynomial

Inherited from Dom::DistributedPolynomial.

nthmonomial - N-th monomial of a polynomial

Inherited from Dom::DistributedPolynomial.

nthterm - N-th term of a polynomial

Inherited from Dom::DistributedPolynomial.

order - Compare two polynomials w.r.t. a given order

Inherited from Dom::MultivariatePolynomial.

orderedVariableList - Ordered list of indeterminates of a polynomial

Inherited from Dom::DistributedPolynomial.

pivotSize - Size of a pivot element

Inherited from Dom::DistributedPolynomial.

reductum - Reductum of a polynomial

Inherited from Dom::DistributedPolynomial.

sortList - Sort a list of polynomials w.r.t. a given order

Inherited from Dom::MultivariatePolynomial.

stableSort - Sort a list of polynomials w.r.t. a given order

Inherited from Dom::MultivariatePolynomial.

subs - Avoid substitution

Inherited from Dom::BaseDomain.

subsex - Avoid extended substitution

Inherited from Dom::BaseDomain.

tcoeff - Lowest coefficient of a polynomial

Dom::UnivariatePolynomial

Inherited from Dom::DistributedPolynomial.

vectorize - Vectorized form of a polynomial

vectorize(a, <n>)

Dom::MultivariatePolynomial

Purpose	Objects kept in factored form
Syntax	<code>Factored(list, <type>, <ring>)</code> <code>Factored(f, <type>, <ring>)</code>
Description	<p>Factored is the domain of objects kept in factored form, such as prime factorization of integers, square-free factorization of polynomials, or the factorization of polynomials in irreducible factors.</p> <p>The argument <code>list</code> must be a list of odd length and of the form <code>[u, f1, e1, f2, e2, ..., fr, er]</code>, where the entries u and f_i are elements of the domain <code>ring</code>, or can be converted into such elements. The e_i must be integers. Here, i ranges from 1 to r.</p> <p>See section “Operands” below for the meaning of the entries of that list.</p> <p>An error message is reported, if one of the list entries is of wrong type.</p> <p>An arithmetical expression <code>f</code> given as the first argument is the same as giving the list <code>[ring::one, f, 1]</code>.</p> <p>See section “Operands” below for the meaning of the entries of that list.</p> <p><code>f</code> must be an element of the domain <code>ring</code>, or must be convertible into such an element, otherwise an error message would be given.</p> <p>The argument <code>type</code> indicates what is known about the factorization. Currently, the following types are known:</p> <ul style="list-style-type: none">• "unknown" – nothing is known about the factorization.• "irreducible" – the f_i are irreducible over the domain <code>ring</code>.• "squarefree" – the f_i are square-free over the domain <code>ring</code>. <p>If this argument is missing, then the type of the created factored object is set to "unknown".</p> <p>The type of factorization is known to any element of <code>Factored</code>. Use the methods <code>getType</code> and <code>setType</code> (see below) to read and set the type of factorization of a given factored object.</p>

Factored

The argument `ring` is the ring of factorization. It must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If this argument is missing, then the domain `Dom::ExpressionField()` is used.

The ring of factorization is known to any element of `Factored`. Use the methods `"getRing"` and `"setRing"` (see below) to read and set the ring of factorization of a given factored object.

You can use the index operator `[]` to extract the factors of an element `f` of the domain `Factored`. E.g., for $f = u f_1^{e_1} f_2^{e_2} \dots$, you have `f[1] = u`, `f[2] = f_1^{e_1}`, `f[3] = f_2^{e_2}` etc.

You can also use the methods `"factors"` and `"exponents"` (see below) to access the operands, i.e., the call `Factored::factors(f)` returns a list of the factors f_i , and `Factored::exponents(g)` returns a list of the exponents e_i ($1 \leq i \leq r$).

The system functions `ifactor`, `factor` and `polylib::sqrfree` are the main application of this domain, they return their result in form of such factored objects (see their help pages for information about the type and ring of factorization).

There may be no need to explicitly create factored objects, but to work with the results of the mentioned system functions.

Note that an element of `Factored` is printed like an expression and behaves like that. As an example, the result of `f := factor(x^2 + 2*x + 1)` is an element of `Factored` and printed as $(x + 1)^2$. The call `type(f)` returns `"_power"` as the expression type of `f`.

For an element `f` of `Factored`, the call `Factored::convert(f, DOM_LIST)` gives a list of all operands of `f`.

Examples

Example 1

The following computes the prime factorization of the integer 20:

```
f := ifactor(20)
```

```
22 5
```

The result is an element of the domain Factored:

```
domtype(f)
```

```
Factored
```

which consists of the following five operands:

```
op(f)
```

```
1, 2, 2, 5, 1
```

They represent the integer 20 in the following form: $20 = 12^2 5$. The factors are prime numbers and can be extracted via `Factor::factors`:

```
Factored::factors(f)
```

```
[2, 5]
```

`ifactor` kept the information that the factorization ring is the ring of integers (represented by the domain `Dom::Integer`), and that the factors of `f` are prime (and therefore irreducible, because `is` an integral domain):

```
Factored::getRing(f), Factored::getType(f)
```

```
Dom::Integer, "irreducible"
```

We can convert such an object into different forms, such as into a list of its operands:

```
Factored::convert_to(f, DOM_LIST)
```

```
[1, 2, 2, 5, 1]
```

or into an unevaluated expression, keeping the factored form:

```
Factored::convert_to(f, DOM_EXPR)
```

```
 $2^2 5$ 
```

or back into an integer:

```
Factored::convert_to(f, Dom::Integer)
```

```
20
```

You may also use the system function `coerce` here, which has the same effect.

Example 2

We compute the factorization of the integers 108 and 512:

```
n1 := ifactor(108); n2 := ifactor(512)
```

```
 $2^2 3^3$ 
```

```
 $2^9$ 
```

The multiplication of these two integers gives the prime factorization of $55296 = 108512$:

```
n1*n2
```

$$2^{11} 3^3$$

Note that the most operations on such objects lead to an un-factored form, such as adding these two integers:

$$n1 + n2$$

$$620$$

You may apply the function `ifactor` to the result, if you are interested in its prime factorization:

```
ifactor(%)
```

$$2^2 5 31$$

You can apply (almost) each function to factored objects, functions that mainly expect arithmetical expressions as their input. Note that, before the operation is applied, the factored object is converted into an arithmetical expression in un-factored form:

```
Re(n1)
```

$$108$$

Example 3

The second system function which deals with elements of `Factored`, is `factor`, which computes all irreducible factors of a polynomial.

For example, if we define the following polynomial of $_{101}$:

```
p := poly(x^12 + x + 1, [x], Dom::IntegerMod(101)):
```

and compute its factorization into irreducible factors, we get:

Factored

```
f := factor(p)
```

```
poly(x2 + 73 x + 29, [x], Dom::IntegerMod(101))
```

```
poly(x5 + 62 x4 + 64 x3 + 63 x2 + 58 x + 100, [x], Dom::IntegerMod(101))
```

```
poly(x5 + 67 x4 + 72 x3 + 100 x2 + 33 x + 94, [x], Dom::IntegerMod(101))
```

If we multiply the factored object with an element that can be converted into an element of the ring of factorization, then we get a new factored object, which then is of the factorization type "unknown":

```
x*f
```

```
poly(x2 + 73 x + 29, [x], Dom::IntegerMod(101))
```

```
poly(x5 + 62 x4 + 64 x3 + 63 x2 + 58 x + 100, [x], Dom::IntegerMod(101))
```

```
poly(x5 + 67 x4 + 72 x3 + 100 x2 + 33 x + 94, [x], Dom::IntegerMod(101)) x
```

```
Factored::getType(%)
```

```
"unknown"
```

You may use the function `expand` which returns the factored object in expanded form as an element of the factorization ring:

```
expand(f)
```

```
poly(x12 + x + 1, [x], Dom::IntegerMod(101))
```

Example 4

The third system function which return elements of Factored is `polylib::sqrfree`, which computes the square-free factorization of polynomials. For example:

```
f := polylib::sqrfree(x^2 + 2*x + 1)
```

```
(x+1)2
```

The factorization type, of course, is "squarefree":

```
Factored::getType(f)
```

```
"squarefree"
```

Parameters**list**

A list of odd length

f

An arithmetical expression

type

A string (default: "unknown")

ring

A domain of category `Cat::IntegralDomain` (default: `Dom::ExpressionField()`)

Function Calls

Calling a factored object as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

Operations

You can apply (almost) every function to factored objects, functions that mainly expect arithmetical expressions as their input.

For example, one may add or multiply those objects, or apply functions such as `expand` and `diff` to them. But the result of such an operation then is usually not any longer of the domain `Factored`, as the factored form could be lost due to the operation (see examples below).

Call `expr(f)` to convert the factored object `f` into an arithmetical expression (as an element of a kernel domain).

The call `coerce(f, DOM_LIST)` returns a list of operands of the factored object `f` (see method "`convert_to`" below).

Operands

An element f of `Factored` consists of the $r + 1$ operands $u, f_1, e_1, f_2, e_2, \dots, f_r, e_r$, such that $f = uf_1^{e_1}f_2^{e_2}\dots f_r^{e_r}$.

The first operand u and the factors f_i are elements of the domain ring. The exponents e_i are integers.

Methods

Mathematical Methods

`_mult` - Multiply factored objects

```
_mult(f, g, )
```

Suppose that `g` is an element of the domain ring (or can be converted into such an element).

If `g` is a unit of ring or a factor of `f`, then the result is a factored object of the same factorization type as `f`. Otherwise, the result is an element of `Factored` with the factorization type "unknown".

If both `f` and `g` are factored objects with factorization type "irreducible", then the result is again a factored object of this type, i.e., the result is still in factored form.

Otherwise, the factored form of `f` is lost, and the result of this method is an element of ring.

This method overloads the function `_mult` for factored objects, i.e., one may use it in the form `f*g*...`, or in functional notation: `_mult(f, g, ...)`.

`_power` - Raise a factored object to a certain power

`_power(f, n)`

If n is a positive integer and f a factored object with factorization type "irreducible" or "squarefree", then the result is still a factored object of this type.

Otherwise, the factored form of f is lost, and the result of this method is an element of ring.

This method overloads the function `_power` for factored objects, i.e., one may use it in the form f^n , or in functional notation: `_power(f, n)`.

expand - Expand a factored object

`expand(f)`

exponents - Get the exponents of a factored object

`exponents(f)`

factor - Factor a factored object

`factor(f)`

If f already is of the factorization type "irreducible", then this method just return f .

Otherwise, this method converts f into an element of the domain ring and calls the method "factor" of ring.

This method returns a factored object of the domain Factored with factorization type "irreducible", if the factorization of f can be computed (otherwise, FAIL is returned).

This method overloads the function `factor` for factored objects, i.e., one may use it in the form `factor(f)`.

factors - Get the factors of a factored object

`factors(f)`

irreducible - Test if a factored object is irreducible

`irreducible(f)`

The test on irreducible is trivial, if `f` has the factorization type "irreducible".

Otherwise, this method converts `f` into an element of `ring` and calls the method "irreducible" of `ring`. The value `FAIL` is returned, if the domain `ring` cannot test if `f` is irreducible.

iszero - Test on zero for factored objects

```
iszero(f)
```

This method overloads the function `iszero` for factored objects, i.e., one may use it in the form `iszero(f)`.

sqrfree - Compute a square-free factorization of a factored object

```
sqrfree(f)
```

If `f` already is of the factorization type "squarefree", then this method just return `f`.

Otherwise, this method converts `f` into an element of the domain `ring` and calls the method "squarefree" of `ring`.

This method returns a factored object of the domain `Factored` with factorization type "squarefree", if the square-free factorization of `f` can be computed (otherwise, `FAIL` is returned).

This method overloads the function `polylib::sqrfree` for factored objects, i.e., one may use it in the form `polylib::sqrfree(f)`.

Access Methods

_index - Extract a term of a factored object

```
_index(f, i)
```

Responds with an error message, if `i` is greater than the number of terms of `f`.

This method overloads the index operator `[]` for factored objects, i.e., one may use it in the form `f[i]`.

getRing - Get the ring of factorization

```
getRing(f)
```

getType - Get the type of factorization

```
getType(f)
```

has - Existence of an object in a factored object

```
has(f, x, )
```

This method overloads the function `has` for factored objects, i.e., one may use it in the form `has(f, x, ...)`.

map - Map a function to the operands of factored objects

```
map(f, func, )
```

See the system function `map` for details.

This method overloads the function `map` for factored objects, i.e., one may use it in the form `map(f, func, ...)`.

nops - Number of operands of a factored object

```
nops(f)
```

This method overloads the function `nops` for factored objects, i.e., one may use it in the form `nops(f)`.

op - Extract an operand of a factored object

```
op(f, i)
```

Returns FAIL, if `i` is greater than the number of operands of `f`.

This method overloads the function `op` for factored objects, i.e., one may use it in the form `op(f, i)`.

select - Select operands of a factored object

```
select(f, func, )
```

This method overloads the function `select` for factored objects, i.e., one may use it in the form `select(f, func, ...)`.

set_index - Set/change a term of a factored object

```
set_index(f, i, x)
```

Responds with an error message, if i is greater than the number of terms of f .

Note Make sure that x either is an element of the domain ring, or an integer.

This method overloads the index operator $[]$ for factored objects, i.e., one may use it in the form $f[i] := x$.

setRing - Set the ring of factorization

```
setRing(f, ring)
```

Note Use this method with caution! Make sure that the factorization of f is still valid over the new ring, and that the operands of f have the correct domain type.

$ring$ must be a domain of category `Cat::IntegralDomain`, which is not checked by this method.

setType - Set the type of factorization

```
setType(f, type)
```

Note Use this method with caution! Make sure that the factorization type corresponds with the factorization of f .

subs - Substitute subexpressions in the operands of a factored object

```
subs(f, x = a, )
```

This method overloads the function `subs` for factored objects, i.e., one may use it in the form `subs(f, x = a, ...)`.

subsop - Substitute operands of a factored object

```
subsop(f, i = a, )
```

This method overloads the function `subsop` for factored objects, i.e., one may use it in the form `subsop(f, i = a, ...)`.

type - Expression type of factored objects

```
type(f)
```

Conversion Methods

convert - Convert an object into a factored object

```
convert(x)
```

If the conversion fails, then `FAIL` is returned.

`x` may either be a list of the form `[u, f1, e1, ..., fr, er]` of odd length (where `u, f1, ..., fr` are of the domain type `ring`, or can be converted into such elements, and `e1, ..., er` are integers), or an element that can be converted into the domain `ring`. The latter case corresponds to the list `[ring::one,x,1]`.

convert_to - Convert factored objects into other domains

```
convert_to(f, T)
```

If the conversion fails, then `FAIL` is returned.

If `T` is the domain `DOM_LIST`, then the list of operands of `f` is returned.

If `T` is the domain `DOM_EXPR`, then the unevaluated expression `u*f1^e1*f2^e2*...*fr^er` is returned, where `u, f1, e1, ...` are the operands of `f`.

Otherwise, the method "convert" of the domain T is called to convert f into an element of the domain T (which could return FAIL).

Use the function expr to convert f into an object of a kernel domain (see below).

create - Create simple and fast a factored objects

```
create(list)
```

```
create(x)
```

This method creates a new factored object with the operands ring::one, x, 1.

expr - Convert a factored object into a kernel domain

```
expr(f)
```

Note Note that the factored form of f may be lost due to this conversion.

expr2text - Convert a factored object into a string

```
expr2text(f)
```

testtype - Type testing for factored objects

```
testtype(f, T)
```

This method is called from the system function testtype.

TeX - LaTeX formatting of a factored object

```
TeX(f)
```

The method "TeX" of the domain ring is used to get the LaTeX-representation of the corresponding operands of f.

This method is called from the system function generate::TeX.

Technical Methods

`_concat` - Concatenate operands of factored objects

```
_concat(f, g)
```

`f` and `g` must have the same factorization type and factorization ring, otherwise an error message is given.

`maprec` - Allow recursive mapping for factored objects

```
maprec(f, x, )
```

First `f` is converted into the unevaluated expression $u \cdot f_1^{e_1} \cdot f_2^{e_2} \cdot \dots \cdot f_r^{e_r}$, where `u`, `f1`, `e1`, ... are the operands of `f`. Then the function `misc::maprec` is called with this expression as its first parameter.

Note that the result of this method is not longer an object of Factored!

`print` - Pretty-print routine for factored objects

```
print(f)
```

`unapply` - Create a procedure from a factored object

```
unapply(f, <x>)
```

This method overloads the function `fp::unapply` for factored objects, i.e., one may use it in the form `fp::unapply(f)`. See `fp::unapply` for details.

Series::Puisseux

Purpose Truncated Puiseux series expansions

Syntax `Series::Puisseux(f, x, <order>, <dir>)`
`Series::Puisseux(f, x = x_0 , <order>, <dir>)`

Description `Series::Puisseux` is a domain for truncated series expansions. Elements of this domain represent initial segments of Taylor, Laurent, or Puiseux series expansions, as well as slightly more general types of series expansions.

The system function `series` is the main application of this domain. It tries to compute a Taylor, Laurent, or Puiseux series or a more general series expansion of a given arithmetical expression, and the result is returned as an element of `Series::Puisseux` or, possibly, of the more general domain `Series::gseries`.

There is usually no need for you to explicitly create elements of this domain. The methods described on this help page apply if you want to process a result returned by `series` further.

Note If you create elements explicitly as described above, then any special mathematical function, such as `sin` or `exp`, involving the series variable is considered as a coefficient. Use `series` to expand such functions as well, and use the constructor only if `f` does not contain any special mathematical functions. Cf. “Example 1” on page 6-409.

Use the type specifier `Type::Series` to determine for an element of this domain, which kind of series expansion it is.

Note The coefficients are allowed to depend sublinearly on the variable of the series expansion. For example, logarithmic terms in the series variable may appear as coefficients. Be aware that this is no Puiseux series in the mathematical sense. Cf. “Example 4” on page 6-418 and the help page for `series`.

Environment Interactions

The function is sensitive to the global variable `ORDER`, which determines the default number of terms of the expansion.

Examples**Example 1**

You can create objects of `Series::Puisseux` in various ways. The standard method is to use the constructor. The second argument specifies the series variable and the expansion point, with default 0 if omitted:

```
Series::Puisseux(x/(1 - x), x);
Series::Puisseux(x/(1 - x), x = 2);
Series::Puisseux(x/(1 - x), x = complexInfinity);
```

$$x + x^2 + x^3 + x^4 + x^5 + x^6 + O(x^7)$$

$$-2 + x - 2 - (x-2)^2 + (x-2)^3 - (x-2)^4 + (x-2)^5 + O((x-2)^6)$$

$$-1 - \frac{1}{x} - \frac{1}{x^2} - \frac{1}{x^3} - \frac{1}{x^4} - \frac{1}{x^5} + O\left(\frac{1}{x^6}\right)$$

The third argument, if present, specifies the desired number of terms. If it is omitted, the value of the environment variable `ORDER` is used:

```
Series::Puisseux(x/(1 - x), x = 2, 4);
ORDER := 2;
Series::Puisseux(x/(1 - x), x);
delete ORDER;
```

$$-2 + x - 2 - (x-2)^2 + (x-2)^3 + O((x-2)^4)$$

$$x + x^2 + O(x^3)$$

Series::Puisseux

The methods `const`, `one`, and `zero` provide shortcuts for creating series expansions with only a constant term or no non-zero term at all. Specifying the order of the error term is mandatory:

```
Series::Puisseux::const(PI, x, 4);  
Series::Puisseux::one(x = 2, 3);  
Series::Puisseux::zero(x = 0, 3/2);  
Series::Puisseux::zero(x = complexInfinity, 5);
```

$$\pi + O(x^4)$$

$$1 + O((x-2)^3)$$

$$O(x^{3/2})$$

$$O\left(\frac{1}{x^5}\right)$$

Note that, e.g., $O(x^{3/2})$ is not an element of `Series::Puisseux`, but can be converted by the constructor:

```
f := O(x^(3/2));  
g := Series::Puisseux(f, x);  
domtype(f), domtype(g)
```

$$O(x^{3/2})$$

$$O(x^{3/2})$$

O , `Series::Puisseux`

Both the constructor `Series::Puisseux` and the method `const` regard special mathematical functions, such as `exp` or `sin`, as coefficients:

```
Series::Puisseux(sin(x)/(1 - x), x, 4);
Series::Puisseux::const(cos(x), x = 1, 3);
```

$$\sin(x) + x \sin(x) + x^2 \sin(x) + x^3 \sin(x) + O(x^4)$$

$$\cos(x) + O((x-1)^3)$$

Use the system function `series` if you want to have special functions expanded as well:

```
series(sin(x)/(1 - x), x, 4);
```

$$x + x^2 + \frac{5x^3}{6} + \frac{5x^4}{6} + O(x^5)$$

The constructor returns `FAIL`, if it cannot convert the input into an element of `Series::Puisseux`. Then `series` may be able to produce a more general expansion:

```
delete a:
Series::Puisseux(x^a/(1 - x), x);
f := series(x^a/(1 - x), x);
domtype(f);
```

`FAIL`

$$x^a + x x^a + x^a x^2 + x^a x^3 + x^a x^4 + x^a x^5 + O(x^a x^6)$$

`Series::gseries`

Series::Puisseux

The method `create` is a purely syntactical constructor, where the operands are specified explicitly. The sixth and seventh arguments are optional and default to 0 and `Undirected`, respectively:

```
Series::Puisseux::create(3, 1, 5, [1/2, 5], x) =  
Series::Puisseux::create(3, 1, 5, [1/2, 5], x, 0, Undirected)
```

$$\frac{x^{1/3}}{2} + 5x^{2/3} + O(x^{5/3}) = \frac{x^{1/3}}{2} + 5x^{2/3} + O(x^{5/3})$$

```
Series::Puisseux::create(1, -2, 1, [ln(x), 0, 3], x, complexInfinity)
```

$$x^2 \ln(x) + 3 + O\left(\frac{1}{x}\right)$$

Example 2

We demonstrate the internal structure of objects of type `Series::Puisseux`:

```
f := series(exp(x), x = 1);  
g := series(sin(sqrt(1/x)), x = infinity);  
h := series(sin(sqrt(-x))/x, x = 0)
```

$$e + e(x-1) + \frac{e(x-1)^2}{2} + \frac{e(x-1)^3}{6} + \frac{e(x-1)^4}{24} + \frac{e(x-1)^5}{120} + O((x-1)^6)$$

$$\frac{1}{\sqrt{x}} - \frac{1}{6x^{3/2}} + \frac{1}{120x^{5/2}} + O\left(\frac{1}{x^{7/2}}\right)$$

$$-\frac{1}{\sqrt{-x}} + \frac{\sqrt{-x}}{6} - \frac{(-x)^{3/2}}{120} + O(x^{5/2})$$

```
op(f);
```

op(g);
op(h)

$$0, 1, 0, 6, \left[e, e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120} \right], x = 1, \text{Undirected}$$

$$0, 2, 1, 7, \left[1, 0, -\frac{1}{6}, 0, \frac{1}{120} \right], x = \text{complexInfinity}, \text{Left}$$

$$1, 2, -1, 5, \left[-\frac{1}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6}, 0, -\frac{(-x)^{3/2}}{120} \right], x = 0, \text{Undirected}$$

The series f and g are of type 0, while h is of type 1:

op(f, 1), op(g, 1), op(h, 1)

0, 0, 1

The branching order of f is 1, and the branching order of both g and h is 2:

op(f, 2), op(g, 2), op(h, 2)

1, 2, 2

The third and the fourth operand determine the order of the leading term and the error term, respectively:

ldegree(f) = op(f, 3)/op(f, 2),
ldegree(g) = op(g, 3)/op(g, 2),
ldegree(h) = op(h, 3)/op(h, 2);
Series::Puisseux::order(f) = op(f, 4)/op(f, 2),
Series::Puisseux::order(g) = op(g, 4)/op(g, 2),

Series::Puisseux

`Series::Puisseux::order(h) = op(h, 4)/op(h, 2);`

$$0 = 0, \frac{1}{2} = \frac{1}{2}, -\frac{1}{2} = -\frac{1}{2}$$

$$6 = 6, \frac{7}{2} = \frac{7}{2}, \frac{5}{2} = \frac{5}{2}$$

For series expansions of type 0, the fifth operand contains the coefficients of the expansion:

`op(f, 5) = [coeff(f)];`

`op(g, 5) = [coeff(g)];`

$$\left[e, e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120} \right] = \left[e, e, \frac{e}{2}, \frac{e}{6}, \frac{e}{24}, \frac{e}{120} \right]$$

$$\left[1, 0, -\frac{1}{6}, 0, \frac{1}{120} \right] = \left[1, 0, -\frac{1}{6}, 0, \frac{1}{120} \right]$$

However, `h` is an expansion of type 1, and then the fifth operand stores the summands:

`op(h, 5);`

`[coeff(h)];`

$$\left[-\frac{1}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6}, 0, -\frac{(-x)^{3/2}}{120} \right]$$

$$\left[-\frac{\sqrt{x}}{\sqrt{-x}}, 0, \frac{\sqrt{-x}}{6\sqrt{x}}, 0, -\frac{(-x)^{3/2}}{120x^{3/2}} \right]$$

The sixth operand contains the series variable and the expansion point:

```
op(f, 6), Series::Puisseux::indet(f), Series::Puisseux::point(f);  
op(g, 6), Series::Puisseux::indet(g), Series::Puisseux::point(g);  
op(h, 6), Series::Puisseux::indet(h), Series::Puisseux::point(h);
```

```
x = 1, x, 1
```

```
x = complexInfinity, x, complexInfinity
```

```
x = 0, x, 0
```

The expansions `f` and `h` are undirected, while `g` is a directed expansion from the left along the real line to the positive infinity:

```
op(f, 7) = Series::Puisseux::direction(f),  
op(g, 7) = Series::Puisseux::direction(g),  
op(h, 7) = Series::Puisseux::direction(h);
```

```
Undirected = Undirected, Left = Left, Undirected = Undirected
```

Note Since the internal structure may be subject to changes, accessing the operands of and element of `Series::Puisseux` via `op` should be avoided. Use the corresponding access methods instead.

Example 3

Around branch points, the series expansions of type 1 can approximate a function in a wider range than those of type 0:

```
f := x -> arcsin(x + 1):  
g := series(f(x), x, 2);  
h := series(f(x), x, 2, Right);
```

Series::Puiseux

$$\frac{\pi}{2} - \sqrt{2} \sqrt{-x} - \frac{\sqrt{2} (-x)^{3/2}}{12} + O(x^{5/2})$$

$$\frac{\pi}{2} - \sqrt{2} \sqrt{x} i + \frac{\sqrt{2} x^{3/2} i}{12} + O(x^{5/2})$$

The expansion `g`, of type 1, approximates `f` well in an open disc centered at the origin. However, the expansion `h`, of type 0, was requested for positive real values of `x` only, and in fact it does not approximate `f` on the negative real axis and in the upper half plane:

```
op(g);  
op(h);
```

$$1, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2} \sqrt{-x}, 0, -\frac{\sqrt{2} (-x)^{3/2}}{12} \right], x = 0, \text{Undirected}$$

$$0, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2} i, 0, \frac{\sqrt{2} i}{12} \right], x = 0, \text{Right}$$

```
DIGITS := 4:  
[f(0.01), f(0.01*I), f(-0.01), f(-0.01*I)];  
map([g(0.01), g(0.01*I), g(-0.01), g(-0.01*I)], float);  
map([h(0.01), h(0.01*I), h(-0.01), h(-0.01*I)], float);  
delete DIGITS:
```

```
[1.571 - 0.1413 i, 1.471 + 0.1001 i, 1.429, 1.471 - 0.1001 i]
```

```
[1.571 - 0.1413 i, 1.471 + 0.1001 i, 1.429, 1.471 - 0.1001 i]
```

```
[1.571 - 0.1413 i, 1.671 - 0.1001 i, 1.712, 1.471 - 0.1001 i]
```

The method `convert01` converts a series expansion of type 0 into one of type 1:

```
h1 := Series::Puisseux::convert01(h);
op(h1);
```

$$\frac{\pi}{2} - \sqrt{2} \sqrt{x} i + \frac{\sqrt{2} x^{3/2} i}{12} + O(x^{5/2})$$

$$1, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2} \sqrt{x} i, 0, \frac{\sqrt{2} x^{3/2} i}{12} \right], x = 0, \text{Right}$$

The reverse conversion, using the method `convert10`, is in not always possible:

```
op(Series::Puisseux::convert10(h1));
op(Series::Puisseux::convert10(g));
```

$$0, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2} i, 0, \frac{\sqrt{2} i}{12} \right], x = 0, \text{Right}$$

$$1, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2} \sqrt{-x}, 0, -\frac{\sqrt{2} (-x)^{3/2}}{12} \right], x = 0, \text{Undirected}$$

You can enforce a conversion by using properties:

```
assume(x > 0);
op(Series::Puisseux::convert10(g));
unassume(x);
```

$$0, 2, 0, 5, \left[\frac{\pi}{2}, -\sqrt{2} i, 0, \frac{\sqrt{2} i}{12} \right], x = 0, \text{Undirected}$$

Series::Puisseux

Example 4

Despite the name, elements of `Series::Puisseux` may contain coefficient functions depending on the series variable:

```
f := series(psi(x), x = infinity, 4);  
domtype(f), coeff(f, 0)
```

$$\ln(x) - \frac{1}{2x} - \frac{1}{12x^2} + O\left(\frac{1}{x^4}\right)$$

`Series::Puisseux, ln(x)`

With respect to differentiation, integration, and composition, such expansions behave like functions of the series variable and not like formal series:

```
diff(f, x) = series(diff(psi(x), x), x = infinity, 4)
```

$$\frac{1}{x} + \frac{1}{2x^2} + \frac{1}{6x^3} + O\left(\frac{1}{x^5}\right) = \frac{1}{x} + \frac{1}{2x^2} + \frac{1}{6x^3} + O\left(\frac{1}{x^5}\right)$$

```
int(f, x) = series(int(psi(x), x), x = infinity, 4)
```

$$x(\ln(x) - 1) - \frac{\ln(x)}{2} + \frac{1}{12x} + O\left(\frac{1}{x^3}\right) = x(\ln(x) - 1) + \frac{\ln(2)}{2} + \frac{\ln(\pi)}{2} - \frac{\ln(x)}{2} + \frac{1}{12x} + O\left(\frac{1}{x^3}\right)$$

```
f @ series(2*x, x = infinity) = series(psi(2*x), x = infinity, 4)
```

$$\ln(2) + \ln(x) - \frac{1}{4x} - \frac{1}{48x^2} + O\left(\frac{1}{x^4}\right) = \ln(2) + \ln(x) - \frac{1}{4x} - \frac{1}{48x^2} + O\left(\frac{1}{x^4}\right)$$

Example 5

The basic arithmetical operations are implemented for elements of Series::Puisseux:

```
f := series(exp(x), x, 4);
g := series(sqrt(x)/(1 - x), x, 4);
h := series(cot(x), x, 4);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + O(x^4)$$

$$\sqrt{x} + x^{3/2} + x^{5/2} + x^{7/2} + O(x^{9/2})$$

$$\frac{1}{x} - \frac{x}{3} + O(x^3)$$

```
f + g + h;
_plus(f, g, h)
```

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + O(x^3)$$

$$\frac{1}{x} + 1 + \sqrt{x} + \frac{2x}{3} + x^{3/2} + \frac{x^2}{2} + x^{5/2} + O(x^3)$$

```
f - h = _subtract(f, h);
-g = _negate(g);
```

$$-\frac{1}{x} + 1 + \frac{4x}{3} + \frac{x^2}{2} + O(x^3) = -\frac{1}{x} + 1 + \frac{4x}{3} + \frac{x^2}{2} + O(x^3)$$

$$-\sqrt{x} - x^{3/2} - x^{5/2} - x^{7/2} + O(x^{9/2}) = -\sqrt{x} - x^{3/2} - x^{5/2} - x^{7/2} + O(x^{9/2})$$

Series::Puisseux

```
f*g*h;  
_mult(f, g, h)
```

$$\frac{1}{\sqrt{x}} + 2\sqrt{x} + \frac{13x^{3/2}}{6} + 2x^{5/2} + O(x^{7/2})$$

$$\frac{1}{\sqrt{x}} + 2\sqrt{x} + \frac{13x^{3/2}}{6} + 2x^{5/2} + O(x^{7/2})$$

```
f/g = _divide(f, g);  
1/h = _invert(h);
```

$$\frac{1}{\sqrt{x}} - \frac{x^{3/2}}{2} - \frac{x^{5/2}}{3} + O(x^{7/2}) = \frac{1}{\sqrt{x}} - \frac{x^{3/2}}{2} - \frac{x^{5/2}}{3} + O(x^{7/2})$$

$$x + \frac{x^3}{3} + O(x^5) = x + \frac{x^3}{3} + O(x^5)$$

Operands that are not of type `Series::Puisseux` are implicitly converted into series expansions with the same expansion point via the constructor before the arithmetical operation is performed:

```
f - 1 - x;  
h * (sin(x) + x);
```

$$\frac{x^2}{2} + \frac{x^3}{6} + O(x^4)$$

$$\frac{\sin(x)}{x} + 1 - \frac{x \sin(x)}{3} - \frac{x^2}{3} + O(x^3)$$

An error occurs when the expansion points differ or the directions of expansion are incompatible:

```
f := series(arccot(x), x = 0, Left);
g := series(sqrt(sin(x)), x = 0, Right);
f + g
```

$$-\frac{\pi}{2} - x + \frac{x^3}{3} - \frac{x^5}{5} + \mathcal{O}(x^7)$$

$$\sqrt{x} - \frac{x^{5/2}}{12} + \frac{x^{9/2}}{1440} + \mathcal{O}(x^{13/2})$$

Error: Inconsistent direction. [Series::Puisseux::plus]

```
h := series(1/x, x = 2, 4);
f * h
```

$$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + \mathcal{O}((x-2)^4)$$

Error: Both series must use the same variables and expansion poi

If the directions are compatible, then the direction of the result specifies the minimal range where all operands are defined:

```
s := series(tanh(x), x, Real);
```

$$x - \frac{x^3}{3} + \frac{2x^5}{15} + \mathcal{O}(x^7)$$

```
f + s;
Series::Puisseux::direction(%)
```

Series::Puisseux

$$-\frac{\pi}{2} - \frac{x^5}{15} + O(x^7)$$

Left

Example 6

The method `scalmult` implements multiplication by a constant or a single term:

```
f := series(1 + 2*x^3, x);  
Series::Puisseux::scalmult(f, 5) = 5*f;  
Series::Puisseux::scalmult(f, 5, 3) = 5*x^3*f;
```

$$1 + 2x^3 + O(x^6)$$

$$5 + 10x^3 + O(x^6) = 5 + 10x^3 + O(x^6)$$

$$5x^3 + 10x^6 + O(x^9) = 5x^3 + 10x^6 + O(x^9)$$

```
g := series(1 + 2*x^3, x = 2, 3);  
Series::Puisseux::scalmult(g, 1, 3) = (x - 2)^3*g
```

$$17 + 24(x-2) + 12(x-2)^2 + O((x-2)^3)$$

$$17(x-2)^3 + 24(x-2)^4 + 12(x-2)^5 + O((x-2)^6) =$$

$$17(x-2)^3 + 24(x-2)^4 + 12(x-2)^5 + O((x-2)^6)$$

```
h := series(1 + 2*x^3, x = complexInfinity);  
Series::Puisseux::scalmult(h, 1, 1/2) = x^(-1/2)*h
```

$$2x^3 + 1 + O\left(\frac{1}{x^3}\right)$$

$$2x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right) = 2x^{5/2} + \frac{1}{\sqrt{x}} + O\left(\frac{1}{x^{7/2}}\right)$$

Example 7

Exponentiation is implemented for integral and rational exponents:

```
f := series(exp(x), x, 3);
f^2 = _power(f, 2);
f^(1/3) = _power(f, 1/3)
```

$$1 + x + \frac{x^2}{2} + O(x^3)$$

$$1 + 2x + 2x^2 + O(x^3) = 1 + 2x + 2x^2 + O(x^3)$$

$$1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3) = 1 + \frac{x}{3} + \frac{x^2}{18} + O(x^3)$$

Exponents are allowed to be non-rational, if the series expansion starts with a constant summand independent of the series variable:

```
f^I = series(exp(I*x), x, 3);
```

$$1 + xi - \frac{x^2}{2} + O(x^3) = 1 + xi - \frac{x^2}{2} + O(x^3)$$

```
g := series(sin(-x), x);
g^I
```

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

Series::Puisseux

Error: The exponent must be a rational number. [Series::Puisseux::_p

If the exponent contains the series variable, then an error occurs:

```
f^x
```

Error: The exponent must not contain the series variable. [Series::

For undirected expansions and rational exponents that are not integral, the result has type 1 in general:

```
g^(1/2);  
op(%, 1);
```

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O(x^{13/2})$$

1

The result simplifies when you specify one of the directions Left or Right:

```
g := series(sin(-x), x, Left):  
g^(1/2);  
op(%, 1);
```

$$-\sqrt{x}i + \frac{x^{5/2}i}{12} - \frac{x^{9/2}i}{1440} + O(x^{13/2})$$

0

```
g := series(sin(-x), x, Right):
g^(1/2);
```

$$\sqrt{x} i - \frac{x^{5/2} i}{12} + \frac{x^{9/2} i}{1440} + O(x^{13/2})$$

Example 8

Functional composition of elements of Series::Puiseux is implemented by the method `_fconcat`:

```
f := series(ln(x), x = 1, 4);
g := series(cos(y), y = 0);
f@g = _fconcat(f, g);
series(ln(cos(y)), y = 0, 4);
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

$$1 - \frac{y^2}{2} + \frac{y^4}{24} + O(y^6)$$

$$-\frac{y^2}{2} - \frac{y^4}{12} + O(y^6) = -\frac{y^2}{2} - \frac{y^4}{12} + O(y^6)$$

$$-\frac{y^2}{2} - \frac{y^4}{12} + O(y^6)$$

If the left argument is not of type Series::Puiseux, it is implicitly expanded around the limit point of the right argument before the composition:

```
f := series(sin(-x), x = 0);
sqrt(y) @ f = Series::Puiseux(sqrt(y), y) @ f;
```

Series::Puisseux

$$-x + \frac{x^3}{6} - \frac{x^5}{120} + O(x^7)$$

$$\sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O(x^{13/2}) = \sqrt{-x} - \frac{(-x)^{5/2}}{12} + \frac{(-x)^{9/2}}{1440} + O(x^{13/2})$$

If the right argument is not of type `Series::Puisseux`, it is implicitly expanded around the origin via the constructor before the composition:

```
f @ sqrt(y) = f @ Series::Puisseux(sqrt(y), y)
```

$$-\sqrt{y} + \frac{y^{3/2}}{6} - \frac{y^{5/2}}{120} + O(y^{7/2}) = -\sqrt{y} + \frac{y^{3/2}}{6} - \frac{y^{5/2}}{120} + O(y^{7/2})$$

This may not work if the argument to be converted contains special mathematical functions, but you can explicitly expand it into a series via `series` in this case:

```
f @ tan(y)
```

FAIL

```
f @ series(tan(y), y = 0)
```

$$-y - \frac{y^3}{6} + \frac{y^5}{40} + O(y^7)$$

Mathematically, the composition of series expansions is not defined if the limit point of the right argument is not the expansion point of the left argument:

```
g := series(y^2 - 1, y = 0);  
f @ g
```

$$-1 + y^2 + O(y^6)$$

FAIL

$$f @ (y^2 - 1)$$

FAIL

$$f @ \text{series}(y^2 - 1, y = 1, 4)$$

$$-2(y-1) - (y-1)^2 + \frac{4(y-1)^3}{3} + 2(y-1)^4 + O((y-1)^5)$$

The method `revert` computes the inverse of a truncated series expansion with respect to composition. The expansion point of the inverse is the limit point of the input and vice versa:

$$f := \text{series}(\ln(x), x = 1, 4);$$

$$\text{revert}(f) = \text{series}(\exp(x), x = 0, 5)$$

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + O(x^5) = 1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + O(x^5)$$

$$f := \text{series}(\cot(x), x = 0);$$

$$\text{revert}(f) = \text{series}(\text{arccot}(x), x = \text{complexInfinity});$$

$$\frac{1}{x} - \frac{x}{3} - \frac{x^3}{45} + O(x^5)$$

Series::Puisseux

$$\frac{1}{x} - \frac{1}{3x^3} + \frac{1}{5x^5} + O\left(\frac{1}{x^7}\right) = \frac{1}{x} - \frac{1}{3x^3} + \frac{1}{5x^5} + O\left(\frac{1}{x^7}\right)$$

f @ revert(f), revert(f) @ f

$$x + O\left(\frac{1}{x^5}\right), x + O(x^7)$$

If the series variable occurs in the coefficients or the type flag is 1, an error occurs:

```
f := series(ln(sin(x)), x);  
g := series(arcsin(x + 1), x, 2);
```

$$\ln(x) - \frac{x^2}{6} - \frac{x^4}{180} + O(x^6)$$

$$\frac{\pi}{2} - \sqrt{2} \sqrt{-x} - \frac{\sqrt{2} (-x)^{3/2}}{12} + O(x^{5/2})$$

revert(f)

Error: Cannot compute the functional inverse. [Series::Puisseux::revert]

revert(g)

Error: Cannot compute the functional inverse. [Series::Puisseux::revert]

Example 9

The methods `diff` and `int` implement term-by-term differentiation and integration:

```
f := series(ln(x), x = 1, 4);
g := diff(f, x);
series(1/x, x = 1, 4);
int(g, x);
```

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

$$1 - (x-1) + (x-1)^2 - (x-1)^3 + O((x-1)^4)$$

$$1 - (x-1) + (x-1)^2 - (x-1)^3 + O((x-1)^4)$$

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - \frac{(x-1)^4}{4} + O((x-1)^5)$$

If you specify a range of integration, then the result is an arithmetical expression plus a symbolic definite integral of the O -term:

```
int(f, x = 1..2);
```

$$\int_1^2 O((x-1)^5, x=1) dx + \frac{11}{30}$$

Example 10

Most special mathematical functions are overloaded for Series::Puisseux:

```
f := series(x/(1 - x), x, 4);
exp(f) = series(exp(x/(1 - x)), x, 4);
ln(f) = series(ln(x/(1 - x)), x, 4);
```

$$x + x^2 + x^3 + x^4 + O(x^5)$$

Series::Puisseux

$$1 + x + \frac{3x^2}{2} + \frac{13x^3}{6} + O(x^4) = 1 + x + \frac{3x^2}{2} + \frac{13x^3}{6} + O(x^4)$$

$$\ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4) = \ln(x) + x + \frac{x^2}{2} + \frac{x^3}{3} + O(x^4)$$

If the system is unable to compute the composition, it returns a symbolic function call with evaluated arguments:

```
delete g:  
g(f)
```

$$g(x + x^2 + x^3 + x^4 + O(x^5))$$

```
exp(series(x + 1/x, x = infinity, 5))
```

$$e^{x + \frac{1}{x} + O\left(\frac{1}{x^4}\right)}$$

In this case, you can try `series` to compute the composition:

```
series(exp(x + 1/x), x = infinity, 5)
```

$$e^x + \frac{e^x}{x} + \frac{e^x}{2x^2} + \frac{e^x}{6x^3} + \frac{e^x}{24x^4} + O\left(\frac{e^x}{x^5}\right)$$

Example 11

The system functions `Re`, `Im`, and `conjugate` work for all real series expansions:

```
f := series(exp(I*x), x, Real);  
Re(f) = series(cos(x), x, Real);  
Im(f) = series(sin(x), x, Real) + O(x^6);  
conjugate(f) = series(exp(-I*x), x, Real);
```

$$1 + xi - \frac{x^2}{2} - \frac{x^3 i}{6} + \frac{x^4}{24} + \frac{x^5 i}{120} + O(x^6)$$

$$1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6) = 1 - \frac{x^2}{2} + \frac{x^4}{24} + O(x^6)$$

$$x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6) = x - \frac{x^3}{6} + \frac{x^5}{120} + O(x^6)$$

$$1 - xi - \frac{x^2}{2} + \frac{x^3 i}{6} + \frac{x^4}{24} - \frac{x^5 i}{120} + O(x^6) = 1 - xi - \frac{x^2}{2} + \frac{x^3 i}{6} + \frac{x^4}{24} - \frac{x^5 i}{120} + O(x^6)$$

Except in trivial cases, a symbolic function call is returned for an undirected expansion:

```
Re(series(PI, x));
Re(series(exp(I*x), x));
```

$$\pi + O(x^6)$$

$$\Re\left(1 + xi - \frac{x^2}{2} - \frac{x^3 i}{6} + \frac{x^4}{24} + \frac{x^5 i}{120} + O(x^6)\right)$$

Example 12

The method `contfrac` converts a series expansion into a continued fraction:

```
f := series(exp(x), x, 10);
contfrac(f);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + \frac{x^8}{40320} + \frac{x^9}{362880} + O(x^{10})$$

Series::Puisseux

$$1 + \frac{x}{1 + \frac{x}{-2 + \frac{x}{-3 + \frac{x}{2 + \frac{x}{5 + \frac{x}{-2 + \frac{x}{-7 + \frac{x}{2 + \frac{x}{9 + O(x)}}}}}}}}}$$

```
g := series(tan(x), x = PI, 10);
contfrac(g);
```

$$x - \pi - \frac{(\pi - x)^3}{3} - \frac{2(\pi - x)^5}{15} - \frac{17(\pi - x)^7}{315} - \frac{62(\pi - x)^9}{2835} + O(-(\pi - x)^{11})$$

$$1 + \frac{-\pi + x}{(\pi - x)^2} \Big/ \left(-3 + \frac{(\pi - x)^2}{5 + \frac{(\pi - x)^2}{-7 + \frac{(\pi - x)^2}{9 + O((\pi - x)^2)}}} \right)$$

If the coefficients of a series expansion depend on the series variable, then so do the coefficients of the corresponding continued fraction:

```
h := series(ln(x + 1/x), x = infinity);
contfrac(h)
```

$$\ln(x) + \frac{1}{x^2} - \frac{1}{2x^4} + O\left(\frac{1}{x^6}\right)$$

$$\ln(x) + \frac{x^{-2}}{1 + \frac{x^{-2}}{2 + O(x^{-2})}}$$

Example 13

For series expansions around the origin, the method `laplace`, overloading `laplace`, computes the Laplace transform term by term, if the second argument is the series variable. The result is a series expansion around infinity:

```
delete s;
f := series(exp(x), x);
g := laplace(f, x, s);
series(laplace(exp(x), x, s), s = infinity);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

$$\frac{1}{s} + \frac{1}{s^2} + \frac{1}{s^3} + \frac{1}{s^4} + \frac{1}{s^5} + \frac{1}{s^6} + O\left(\frac{1}{s^7}\right)$$

$$\frac{1}{s} + \frac{1}{s^2} + \frac{1}{s^3} + \frac{1}{s^4} + \frac{1}{s^5} + \frac{1}{s^6} + O\left(\frac{1}{s^7}\right)$$

Similarly, the method `ilaplace` computes the inverse Laplace transform term by term for series expansions around infinity, if the second argument is the series variable. The result is a series expansion around 0:

```
ilaplace(g, s, x)
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + O(x^6)$$

Series::Puisseux

The Laplace transform and the inverse Laplace transform, respectively, of a series do not make sense for expansion points other than 0 or infinity, respectively, and in these cases a symbolic function call is returned:

```
laplace(series(ln(x), x = 1, 2), x, s);
```

$$\text{laplace}\left(x - 1 - \frac{(x-1)^2}{2} + O((x-1)^3), x, s\right)$$

If the second argument is not the series variable, then the coefficients are transformed:

```
h := series(sin(x*y), x = 1, 2);  
laplace(h, y, s);
```

$$\sin(y) + y \cos(y) (x-1) + O((x-1)^2)$$

$$\frac{1}{s^2+1} - \left(\frac{1}{s^2+1} - \frac{2s^2}{(s^2+1)^2} \right) (x-1) + O((x-1)^2)$$

Example 14

When called with one argument, the method `coeff` returns the sequence of all coefficients of a series expansion:

```
f := series(tan(x), x);  
coeff(f)
```

$$x + \frac{x^3}{3} + \frac{2x^5}{15} + O(x^7)$$

$$1, 0, \frac{1}{3}, 0, \frac{2}{15}$$

```
g := series(1/(x - 1)^2, x = infinity);
coeff(g)
```

$$\frac{1}{x^2} + \frac{2}{x^3} + \frac{3}{x^4} + \frac{4}{x^5} + \frac{5}{x^6} + \frac{6}{x^7} + O\left(\frac{1}{x^8}\right)$$

1, 2, 3, 4, 5, 6

When called with two arguments, `coeff` returns an individual coefficient:

```
coeff(f, -1), coeff(f, 1), coeff(f, 2), coeff(f, 13/2);
```

0, 1, 0, 0

If the second argument exceeds the order of the error term, `coeff` returns FAIL:

```
coeff(f, 10)
```

FAIL

When the expansion point is `complexInfinity`, `coeff(s, n)` returns the coefficient of $\frac{1}{x^n}$, where x is the series variable of s :

```
coeff(g, 2), coeff(g, -3), coeff(g, -15/2)
```

0, 2, 0

Specifying the series variable as second or third argument, respectively, is optional:

```
coeff(f) = coeff(f, x);
```

Series::Puisseux

```
coeff(f, 3) = coeff(f, x, 3)
```

$$\left(1, 0, \frac{1}{3}, 0, \frac{2}{15}\right) = \left(1, 0, \frac{1}{3}, 0, \frac{2}{15}\right)$$

$$\frac{1}{3} = \frac{1}{3}$$

For series expansions of type 1, the “coefficients” in general involve the series variable:

```
h := series(sin(sqrt(-x)), x);  
coeff(h);  
coeff(h, 3/2);
```

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O(x^{7/2})$$

$$\frac{\sqrt{-x}}{\sqrt{x}}, 0, -\frac{(-x)^{3/2}}{6x^{3/2}}, 0, \frac{(-x)^{5/2}}{120x^{5/2}}$$

$$-\frac{(-x)^{3/2}}{6x^{3/2}}$$

Example 15

The method `ldegree` returns the order of the leading term of a series expansion. When the expansion point is `complexInfinity` and the

leading term is $\frac{1}{x^n}$, then this is n :

```
f := series(x*sin(sqrt(-x)), x);  
g := series(cot(x), x = PI);  
h := series(2*arccot(x), x = infinity);
```

$$-(-x)^{3/2} + \frac{(-x)^{5/2}}{6} - \frac{(-x)^{7/2}}{120} + O(x^{9/2})$$

$$-\frac{1}{\pi-x} - \frac{x-\pi}{3} + \frac{(\pi-x)^3}{45} + O(-(\pi-x)^5)$$

$$\frac{2}{x} - \frac{2}{3x^3} + \frac{2}{5x^5} + O\left(\frac{1}{x^7}\right)$$

`ldegree(f)`, `ldegree(g)`, `ldegree(h)`

$$\frac{3}{2}, -1, 1$$

The method `lcoeff` returns the coefficient of the leading term. For an expansion of type 1, it generally involves the series variable:

`lcoeff(f)`, `lcoeff(g)`, `lcoeff(h)`

$$-\frac{(-x)^{3/2}}{x^{3/2}}, 1, 2$$

The method `lterm` returns the leading term itself:

`lterm(f)`, `lterm(g)`, `lterm(h)`

$$x^{3/2}, -\frac{1}{\pi-x}, \frac{1}{x}$$

Finally, the method `lmonomial` returns the whole summand:

`lmonomial(f) = lcoeff(f)*lterm(f);`
`lmonomial(g) = lcoeff(g)*lterm(g);`

Series::Puisseux

```
lmonomial(h) = lcoeff(h)*lterm(h);
```

$$-(-x)^{3/2} = -(-x)^{3/2}$$

$$-\frac{1}{\pi-x} = -\frac{1}{\pi-x}$$

$$\frac{2}{x} = \frac{2}{x}$$

If the series expansion consists only of an O -term, all four methods return FAIL:

```
s := Series::Puisseux::zero(x, 6);  
ldegree(s), lcoeff(s), lterm(s), lmonomial(s)
```

$$O(x^6)$$

FAIL, FAIL, FAIL, FAIL

Example 16

The methods `nthcoeff`, `nthmonomial`, and `nthterm` return the n th non-zero coefficient, monomial, or term, respectively, of a series expansion. In contrast to polynomials, they count from the term of lowest order on, i.e., the ordering is ascending by exponent for finite expansion points and descending by exponent when the expansion point is `complexInfinity`:

```
f := series(x*sin(sqrt(-x)), x);  
g := series(cot(x), x = PI);  
h := series(2*arccot(x), x = infinity);
```

$$-(-x)^{3/2} + \frac{(-x)^{5/2}}{6} - \frac{(-x)^{7/2}}{120} + O(x^{9/2})$$

$$-\frac{1}{\pi-x} - \frac{x-\pi}{3} + \frac{(\pi-x)^3}{45} + O(-(\pi-x)^5)$$

$$\frac{2}{x} - \frac{2}{3x^3} + \frac{2}{5x^5} + O\left(\frac{1}{x^7}\right)$$

`nthcoeff(f, 1) = lcoeff(f);`
`nthmonomial(g, 1) = lmonomial(g);`
`nthterm(h, 1) = lterm(h);`

$$-\frac{(-x)^{3/2}}{x^{3/2}} = -\frac{(-x)^{3/2}}{x^{3/2}}$$

$$-\frac{1}{\pi-x} = -\frac{1}{\pi-x}$$

$$\frac{1}{x} = \frac{1}{x}$$

`nthcoeff(f, 3), nthmonomial(f, 3), nthterm(f, 3);`
`nthcoeff(g, 3), nthmonomial(g, 3), nthterm(g, 3);`
`nthcoeff(h, 3), nthmonomial(h, 3), nthterm(h, 3);`

$$-\frac{(-x)^{7/2}}{120x^{7/2}}, -\frac{(-x)^{7/2}}{120}, x^{7/2}$$

$$-\frac{1}{45}, \frac{(\pi-x)^3}{45}, -(\pi-x)^3$$

Series::Puisseux

$$\frac{2}{5}, \frac{2}{5x^5}, \frac{1}{x^5}$$

If the second argument is not positive or exceeds the number of non-zero summands, all three methods return FAIL:

```
nthcoeff(f, -4), nthterm(g, 0), nthmonomial(h, 4)
```

FAIL, FAIL, FAIL

Example 17

We illustrate the difference between the ordering of terms in polynomials and series expansions. The ordering of the terms in a polynomial agrees with the ordering of the terms in a series expansion with expansion point `complexInfinity`:

```
f := poly(2*(x^2 + x)^3);
g := series(f, x = complexInfinity);
[lcoeff(f), lmonomial(f), lterm(f)];
[lcoeff(g), lmonomial(g), lterm(g)];
```

```
poly(2 x^6 + 6 x^5 + 6 x^4 + 2 x^3, [x])
```

```
2 x^6 + 6 x^5 + 6 x^4 + 2 x^3 + O(1)
```

```
[2, poly(2 x^6, [x]), poly(x^6, [x])]
```

```
[2, 2 x^6, x^6]
```

```
[nthcoeff(f, 2), nthmonomial(f, 3), nthterm(f, 4)];
[nthcoeff(g, 2), nthmonomial(g, 3), nthterm(g, 4)];
```

```
[6, poly(6 x^4, [x]), poly(x^3, [x])]
```

```
[6, 6 x^4, x^3]
```

For finite expansion points, however, the ordering of the terms in a series expansion is the reverse of the ordering of the terms in the corresponding polynomial:

```
h := series(f, x = 0);
[lcoeff(h), lmonomial(h), lterm(h)];
[nthcoeff(h, 2), nthmonomial(h, 3), nthterm(h, 4)];
```

```
2 x^3 + 6 x^4 + 6 x^5 + 2 x^6 + O(x^9)
```

```
[2, 2 x^3, x^3]
```

```
[6, 6 x^5, x^6]
```

Example 18

The method `iszero` checks whether a series expansion has no non-zero summands apart from the O -term:

```
f := series(exp(x), x);
g := Series::Puisseux(0, x = 2, 4);
iszero(f), iszero(g)
```

```
1 + x + x^2/2 + x^3/6 + x^4/24 + x^5/120 + O(x^6)
```

```
O((x-2)^4)
```

```
FALSE, TRUE
```

Series::Puisseux

Example 19

The methods `convert` tries to convert an arbitrary object into an element of `Series::Puisseux`. If the input does not suggest an expansion point, `convert` uses the origin:

```
f := asympt(1/(x + 1), x = infinity);  
g := sin(x)/(1 - x);  
h := poly((x + 1)^10);  
u := O((x - 1)^3, x = 1);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$
$$- \frac{\sin(x)}{x-1}$$

$$\text{poly}(x^{10} + 10x^9 + 45x^8 + 120x^7 + 210x^6 + 252x^5 + 210x^4 + 120x^3 + 45x^2 + 10x + 1, [x])$$

$$O((x-1)^3, x=1)$$

```
domtype(f), domtype(g), domtype(h), domtype(u)
```

```
Series::gseries, DOM_EXPR, DOM_POLY, O
```

```
F := Series::Puisseux::convert(f);  
G := Series::Puisseux::convert(g);  
H := Series::Puisseux::convert(h);  
U := Series::Puisseux::convert(u);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$\sin(x) + x \sin(x) + x^2 \sin(x) + x^3 \sin(x) + x^4 \sin(x) + x^5 \sin(x) + O(x^6)$$

$$1 + 10x + 45x^2 + 120x^3 + 210x^4 + 252x^5 + 210x^6 + 120x^7 + 45x^8 + 10x^9 + x^{10} + O(x^{16})$$

$$O((x-1)^3)$$

convert returns FAIL, if it is unable to convert the input, e.g., because the input contains no or more than one indeterminate:

```
Series::Puisseux::convert(sin(1)),
Series::Puisseux::convert([1, y, 3])
```

FAIL, FAIL

The method convert_to tries to convert an element of Series::Puisseux into a specified type:

```
Series::Puisseux::convert_to(F, Series::gseries);
Series::Puisseux::convert_to(F, contfrac);
Series::Puisseux::convert_to(G, DOM_EXPR);
Series::Puisseux::convert_to(H, DOM_POLY);
Series::Puisseux::convert_to(H, 0);
Series::Puisseux::convert_to(U, 0);
```

$$\frac{1}{x} - \frac{1}{x^2} + \frac{1}{x^3} - \frac{1}{x^4} + \frac{1}{x^5} - \frac{1}{x^6} + O\left(\frac{1}{x^7}\right)$$

$$\frac{x^{-1}}{1 + \frac{x^{-1}}{1 + O(x^{-5})}}$$

$$\sin(x) + x^2 \sin(x) + x^3 \sin(x) + x^4 \sin(x) + x^5 \sin(x) + x \sin(x)$$

Series::Puisseux

```
poly(x10 + 10 x9 + 45 x8 + 120 x7 + 210 x6 + 252 x5 + 210 x4 + 120 x3 + 45 x2 + 10 x + 1, [x])
```

```
O(1)
```

```
O((x - 1)3, x = 1)
```

convert_to returns FAIL, if it is unable to perform the requested conversion:

```
Series::Puisseux::convert_to(F, 0),  
Series::Puisseux::convert_to(F, DOM_LIST)
```

```
FAIL, FAIL
```

Example 20

The method `expr` converts an element of `Series::Puisseux` into an arithmetical expression, discarding the O -term. In general, the ordering of the summands is not preserved:

```
f := series(exp(x*y), x);  
g := series(ln(x), x = 1, 3);
```

$$1 + x y + \frac{x^2 y^2}{2} + \frac{x^3 y^3}{6} + \frac{x^4 y^4}{24} + \frac{x^5 y^5}{120} + O(x^6)$$

$$x - 1 - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} + O((x-1)^4)$$

```
expr(f);  
expr(g);
```

$$\frac{x^5 y^5}{120} + \frac{x^4 y^4}{24} + \frac{x^3 y^3}{6} + \frac{x^2 y^2}{2} + x y + 1$$

$$x - \frac{(x-1)^2}{2} + \frac{(x-1)^3}{3} - 1$$

The method `float` applies the system function `float` to all coefficients:

```
float(f);
float(g);
```

$$1.0 + x y + 0.5 x^2 y^2 + 0.1666666667 x^3 y^3 + 0.04166666667 x^4 y^4 + 0.008333333333 x^5 y^5 + O(x^6)$$

$$1.0 (x-1) - 0.5 (x-1)^2 + 0.3333333333 (x-1)^3 + O((x-1)^4)$$

Example 21

The methods `combine`, `expand`, and `normal` apply the corresponding system functions to all coefficients:

```
delete a, y;
f := series(y/(x + y^a), x, 4);
g := combine(f);
expand(g);
```

$$\frac{y}{y^a} - \frac{x y}{y^{2a}} + \frac{x^2 y}{y^{3a}} - \frac{x^3 y}{y^{4a}} + O(x^4)$$

$$y^{1-a} - x y^{1-2a} + x^2 y^{1-3a} - x^3 y^{1-4a} + O(x^4)$$

$$\frac{y}{y^a} - \frac{x y}{y^{2a}} + \frac{x^2 y}{y^{3a}} - \frac{x^3 y}{y^{4a}} + O(x^4)$$

Series::Puisseux

For efficiency reasons, the arithmetical methods of `Series::Puisseux` usually do not perform any symbolic simplifications. Use `expand` or `normal` to simplify the results:

```
h := series(exp(x), x, 4)^a;
expand(h);
normal(h);
```

$$1 + ax + x^2 \left(\frac{a}{2} + \frac{a(a-1)}{2} \right) + x^3 \left(\frac{a}{6} + \frac{\left(\frac{a}{2} + \frac{a(a-1)}{2} \right) (a-2)}{3} + \frac{a(2a-1)}{6} \right) + O(x^4)$$

$$1 + ax + \frac{a^2 x^2}{2} + \frac{a^3 x^3}{6} + O(x^4)$$

$$1 + ax + \frac{a^2 x^2}{2} + \frac{a^3 x^3}{6} + O(x^4)$$

```
u := series(arctanh(x + y), x, 4);
normal(u);
```

$$\operatorname{arctanh}(y) - \frac{xi}{y^2 i - i} + \frac{x^2 y}{(y^2 - 1)^2} - \frac{x^3 (3y^2 + 1)}{3 (y^2 - 1)^3} + O(x^4)$$

$$\operatorname{arctanh}(y) - \frac{x}{y^2 - 1} + \frac{x^2 y}{(y^2 - 1)^2} - \frac{x^3 (3y^2 + 1)}{3 (y^2 - 1)^3} + O(x^4)$$

Besides normalizing the coefficients, the method `normal` also removes leading and trailing zeroes from the coefficient list:

```
v := Series::Puisseux::create(1, 3, 10,
                               [0, 1/2, 0, 5, 0, 0], x, 2);
coeff(v);
normal(v);
```

```
coeff(%);
```

$$\frac{(x-2)^4}{2} + 5(x-2)^6 + O((x-2)^{10})$$

$$0, \frac{1}{2}, 0, 5, 0, 0$$

$$\frac{(x-2)^4}{2} + 5(x-2)^6 + O((x-2)^{10})$$

$$\frac{1}{2}, 0, 5$$

The method `map` applies a given function to all coefficients. E.g., the system function `factor` is not overloaded for `Series::Puisseux`, but you can use `map` to express all coefficients in factored form:

```
map(u, factor);
```

$$\operatorname{arctanh}(y) - \frac{x}{(y-1)(y+1)} + \frac{yx^2}{(y-1)^2(y+1)^2} - \frac{(3y^2+1)x^3}{3(y-1)^3(y+1)^3} + O(x^4)$$

In the next example, we use `map` to multiply all coefficients of a series expansion by a constant:

```
w := series(exp(x), x, 3);
map(w, _mult, PI) = PI*w
```

$$1 + x + \frac{x^2}{2} + O(x^3)$$

$$\pi + \pi x + \frac{\pi x^2}{2} + O(x^3) = \pi + \pi x + \frac{\pi x^2}{2} + O(x^3)$$

Series::Puisseux

For series expansions of type 1, map applies the function to all non-zero coefficients as returned by coeff:

```
z := series(sin(sqrt(-x)), x);  
coeff(z);  
map(z, cos);
```

$$\sqrt{-x} - \frac{(-x)^{3/2}}{6} + \frac{(-x)^{5/2}}{120} + O(x^{7/2})$$

$$\frac{\sqrt{-x}}{\sqrt{x}}, 0, -\frac{(-x)^{3/2}}{6x^{3/2}}, 0, \frac{(-x)^{5/2}}{120x^{5/2}}$$

$$\sqrt{x} \cos\left(\frac{\sqrt{-x}}{\sqrt{x}}\right) + x^{3/2} \cos\left(\frac{(-x)^{3/2}}{6x^{3/2}}\right) + x^{5/2} \cos\left(\frac{(-x)^{5/2}}{120x^{5/2}}\right) + O(x^{7/2})$$

Example 22

Three different methods can be used to substitute for the series variable: `_fconcat`, `func_call`, and `subs`. Suppose `f` is an element of `Series::Puisseux` and we want to substitute an expression `t` for the series variable `x`. Then `_fconcat` converts `t` into a series expansion around the origin via the constructor, computes the functional composition, and returns the result as an element of `Series::Puisseux`:

```
f := series(exp(x), x = 0, 5);  
Series::Puisseux::_fconcat(f, y) = f @ y;  
f @ (y^2 + y);
```

$$1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + O(x^5)$$

$$1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + O(y^5) = 1 + y + \frac{y^2}{2} + \frac{y^3}{6} + \frac{y^4}{24} + O(y^5)$$

$$1 + y + \frac{3y^2}{2} + \frac{7y^3}{6} + \frac{25y^4}{24} + O(y^5)$$

The composition may fail if the limit point of t around the origin differs from the expansion point of f or if t contains special mathematical functions:

`f @ (y + 1);`

FAIL

`f @ sin(y);`

FAIL

Moreover, the composition does not work if the expression t is constant or contains more than one indeterminate:

`f @ PI;`

Error: Cannot compute composition. [Series::Puisseux::_fconcat]

`f @ (x + y);`

Error: Cannot compute composition. [Series::Puisseux::_fconcat]

You can enforce the composition by explicitly converting t into a series:

Series::Puisseux

```
f @ series(y + 1, y = -1);  
f @ series(sin(y), y = 0);  
f @ series(x + y, x = -y);
```

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + O((y+1)^5)$$

$$1 + y + \frac{y^2}{2} - \frac{y^4}{8} + O(y^5)$$

$$1 + x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + O((x+y)^5)$$

Substitution with `func_call` always works. It discards the error term, `t` is substituted literally, and the result is an expression and not an object of type `Series::Puisseux`:

```
f(5) = Series::Puisseux::func_call(f, 5);  
f(y) = Series::Puisseux::func_call(f, y);
```

$$\frac{523}{8} = \frac{523}{8}$$

$$\frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1 = \frac{y^4}{24} + \frac{y^3}{6} + \frac{y^2}{2} + y + 1$$

```
f(y^2 + y);  
f(y + 1);  
f(sin(y));  
f(PI);  
f(x + y);
```

$$y + \frac{(y^2+y)^2}{2} + \frac{(y^2+y)^3}{6} + \frac{(y^2+y)^4}{24} + y^2 + 1$$

$$y + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + 2$$

$$\frac{\sin(y)^4}{24} + \frac{\sin(y)^3}{6} + \frac{\sin(y)^2}{2} + \sin(y) + 1$$

$$\pi + \frac{\pi^2}{2} + \frac{\pi^3}{6} + \frac{\pi^4}{24} + 1$$

$$x + y + \frac{(x+y)^2}{2} + \frac{(x+y)^3}{6} + \frac{(x+y)^4}{24} + 1$$

Finally, if `subs` is used to substitute for the series variable, only very special substitutions are allowed (see the description of `subs` above for more details). Then a change of variable is performed, and the result is again of type `Series::Puiseux`:

```
subs(f, x = y^2 + y)
```

```
Error: Invalid substitution. [Series::Puiseux::subs]
```

```
subs(f, x = y + 1)
```

$$1 + y + 1 + \frac{(y+1)^2}{2} + \frac{(y+1)^3}{6} + \frac{(y+1)^4}{24} + O((y+1)^5)$$

```
subs(f, x = sin(y))
```

```
Error: Invalid substitution. [Series::Puiseux::subs]
```

Series::Puisseux

```
subs(f, x = PI)
```

Error: The substitution is invalid. Exactly one indeterminate is ex

```
subs(f, x = x + y)
```

Error: The substitution is invalid. Exactly one indeterminate is ex

All three methods can handle the case where the series variable occurs in the coefficients:

```
s := series(ln(x^2 + x), x);  
s @ (2*y);  
s(2*y);  
subs(s, x = 2*y);
```

$$\ln(x) + x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} + O(x^6)$$

$$\ln(2) + \ln(y) + 2y - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5} + O(y^6)$$

$$2y + \ln(2y) - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5}$$

$$\ln(2y) + 2y - 2y^2 + \frac{8y^3}{3} - 4y^4 + \frac{32y^5}{5} + O(y^6)$$

Of course, subs can also be used to substitute for other objects than the series variable in the coefficients and in the expansion point:

```
g := series(cos(x + y), x, 4);
h := series(1/x, x = y, 4);
```

$$\cos(y) - x \sin(y) - \frac{x^2 \cos(y)}{2} + \frac{x^3 \sin(y)}{6} + O(x^4)$$

$$\frac{1}{y} - \frac{x-y}{y^2} + \frac{(x-y)^2}{y^3} - \frac{(x-y)^3}{y^4} + O((x-y)^4)$$

```
subs(g, y = PI) = series(cos(x + PI), x, 4);
subs(h, y = 2) = series(1/x, x = 2, 4);
```

$$-1 + \frac{x^2}{2} + O(x^4) = -1 + \frac{x^2}{2} + O(x^4)$$

$$\frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4) = \frac{1}{2} - \frac{x-2}{4} + \frac{(x-2)^2}{8} - \frac{(x-2)^3}{16} + O((x-2)^4)$$

Even simultaneous substitutions are possible in the coefficients:

```
subs(g, [hold(sin) = cos, hold(cos) = sin, y = 2])
```

$$\sin(2) - x \cos(2) - \frac{x^2 \sin(2)}{2} + \frac{x^3 \cos(2)}{6} + O(x^4)$$

An error occurs, if the right hand side contains the series variable:

```
subs(h, y = x)
```

Error: The substitution is invalid. The right side must not contain

Example 23

The method `has` checks, whether an object occurs syntactically in the coefficients, the series variable, the expansion point, or the direction of an element of `Series::Puisseux`:

```
f := series(sin(x + 2*y), x = PI, 2);
has(f, x), has(f, y), has(f, PI), has(f, 2), has(f, Undirected);
has(f, hold(sin)), has(f, 3), has(f, sin(2*y)), has(f, x - PI);
```

```
- sin(2 y) + cos(2 y) (π - x) + O((π - x)2)
```

```
TRUE, TRUE, TRUE, TRUE, TRUE
```

```
TRUE, FALSE, TRUE, FALSE
```

The last call returns `FALSE` since the expression `x - PI` occurs only in the screen output, but not in the internal representation of `f`.

```
g := series(sign(x), x, Right);
has(g, Right), has(g, Undirected);
```

```
1 + O(x6)
```

```
TRUE, FALSE
```

Example 24

The method `truncate` discards summands up to the given order:

```
f := series(x*sin(sqrt(x)), x);
Series::Puisseux::truncate(f, 10);
Series::Puisseux::truncate(f, 9/2);
Series::Puisseux::truncate(f, 7/2);
Series::Puisseux::truncate(f, 3);
```

```
Series::Puisseux::truncate(f, 3/2);
Series::Puisseux::truncate(f, 1);
```

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O(x^{9/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O(x^{9/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + \frac{x^{7/2}}{120} + O(x^{9/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + O(x^{7/2})$$

$$x^{3/2} - \frac{x^{5/2}}{6} + O(x^{7/2})$$

$$O(x^{3/2})$$

$$O(x^{3/2})$$

Parameters

f

An arithmetical expression representing a function in x

x

An identifier

x₀

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used.

Series::Puisseux

order

The number of terms to be computed: a nonnegative integer. The default order is given by the environment variable ORDER (default value 6).

dir

Either `Left`, `Right`, `Real`, or `Undirected`. This optional argument can be used to specify that the resulting expansion is possibly valid along the real line only. The default is `Undirected`, which means that the expansion is valid in a neighborhood of the expansion point in the complex plane.

Return Values

an object of domain type `Series::Puisseux`, or the value `FAIL`, if the `f` cannot be converted, e.g., if powers with non-rational exponents occur in `f`.

Function Calls

Calling an element of `Series::Puisseux` as a function discards the error term and substitutes the first argument for the series variable. See the description of the method `"func_call"` and "Example 22" on page 6-448.

Operations

`Series::Puisseux` implements the basic arithmetic of truncated series expansions. Use the ordinary arithmetical operators `+`, `-`, `*`, `/`, `^`, and `@` for composition.

The arithmetical methods of `Series::Puisseux` usually do not perform any symbolic simplifications. Use `combine`, `expand`, or `normal` to request such simplifications explicitly.

See "Example 5" on page 6-419 and "Example 21" on page 6-445.

Special mathematical functions, such as `exp` or `sin`, are overloaded for elements of `Series::Puisseux`; cf. "Example 10" on page 6-429.

The system functions `coeff`, `lcoeff`, `nthcoeff`, `ldegree`, `lmonomial`, `nthmonomial`, `lterm`, and `nthterm` work on truncated series expansions. Note that in contrast to polynomials, coefficients, monomials, and terms are counted from the term of lowest order term on. Cf. "Example 17" on page 6-440.

Use the function `expr` to convert a series expansion to an arithmetical expression (as an element of a kernel domain).

Operands

A series of the domain type `Series::Puisseux` has the following seven operands:

- 1** a *type flag* $\{0, 1\}$,
- 2** the *branching order* b , a positive integer,
- 3** an integer v such that $\frac{v}{b}$ is the order of the leading term,
- 4** an integer $e \geq v$ such that $\frac{e}{b}$ is the order of the error term,
- 5** a list of coefficients l_1, \dots, l_n ,
- 6** the *series variable* x and the *expansion point* x_0 in form of an equation $x = x_0$; the expansion point x_0 may be `complexInfinity` as well,
- 7** a *direction*, `Undirected`, `Real`, `Left`, or `Right`.

The type flag distinguishes between two different internal representations.

If $t = 0$, then the operands above represent the truncated series expansion

$$\sum_{1 \leq i \leq n} \left(l_i (x - x_0)^{\frac{(v+i-1)}{b}} + \mathcal{O}\left((x - x_0)^{e/b}\right) \right)$$

If the expansion point x_0 is `complexInfinity`, then the operands represent the truncated expansion

Series::Puisseux

$$\sum_{1 \leq i \leq n} \left(\frac{l_i}{x^{\frac{(i+v-1)}{b}}} + O\left(\frac{1}{x^{\frac{\epsilon}{b}}}\right) \right)$$

- A summand $l_i(x-x_0)^{\frac{(v+i-1)}{b}}$ (or $\frac{l_i}{x^{\frac{(i+v-1)}{b}}}$, respectively) is called a *monomial* of the expansion,
- the power $(x-x_0)^{\frac{(v+i-1)}{b}}$ (or $\frac{1}{x^{\frac{(i+v-1)}{b}}}$, respectively) is called a *term*,
- l_i is the corresponding *coefficient*, and
- the exponent $\frac{(v+i-1)}{b}$ is the *order* of the corresponding term or monomial.

If $t = 1$, then the operands above represent the expansion

$$\sum_{1 \leq i \leq n} \left(l_i + O\left((x-x_0)^{\epsilon/b}\right) \right)$$

In this case, the powers of $x - x_0$ are explicitly stored in the list, and

l_i contains only terms of growth order $O\left((x-x_0)^{\frac{(v+i-1)}{b}}\right)$. The corresponding expansion for $x_0 = \text{complexInfinity}$ is

$$\sum_{1 \leq i \leq n} \left(l_i + O\left(\frac{1}{x^{\frac{\epsilon}{b}}}\right) \right),$$

and l_i contains only terms of growth order $O\left(\frac{1}{x^{\frac{(v+i-1)}{b}}}\right)$.

The notions term and order are the same as for $t = 0$, a summand l_i is called a monomial, and the corresponding coefficient is

$$\frac{l_i}{(x - x_0)^{\frac{v+i-1}{b}}}$$

(or

$$\frac{\frac{l_i}{1}}{x^{\frac{v+i-1}{b}}},$$

respectively).

The latter type of representation serves for correct expansions around branch points. For example, if we want to expand $f(x) = \sqrt{x}$ around

$x = 0$, then the truncated Puiseux series $\sqrt{-1} \sqrt{x} + \mathcal{O}(x^{13/2})$ does not approximate $f(x)$ in the lower half of the complex plane. With $t =$

1, the expansion $\sqrt{(-x)} + \mathcal{O}(x^{13/2})$, which approximates $f(x)$ also in the lower part of the complex plane near the origin, can be represented as an object of domain type `Series::Puiseux`.

The direction d has the same meaning as the parameter `dir` of the constructor. If $d = \text{Undirected}$, the operands above represent an expansion valid in some neighborhood of the expansion point in the complex plane. Usually, this is an open disc centered at x_0 . If $d \neq \text{Undirected}$ and x_0 represents a real number, this means that the expansion is valid for real values of x only. If $d = \text{Left}$ or $d = \text{Right}$, then the expansion is valid for $x < x_0$ or $x > x_0$, respectively.

In the case $x_0 = \text{complexInfinity}$, and if $d = \text{Undirected}$, we have an expansion valid in the neighborhood of the north pole of the Riemann sphere, i.e., for all $x \in \mathbb{C}$ of sufficiently large absolute value. If $d =$

Left, we have an expansion around the positive real infinity valid for sufficiently large real values of x . Similarly, if $d = \textit{Right}$, we have an expansion around the negative real infinity valid for sufficiently large negative real values of x . Finally, if $d = \textit{Real}$, the expansion is valid both around *infinity* and around $-\infty$.

Cf. “Example 2” on page 6-412.

Element Creation

Typically, objects of type `Series::Puisseux` are generated by calls to `series` or `taylor`.

Methods

Mathematical Methods

conjugate - Complex conjugation

`conjugate(s)`

This method overloads the system function `conjugate`. Cf. “Example 11” on page 6-430.

contfrac - Conversion into a continued fraction

`contfrac(s)`

This method overloads the system function `contfrac`. Cf. “Example 12” on page 6-431.

diff - Differentiation

`diff(s, t)`

This method overloads the system function `diff`. Cf. “Example 9” on page 6-428.

_divide - Division

`_divide(s, t)`

_fconcat - Functional composition

`_fconcat(s, t)`

If both s and t are of type `Series::Puisseux`, then the functional composition can only be defined if the limit point of t for values

close to its expansion point is equal to the expansion point of s . Otherwise, an error occurs.

At least one of the arguments must be of type `Series::Puisseux`. If one of the arguments is not of this type, then it is converted into an element of `Series::Puisseux` via the constructor. If s is not of type `Series::Puisseux`, then it is converted into a series expansion around the limit point of t . If t is not of type `Series::Puisseux`, then it is converted into a series expansion around 0. The implicit conversion is performed only if the corresponding expression contains exactly one free variable.

This method overloads the system function `_fconcat` for series expansions, i.e., you may use it in the form $s@t$. See “Example 8” on page 6-425 and “Example 22” on page 6-448.

Im - Imaginary part

`Im(s)`

This method overloads the system function `Im`. Cf. “Example 11” on page 6-430.

int - Integration

`int(s, t | t = a .. b)`

This method overloads the system function `int`. Cf. “Example 9” on page 6-428, and the help page of `int` for a description of further optional arguments.

invert - Reciprocal of a series

`_invert(s)`

This method overloads the system function `_invert`, i.e., you may use it in the form $1/s$.

ilaplace - Inverse Laplace transform

`ilaplace(s, u, v)`

If u is not the series variable of s , then the coefficients of s are transformed, but not the expansion point. Otherwise, the

expansion point of s must be infinity, v must be an identifier, and s is transformed term by term. The result is then a series expansion around $v = 0$.

This method overloads the function `ilaplace` for series expansions. Cf. “Example 13” on page 6-433.

laplace - Laplace transform

```
laplace(s, u, v)
```

If u is not the series variable of s , then the coefficients of s are transformed, but not the expansion point. Otherwise, the expansion point of s must be 0, the order of the leading term of s must be nonnegative, v must be an identifier, and s is transformed term by term. The result is then a series expansion around $v = \infty$.

This method overloads the function `laplace` for series expansions. Cf. “Example 13” on page 6-433.

_mult - Multiplication

```
_mult(s, t, , )
```

Use the method `Series::Puisseux::scalmult` to multiply a series expansion s by a constant or a power of $x - x_0$.

This method overloads the system function `_mult` for series expansions, i.e., you may use it in the form `s*t*...` Cf. “Example 5” on page 6-419.

_negate - Negation

```
_negate(s)
```

This method overloads the system function `_negate`, i.e., you may use it in the form `-s`.

_plus - Addition

```
_plus(s, t, , )
```

This method overloads the system function `_plus` for series expansions, i.e., you may use it in the form `s+t+...`. Cf. “Example 5” on page 6-419.

`_power` - Exponentiation

`_power(s, n)`

If n is a rational number, the direction of s is `Undirected` or `Real`, and the leading coefficient of s is not positive, then the type flag of the result is 1 in general.

If n is not a rational number, then the leading summand of s must not contain the series variable. Otherwise, an error occurs.

This method overloads the system function `_power` for series expansions, i.e., you may use it in the form `s^n`. Cf. “Example 7” on page 6-423.

`Re` - Real part

`Re(s)`

This method overloads the system function `Re`. Cf. “Example 11” on page 6-430.

`revert` - Functional inversion

`revert(s)`

The expansion point of the inverse is the limit point of s .

This method overloads the system function `revert`. Cf. “Example 8” on page 6-425.

`scalmult` - Multiplication by a single monomial

`Series::Puisseux::scalmult(s, a, k)`

`series` - Serie expansion

`series(s, y | y = y0, <order>, <dir>)`

This method overloads the system function `series`.

`_subtract` - Subtraction

`_subtract(s, t)`

Access Methods

coeff - Extract coefficients

`coeff(s, <x>, n)`

`coeff(s, <x>)`

The second call returns the sequence of all coefficients of s , starting with the coefficient of lowest order. (This is the coefficient of the term with the highest exponent if $x_0 = \text{complexInfinity}$.)

Specifying the variable x is optional; if it is present, it must coincide with the series variable of s .

This method overloads the system function `coeff`. Cf. “Example 14” on page 6-434.

direction - Direction of expansion

`Series::Puisseux::direction(s)`

indet - Serie variable

`Series::Puisseux::indet(s)`

iszero - Zero test

`iszero(s)`

This method overloads the system function `iszero`. Cf. “Example 18” on page 6-441.

lcoeff - Leading coefficient (of lowest order)

`lcoeff(s)`

This method overloads the system function `lcoeff`. See “Example 15” on page 6-436 and “Example 17” on page 6-440.

ldegree - Leading degree

`ldegree(s)`

This method overloads the system function `ldegree`. See “Example 2” on page 6-412 and “Example 15” on page 6-436.

lmonomial - Leading monomial (of lowest order)

`lmonomial(s)`

This method overloads the system function `lmonomial`. See “Example 15” on page 6-436 and “Example 17” on page 6-440.

lterm - Leading term (of lowest order)

`lterm(s)`

This method overloads the system function `lterm`. See “Example 15” on page 6-436 and “Example 17” on page 6-440.

nthcoeff - Extract coefficients

`nthcoeff(s, n)`

This method overloads the system function `nthcoeff`. See “Example 16” on page 6-438 and “Example 17” on page 6-440.

nthmonomial - Extract monomials

`nthmonomial(s, n)`

This method overloads the system function `nthmonomial`. See “Example 16” on page 6-438 and “Example 17” on page 6-440.

nthterm - Extract terms

`nthterm(s, n)`

This method overloads the system function `nthterm`. See “Example 16” on page 6-438 and “Example 17” on page 6-440.

order - Order of the error term

`Series::Puiseux::order(s)`

point - Expansion point

`Series::Puiseux::point(s)`

Conversion Methods

convert - Convert any object into a series expansion

`convert(f)`

If no expansion point can be determined from `f`, the origin is used. Cf. “Example 19” on page 6-442.

convert_to - Convert a series expansion into another domain

`convert_to(s, T)`

Use the function `expr` to convert `s` into an object of a kernel domain.

convert01 - Convert into a series expansion of type 1

`Series::Puisseux::convert01(s)`

convert10 - Try to convert into a series expansion of type 0

`Series::Puisseux::convert10(s)`

For undirected expansions, the conversion is not possible in general, and then `s` is returned. However, you can enforce a conversion (with a not necessarily equivalent result) by using properties. Cf. “Example 3” on page 6-415.

expr - Convert a series expansion into an element of a kernel domain

`expr(s)`

This method overloads the system function `expr`. Cf. “Example 20” on page 6-444.

float - Convert numeric parts of the coefficients into floats

`float(s)`

This method overloads the system function `float`. Cf. “Example 20” on page 6-444.

Technical Methods

combine - Combine coefficients

`combine(s)`

This method overloads the system function `combine`; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 6-445.

const - Convert a constant expression into a truncated series

`Series::Puisseux::const(f, x | x = x0, n, <d>)`

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-409.

create - Syntactical constructor

`Series::Puisseux::create(b, v, e, l, x, <x0>, <d>)`

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-409.

expand - Expand coefficients

`expand(s)`

This method overloads the system function `expand`; see the corresponding help page for further optional arguments. Cf. “Example 21” on page 6-445.

func_call - Evaluation at a point

`Series::Puisseux::func_call(s, t)`

You may also use this method in the form `s(t)`. Cf. “Example 22” on page 6-448.

has - Check whether an object occurs syntactically

`has(s, t)`

This method overloads the system function `has`. Cf. “Example 23” on page 6-454.

map - Apply a function to all non-zero coefficients

`map(s, f, <arg1, , >)`

This method overloads the system function `map`. Cf. “Example 21” on page 6-445.

normal - Normal form

`normal(s)`

This method overloads the system function `normal`. Cf. “Example 21” on page 6-445.

one - Create a truncated series with constant term 1

`Series::Puisseux::one(x, <x0>, n, <d>)`

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Use with care, since this function does not perform type checking. Cf. “Example 1” on page 6-409.

print - Pretty-print routine

`print(s)`

truncate - Truncate a series expansion

`Series::Puisseux::truncate(s, n)`

Cf. “Example 24” on page 6-454.

subs - Replace subexpressions

`subs(s, old = new)`

`subs(s, [old1 = new1, old2 = new2,])`

If the series variable `x` of `s` does not occur in the left hand sides `old`, `old1`, `old2`, ..., then the substitution takes place in the

coefficients and in the expansion point of s . The series variable must not occur in the right hand sides new , $new1$, $new2$,

Note In contrast to the usual behavior of `subs`, the result of the substitution is subjected to an additional evaluation.

In the second call, the series variable x of s must not occur anywhere in the substitution equations. In the first call, x is allowed to occur in `old` only if `old` equals x . In this case, a change of variable is performed, and `new` must be of the form

$$x0 + a*(b*y - c)^k$$

if `x0 <> complexInfinity` and

$$a*(b*y - c)^k$$

if `x0 = complexInfinity`, where

- `x0` is the expansion point of s
- k is a non-zero rational number
- y is an identifier, which may well be equal to x , and otherwise y must not occur in the coefficients of s .
- a , b , c are arithmetical expressions not involving y , with a , b being non-zero. If the direction of s is not `Undirected`, then a and b must represent real numbers.
- c is zero if either `x0 <> complexInfinity` and k is positive or `x0 = complexInfinity` and k is negative. In this case, the result of the substitution has expansion point `complexInfinity`.
- If c is non-zero, then the result of the substitution has expansion point c/b .

Series::Puisseux

Use one of the methods "`_fconcat`" or "`func_call`" for more general substitutions for the series variable.

This method overloads the system function `subs`; Cf. "Example 22" on page 6-448.

zero - Create a truncated series with an error term only

`Series::Puisseux::zero(x, <x0>, n, <d>)`

If the expansion point `x0` is omitted, `x0 = 0` is assumed. If the direction `d` is omitted, `d = Undirected` is assumed.

Note Although `Series::Puisseux::zero(x, n)` and `0(x^n)` are mathematically equivalent and are printed in the same way, they are different MuPAD objects. The former is an element of type `Series::Puisseux`, while the latter is an element of type `0`.

Use with care, since this function does not perform type checking. Cf. "Example 1" on page 6-409.

MuPAD Domains

`Series::gseries`

Purpose Generalized series expansions

Syntax `Series::gseries(f, x, <order>, <Left | Right>)`
`Series::gseries(f, x = a, <order>, <Left | Right>)`

Description `Series::gseries` is the domain of series expansions generalizing Taylor, Laurent and Puiseux expansions.

The call `Series::gseries(f, x)` computes a series expansion at the right hand side of $x = 0$.

The system functions `series` and `asymp` are the main application of this domain. The latter function only returns elements of this domain, whereas `series` can return an element of `Series::gseries` in cases, where a Puiseux series expansion does not exist.

There may be no need to explicitly create elements of this domain, but to work with the results of the mentioned system functions.

See the help page of the system function `asymp` for a detailed description of the parameters and examples for working with elements of the domain `Series::gseries`.

Note Note that elements of `Series::gseries` only represents *directional* (real) series expansions.

Environment Interactions The function is sensitive to the global variable `ORDER`, which determines the default number of terms of the expansion.

Parameters

f
An arithmetical expression

x
The series variable: an identifier

a

Series::gseries

The expansion point: an arithmetical expression or \pm infinity

order

The truncation order: a nonnegative integer

Options

Left

Compute a series expansion that is valid for real x smaller than a .

Right

Compute a series expansion that is valid for real x larger than a (the default case).

Return Values

Object of domain type `Series::gseries`, or the value `FAIL`.

Function Calls

Calling an element of `Series::gseries` as a function yields the object itself, regardless of the arguments. The arguments are *not* evaluated.

Operations

`Series::gseries` implements standard arithmetic of generalized series expansions. Use the ordinary arithmetical operators $+$, $-$, $*$, $/$, and $^$.

The system functions `coeff`, `lcoeff`, `nthcoeff`, `lterm`, `nthterm`, `lmonomial`, `nthmonomial`, and `ldegree` work on generalized series expansions. See the corresponding help pages of these functions for calling parameters. See the description of these methods below for further details.

The method `"indet"` returns the series variable of the series expansion, i.e., if `s` is an object of the domain `Series::gseries`, then `s::dom::indet(s)` returns the series variable.

The method `"point"` returns the expansion point of the series.

Use the function `expr` to convert a generalized series expansion into an arithmetical expression (as an element of a kernel domain).

Operands

A series of the domain type `Series::gseries` consists of four operands:

- 1 A list of pairs $[c_i, f_i]$. Each pair represents a *monomial* $c_i f_i$ of the series expansion, where the c_i are the *coefficients* and f_i the *terms* of s . The coefficients do not contain the series variable.

This list can be empty, if the order of the expansion is zero.

- 2 An arithmetical expression g representing the *error term* of the form $O(g)$. It may be the integer 0, in which case the expansion is exact.
- 3 The *series variable* x .
- 4 The *expansion point* a .

Methods

Mathematical Methods

`_divide` - Divide two series expansions

```
_divide(s, t)
```

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. FAIL is returned, if one of these conversions fails.

This method overloads the function `_divide` for elements of `Series::gseries`, i.e., you may use it in the form s/t .

`_invert` - Multiplicative inverse of a series expansion

```
_invert(s)
```

This method overloads the function `_invert` for elements of `Series::gseries`, i.e., you may use it in the form $1/s$.

`_mult` - Multiply series expansions

```
_mult(s, t, )
```

If both s and t are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have

the same series variable and expansion point, otherwise FAIL is returned.

If `s` or `t` is a series expansion of the domain `Series::Puisseux`, then it is converted into an object of `Series::gseries`. If this fails, then FAIL is returned. Otherwise, the product is computed and returned as an object of the domain `Series::gseries`.

If `s` is a series expansion and `t` is an arithmetical expression, then `t` is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then FAIL is returned.

This method overloads the function `_mult` for elements of `Series::gseries`, i.e., you may use it in the form `s*t*...`

`_negate` - Negative of a series expansion

`_negate(s)`

This method overloads the function `_negate` for elements of `Series::gseries`, i.e., you may use it in the form `-s`.

`_plus` - Add series expansions

`_plus(s, t,)`

If both `s` and `t` are series expansions of the domain `Series::gseries`, then the result is a series expansion of the domain `Series::gseries`, too. Both series expansions must have the same series variable and expansion point, otherwise FAIL is returned.

If `s` or `t` is a series expansion of the domain `Series::Puisseux`, then it is converted into an object of `Series::gseries`. If this fails, then FAIL is returned. Otherwise, the sum is computed and returned as an object of the domain `Series::gseries`.

If s is a series expansion and t is an arithmetical expression, then t is converted into a series expansion via the constructor `Series::gseries` (and vice versa).

Each argument of this method that is not of the domain type `Series::gseries` is converted into such an element, i.e., a generalized series expansion is computed. If this fails, then `FAIL` is returned.

This method overloads the function `_plus` for elements of `Series::gseries`, i.e., you may use it in the form `s+t+ ...`

`_power` - Exponentiation of a series expansion

`_power(s, n)`

The exponent n must not involve the series variable of s . Otherwise, an error occurs.

If n is a positive integer, then repeated squaring is used for computing the n th power of s . Otherwise, the binomial theorem is applied after factoring out the leading monomial.

This method overloads the function `_power` for elements of `Series::gseries`, i.e., you may use it in the form `s^n`.

`_subtract` - Subtract two series expansions

`_subtract(s, t)`

If the arguments are not of domain type `Series::gseries`, then they are converted into such objects. `FAIL` is returned, if one of these conversions fails.

This method overloads the function `_subtract` for elements of `Series::gseries`, i.e., you may use it in the form `s-t`.

Access Methods

`coeff` - Extract coefficients

`coeff(s, <n>)`

Series::gseries

This method overloads the function `coeff` for elements of `Series::gseries`.

indet - Serie variable

`Series::gseries::indet(s)`

Use the method "point" to get the expansion point of s.

iszero - Zero test

`iszero(s)`

This method overloads the function `iszero` for elements of `Series::gseries`.

lcoeff - Leading coefficient

`lcoeff(s)`

This method overloads the function `lcoeff` for elements of `Series::gseries`.

ldegree - Leading degree

`ldegree(s)`

This method overloads the function `ldegree` for elements of `Series::gseries`.

lmonomial - Leading monomial

`lmonomial(s)`

This method overloads the function `lmonomial` for elements of `Series::gseries`.

lterm - Leading term

`lterm(s)`

This method overloads the function `lterm` for elements of `Series::gseries`.

nthcoeff - Extract a coefficient

`nthcoeff(s, n)`

This method overloads the function `nthcoeff` for elements of `Series::gseries`.

nthmonomial - Extract a monomial

```
nthmonomial(s, n)
```

This method overloads the function `nthmonomial` for elements of `Series::gseries`.

nthterm - Extract a term

```
nthterm(s, n)
```

This method overloads the function `nthterm` for elements of `Series::gseries`.

point - Expansion point

```
Series::gseries::point(s)
```

Use the method `"indet"` to get the series variable of `s`.

Conversion Methods

convert - Convert an object into a generalized series expansion

```
Series::gseries::convert(x)
```

convert_to - Convert a generalized series expansion into other domains

```
Series::gseries::convert_to(s, T)
```

`T` might be the domain `DOM_POLY`, where the sum of monomials is considered as a polynomial in the indeterminates of the third operand of `s`.

If `T` is the domain `DOM_EXPR`, then the conversion is the same as implemented by the method `"expr"` (see below).

If `T` is the domain `Series::Puiseux`, then the system tries to convert `s` into a `Puiseux` series. If the conversion is not possible, `FAIL` is returned.

Series::gseries

Use the function `expr` to convert `s` into an object of a kernel domain.

create - Create simple and fast a generalized series expansion

```
Series::gseries::create(list, errorTerm, x = a)
```

Note This method should be used with caution, because no argument checking is performed. Use it to *create*, not to compute elements of `Series::gseries`.

expr - Convert a generalized series expansion into an element of a kernel domain

```
expr(s)
```

This method overloads the function `expr` for elements of `Series::gseries`.

series - Apply the function series to a generalized series expansion

```
series(s, x | x = x0, <order>, <dir>)
```

This method overloads the function `series` for elements of `Series::gseries`. See the corresponding help page for a description of the possible arguments.

Technical Methods

combine - Apply the function combine to all terms

```
combine(s, <target>)
```

This method overloads the system function `combine`. See the corresponding help page for a description of the optional argument `target`.

has - Check whether an object occurs syntactically

```
has(s, t)
```

This method overloads the system function `has`.

map - Map a function to the coefficients

```
map(s, func, )
```

This method overloads the function `map` for elements of `Series::gseries`.

print - Pretty-print routine

```
print(s)
```

subs - Substitute into a generalized series expansion

```
subs(s, x = a, )
```

This method overloads the function `subs` for elements of `Series::gseries`.

TeX - LaTeX formatting

```
Series::gseries::TeX(s)
```

This method is called by the system function `generate::TeX`.

MuPAD Domains

`Series::Puisseux`

Series::gseries

export – Export Data

export::stl

export::stl

Purpose

Export STL data

Syntax

```
export::stl(filename, [x, y, z], u = umin .. umax,  
v = vmin .. vmax, options)  
export::stl(n, [x, y, z], u = umin .. umax, v =  
vmin .. vmax, options)  
export::stl(filename, object1, <object2, >, options)  
export::stl(n, object1, <object2, >, options)
```

Description

`export::stl` is used to create a triangulation of a parametrized surface and write the triangulation data in STL format to an external file.

STL files contain triangulation data of 3D surfaces. Each triangle is stored as a unit normal and three vertices. The normal and the vertices are specified by three coordinates each, so there is a total of 12 numbers stored for each triangle. Read the “Background” section of this help page for further details.

If the surface is closed, it is regarded as the boundary of a 3D solid. The normals of the triangles written into the STL file should point from the inside of the body to the outside.

Note Note that the direction of the normals that `export::stl` writes into the STL file depend on the parametrization $x(u, v), y(u, v), z(u, v)$!

If $p_1 = (x(u, v), y(u, v), z(u, v)), p_2 = (x(u + du, v), y(u + du, v), z(u + du, v)), p_3 = (x(u, v + dv), y(u, v + dv), z(u, v + dv))$ are the corners of a triangle, the normal associated with this triangle is the cross product of the side $p_2 - p_1$ times the side $p_3 - p_1$. The routine `export::stl` chooses neighboring values of the surface parameters with $du = (u_{\max} - u_{\min}) / (n_u - 1)$ and $dv = (v_{\max} - v_{\min}) / (n_v - 1)$, respectively.

Note Thus, if your parametrization is such that the cross product of the vectors $p_2 - p_1$ and $p_3 - p_1$ does not point to the outside of your body, you just need to let one of the parameters (u , say) run from u_{\max} to u_{\min} instead of from u_{\min} to u_{\max} . Just replace your call

```
export::stl(filename, [x,y,z], u = `u_{min}` .. `u_{max}`,
v = `v_{min}` .. `v_{max}`)
```

by

```
export::stl(filename, [x,y,z], u = `u_{max}` .. `u_{min}`,
v = `v_{min}` .. `v_{max}`).
```

Up to the irrelevant ordering in the STL file, the triangles generated by these calls are the same apart from the direction of the normal associated with each triangle.

If the file is specified by a character string, the corresponding file is opened and closed, automatically.

As an alternative to specifying the file by a string, the user may open the file herself via `fopen` in `Write` mode and pass the file descriptor returned by `fopen` to `export::stl`. If binary data are to be written to the file, make sure that it is opened with the `Raw`, i.e., call `fopen(filename, Write, Raw)`.

Note Note that `export::stl` does not close the file automatically if it is specified by a file descriptor. It remains open after `export::stl` has finished its job. The file needs to be closed explicitly by the user using `fclose`.

If the file is specified by a character string, the name may correspond to an absolute or a relative path name. In particular, the environment

variable `WRITEPATH` is taken into account. The details on the help page of `fopen` hold for `export::stl`, too.

Note With the option `Append`, the file is first opened for reading and, after reading of the data in the file, opened for writing. If no absolute pathname is used to specify the file, make sure that the environment variables `READPATH` and `WRITEPATH` point to the same folder. Alternatively, it is a good idea to place the file in the same folder as the MuPAD notebook which you are currently using. If this notebook is saved on the disk of your computer, the absolute path is available as the environment variable `NOTEBOOKPATH`. Thus, specifying a file named “myfile.stl”, say, by the absolute path name `NOTEBOOKPATH."myfile.stl"` ensures that the file is found in the same folder as your notebook.

Text files generated with the option `Text` or the equivalent `Ascii` can be opened and read with any text editor. However, binary files generated with the option `Bin` or the equivalent options `Binary` or `Raw` are faster to create and to process.

The file generated by `export::stl` can be read and visualized in MuPAD using the plot primitive `plot::SurfaceSTL`.

If the file name given ends in “.gz”, `export::stl` writes a compressed file which can be read by any program supporting `gzip` compression.

Environment Interactions

The function is sensitive to the environment variable `DIGITS` which determines the numerical working precision. The current value of `DIGITS` determines the number of significant decimal digits with which the STL data are written to the specified file. (This holds for text files. In binary STL files all numerical values have a precision of about 7 decimal digits.) For the internal computation of the data by MuPAD, the value of `DIGITS` is temporarily increased by 10 to minimize round-off effects.

The STL data generated by `export::stl` are written to the specified file.

Examples

Example 1

We generate a sphere given by the following parametrization:

```
x:= cos(u)*sin(v):
y:= sin(u)*sin(v):
z:= cos(v):
```

We call `export::stl` to generate the STL data and write them into a file named “sphere.stl”. The file is to be generated in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk of your computer, this path is available in the environment variable `NOTEBOOKPATH`:

```
filename:= NOTEBOOKPATH."sphere.stl":
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, Text)
```

Since the file was created in Text format, it can be opened with any text editor. It should look like this:

```
solid MuPADtoSTL1
facet normal -0.06540070486 -0.008610166138 -0.9978219344
  outer loop
    vertex 100.0 100.0 300.0
    vertex 112.607862 103.3782664 298.7167292
    vertex 113.0526192 100.0 298.7167292
  endloop
endfacet
facet normal -0.1950260058 -0.02567566076 -0.9804619409
  outer loop
    vertex 113.0526192 100.0 298.7167292
    vertex 112.607862 103.3782664 298.7167292
    vertex 125.0 106.6987298 294.8888739
```

export::stl

```
        endloop
    endfacet
    ...
endsolid MuPADtoSTL1
```

We reimport the STL data and visualize the surface using `plot::SurfaceSTL`:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

We reduce the number of significant output digits to a reasonable size. Further, we specify a mesh size and request a specific output box:

```
DIGITS:= 7:
```

```
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI, MeshVisible,
            OutputBox = [-100 .. 100, -100 .. 100, -100 .. 100],
```

The file now should look like this:

```
solid MuPADtoSTL2
  facet normal -0.1733024 -0.06307691 -0.9828467
    outer loop
      vertex -3.10912 0.000000002143114 100.0
      vertex 24.32249 22.66816 93.96926
      vertex 32.7003 0.000000002143114 93.96926
    endloop
  endfacet
  ...
endsolid MuPADtoSTL2
```

We visualize the new content of the file:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

```
delete x, y, z, filename, DIGITS:
```

Example 2

We specify the parametrization of the surface by a mixture of expressions and procedures:

```
x:= piecewise([0.1 < u < 0.9, u*cos(v)], [Otherwise, 0]):  
y:= (u, v) -> piecewise([0.1 < u < 0.9, u*sin(v)], [Otherwise, 0]):  
z:= (u, v) -> if u <= 0.1 then exp(-0.1)  
               elif u < 0.9 then exp(-u)  
               else exp(-0.9)  
               end_if:
```

This is the surface that we wish to export to STL:

```
plot(plot::Surface([x, y, z], u = 0 .. 1, v = 0 .. 2*PI, Mesh = [10
```

We assume that there is no external file “sample.stl”. We create it by opening it in Write mode in the same directory as the current MuPAD notebook that we are using. Hence, we specify an absolute path name for the file using the path of the current notebook. If this notebook was saved to the disk drive of your computer, this path is available in the environment variable NOTEBOOKPATH. The file descriptor `n` returned by `fopen` is passed to `export::stl`:

```
filename:= NOTEBOOKPATH."sample.stl":  
DIGITS:= 7:  
export::stl(filename, [x, y, z], u = 0 .. 1, v = 0 .. 2*PI, MeshVisible)
```

We reimport the STL data and visualize the surface using `plot::SurfaceSTL`:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

export::stl

We can append a further surface to the file using the option Append:

```
export::stl(filename, [x, y, -z], u = 0 .. 1, v = 0 .. 2*PI,  
            Mesh = [30, 36], OutputBox = [0 .. 100, 0 .. 100, -100  
            Append)
```

We visualize the new content of the file via plot::SurfaceSTL:

```
plot(plot::SurfaceSTL(filename, MeshVisible))
```

```
delete x, y, z, filename, DIGITS:
```

Example 3

We wish to create a closed surface consisting of a “bowl” with a “lid”.

```
bowl:= [u*cos(v), u*sin(v), u^2], u = 0 .. 1, v = 0 .. 2*PI:
lid:= [u*cos(v), u*sin(v), 1 ], u = 0 .. 1, v = 0 .. 2*PI:
```

```
filename:= NOTEBOOKPATH."sample.stl":
DIGITS:= 7:
export::stl(filename, bowl, Mesh = [30, 36]):
export::stl(filename, lid, Mesh = [30, 36], Append):
plot(plot::SurfaceSTL(filename), Scaling = Constrained):
```

delete filename, DIGITS:

Example 4

We demonstrate the options `Scaling = Constrained` and `Scaling = Unconstrained`. With `Scaling = Constrained`, the coordinates given by the parametrization x , y , z are scaled by the same factor to fit the surface into the output box. Here, we create a sphere of radius 1. The output box is not a cube: the range for the z coordinate is notably larger than for x and y . Nevertheless, the sphere stays a sphere when using `Scaling = Constrained`. However, the output box is not completely filled by the sphere:

```
x:= cos(u)*sin(v):  
y:= sin(u)*sin(v):  
z:= cos(v):  
DIGITS:= 7:  
filename:= NOTEBOOKPATH."sphere.stl":
```

```
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI,  
            OutputBox = [-1 .. 1, -1 .. 1, -3 .. 3],  
            Scaling = Constrained):  
plot(plot::SurfaceSTL(filename, Scaling = Constrained, MeshVisib
```

With `Scaling = Unconstrained`, the sphere is deformed to an ellipsoid filling the output box:

```
export::stl(filename, [x, y, z], u = 0 .. 2*PI, v = 0 .. PI,  
            OutputBox = [-1 .. 1, -1 .. 1, -3 .. 3],  
            Scaling = Unconstrained):  
plot(plot::SurfaceSTL(filename, Scaling = Constrained, MeshVisib
```

delete *x*, *y*, *z*, *filename*, DIGITS:

Parameters

filename

A file name: a non-empty character string

n

A file descriptor provided by `fopen`: a positive integer

object₁, object₂, ...

3D graphical objects of the `plot` library

x*, *y*, *z

The coordinate functions: arithmetical expressions or `piecewise` objects depending on the surface parameters u and v .

Alternatively, procedures that accept 2 input parameters u, v

and return a numerical value when the input parameters are numerical.

u

The first surface parameter: an identifier or an indexed identifier.

u_{min} .. u_{max}

The range for the parameter u : u_{\min} , u_{\max} must be numerical real values.

v

The second surface parameter: an identifier or an indexed identifier.

v_{min} .. v_{max}

The range for the parameter v : v_{\min} , v_{\max} must be numerical real values.

Options

Mesh

Option, specified as Mesh = [nu, nv]

Sets the mesh size: the integer n_u determines, how many equidistant points in the u direction are used to sample the parametrization x , y , z numerically. Correspondingly, the integer n_v determines, how many equidistant points in the v direction are used. Thus, a regular mesh of $(n_u - 1)(n_v - 1)$ rectangles is used. Each rectangle is split into 2 triangles, resulting in a triangulation consisting of $2(n_u - 1)(n_v - 1)$ triangles. The default is Mesh = [25, 25].

OutputBox

Option, specified as OutputBox = [xmin .. xmax, ymin .. ymax, zmin .. zmax]

By default, the coordinates of the mesh points defining the STL object are written into the file as provided by the parametrization of the surface. Thus, if several objects are written into the file

via the option `Append`, the position of the objects in space is transparent and can be controlled by the user via a suitable parametrization. However, many devices such as Rapid Prototyping tools with which the STL file shall be processed, impose severe restrictions on the data in the STL file. E.g., the original STL specification requires that the x, y, z coordinates of the mesh points are positive. Many devices require that the coordinates must lie in a prescribed range (between 0 and 100, say). The option `OutputBox` provides a simple mean to shift and scale the coordinates given by the parametrization to a prescribed range.

The option `OutputBox = [xmin ··· xmax, ymin ··· ymax, zmin ··· zmax]` sets the output box defined by numerical values x_{\min} , x_{\max} , y_{\min} , y_{\max} , z_{\min} , z_{\max} . The mathematical coordinates $x(u, v)$, $y(u, v)$, $z(u, v)$ with u, v ranging from u_{\min} to u_{\max} and from v_{\min} to v_{\max} , respectively, are shifted and scaled such that the output coordinates written to the STL file range between the values x_{\min} and x_{\max} , y_{\min} and y_{\max} , z_{\min} and z_{\max} .

Note If several objects are written to the file via the option `Append`, only the very last call of `export::stl` should bear the option `OutputBox`!

This last call shifts and scales all coordinates of all surfaces inside the file such that the entire scene of objects fits into the output box. The relative size and positions of the objects are preserved.

See “Example 3” on page 7-11.

This option is rather expensive since all data in the STL file need to be modified!

This option is not available if the file was opened outside `export::stl` and passed by a file descriptor `n`.

Scaling

Option, specified as `Scaling = Unconstrained` or `Scaling = Constrained`

With `Scaling = Unconstrained`, the surface is scaled by different factors in the x, y, and z direction, such that it fills the output box set by the option `OutputBox = [`x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`, `z_{min}` .. `z_{max}`]`. Thus, the output coordinates of a sphere define an ellipsoid with diameters given by the side lengths of the output box. This is the default setting.

With `Scaling = Constrained`, the surface is scaled by the same factor in the x, y, and z direction such that it fits into the output box set by the option `OutputBox = [`x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`, `z_{min}` .. `z_{max}`]`. A sphere will remain a sphere even if the sides of the output box have different lengths.

This option is ignored if not used in conjunction with the `OutputBox` option.

Ascii, Bin, Binary, Raw, Text

With the synonymous flags `Bin`, `Binary`, or `Raw`, respectively, the STL file is created as a binary file. If a binary file is specified by a file descriptor `n`, make sure that it was opened by the command `n := fopen(filename, Write, Raw)`. With the synonymous flags `Text` and `Ascii`, respectively, the STL file is created as a text file. The default is `Bin`.

Append

With this flag, the STL data of the surface are appended to an existing STL file named “filename”. If no such file exists, it is created and processed as without `Append`. This option is not available if the file was opened outside `export:stl` and passed by a file descriptor `n`.

Return Values

`null()` object.

Algorithms

There are two storage formats available for STL files, which are ASCII and BINARY. ASCII files are human-readable while BINARY files are smaller and faster to process. Both ASCII as well as BINARY files can be generated by `export::stl`. A typical ASCII STL file looks like this:

```
solid sample
  facet normal -4.470293E-02 7.003503E-01 -7.123981E-01
    outer loop
      vertex -2.812284E+00 2.298693E+01 0.000000E+00
      vertex -2.812284E+00 2.296699E+01 -1.960784E-02
      vertex -3.124760E+00 2.296699E+01 0.000000E+00
    endloop
  endfacet
  ...
endsolid sample
```

STL BINARY files have the following format:

Bytes	Type	Description
80	ASCII	header, no data significance
4	uint	number of facets in file
4	float	normal x - start of facet
4	float	normal y
4	float	normal z
4	float	vertex1 x
4	float	vertex1 y
4	float	vertex1 z
4	float	vertex2 x
4	float	vertex2 y
4	float	vertex2 z

```
4      float  vertex3 x
4      float  vertex3 y
4      float  vertex3 z
2      byte   not used - end of facet
...

```

Facet orientation: The facets define the surface of a 3D object. As such, each facet is part of the boundary between the interior and the exterior of the object. The orientation of the facets (which way is "out" and which way is "in") is specified redundantly in two ways which should be consistent. First, the direction of the normal is outward. Second, which is most commonly used nowadays, the facet vertices are listed in counter-clockwise order when looking at the object from the outside (right-hand rule).

Vertex-to-vertex rule: Each triangle must share two vertices with each of its adjacent triangles. In other words, a vertex of one triangle cannot lie on the side of another.

Axes: The format specifies that all vertex coordinates must be strictly positive numbers. However, it seems that – with a few exceptions – most software used today (MuPAD included) allow negative coordinates as well.

Units: The STL file does not contain any scale information; the coordinates may be interpreted in arbitrary units.

Further details about the STL file format are available in the web, e.g., at:

- www.ennex.com/fabbers/StL.asp,
- www.math.iastate.edu/burkardt/data/stl/stl.html and

MuPAD Graphical Primitives

`plot::SurfaceSTL`

fp – Functional Programming

fp::apply
fp::bottom
fp::curry
fp::expr_unapply
fp::fixargs
fp::fixedpt
fp::fold
fp::nest
fp::nestvals
fp::unapply

fp::apply

Purpose	Apply function to arguments
Syntax	<code>fp::apply(f, <e, >)</code>
Description	<code>fp::apply(f, a)</code> returns <code>f(a)</code> . <code>fp::apply</code> applies the function <code>f</code> to the arguments given by <code>e,</code>
Environment Interactions	Same side effects as when calling <code>f(e, ...)</code> directly.
Examples	Example 1 Apply the function <code>f</code> to <code>x</code> and <code>y</code> : <code>fp::apply(f, x, y)</code> <code>f(x, y)</code>
	Example 2 Apply the functions of the first list to the arguments given by the second list: <code>zip([sin, cos], [x, y], fp::apply)</code> <code>[sin(x), cos(y)]</code>
Parameters	f Function e Object used as argument
Return Values	Result of the function call <code>f(e, ...)</code> .

Purpose Function that never returns

Syntax `fp::bottom()`

Description `fp::bottom()` never returns because it raises an error.

Environment Interactions Raises an error in any case.

Examples **Example 1**

Calling `fp::bottom` is equivalent to calling `error` with a fixed error string:

```
fp::bottom()
```

```
Error: The bottom is reached. [fp::bottom]
```

`fp::bottom` is used to indicate the bottom of a recursion inside a `traperror` call. In most cases, programs not using `fp::bottom` will be more readable.

Return Values This function never returns.

fp::curry

Purpose Curry an n-ary function

Syntax `fp::curry(f, <n>)`

Description `fp::curry(f)` returns the higher-order function $x \rightarrow (y \rightarrow f(x, y))$.

`fp::curry` returns the curried version of the n-ary function `f`. If no arity `n` is given, then the function is assumed to be binary.

If `n` is smaller than 2 then `f` is returned. Otherwise, given a *n*-ary function *f*, `fp::curry` returns the function

$x_1 \rightarrow ((x_2, \dots, x_n) \rightarrow f(x_1, \dots, x_n))$

Examples

Example 1

Create curried versions of binary and 3-nary functions:

```
cf := fp::curry(f):  
cf(x)(y)
```

$f(x, y)$

```
cg := fp::curry(g, 3):  
cg(x)(y)(z)
```

$g(x, y, z)$

Example 2

A curried version of `_plus` may be used to create a function which increments its argument by 1:

```
inc := fp::curry(_plus)(1):  
inc(x)
```

$x+1$

Parameters

f
n-ary function

n
Nonnegative integer

Return Values
Unary higher-order function.

fp::expr_unapply

Purpose Create a functional expression from an expression

Syntax `fp::expr_unapply(e, <x, >)`

Description `fp::expr_unapply(e, x)` tries to interpret the expression `e` as a function in `x` and to return a functional expression computing that function.

`fp::expr_unapply` views the expression `e` as a function in the indeterminates `x, ...` and tries to return a functional expression computing that function. If `fp::expr_unapply` cannot find a functional expression FAIL is returned.

If no indeterminates are given, any indeterminates of `e` found by `indets` are used.

Examples

Example 1

Get the functional expression computing $\sin(x)$:

```
fp::expr_unapply(sin(x), x)
```

\sin

```
fp::expr_unapply(sin(x[1]), x[1])
```

\sin

Example 2

Get the functional expression computing $\sin(x)^2 + \cos(x)^2$:

```
fp::expr_unapply(sin(x)^2 + cos(x)^2)
```

$\sin^2 + \cos^2$

Parameters**e**

Expression

x

Identifier or indexed identifier

Return Values

Functional expression or FAIL.

See Also**MuPAD Functions**

fp::unapply

fp::fixargs

Purpose Create function by fixing all but one argument

Syntax `fp::fixargs(f, n, <e, >)`

Description `fp::fixargs(f, 1, y)` returns the function $x \rightarrow f(x, y)$.

`fp::fixargs` returns an unary function, defined by fixing all but the n-th argument of the function `f` to the values given by `e...`

Thus, given a m -ary function f and $m - 1$ values e_1, \dots, e_{m-1} , `fp::fixargs` returns the function

$$x \rightarrow f(e_1, \dots, e_{n-1}, x, e_n, \dots, e_{m-1})$$

Examples

Example 1

Fix the first and third argument of `f` to `x1` and `x3`:

```
fp::fixargs(f, 2, x1, x3)(y)
```

```
f(x1, y, x3)
```

Example 2

Create a function which increments its argument by one:

```
inc := fp::fixargs(_plus, 1, 1):  
inc(x)
```

```
x+1
```

Example 3

Create a function which tests the identifier `x` for a type:

```
type_of_x := fp::fixargs(testtype, 2, x):  
map([DOM_INT, DOM_IDENT], type_of_x)
```

[FALSE, TRUE]

Parameters

f

Function

n

Positive integer defining free argument

e

Object used as fixed argument

**Return
Values**

Unary function.

fp::fixedpt

Purpose Returns fixed point of a function

Syntax `fp::fixedpt(f)`

Description `fp::fixedpt(f)` returns the fixed point of the unary function `f`.
`fp::fixedpt` is implemented as the *Y* combinator which is defined as follows:

$$Y: f \rightarrow g(f)(g(f))$$

where the function *g* is defined as

$$g: f \rightarrow h \rightarrow x \rightarrow f(h(h))(x)$$

Examples **Example 1**

A function computing the Fibonacci numbers is created as a fixed point:

```
fb2 := (f,n) -> if n <= 2 then 1 else f(n-1) + f(n-2) end:  
fib := fp::fixedpt(fp::curry(fb2)):  
fib(i) $ i=1..9
```

1, 1, 2, 3, 5, 8, 13, 21, 34

Parameters **f**
Unary function

Return Values Unary function.

- Purpose** Create function which iterates over sequences
- Syntax** `fp::fold(f, <e, >)`
- Description** `fp::fold` returns a function which repeatedly applies `f` to sequences of arguments, where the expressions `e...` are used as starting values.
- Thus, given the function f and the starting values e_1, \dots, e_n , `fp::fold` returns the function which is defined by

$$(x_1, x_2, \dots, x_m) \rightarrow f(x_m, \dots f(x_2, f(x_1, e_1, \dots, e_n)) \dots)$$

for any positive integer m . If the argument sequence is void (i.e. $m = 0$) the function simply returns the sequence (e_1, \dots, e_n) .

Examples

Example 1

A call to `fp::fold` returns a function, which accepts an arbitrary number of arguments:

```
fp::fold(f, x)(y1, y2, y3)
```

```
f(y3, f(y2, f(y1, x)))
```

Example 2

The function `pset` returns the power set of the set given by its arguments:

```
addelem := (x,y) -> y union map(y, _union, {x}):
pset := fp::fold(addelem, {{}}):
pset(a,b,c)
```

```
{∅, {c}, {a}, {b}, {b, c}, {a, b}, {a, c}, {a, b, c}}
```

fp::fold

Parameters

f

Function

e

Object used as starting value

Return Values

Function.

Purpose Repeated composition of function

Syntax `fp::nest(f, n)`

Description `fp::nest(f, n)` returns the n-fold repeated composition of the function `f`.

Thus, given the function `f`, `fp::nest` returns the identity function `id` if `n` is 0 and otherwise the function

$$f(f(\dots f(x)\dots))$$

n-fold repeated.

Note that `fp::nest` is obsolete, one should use the `@@` operator or its functional form `_fnest` instead. It is only supported for compatibility with former versions of MuPAD.

Examples

Example 1

Apply the 3-fold repeated composition of `f` to `x`:

```
fp::nest(f, 3)(x)
```

$$f(f(f(x)))$$

Example 2

Numerically finding a fixed point of the function `cos` by repeated application:

```
p :=fp::nest(cos, 100)(1.0):
p, cos(p)
```

```
0.7390851332, 0.7390851332
```

fp::nest

Parameters

f

Function

n

Nonnegative integer

Return Values

Function.

See Also

MuPAD Functions

`_fconcat` | `_fnest` | `fp::nestvals`

Purpose	Repeated composition returning intermediate values
Syntax	<code>fp::nestvals(f, n)</code>
Description	<p><code>fp::nestvals(f, n)</code> returns a function which applies the function <code>f</code> <code>n</code>-fold repeatedly to its argument and returns the intermediate <code>n + 1</code> values as a list.</p> <p>Thus <code>fp::nestvals</code> returns the function <code>[x, f(x), ..., f(f(...f(x)...))]</code></p> <p>The function returned is equivalent to <code>[_fnest(f, i) \$i=0..n]</code>, but more efficient.</p>
Examples	<p>Example 1</p> <p>Apply <code>f</code> 3 times nested to <code>x</code>:</p> <pre>fp::nestvals(f, 3)(x)</pre> <pre>[x, f(x), f(f(x)), f(f(f(x)))]</pre> <p>Example 2</p> <p>Apply <code>cos</code> 4 times nested to <code>1.0</code> and return the result and intermediate values:</p> <pre>fp::nestvals(cos, 4)(1.0)</pre> <pre>[1.0, 0.5403023059, 0.8575532158, 0.6542897905, 0.7934803587]</pre>
Parameters	<p>f</p> <p>Function</p> <p>n</p> <p>Nonnegative integer</p>

fp::nestvals

Return Values

Function.

fp::unapply

generate – Generate Input to Other Programs

generate::C
generate::fortran
generate::MATLAB
generate::MathML
generate::optimize
generate::Simscape
generate::TeX

generate::C

Purpose Generate C formatted string

Syntax `generate::C(e, <NoWarning>)`

Description `generate::C(e)` generates C code for the MuPAD expression `e`.
`generate::C` returns a C formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in C code. The type of the assignment is `double`.

When generating C code for a matrix, the generator assigns only nonzero elements. See “Example 3” on page 9-3.

To print an output string to a file, use the `fprint` function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to C code. See “Example 5” on page 9-4.

The `NoWarning` option lets you suppress warnings. See “Example 6” on page 9-5.

Examples

Example 1

The code generator converts a list of equations to a sequence of assignments:

```
generate::C([x1 = y2^2*(y1 + sin(z)), x2 = tan(x1^4)]):  
print(Unquoted, %)
```

```
x1 = (y2*y2)*(y1+sin(z));  
x2 = tan(x1*x1*x1*x1);
```

Example 2

MuPAD matrix and array indexing differs from C array indexing. By default, MuPAD array indices start with 1, and C array indices start with 0. To create the code compatible with the default indexing in C, the `generate::C` function decrements each index by one:

```
A:= matrix([[1,2],[3,4]]):
generate::C(A)."\n".
  generate::C(hold(Determinante = A[1,1]*A[2,2] - A[1,2]*A[2,1]))
print(Unquoted, %)
```

```
A[0][0] = 1.0;
A[0][1] = 2.0;
A[1][0] = 3.0;
A[1][1] = 4.0;
```

```
Determinante = A[0][0]*A[1][1]-A[0][1]*A[1][0];
```

Example 3

Generated C code does not include assignments for zero elements of a matrix:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):
print(Unquoted, generate::C(A))
```

```
A[0][0] = 1.0;
A[1][2] = 1.0;
```

Example 4

If the first index of an array is not 1, the `generate::C` function issues a warning:

generate::C

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):  
print(Unquoted, generate::C(A))
```

Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM

```
A[0][1] = 1.0;  
A[0][2] = 2.0;  
A[1][1] = 3.0;  
A[1][2] = 4.0;
```

Example 5

The `generate::C` function does not optimize your code:

```
print(Unquoted,  
      generate::C([x = a + b, y = (a + b)^2])):  
  
x = a+b;  
y = pow(a+b,2.0);
```

You can use the `generate::optimize` function before converting your MuPAD expression to C code. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,  
      generate::C(  
        generate::optimize([x = a + b, y = (a + b)^2])  
      )):  
  
x = a+b;  
y = x*x;
```

Example 6

By default, the `generate::C` function can issue warnings:

```
print(Unquoted, generate::C(f(x)))
```

```
Warning: Function "f" is not verified to be a valid C function.
```

```
t0 = f(x);
```

If you started using `generate::C` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::C(f(x), NoWarning))
```

```
t0 = f(x);
```

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

`generate::C` returns a string containing C code.

generate::C

See Also

MuPAD Functions

`fprint` | `print` | `generate::optimize`

Purpose Generate FORTRAN formatted string

Syntax `generate::fortran(e, <NoWarning>)`

Description `generate::fortran(e)` generates FORTRAN code for the MuPAD expression `e`.

`generate::fortran` returns a FORTRAN formatted string representing an expression, equation, list of equations or a matrix.

An equation represents an assignment in FORTRAN code. The type of the assignment is `double`.

When generating FORTRAN code for a matrix, the generator assigns only nonzero elements. See “Example 2” on page 9-8.

To print an output string to a file, use the `fprint` function. Use the printing option `Unquoted` to remove quotation marks and to expand special characters like line breaks and tabs.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to FORTRAN code. See “Example 4” on page 9-8.

The `NoWarning` option lets you suppress warnings. See “Example 5” on page 9-9.

Examples **Example 1**

The code generator converts a list of equations to a sequence of assignments:

```
generate::fortran([x[1] = y[2 + i]^2*(y[1] + sin(z)), x[2] = tan  
print(Unquoted,%)
```

```
x(1) = (sin(z)+y(1))*y(i+2)**2  
x(2) = tan(x(1)**4)
```

Example 2

Generated FORTRAN code does not include assignments for zero elements of a matrix:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):  
print(Unquoted, generate::fortran(A))
```

```
A(1,1) = 1.0D0  
A(2,3) = 1.0D0
```

Example 3

If the first index of an array is not 1, the generate::fortran function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):  
print(Unquoted, generate::fortran(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [DOM]
```

```
A(1,2) = 1.0D0  
A(1,3) = 2.0D0  
A(2,2) = 3.0D0  
A(2,3) = 4.0D0
```

Example 4

The generate::fortran function does not optimize your code:

```
print(Unquoted,  
      generate::fortran([x = a + b, y = (a + b)^2])):
```

```
x = a+b  
y = (a+b)**2
```

You can use the `generate::optimize` function before converting your MuPAD expression to FORTRAN code. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,  
      generate::fortran(  
        generate::optimize([x = a + b, y = (a + b)^2])  
      )):
```

```
x = a+b  
y = x**2
```

Example 5

By default, the `generate::fortran` function can issue warnings:

```
print(Unquoted, generate::fortran(gamma(x)))
```

```
Warning: Function "gamma" requires a FORTRAN_2008 compiler.
```

```
t0 = gamma(x)
```

If you started using `generate::fortran` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::fortran(gamma(x), NoWarning))
```

generate::fortran

```
t0 = gamma(x)
```

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

generate::fortran returns a string containing FORTRAN code.

See Also

MuPAD Functions

fprint | print | generate::optimize

Purpose	Generate MATLAB formatted string

See “Example 5” on page 9-13.</p> <p>To display generated MATLAB code on screen, use the <code>print</code> function. Use the printing option <code>Unquoted</code> to remove quotation marks and to expand special characters like line breaks and tabs. If a generated code line is longer than the <code>TEXTWIDTH</code> setting, the <code>print</code> function breaks that line into several shorter lines. The inserted line continuation character (<code>\</code>) is not valid in MATLAB. To avoid inserting line continuation characters, increase the <code>TEXTWIDTH</code> setting or use the <code>fprint</code> function to write generated code to a file.</p> <p><code>generate::MATLAB</code> does not create a MATLAB function. You can print an output string to a file using the <code>fprint</code> function with the <code>Unquoted</code> option. See “Example 6” on page 9-14.</p> <p>Working from the MATLAB workspace you can create a MATLAB function containing your expression. To call the MuPAD expression from the MATLAB workspace, use <code>evalin</code> or <code>feval</code> functions. See “Create MATLAB Functions from MuPAD Expressions”.</p>

If you work with the Simulink® products, you can copy the generated code and paste it into a Simulink block. Also, you can call the MuPAD expression from the MATLAB workspace using `evalin` or `feval` functions. Working from the MATLAB workspace you can automatically create a Simulink block containing your expression. See “Create MATLAB Function Blocks from MuPAD Expressions”.

The `NoWarning` option lets you suppress warnings. See “Example 7” on page 9-14.

Examples

Example 1

By default, MATLAB stores all numeric values as double-precision floating-point. In accordance with the default MATLAB data type, `generate::MATLAB` converts the elements of expressions, equations, and matrices to the `double` format:

```
print(Unquoted, generate::MATLAB(x^2 + y/3 + 1/6))
```

```
t0 = y*(1.0/3.0)+x^2+1.0/6.0;
```

Example 2

The generator produces a matrix of zeros, and then it replaces nonzero elements:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):  
print(Unquoted, generate::MATLAB(A))
```

```
A = zeros(2,3);  
A(1,1) = 1.0;  
A(2,3) = 1.0;
```

Example 3

If the first index of an array is not 1, the `generate::MATLAB` function issues a warning:

```
A:= array(1..2, 2..3, [[1,2],[3,4]]):  
print(Unquoted, generate::MATLAB(A))
```

```
Warning: The array index 'A[1..2, 2..3]' is out of range 1..n. [
```

```
A = zeros(2,2);  
A(1,2) = 1.0;  
A(1,3) = 2.0;  
A(2,2) = 3.0;  
A(2,3) = 4.0;
```

Example 4

When generating MATLAB code from equations, you get assignments instead of equations. For example, generate MATLAB code for the following list of equations:

```
f := generate::MATLAB([x = exp(t*s), y = sin(t)*cos(s)]):  
print(Unquoted, f)
```

```
x = exp(s*t);  
y = cos(s)*sin(t);
```

Example 5

The `generate::MATLAB` function does not optimize your code:

```
print(Unquoted,
```

```
generate::MATLAB([x = a + b, y = (a + b)^2]):
```

```
x = a+b;  
y = (a+b)^2;
```

You can use the `generate::optimize` function before converting your MuPAD code to MATLAB syntax. For example, this function can reduce the number of operations by finding common subexpressions:

```
f := generate::optimize([x = a + b, y = (a + b)^2]):  
print(Unquoted,  
      generate::MATLAB(f)):
```

```
x = a+b;  
y = x^2;
```

Example 6

To create a file with a MATLAB formatted string representing a symbolic expression, use the `fprint` function:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):  
fprint(Unquoted, Text, "matrixA.m", generate::MATLAB(A))
```

If the file `matrixA.m` already exists, `fprint` replaces the existing MATLAB code with the converted symbolic expression. You can open and edit the resulting file.

Example 7

By default, the `generate::MATLAB` function can issue warnings:

```
print(Unquoted, generate::MATLAB(g(x)))
```

Warning: Function "g" is not verified to be a valid MATLAB function.

```
t0 = g(x);
```

If you started using `generate::MATLAB` recently, the warnings can help you identify the potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::MATLAB(g(x), NoWarning))
```

```
t0 = g(x);
```

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

`generate::MATLAB` returns a string containing MATLAB code.

generate::MathML

Purpose Generate MathML from expressions

Syntax `generate::MathML(e, options)`

Description `generate::MathML(e)` returns a MathML object representing `e`. This object may be printed to a file using `fprint`.

Examples **Example 1**

`generate::MathML` generates an object containing the MathML code:

```
generate::MathML(hold(int)(exp(x^2)/x, x))
```

```
<math xmlns='http://www.w3.org/1998/Math/MathML'>
  <semantics>
    <mrow xref='ao7X0Bn'>
      <mo>⋅</mo>
      <mfrac xref='K5ZqTZC'>
        <msup xref='f9Ypr6T'>
          <mn>⋅</mn>
          <msup xref='amIZwNJ'>
            <mi xref='a5zFKQO'>x</mi>
            <mn xref='BCapBxj'>2</mn>
          </msup>
        </msup>
        <mi xref='jS17Msi'>x</mi>
      </mfrac>
      <mo>⋅</mo>
      <mi xref='ZrsPUxf'>x</mi>
    </mrow>
    <annotation-xml encoding='MathML-Content'>
      <apply id='ao7X0Bn'>
        <int/>
        <bvar>
          <ci id='ZrsPUxf'>x</ci>
        </bvar>
      </apply>
    </annotation-xml>
  </semantics>
</math>
```

```

<apply id='K5ZqTZC'>
  <divide/>
  <apply id='f9Ypr6T'>
    <exp/>
    <apply id='amIZwNJ'>
      <power/>
      <ci id='a5zFKQ0'>x</ci>
      <cn id='BCapBxj' type='integer'>2</cn>
    </apply>
  </apply>
  <ci id='jS17Msi'>x</ci>
</apply>
</annotation-xml>
<annotation encoding='MuPAD'>
  int(exp(x^2)/x, x)
</annotation>
</semantics>
</math>

```

The output of annotations and MathML presentation can be suppressed with the options `Presentation` and `Annotation`:

```

generate::MathML(hold(int)(exp(x^2)/x, x),
  Presentation = FALSE, Annotation = FALSE)

```

```

<math xmlns='http://www.w3.org/1998/Math/MathML'>
  <apply>
    <int/>
    <bvar>
      <ci>x</ci>
    </bvar>
  </apply>
  <divide/>
  <apply>

```

generate::MathML

```
<exp/>
  <apply>
    <power/>
    <ci>x</ci>
    <cn type='integer'>2</cn>
  </apply>
</apply>
<ci>x</ci>
</apply>
</apply>
</math>
```

MathML output can be written into a file using `fprint`:

```
fprint(Text, "filename.mathml",
       generate::MathML(hold(int)(exp(x^2)/x, x))):
```

Parameters

e

An arithmetical expression

Options

Annotation

Option, specified as `Annotation = FALSE`

Disables the output of annotations.

Content

Option, specified as `Content = FALSE`

Disables the MathML Content output.

Presentation

Option, specified as `Presentation = FALSE`

Disables the MathML Presentation output.

Return Values

generate::MathML returns an object containing MathML code.

Overloaded By

e

See Also**MuPAD Functions**

fprint | print

generate::optimize

Purpose Generate optimized code

Syntax `generate::optimize(r)`

Description `generate::optimize(r)` returns a sequence of equations representing an “optimized computation sequence” for the input expression `r`. Each equation in the sequence corresponds to an assignment of a subexpression of the input expression to a “temporary variable.” Common subexpressions are computed only once, thus reducing the total operation count.

The number of operations, namely additions (or subtractions), multiplications (or divisions) and in particular functions calls of the output is usually lower than the number of such operations of the input. This facility is useful for code generation.

Examples

Example 1

In this first example, we show the effects of optimization for a simple expression:

```
generate::optimize(cos(x^2) + x^2*sin(x^2) + x^4)
```

```
[t2 = x2, t1 = cos(t2) + t2 sin(t2) + t22]
```

The “blind” computation of the input expression requires 7 multiplications, 2 additions and 2 function calls. The optimized version introduces a “temporary variable” `t2` storing the subexpression `x2` that is used to compute the final result `t1`. This reduces the total cost to 3 multiplications, 2 additions and 2 function calls, albeit using 1 extra assignment to the temporary variable `t2`.

Example 2

Here we repeat the exercise of the first example but with an array of expressions:

```
generate::optimize(array(1..2, 1..2, [[x^3, x^2],[x^2, x^4]]))
```

$$\left[t2 = x^2, t1 = \begin{pmatrix} t2 x & t2 \\ t2 & t2^2 \end{pmatrix} \right]$$

The original input requires 6 multiplications. The optimized version needs only 3 multiplications and 1 extra assignment.

Example 3

We optimize a list of equations representing a computation sequence for 3 variables t, C[1], C[2]:

```
generate::optimize([t = u, C[1] = t*(u - w)^2, C[2] = 2*(u - w)^
```

$$\left[t = u, t1 = u - w, t2 = t1^2, C_1 = t t2, C_2 = 2 t1 t2 \right]$$

The original computation requires 5 multiplications and 2 subtractions. The optimized version needs 4 multiplications and 1 subtraction.

Note that since these examples involve small expressions, the computational savings are slight. In the case of very large expressions, optimization can yield a considerable dividend.

Parameters

r

An expression, array or list of equations

Return Values

List of equations.

Algorithms

A number of FORTRAN compilers provide optimizers. However, they use algorithms of complexity $O(n^2)$ and $O(n^3)$ where n is the size of the input expressions. For large amounts of code, these algorithms may “break.” MuPAD provides a reasonably good scalar (as in non-vectorized and non-parallelized) optimizer which is limited to common subexpression optimization and using binary powering for integer powers. It uses hashing of expressions so that given a

sub-expression, it can determine in constant time if this subexpression has already occurred. This results in an overall efficiency which is of lower complexity namely, $O(n)$ i.e. linear in the size of the input expressions to be optimized, Hence overall efficiency is not compromised by very large expressions. This does mean that not all possible optimizations are made but nonetheless a number of reductions including the exploitation of some symmetries are possible.

It should be understood that “optimization” is meant in the sense of compiler optimization. The end-result rarely corresponds to the absolute irreducible minimum number of operations – or as in the case of FORTRAN code generation, the absolute minimum of floating-point operations (FLOPS). Achieving this limit can be extremely difficult if not impossible especially for large computational sequences. Nonetheless, in a number of real-life instances, the MuPAD optimizer can yield a very useful result. Additionally, MuPAD provides symbolic manipulation tools such as `factor` which can yield additional reduction in operation costs.

In many cases of optimization, it is most often a matter of how best to pose the problem so as to fully exploit every possible symmetry or useful natural property of the given problem.

Purpose Generate Simscape equation

Syntax `generate::Simscape(e, <NoWarning>)`

Description `generate::Simscape(e)` generates Simscape™ code for the MuPAD expression `e`.

Simscape software extends the Simulink product line with tools for modeling and simulating multidomain physical systems, such as those with mechanical, hydraulic, pneumatic, thermal, and electrical components. Unlike other Simulink blocks, which represent mathematical operations or operate on signals, Simscape blocks represent physical components or relationships directly. With Simscape blocks, you build a model of a system just as you would assemble a physical system. For more information about Simscape software, see “Simscape”.

You can extend the Simscape modeling environment by creating custom components. When you define a component, use the equation section of the component file to establish the mathematical relationships among a component’s variables, parameters, inputs, outputs, time, and the time derivatives of each of these entities. MuPAD and Simscape software let you perform symbolic computations and use the results of these computations in the equation section. The `generate::Simscape` function translates the results of symbolic computations to Simscape language equations.

`generate::Simscape` returns a Simscape formatted string representing an expression, equation, list of expressions or equations, or a matrix.

`generate::Simscape` converts the identifier `t` to the variable `time` in the resulting Simscape code. However, the name `t` of a function call does not change during conversion. See “Example 1” on page 9-25 and “Example 2” on page 9-25.

`generate::Simscape` converts any derivative with respect to the variable `t` to the Simscape notation `x.der`, where `x` is the time-dependent variable. See “Example 3” on page 9-26.

`generate::Simscape` assumes that the type of converted data is `double`. See “Example 4” on page 9-26.

When generating Simscape code for a matrix, the generator produces a dense matrix. See “Example 5” on page 9-27.

Use the `generate::optimize` function to optimize the MuPAD code before converting it to the Simscape syntax. See “Example 6” on page 9-27.

`generate::Simscape` converts piecewise expressions to Simscape code by using the `if` statements. See “Example 7” on page 9-28.

The equation section of a Simscape component file supports a limited number of functions. For details and the list of supported functions, see Simscape equations. If a symbolic equation contains the functions that are not available in the equation section of a Simscape component file, `generate::Simscape` cannot correctly convert these equations to Simscape equations. Such expressions do not trigger an error. The following types of expressions are prone to invalid conversion:

- Expressions with infinities
- Expressions that contain programming structures, such as loops, conditional statements (except for the `if` statement), and `map` function calls
- Expressions that contain intervals, sets, and lists

To display generated Simscape code on screen, use the `print` function. To remove quotation marks and to expand special characters like line breaks and tabs, use the printing option `Unquoted`. If a generated code line is longer than the `TEXTWIDTH` setting, the `print` function breaks that line into several shorter lines. The inserted line continuation character (`\`) is not valid in Simscape. To avoid inserting line continuation characters, increase the `TEXTWIDTH` setting or use the `fprint` function to write generated code to a file.

To write generated Simscape code to a file, use the `fprint` function with the `Unquoted` option. See “Example 8” on page 9-28.

The NoWarning option lets you suppress warnings. See “Example 2” on page 9-25.

Examples

Example 1

The `generate::Simscape` function replaces all instances of the MuPAD identifier `t` with the variable `time`. For example, convert the following equation to the Simscape equation:

```
e := A*sin(w*t) + B*cos(w*t) = 0;  
print(Unquoted, generate::Simscape(e))
```

```
B*cos(time*w)+A*sin(time*w) == 0.0;
```

Example 2

The `generate::Simscape` function does not change the function name `t` in function calls:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)]))
```

```
Warning: Function "t" is not verified to be a valid Simscape fun
```

```
Warning: Function "t" is not verified to be a valid Simscape fun
```

```
Warning: Function "t" is not verified to be a valid Simscape fun
```

```
t();  
t(0.0);
```

```
t(x);
```

This example produces a few identical warnings. If you started using `generate::Simscape` recently, warnings can help you identify potential issues in the converted code. If you want to suppress warnings, use the `NoWarning` option:

```
print(Unquoted, generate::Simscape([t(), t(0), t(x)], NoWarning))
```

```
t();  
t(0.0);  
t(x);
```

Example 3

When generating Simscape code, the `generate::Simscape` function converts the derivatives with respect to the variable `t` to the Simscape notation `x.der`. Here `x` is the time-dependent variable. For example, generate the Simscape code for the equation `e` that has two time-dependent variables:

```
e := x'(t) + diff(y(t), t) + 2*x + 5 = 0:  
print(Unquoted, generate::Simscape(e))
```

```
x*2.0+x.der+y.der+5.0 == 0.0;
```

Example 4

By default, Simscape stores all numeric values as double-precision floating-point values. In accordance with this default data type, `generate::Simscape` converts the elements of expressions, equations, and matrices to the double format:

```
print(Unquoted, generate::Simscape(x^2 + y/3 + 1/6))
```

```
y*(1.0/3.0)+x^2+1.0/6.0;
```

Example 5

`generate::Simscape` can generate Simscape code for a MuPAD matrix. In contrast to `generate::MATLAB` (which produces sparse matrices), the Simscape code generator produces dense matrices:

```
A:= matrix([[1, 0, 0],[0, 0, 1]]):  
print(Unquoted, generate::Simscape(A))
```

```
A = [  
1.0 0.0 0.0  
0.0 0.0 1.0  
];
```

Example 6

The `generate::Simscape` function does not optimize your code:

```
print(Unquoted,  
      generate::Simscape([x = a + b, y = (a + b)^2])):  
  
x == a+b;  
y == (a+b)^2;
```

You can use the `generate::optimize` function before converting your MuPAD code to Simscape syntax. For example, this function can reduce the number of operations by finding common subexpressions:

```
print(Unquoted,  
      generate::Simscape(  
        generate::optimize([x = a + b, y = (a + b)^2])
```

generate::Simscape

```
)):
```

```
x == a+b;  
y == x^2;
```

Example 7

The `generate::Simscape` function also accepts piecewise expressions. The function uses `if` statements when generating Simscape code for piecewise expressions. For example, the Fourier transform of the following expression is a piecewise function:

```
FT := fourier(exp(-abs(x)*abs(t))*sin(t)/t, t, s)
```

$$\left\{ \begin{array}{l} \arctan\left(\frac{s+1}{|x|}\right) - \arctan\left(\frac{s-1}{|x|}\right) \text{ if } x \neq 0 \\ \end{array} \right.$$

`generate::Simscape` converts this result to a valid Simscape expression:

```
print(Unquoted, generate::Simscape(FT))
```

```
if (x ~= 0.0),  
    -atan((s-1.0)/abs(x))+atan((s+1.0)/abs(x));  
else  
    NaN;  
end
```

Example 8

To create a text file with a Simscape formatted string representing a symbolic expression, use the `fprint` command:

```
e := x'(t) + 2*x + 5 = 0:
```

```
fprint(Unquoted, Text, "eqn.txt", generate::Simscape(e))
```

If the file `eqn.txt` already exists, `fprint` replaces the existing Simscape code with the converted symbolic expression. You can open and edit the resulting text file.

Parameters

e

An expression, equation, list of equations, or a matrix

Options

NoWarning

Suppress warnings.

Return Values

`generate::Simscape` returns a string containing Simscape code. In case of invalid conversion, the returned value is an arbitrary string.

MuPAD Functions

`fprint` | `print` | `generate::optimize` | `generate::MATLAB`

generate::TeX

Purpose Generate formatted string from expressions

Syntax `generate::TeX(e)`

Description `generate::TeX(e)` returns a TeX formatted string representing `e`. This string may be printed to a file using `fprint`. Use the printing option `Unquoted` to remove quotes and to expand special characters like newlines and tabs.

The output string may be used in the math-mode of TeX. Note that `generate::TeX` doesn't break large formulas into smaller ones.

Examples

Example 1

`generate::TeX` generates a string containing the TeX code:

```
generate::TeX(hold(int)(exp(x^2)/x, x))
```

```
"int \frac{\mathrm{e}^{x^2}}{x} \,\mathrm{d} x"
```

Use `print` with option `Unquoted` to get a more readable output:

```
print(Unquoted, generate::TeX(hold(int)(exp(x^2)/x, x)))
```

```
\int \frac{\mathrm{e}^{x^2}}{x} \,\mathrm{d} x
```

Example 2

This example shows how to write a "TeX"-method for a domain. The domain elements represent open intervals. The "TeX"-method makes recursive use of `generate::TeX` in order to TeX-format its operands and concatenates the resulting strings to a new string containing the TeX output of the interval.

```
Interval := newDomain("Interval"):
Interval::TeX :=
```

```
e -> "\\left].generate::TeX(extop(e, 1)).
      ", ".generate::TeX(extop(e, 2))."\\right[" :
print(Unquoted,
      generate::TeX(new(Interval, 1, x^(a+2))))):
```

```
\left]1, x^{a + 2}\right[
```

Parameters**e**

An arithmetical expression

Return Values

generate::TeX returns a string containing TeX code.

Overloaded By**e****Algorithms**

The TeX packages amsmath and amssymb are needed.

A domain overloading generate::TeX has to provide a function as its "TeX"-slot which translates its elements into a TeX formatted string. This function may use generate::TeX recursively. See “Example 2” on page 9-30.

Purpose Adds one or several edges to a graph

Syntax `Graph::addEdges(G, Edge)`
`Graph::addEdges(G, Edge, <EdgeWeights = ew>, <EdgeCosts = ec>, <EdgeDescriptions = ed>)`

Description `Graph::addEdges` adds one or several edges to an already existing Graph. An edge is represented by a list containing two vertices of the graph. A warning is raised if one of the specified edges does already exist in the graph.

`Graph::addEdges(G, Edge)` adds the edge(s) `Edge` to the graph `G`. The two vertices of each edge must be vertices in the given graph. Otherwise an error is raised. If an edge is specified that already exists, a warning will be printed that this edge is not used.

With `Graph::addEdges(G, Edge, EdgeWeights=ew, EdgeCosts=ec, EdgeDescriptions=ed)` the weight, cost and description of each edge can be set to every edge additionally. If these specifications are missing, the default value 0(=None) is assumed. If a specification is used it has to hold exactly the same number of values as there are edges. Otherwise an error will be raised.

Note The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

Examples

Example 1

First, an undirected graph with two vertices and no edges is created. Then two edges are added:

```
G := Graph([a, b, c, d], []):  
Graph::printEdgeInformation(G):  
G := Graph::addEdges(G, [[a, b], [c, d]]):  
Graph::printEdgeInformation(G)
```

No edges.

Graph::addEdges

Edges existing in the graph:

[a, b], [c, d], [b, a], [d, c]

As you can see, [b,a] and [d,c] were inserted automatically.

```
G2 := Graph::addEdges(G, [[a,d]]) : Graph::getEdges(G2)
```

```
[[a, d], [d, a], [a, b], [c, d], [b, a], [d, c]]
```

Now, what happens if an edge is inserted that already exists in the graph?

```
G := Graph::addEdges(G, [[d, c]])
```

```
Warning: The following edges were not used for operation: [[d, c]].
```

```
Graph(...)
```

Suppose, we try to insert an edge with a vertex not existing in the graph:

```
G := Graph::addEdges(G, [[a, 5]])
```

```
Error: One or more edges contain vertices that are not in list '[5]
```

Now let's see what happens when a directed graph is created:

```
G := Graph([a, b, c, d], [], Directed):
```

```
G := Graph::addEdges(G, [[a, b], [b, c], [c, d]],  
                    EdgeWeights = [2/8, -5, PI],  
                    EdgeCosts = [30, -40, None]):  
Graph::printGraphInformation(G)
```

```
Vertices: [a, b, c, d]  
Edges: [[a, b], [b, c], [c, d]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI (other exist  
Edge costs: [a, b] = 30, [b, c] = -40 (other existing edges have  
Adjacency list (out): a = [b], b = [c], c = [d], d = []  
Adjacency list (in): a = [], b = [a], c = [b], d = [c]  
Graph is directed.
```

Have a close look at the Edge costs line. The edge [c,d] is not mentioned explicitly due to the value None:

```
G2 := Graph::addEdges(G, [[a, b], [a, d]], EdgeWeights=[10, 20],  
                    EdgeCosts = [80, 90],  
                    EdgeDescriptions = ["First way", "Second way"]  
Graph::printGraphInformation(G2)
```

Warning: The following edges were not used for operation: [[a, b

```
Vertices: [a, b, c, d]  
Edges: [[a, d], [a, b], [b, c], [c, d]]  
Vertex weights: no vertex weights.  
Edge descriptions: [a, d] = "Second way"  
Edge weights: [a, b] = 1/4, [b, c] = -5, [c, d] = PI, [a, d] = 2  
Edge costs: [a, b] = 30, [b, c] = -40, [a, d] = 90 (other existi  
Adjacency list (out): a = [b, d], b = [c], c = [d], d = []
```

Graph::addEdges

Adjacency list (in): a = [], b = [a], c = [b], d = [a, c]
Graph is directed.

If an edge has specifications, but exist already in the graph, the specifications will not change. (see Information for edge [a, b] above)

Parameters

G

Graph

Edge

List of one or more edges

ew, ec

Lists of numbers

ed

List of texts

b

Boolean value

Options

EdgeWeights

The weight(s) of the new edge(s). Default is 0.

EdgeCosts

The cost(s) of the new edge(s). Default is 0.

EdgeDescriptions

The description(s) for the new edge(s). Default is no text.

Return Values

Graph with the correct edges inserted.

Purpose

Adds one or several vertices to a graph

Syntax

```
Graph::addVertices(G, Vertex, <VertexWeights = vw>)
```

Description

`Graph::addVertices` adds one or several vertices to an already existing graph. A vertex is represented by an arbitrary expression. A warning is raised if one of the specified vertices does already exist in the graph.

`Graph::addVertices(G, Vertex)` adds the vertices in `Vertex` to the graph `G`. If a vertex is specified that already exists, a warning will be printed that this vertex (and its vertex weight) is not used.

With `Graph::addVertices(G, Vertex, VertexWeights=vw)` the weight can be set to every vertex additionally. If these specifications are missing, the default value 0(=None) is assumed. If a specification is used it has to hold exactly the same number of values as there are vertices. Otherwise an error will be raised.

Note The value `None` can be used in the specification lists for every edge that is not to be specified explicitly.

Examples**Example 1**

First, an undirected graph with two vertices and no edges is created. Then two vertices are added:

```
G := Graph([a, b, c, d], []):
Graph::printVertexInformation(G):
G := Graph::addVertices(G, [e, f]):
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
```

```
-----
Vertex a has weight None
Vertex b has weight None
```

Graph::addVertices

```
Vertex c has weight None
Vertex d has weight None
```

```
Vertices existing in the graph:
```

```
-----
Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
Vertex e has weight None
Vertex f has weight None
```

No weights were specified, so every vertex has weight None. In the algorithms default-values will be used accordingly.

Now, what happens if a vertex is inserted that already exists in the graph?

```
G2 := Graph::addVertices(G, [a, g], VertexWeights=[10, 100]):
Graph::printVertexInformation(G2)
```

```
Warning: The following vertices already exist: [a]. [Graph::selectV
```

```
Vertices existing in the graph:
```

```
-----
Vertex a has weight None
Vertex b has weight None
Vertex c has weight None
Vertex d has weight None
Vertex e has weight None
Vertex f has weight None
```

Vertex g has weight 100

If a vertex weight is specified for a vertex already existing, it will not be changed (see Vertex a above)

Parameters

G

Graph

Vertex

List of one or more vertices

vw

Lists of numbers

Options

VertexWeights

The weight(s) of the new vertex/vertices. Default is 0.

Return Values

Graph with the correct vertices inserted.

Graph::admissibleFlow

Purpose Checks a flow for admissibility in a Graph

Syntax Graph::admissibleFlow(G, f)

Description Graph::admissibleFlow(G, f) checks if the flow f is admissible in the Graph G according to its vertices and their capacities.

Graph::admissibleFlow checks whether a given flow is an admissible flow in the specified graph. A flow in a graph is a table t, where t[[i, j]] gives the number of units flowing from vertex i to vertex j. Graph::admissibleFlow returns TRUE if the flow is admissible. Otherwise FALSE is returned.

Graph::admissibleFlow does not check whether the flow is admissible, if a flow from vertex i to vertex j is allowed to pass through other vertices. See “Example 2” on page 10-10.

Examples

Example 1

In a cyclic graph with default capacities (1), the flow with one unit flowing from each vertex to its successor is certainly admissible:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):  
Graph::admissibleFlow(G1, table([v1, v2] = 1,  
                                [v2, v3] = 1,  
                                [v3, v4] = 1,  
                                [v4, v1] = 1))
```

TRUE

Example 2

The flow must be specified in whole. Graph::admissibleFlow does not include “hops”, like skipping vertices in the path:

```
Graph::admissibleFlow(Graph::createCircleGraph([v1, v2, v3]),  
                      table([v1, v3] = 1))
```

FALSE

Parameters

G

Graph

f

The flow, specified in a table

Return Values

Either TRUE or FALSE

Graph::bipartite

Purpose Finds out if a graph is bipartite.

Syntax Graph::bipartite(G, <Bool | Lists>)

Description Graph::bipartite(G) finds out whether G is bipartite or not.
Graph::bipartite(G, Sets): If G is bipartite, then a list containing two lists will be returned. Each of the lists contains the vertices belonging to the set. If G is not bipartite, then FAIL will be returned instead of any list.
Graph::bipartite(G, Bool) offers the same result as Graph::bipartite(G). If G is bipartite, then TRUE will be returned, otherwise FALSE.

Examples **Example 1**

A small graph containing 3 vertices with 2 edges connecting them is created:

```
G := Graph([a, b, c], [[a, b], [b, c]]):  
Graph::bipartite(G, Lists);  
Graph::bipartite(G, Bool)
```

```
[[b], [a, c]]
```

```
TRUE
```

Two lists with vertices are shown. Another word for bipartite is two-colorable. This means that the graph above can be colored with only two colors so that no two vertices have the same color if connected with an edge. The bottom output could also be accomplished without using the parameter Bool:

```
Graph::bipartite(G)
```

TRUE

The following example shows what happens when a graph is not bipartite (an edge is added to connect the vertices a and c):

```
G2 := Graph::addEdges(G, [[a, c]]):  
Graph::bipartite(G2, Lists);  
Graph::bipartite(G2, Bool)
```

FAIL

FALSE

Parameters

G

Graph

Options

Lists

If Lists is stated the return value will be a list of two lists containing the (sorted) vertices belonging to each set, or FAIL.

Bool

If Bool is stated the return value will be either TRUE or FALSE. This is the default.

Return Values

Depending on the options either a boolean value or list-sets will be returned.

Graph::breadthFirstSearch

Purpose Makes a breadth first Search in a graph.

Syntax Graph::breadthFirstSearch(G, <StartVertex = v>)

Description Graph::breadthFirstSearch traverses through a graph via breadth first search. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Graph::breadthFirstSearch(G, StartVertex = v) traverses through a graph via breadth first search starting from vertex v. The output shows the first time of identification and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Examples **Example 1**

A typical tree is created and drawn for a better understanding of the algorithm:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed);
plot(
  Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
    VertexOrder = [
      None, None, None, None, None, None, a, None, None, None, None,
      None, None, b, None, None, None, None, None, None, c, None,
      None, d, None, None, e, None, None, f, None, None, g,
      h, None, None, i, None, j, None, None, k, None, None,
    ]
  )
)
```

Now we call breadthFirstSearch to find out the starting times and predecessors

Graph::breadthFirstSearch(G)

a	1	a	0	a	a
b	2	b	1	b	a
c	3	c	1	c	a
d	4	d	2	d	b
e	5	e	2	e	b
f	6	f	2	f	c
g	7	g	2	g	c
h	8	h	3	h	d
i	9	i	3	i	e
j	10	j	3	j	e
k	11	k	3	k	f
l	12	l	3	l	g

Graph::breadthFirstSearch

Vertex a is discovered first, then vertex b and so on. The right table shows the predecessor of every vertex. The backtracking from a single vertex is therefore really simple. a as the first vertex discovered in its component can not be backtracked any further. The distance of each vertex in its component can be read in the middle table. Root-vertices always have the value 0 (they are the roots).

Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a breadth first search is invoked on the graph:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):
```

```
G2 := Graph::addVertices(G, [m]):
Graph::breadthFirstSearch(G2, StartVertex = [a])
```

a	1	a	0	a	a
b	2	b	1	b	a
c	3	c	1	c	a
d	4	d	2	d	b
e	5	e	2	e	b
f	6	f	2	f	c
g	7	g	2	g	c
h	8	h	3	h	d
i	9	i	3	i	e
j	10	j	3	j	e
k	11	k	3	k	f
l	12	l	3	l	g
m	13	m	0	m	∞

The newly inserted vertex m has no predecessor. The predecessor therefore holds the value *infinity*.

Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):
```

```
Graph::breadthFirstSearch(G, StartVertex = [c])
```

a	6	a	0	a	a
b	7	b	1	b	a
c	1	c	0	c	c
d	8	d	2	d	b
e	9	e	2	e	b
f	2	f	1	f	c
g	3	g	1	g	c
h	10	h	3	h	d
i	11	i	3	i	e
j	12	j	3	j	e
k	4	k	2	k	f
l	5	l	2	l	g

The predecessor of `c` is `c`, but if we look at the graph it should be `a`. This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to `l`.

Parameters

G

Graph

v

List containing one vertex.

Graph::breadthFirstSearch

Options

StartVertex

Defines a vertex from which to start the breadth first traversal.

Return Values

List containing three tables. The first table holds the timestamp of the discovery. The second the distance to the root-vertex. The last table holds the predecessor vertices.

Purpose	Checks if all vertices in edges really exist.
Syntax	<code>Graph::checkForVertices(Edge, Vertex)</code>
Description	<code>Graph::checkForVertices(Edge, Vertex)</code> checks if all vertices out of Edge are in Vertex.
Examples	<p>Example 1</p> <p>What vertices are within the stated edges, but not in the vertex list?</p> <pre>Graph::checkForVertices([[a, b], [1, 2]], [a, 2])</pre> <pre>[b, 1]</pre> <p>Neither b nor 1 were in the second list. a was in the first edge and 2 in the second.</p> <p>Example 2</p> <p>A more complex example. The second list contains a vertex that does not exist in the graph at all. For the checking it does not matter though. Every vertex NOT in the second list is to be returned. In the end it does not matter if the vertex-list contains vertices that are not existent, because only existing vertices are returned.</p> <pre>G := Graph::createCompleteGraph(10): Graph::checkForVertices(Graph::getEdges(G), [1, 2, 3, 11])</pre> <pre>[4, 5, 6, 7, 8, 9, 10]</pre>
Parameters	<p>Edge</p> <p>List of one or more Edges</p> <p>Vertex</p> <p>List of one or more vertices</p>

Graph::checkForVertices

Return Values

List with the vertices out of the Edges that were not stated in Vertex.

Purpose Chromatic number of a graph

Syntax `Graph::chromaticNumber(G)`

Description `Graph::chromaticNumber(G)` returns the chromatic number of the graph `G`. The chromatic number of a graph is defined to be the number of colors necessary to color it such that no two adjacent vertices have the same color.

Examples **Example 1**

We compute the chromatic number of the complete graph with 5 vertices; it must be 5 since any two vertices are adjacent:

```
Graph::chromaticNumber(Graph::createCompleteGraph(5))
```

```
5
```

Parameters **G**
An undirected graph

Return Values Positive integer

Algorithms Internally, the chromatic polynomial is used to compute the chromatic number.

See Also

MuPAD Functions `Graph::chromaticPolynomial`

Graph::chromaticPolynomial

Purpose Calculates a chromatic polynomial

Syntax `Graph::chromaticPolynomial(G, x)`

Description `Graph::chromaticPolynomial(G, x)` returns the chromatic polynomial of the graph `G`. Evaluating the result at $x = n$, for any integer n , gives the number of possible ways to color the graph `G` using n colors such that no two adjacent vertices have the same color.

`G` must be an undirected graph: if an edge goes from a to b , another edge must go from b to a , for any two vertices a, b .

Examples **Example 1**

We compute the chromatic polynomial of the complete graph with 5 vertices:

```
f := Graph::chromaticPolynomial(Graph::createCompleteGraph(5), x)
```

```
poly(x5 - 10 x4 + 35 x3 - 50 x2 + 24 x, [x])
```

There are 240 ways to color a complete graph with 5 vertices, since this is the number of bijective mappings between the set of colors and the set of vertices:

```
f(5)
```

```
120
```

```
delete f:
```

Example 2

Now let us delete one edge from a complete graph:

```
G := Graph::createCompleteGraph(5):  
G := Graph::removeEdge(G, [[2, 3]]):
```

```
G:= Graph::removeEdge(G, [[3, 2]])
```

```
Graph(...)
```

Now there are some additional possible colourings: vertices 2 and 3 may now have the same color, in five different ways; in each case, there must be one of the four remaining colors that does not occur at all. In each of the 20 cases, we are left with 3 vertices that form a complete graph and 3 colors, such that there are 6 colourings. Altogether this gives us 120 additional colourings:

```
Graph::chromaticPolynomial(G, x)(5)
```

```
240
```

Parameters

G

An undirected graph

x

An identifier

Return Values

polynomial

Algorithms

Computing the chromatic polynomial of a graph with n vertices reduces to computing two chromatic polynomials of graphs with $n - 1$ vertices. The running time is hence roughly 2^n .

See Birkhoff and Lewis, *Chromatic Polynomials*, Trans. AMS, Vol. 60, p.355–451, 1946.

Graph::contract

Purpose Contracts vertices

Syntax Graph::contract(G, VertexTable)

Description Graph::contract(G, VertexTable) contracts the vertices for each entry in the table.

Note The graph to be contracted must not have edge weights, costs or descriptions. If it has, an error will be raised.

Note If VertexTable contains vertices not in G, these will be skipped.

Examples

Example 1

A simple example to see how a contraction is done.

```
ConG := Graph([a, b, c, d, e, f],
              [[a, c], [d, a], [f, c], [d, f], [e, b]],
              Directed):
Graph::printGraphInformation(ConG)
```

```
Vertices: [a, b, c, d, e, f]
Edges: [[a, c], [d, a], [d, f], [e, b], [f, c]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): a = [c], b = [], c = [], d = [a, f], e = [b],
Adjacency list (in): a = [d], b = [e], c = [a, f], d = [], e = [],
Graph is directed.
```

```
plot(  
  Graph::plotGridGraph(ConG,  
    VerticesPerLine = 3,  
    VertexOrder = [None, b,   None,  
                   a,   None, c,  
                   None, e,   None,  
                   d,   None, f],  
    EdgeColor = RGB::Black))
```

```
t := table(A = [a, b, c],  
          B = [d, f])
```

$$\begin{array}{l|l} A & [a, b, c] \\ B & [d, f] \end{array}$$

```
newG := Graph::contract(ConG, t):
```

Graph::contract

```
Graph::printGraphInformation(newG)
```

```
Vertices: [A, B, e]
Edges: [[A, A], [B, A], [B, B], [e, A]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): e = [A], A = [A], B = [A, B]
Adjacency list (in): e = [], A = [A, B, e], B = [B]
Graph is directed.
```

Since vertices a, b, c were contracted to vertex A , edge $[a,c]$ was removed and edge $[A, A]$ was created. Vertices d, f took care of the deletion of edges $[d, a], [d, f], [f, c]$. Instead edges $[B, A]$ and $[B, B]$ were created. In the end edge $[e, b]$ was changed to $[e, A]$ since vertex b does not exist any longer because it was replaced by A .

```
plot(Graph::plotGridGraph(newG,
    VerticesPerLine = 2,
    VertexOrder = [None, B,
                   A,   None,
                   None, e]))
```

Example 2

Graph::contract ignores vertices not in the graph:

```
Con2 := Graph([], []):  
t := table(A = [a, b, c], B = [d, f]):  
Graph::printGraphInformation(Graph::contract(Con2, t))
```

```
Vertices: no vertices.  
Edges: []  
Adjacency list (out): no edges.  
Adjacency list (in): no edges.  
Graph is undirected.
```

Graph::contract

Parameters

G

Graph

VertexTable

A table with the name of the new vertex on the left side and a list of vertices to contract on the right side.

Return Values

Graph consisting of the new vertices and edges.

Purpose

Converts a Graph into a single source single sink Graph

Syntax

```
Graph::convertSSQ(G, q, s)
```

Description

`Graph::convertSSQ(G, q, s)` converts the graph `G` into a directed single source single sink graph. The specified vertices `q` and `s` are added to the graph. It is an error if they are already predefined. Otherwise they are connected to the other vertices of the graph in the following way:

A new edge `[q, i]` is added for every vertex `i` with a positive weight.
A new edge `[i, s]` is added for every vertex `i` with a negative weight.
The capacities of these edges are in each case the weight of node `i`.
The edge weights are zero.

Examples

Example 1

A testexample to show the transformation.

```
V := [1, 2, 3, 4]:  
Vw := [4, 0, 0, -4]:  
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4]]:  
Ec := [2, 2, 1, 3, 1]:  
Ew := [4, 2, 2, 3, 5]:  
G1 := Graph(V, Ed, VertexWeights = Vw,  
            EdgeWeights = Ew, EdgeCosts = Ec):  
G2 := Graph::convertSSQ(G1, [q], [s]):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, q, s]  
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [2, 4], [3, 1], [3, 2],  
Vertex weights: 1 = 0, 2 = 0, 3 = 0, 4 = 0, q = 4, s = -4 (other  
Edge descriptions: no edge descriptions.  
Edge weights: [1, 2] = 4, [1, 3] = 2, [2, 3] = 2, [2, 4] = 3, [3,  
3, [4, 3] = 5, [q, 1] = 4, [4, s] = 4 (other existing edges have  
Edge costs: [1, 2] = 2, [1, 3] = 2, [2, 3] = 1, [2, 4] = 3, [3,
```

Graph::convertSSQ

$[4, 3] = 1$, $[q, 1] = 0$, $[4, s] = 0$ (other existing edges have cost 1)
Adjacency list (out): 1 = [2, 3], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [1, 2, 3, q]
Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3, 4], 3 = [1, 2, 4], 4 = [1, 2, 3, q]
Graph is directed.

The former undirected graph was transformed into a directed one!

Parameters

q, s

Vertices not predefined in the Graph

G

A Graph

Return Values

Directed augmented Graph

Algorithms

Both, Bellman and Dijkstra expect a Graph without negative circles.
Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin:
Dom::Graph Flows, Prentice-Hall, 1993 Section 5.4

Purpose

Generates a circle Graph

Syntax

```
Graph::createCircleGraph(L, <Directed | Undirected>)  
Graph::createCircleGraph(N, <Directed | Undirected>)
```

Description

Graph::createCircleGraph(L) generates a circle Graph

Graph::createCircleGraph([v1, ..., vn]) generates a new graph which is the cycle [v1,v2], [v2,v3], ..., [vn,v1]. The values for the edge weights, edge costs and vertex weights can be set manually via Graph::setEdgeWeights, Graph::setEdgeCosts and Graph::setVertexWeights

Graph::createCircleGraph(3) generates a new graph which is the cycle [1,2], [2,3], [3,1]. The values for the edge weights, edge capacities and vertex weights can be set manually via Graph::setEdgeWeights, Graph::setEdgeCosts and Graph::setVertexWeights

Graph::createCircleGraph(3, Undirected) generates a new graph which includes the vertices [1,2], [2,3], [3,1][2,1], [3,2], [1,3].

Examples

Example 1

A (directed) circle graph with four vertices:

```
G1 := Graph::createCircleGraph(4):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [1]  
Adjacency list (in): 1 = [4], 2 = [1], 3 = [2], 4 = [3]
```

Graph::createCircleGraph

Graph is directed.

Example 2

The same graph but this time with parameter Undirected:

```
G2 := Graph::createCircleGraph(4, Undirected):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4]  
Edges: [[1, 2], [1, 4], [2, 1], [2, 3], [3, 2], [3, 4], [4, 1], [4, 3]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3]  
Adjacency list (in): 1 = [2, 4], 2 = [1, 3], 3 = [2, 4], 4 = [1, 3]  
Graph is undirected.
```

Example 3

The circle graph with predefined vertices:

```
G3 := Graph::createCircleGraph([a, b, c, d, 4, 5, 6]):  
Graph::printGraphInformation(G3)
```

```
Vertices: [4, 5, 6, a, b, c, d]  
Edges: [[4, 5], [5, 6], [6, a], [a, b], [b, c], [c, d], [d, 4]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): a = [b], b = [c], c = [d], d = [4], 4 = [5],  
Adjacency list (in): a = [6], b = [a], c = [b], d = [c], 4 = [d], 5 = [4],  
Graph is directed.
```

Parameters

L

List of vertices

N

A positive Integer

Options

Directed

The Graph is created as a directed graph. Default.

Undirected

The Graph is created as an undirected graph.

Return Values

Graph

Graph::createCompleteGraph

Purpose Generates a complete graph

Syntax Graph::createCompleteGraph(n)

Description Graph::createCompleteGraph(n) generates the complete Graph with n vertices. A complete graph has a connection between each pair of vertices (except to itself).

The vertices of the generated graph are labeled with the numbers 1 to n.

Examples **Example 1**

The complete Graph with three vertices has $3 \cdot 2 = 6$ edges:

```
G := Graph::createCompleteGraph(3):  
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]  
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]  
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]  
Graph is undirected.
```

Parameters **n**

A positive integer

Return Values Graph

Purpose

Transfers a squared matrix into a directed graph

Syntax

```
Graph::createGraphFromMatrix(M)
```

Description

`Graph::createGraphFromMatrix(M)` generates a directed Graph where each $m_{i,j}$ in the matrix defines an edge from i to j . The value of the cell defines the weight of the resulting edge.

The vertices of the generated graph are labeled with the numbers 1 to n , where n defines the column/row-dimension of the matrix. Since the matrix has to be squared, n stays the same.

Examples

Example 1

A matrix is defined and the resulting squared matrix is transferred into a Graph.

```
a := matrix([[3, 2, 4], [2, 3, 6], [4, 8, 3]]);  
G := Graph::createGraphFromMatrix(a);  
Graph::printGraphInformation(G)
```

$$\begin{pmatrix} 3 & 2 & 4 \\ 2 & 3 & 6 \\ 4 & 8 & 3 \end{pmatrix}$$

Vertices: [1, 2, 3]

Edges: [[1, 1], [1, 2], [1, 3], [2, 1], [2, 2], [2, 3], [3, 1],

Vertex weights: no vertex weights.

Edge descriptions: no edge descriptions.

Edge weights: [1, 1] = 3, [1, 2] = 2, [1, 3] = 4, [2, 1] = 2, [2, 3] = 6 (other existing edges have no weight)

Edge costs: no edge costs.

Adjacency list (out): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3]

Adjacency list (in): 1 = [1, 2, 3], 2 = [1, 2, 3], 3 = [1, 2, 3]

Graph is directed.

Graph::createGraphFromMatrix

Parameters

M

A matrix

Return Values

Graph

Graph::createRandomEdgeWeights

Purpose Sets random weights to edges

Syntax `Graph::createRandomEdgeWeights(G, r, <Dom::Integer
| Dom::Real>)`

Description `Graph::createRandomEdgeWeights(G, x..y)` creates random integer edge weights within the range `x..y`.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Integer)` does exactly the same.

`Graph::createRandomEdgeWeights(G, x..y, Dom::Real)` creates random real edge weights within the range `x..y`.

Note Already existing edge weights will be changed, too!

Examples

Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
```

```
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]
```

```
Vertex weights: no vertex weights.
```

```
Edge descriptions: no edge descriptions.
```

```
Edge weights: no edge weights.
```

```
Edge costs: no edge costs.
```

```
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]
```

```
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
```

```
Graph is directed.
```

Graph::createRandomEdgeWeights

Now the weights are set within the range -100..50 (your output may differ due random assignment):

```
G2 := Graph::createRandomEdgeWeights(G1, -100..50):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1, [5, 1] = 1  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

If the weights should be of type Real it can be set optionally:

```
G2 := Graph::createRandomEdgeWeights(G1, -100..50, Dom::Real):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] = 662729 (other existing edges have no weight)  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

Graph::createRandomEdgeWeights

Parameters

G

A graph

r

A range

Return Values

Graph

Graph::createRandomEdgeCosts

Purpose	Sets random costs to edges
Syntax	<code>Graph::createRandomEdgeCosts(G, r, <Dom::Integer Dom::Real>)</code>
Description	<p><code>Graph::createRandomEdgeCosts(G, x..y)</code> creates random edge weights of type <code>Integer</code> within the range <code>x..y</code>.</p> <p><code>Graph::createRandomEdgeCosts(G, x..y, Dom::Integer)</code> does exactly the same.</p> <p><code>Graph::createRandomEdgeCosts(G, x..y, Dom::Real)</code> creates random edge weights of type <code>Real</code> within the range <code>x..y</code>.</p>

Note Already existing edge costs will be changed, too!

Examples

Example 1

Creating edge weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

Graph::createRandomEdgeCosts

Now the costs are set within the range -100..50 (your output may differ due random assignment):

```
G2 := Graph::createRandomEdgeCosts(G1, -100..50):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: [1, 2] = 47, [2, 3] = -12, [3, 4] = 28, [4, 5] = 1,  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

If the costs should be of type Real it can be set optionally:

```
G2 := Graph::createRandomEdgeCosts(G1, -100..50, Dom::Real):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: [1, 2] = -67.72964183, [2, 3] = -10.16896282, [3, 4] =  
2729 (other existing edges have costs zero)  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

Graph::createRandomEdgeCosts

Parameters

G

A graph

r

A range

Return Values

Graph

Purpose

Generates a random graph.

Syntax

```
Graph::createRandomGraph(VertexNr, EdgeNr,  
<Directed | Undirected>)
```

Description

Graph::createRandomGraph generates a random graph.

Graph::createRandomGraph(VertexNr, EdgeNr) generates a random graph with VertexNr vertices and EdgeNr edges.

Note If the number EdgeNr is too great (i.e.

$EdgeNr \geq \frac{VertexNr (VertexNr - 1)}{2}$), a complete graph will be created.

Graph::createRandomGraph(VertexNr, EdgeNr, Undirected) generates a random graph with VertexNr vertices and $2EdgeNr$ edges is created. This is due to the fact that no odd number of undirected edges could be created otherwise.

Examples

Example 1

The following graph was created randomly, meaning that your results will most probably differ:

```
G := Graph::createRandomGraph(5,6):  
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 4], [2, 1], [2, 4], [2, 5], [3, 1], [3, 4]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [4], 2 = [1, 4, 5], 3 = [1, 4], 4 = []  
Adjacency list (in): 1 = [2, 3], 2 = [], 3 = [], 4 = [1, 2, 3],
```

Graph::createRandomGraph

Graph is directed.

Example 2

The same number of vertices, but this time the edges are undirected (and therefore the number of Edges is $(2EdgeNr)$). As you can clearly see, the edges differ from the edges created above:

```
G := Graph::createRandomGraph(5, 6, Undirected):  
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 4], [1, 5], [2, 3], [2, 4], [2, 5], [3, 2], [4, 1], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 = [1, 2, 3, 4]  
Adjacency list (in): 1 = [4, 5], 2 = [3, 4, 5], 3 = [2], 4 = [1, 2, 5], 5 = [1, 2, 3, 4]  
Graph is undirected.
```

Example 3

If the number of edges to be created extends the possible limit

$(\frac{\text{vertices}(\text{vertices}-1)}{2})$, a complete graph will be returned:

```
G := Graph::createRandomGraph(3, 6, Undirected):  
Graph::printGraphInformation(G)
```

Warning: Cannot produce the required number of edges. Creating a complete graph.

```
Vertices: [1, 2, 3]
```

```
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]
Graph is undirected.
```

Parameters

VertexNr

Positive integer

EdgeNr

Positive integer

Options

Directed

If Directed is stated, a directed Graph is created Default

Undirected

If Undirected is stated, an undirected Graph is created.

Return Values

Graph

Graph::createRandomVertexWeights

Purpose	Sets random weights to vertices
Syntax	<code>Graph::createRandomVertexWeights(G, r, <Int Real>)</code>
Description	<code>Graph::createRandomVertexWeights(G, x..y)</code> creates random vertex weights of type Integer within the range x..y. <code>Graph::createRandomVertexWeights(G, x..y, Real)</code> creates random vertex weights of type Real within the range x..y.

Note Already existing vertex weights will be changed, too!

Examples

Example 1

Creating vertex weights for a small cyclic graph. First, it has no specified weights:

```
G1 := Graph::createCircleGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

Now the weights are set within the range -100..50 (your output may differ due random assignment):

Graph::createRandomVertexWeights

```
G2 := Graph::createRandomVertexWeights(G1, -100..50):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: 1 = 47, 2 = -12, 3 = 28, 4 = 1, 5 = -36 (other e  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

If the weights should be of type Real it can be set optionally:

```
G2 := Graph::createRandomVertexWeights(G1, -100..50, Real):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: 1 = -67.72964183, 2 = -10.16896282, 3 = -72.8468  
vertices have no weight)  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

Parameters

G

A graph

r

Graph::createRandomVertexWeights

A range

Options

Int

If stated, the weights are only of type integer. (Default)

Real

If stated, the weights are only of type real.

Return Values

Graph

Purpose

Makes a depth first Search in a graph.

Syntax

```
Graph::depthFirstSearch(G, <StartVertex = v>)
```

Description

Graph::depthFirstSearch traverses through a graph via depth first search. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Graph::depthFirstSearch(G, StartVertex=v) traverses through a graph via depth first search starting from vertex v. The output shows the first time of identification, the finishing time and the predecessor of each vertex. If a vertex is a single vertex with no predecessor its predecessor is *infinity*.

Examples

Example 1

A typical tree is created and drawn for a better understanding of the algorithm.

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed);
plot(
  Graph::plotGridGraph(G, VerticesPerLine = [12, 12, 12, 12],
    VertexOrder = [
      None, None, None, None, None, None, a, None, None, None, No
      None, None, b, None, None, None, None, None, None, c, No
      None, d, None, None, e, None, None, f, None, None, g,
      h, None, None, i, None, j, None, None, k, None, No
    ]
  )
)
```

Graph::depthFirstSearch

Now we call `Graph::depthFirstSearch` to find out the starting times, the finishing times and the predecessors of each vertex:

`Graph::depthFirstSearch(G)`

<i>a</i>	1	<i>a</i>	24	<i>a</i>	<i>a</i>
<i>b</i>	2	<i>b</i>	13	<i>b</i>	<i>a</i>
<i>c</i>	14	<i>c</i>	23	<i>c</i>	<i>a</i>
<i>d</i>	3	<i>d</i>	6	<i>d</i>	<i>b</i>
<i>e</i>	7	<i>e</i>	12	<i>e</i>	<i>b</i>
<i>f</i>	15	<i>f</i>	18	<i>f</i>	<i>c</i>
<i>g</i>	19	<i>g</i>	22	<i>g</i>	<i>c</i>
<i>h</i>	4	<i>h</i>	5	<i>h</i>	<i>d</i>
<i>i</i>	8	<i>i</i>	9	<i>i</i>	<i>e</i>
<i>j</i>	10	<i>j</i>	11	<i>j</i>	<i>e</i>
<i>k</i>	16	<i>k</i>	17	<i>k</i>	<i>f</i>
<i>l</i>	20	<i>l</i>	21	<i>l</i>	<i>g</i>

Vertex a is discovered first, then vertex b and so on. The table in the middle shows the finishing times. h for example has the finishing time of 5, meaning that vertices a, b, c, d and h itself were visited before it was recognized that h is a leaf (finishing time = starting time + 1). The right table shows the predecessor of every vertex. The backtracking from a single vertex is therefore really simple. a as the first vertex discovered in its component can not be backtracked any further.

Example 2

What happens now, if there exist a vertex that has no connection to any other vertex. The upper example is taken and a single vertex is added without changing anything else. Then a depth first search is invoked on the graph:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed);

G2 := Graph::addVertices(G, [m]);
Graph::depthFirstSearch(G2, StartVertex = [a])
```

a	1	a	24	a	a
b	2	b	13	b	a
c	14	c	23	c	a
d	3	d	6	d	b
e	7	e	12	e	b
f	15	f	18	f	c
g	19	g	22	g	c
h	4	h	5	h	d
i	8	i	9	i	e
j	10	j	11	j	e
k	16	k	17	k	f
l	20	l	21	l	g
m	25	m	26	m	∞

Graph::depthFirstSearch

The newly inserted vertex m has no predecessor. The predecessor holds therefore the value *infinity*.

Example 3

If we start somewhere in the graph without knowing the root of the DAG, the results are of course different:

```
G := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
           [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
            [d, h], [e, i], [e, j], [f, k], [g, l]],
           Directed):
```

```
Graph::depthFirstSearch(G, StartVertex = [c])
```

a	11	a	24	a	a
b	12	b	23	b	a
c	1	c	10	c	c
d	13	d	16	d	b
e	17	e	22	e	b
f	2	f	5	f	c
g	6	g	9	g	c
h	14	h	15	h	d
i	18	i	19	i	e
j	20	j	21	j	e
k	3	k	4	k	f
l	7	l	8	l	g

The predecessor of c is c , but if we look at the graph it should be a . This is nevertheless not quite correct. Breadth first search takes the given vertex and uses this as the root of the graph (no in-vertices!). This explains also why the next call shows a *infinity* as predecessor to l :

```
Graph::depthFirstSearch(G, StartVertex = [l])
```

a	3	a	24	a	a
b	4	b	15	b	a
c	16	c	23	c	a
d	5	d	8	d	b
e	9	e	14	e	b
f	17	f	20	f	c
g	21	g	22	g	c
h	6	h	7	h	d
i	10	i	11	i	e
j	12	j	13	j	e
k	18	k	19	k	f
l	1	l	2	l	∞

Parameters

G

Graph

v

List containing one vertex.

Options

StartVertex

Defines a vertex from which to start the depth first traversal.

Return Values

List containing three tables. The first table holds the first identification timestamp of each vertex, the second the finishing timestamp and the third the predecessor vertex.

Graph::getAdjacentEdgesEntering

Purpose Returns the incident edges.

Syntax Graph::getAdjacentEdgesEntering(G, Vertex)

Description Graph::getAdjacentEdgesEntering(G, Vertex) returns a list with vertices $v_1..v_n$, where $[v_1, \text{Vertex}] \dots [v_n, \text{Vertex}]$ are incident (incoming) Edges to Vertex.

Examples **Example 1**

First, a complete graph is defined:

```
G1 := Graph::createCompleteGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2,  
[4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,  
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,  
Graph is undirected.
```

Now we get the vertices that form all incident edges $[2, 1] \dots [5, 1]$:

```
Graph::getAdjacentEdgesEntering(G1, [1])  
  
[2, 3, 4, 5]
```

Graph::getAdjacentEdgesEntering

Now we get the vertices that form all incident edges [1, 5] .. [4, 5]:

```
Graph::getAdjacentEdgesEntering(G1, [5])
```

```
[1, 2, 3, 4]
```

Parameters

G

A graph

Vertex

One vertex of G.

Return Values

List

Graph::getAdjacentEdgesLeaving

Purpose Returns the adjacent edges.

Syntax Graph::getAdjacentEdgesLeaving(G, Vertex)

Description Graph::getAdjacentEdgesLeaving(G, Vertex) returns a list with vertices v1..vn, where [Vertex, v1] .. [Vertex, vn] are adjacent (outgoing) Edges to Vertex.

Examples **Example 1**

First, a complete graph is defined:

```
G1 := Graph::createCompleteGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2,  
[4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,  
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2,  
Graph is undirected.
```

Now we get the vertices that form all adjacent edges [1, 2] .. [1, 5]:

```
Graph::getAdjacentEdgesLeaving(G1, [1])  
  
[2, 3, 4, 5]
```

Graph::getAdjacentEdgesLeaving

Now we get the vertices that form all adjacent edges [2, 1] .. [2, 5]:

```
Graph::getAdjacentEdgesLeaving(G1, [2])
```

```
[1, 3, 4, 5]
```

Parameters

G

A graph

Vertex

One vertex of G.

Return Values

List

Graph::getBestAdjacentEdge

Purpose Returns the "best" incident edges.

Syntax `Graph::getBestAdjacentEdge(G, Vertex, Vertices, <Min | Max>, <Weights | Costs>)`

Description `Graph::getBestAdjacentEdge(G, Vertex)` returns the best incident edge according to specified attributes.

`Graph::getBestAdjacentEdge(G, Vertex, Vertices)` returns a vertex *v* out of *Vertices*. The best edge is (Vertex, *v*) according to the specifications.

Examples **Example 1**

Let us create a graph and find out the edge with the least weight:

```
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]],
            EdgeWeights = [10, 20, 30],
            EdgeCosts = [30, 20, 10]);
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1)),
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Min, Weights)
```

a, a

The result shows that edge [1, a] has the least weight. It also shows that `Min` and `Weights` are the defaults if omitted. Next, we want to know the edge with maximum weight:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Max)
```

4

The vertex with maximum weight is edge [1,4]. Now we have a look at the costs. The minimum cost edge can be found with:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Costs)
```

4

So the vertex with maximum weight is also the edge with minimum costs. Finally let us search for the edge with maximum costs:

```
Graph::getBestAdjacentEdge(G1, [1], Graph::getVertices(G1), Cost
```

a

Parameters

G

A graph

Vertex

One vertex of G.

Vertices

Vertices in G.

Options

Min

If stated, the edge with the minimum attribute will be found. (Default)

Max

If stated, the edge with the maximum attribute will be found.

Weights

If stated, edge weights will be used for comparison. (Default)

Costs

If stated, edge costs will be used for comparison.

Return Values

Vertex

Graph::getEdgeCosts

Purpose Returns a table with the edge costs.

Syntax `Graph::getEdgeCosts(G)`

Description `Graph::getEdgeCosts(G)` returns a table with the edge costs of the graph G. Thus `Graph::getEdgeCosts(G)` returns the costs of all edges in G.

Note Costs will most probably only be defined, if transportation problems occur.

Note If FAIL is returned, no costs were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge costs:

```
G1 := Graph::createCircleGraph(3):  
Graph::getEdgeCosts(G1)
```

FAIL

FAIL was returned, because no edge costs were defined.

```
Graph::getEdges(G1);  
G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):  
Graph::getEdgeCosts(G1)
```

[[1, 2], [2, 3], [3, 1]]

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge costs.

Parameters

G

A graph

Return Values

Table

Graph::getEdgeDescriptions

Purpose Returns a table with the edge descriptions.

Syntax Graph::getEdgeDescriptions(G)

Description Graph::getEdgeDescriptions(G) returns a table with the edge descriptions of the graph G. Thus Graph::getEdgeDescriptions(G) returns the weight of all edges in G.

Note Descriptions will most probably only be defined, if transportation problems occur.

Note If FAIL is returned, no descriptions were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge descriptions:

```
G1 := Graph::createCircleGraph(3):  
Graph::getEdgeDescriptions(G1)
```

FAIL

FAIL was returned, because no edge descriptions were defined.

```
Graph::getEdges(G1);  
G1 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],  
                                     ["Shortcut", "Highway 66"]):  
Graph::getEdgeDescriptions(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

```
[1, 2] | "Shortcut"  
[3, 1] | "Highway 66"
```

The first output shows all the edges and the second one the assigned edge descriptions.

Parameters

G

A graph

Return Values

Table

Graph::getEdges

Purpose Returns a list with all edges

Syntax `Graph::getEdges(G)`

Description `Graph::getEdges(G)` returns a list containing all edges of the graph G. Each edge is represented by a list containing the two connected vertices.

Examples **Example 1**

`Graph::getEdges` only returns the edges, without their capacities:

```
G1 := Graph::createCircleGraph([v1, v2, v3, v4]):  
Graph::getEdges(G1)
```

```
[[v1, v2], [v2, v3], [v3, v4], [v4, v1]]
```

```
G2 := Graph::createCompleteGraph(3):  
Graph::getEdges(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

Parameters **G**

A Graph

Return Values List of all edges, a list of lists

Purpose Returns the incoming edges

Syntax Graph::getEdgesEntering(G)

Description Graph::getEdgesEntering(G) returns a table with the adjacency lists for incident (incoming) edges. Thus Graph::getEdgesEntering(G) returns a table containing all those vertices w for which there is an edge [w, v] in G.

Examples **Example 1**

A small directed graph is created to show the incoming (incident) edges:

```
V := [1, 2, 3, 4, 5]:  
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:  
G1 := Graph(V, Ed, Directed):  
Graph::getEdgesEntering(G1)
```

```
1 | []  
2 | [1]  
3 | [1, 2]  
4 | [2, 3]  
5 | [3, 4]
```

In an undirected graph the output could look like this:

```
G1 := Graph::createCompleteGraph(5):  
Graph::getEdgesEntering(G1)
```

Graph::getEdgesEntering

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

Parameters

G

A graph

Return Values

Table

Purpose Returns the outgoing edges

Syntax `Graph::getEdgesLeaving(G)`

Description `Graph::getEdgesLeaving(G)` returns a table with the adjacency lists for adjacent (outgoing) edges. Thus `Graph::getEdgesLeaving(G)` returns a table containing all those vertices w for which there is an edge $[v, w]$ in G .

Examples **Example 1**

A small directed graph is created to show the outgoing (adjacent) edges:

```
V := [1, 2, 3, 4, 5]:  
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:  
G1 := Graph(V, Ed, Directed):  
Graph::getEdgesLeaving(G1)
```

```
1 | [2, 3]  
2 | [3, 4]  
3 | [4, 5]  
4 | [5]  
5 | []
```

In an undirected graph the output could look like this:

```
G1 := Graph::createCompleteGraph(5):  
Graph::getEdgesLeaving(G1)
```

Graph::getEdgesLeaving

1	[2, 3, 4, 5]
2	[1, 3, 4, 5]
3	[1, 2, 4, 5]
4	[1, 2, 3, 5]
5	[1, 2, 3, 4]

Parameters **G**

A graph

Return Values

Table

Purpose Returns the number of edges.

Syntax `Graph::getEdgeNumber(G)`

Description `Graph::getEdgeNumber(G)` returns a number representing the number of edges in G.

Examples **Example 1**

Let us create a graph and find out the number of edges:

```
G1 := Graph([1, a, 3, 4], [[1, a], [1, 3], [1, 4]]):  
Graph::getEdgeNumber(G1)
```

6

We know that a complete graph consists of $|Vertices|^2 - |Vertices|$ edges:

```
G2 := Graph::createCompleteGraph(4):  
Graph::getEdgeNumber(G2)
```

12

Parameters **G**
A graph

Return Values Number

Graph::getEdgeWeights

Purpose Returns a table with the edge weights.

Syntax Graph::getEdgeWeights(G)

Description Graph::getEdgeWeights(G) returns a table with the edge weights of the graph G. Thus Graph::getEdgeWeights(G) returns the weight of all edges in G.

Note Weights will most probably only be defined, if transportation problems occur.

Note If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without edge weights:

```
G1 := Graph::createCircleGraph(3):  
Graph::getEdgeWeights(G1)
```

FAIL

FAIL was returned, because no edge weights were defined.

```
Graph::getEdges(G1);  
G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):  
Graph::getEdgeWeights(G1)
```

[[1, 2], [2, 3], [3, 1]]

[1, 2]	5
[3, 1]	$\frac{1}{2}$

The first output shows all the edges and the second one the assigned edge weights.

Parameters

G

A graph

Return Values

Table

Graph::getSubGraph

Purpose Returns a subgraph.

Syntax Graph::getSubGraph(G, Vertex)

Description Graph::getSubGraph(G, Vertex) returns a subgraph according to the specified vertices.

Graph::getSubGraph(G) returns a graph that only holds the specified vertices and the belonging edges.

Examples

Example 1

First, a complete graph is defined with some additional settings:

```
G1 := Graph::createCompleteGraph(5):
G1 := Graph::setEdgeWeights(G1, [[1,2]], [20]):
G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]
Edges: [[1, 2], [1, 3], [1, 4], [1, 5], [2, 1], [2, 3], [2, 4], [2,
      [4, 3], [4, 5], [5, 1], [5, 2], [5, 3], [5, 4]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut"
Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have n
Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have cos
Adjacency list (out): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2
Adjacency list (in): 1 = [2, 3, 4, 5], 2 = [1, 3, 4, 5], 3 = [1, 2
Graph is undirected.
```

Now we get the subgraph for the vertices 1,2,4:

```
G2 := Graph::getSubGraph(G1, [1, 2, 4]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 4]
Edges: [[1, 2], [1, 4], [2, 1], [2, 4], [4, 1], [4, 2]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut", [2, 1] = "Shortcut"
Edge weights: [1, 2] = 20, [2, 1] = 20 (other existing edges have
Edge costs: [1, 2] = 20, [2, 1] = 20 (other existing edges have
Adjacency list (out): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2]
Adjacency list (in): 1 = [2, 4], 2 = [1, 4], 4 = [1, 2]
Graph is undirected.
```

The subgraph for the vertices 1,3,4 looks like:

```
G2 := Graph::getSubGraph(G1, [1, 3, 4]):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 3, 4]
Edges: [[1, 3], [1, 4], [3, 1], [3, 4], [4, 1], [4, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3]
Adjacency list (in): 1 = [3, 4], 3 = [1, 4], 4 = [1, 3]
Graph is undirected.
```

Parameters

G

A graph

Vertex

A list containing one or more vertices of G.

Graph::getSubGraph

Return Values

Graph

Purpose Returns the number of vertices.

Syntax `Graph::getVertexNumber(G)`

Description `Graph::getVertexNumber(G)` returns a number representing the number of vertices in G.

Examples **Example 1**

An example with 100 vertices:

```
G1 := Graph::createCompleteGraph(100):  
Graph::getVertexNumber(G1)
```

```
100
```

Parameters **G**
A graph

Return Values
Number

Graph::getVertexWeights

Purpose Returns a table with the vertex weights.

Syntax `Graph::getVertexWeights(G)`

Description `Graph::getVertexWeights(G)` returns a table with the vertex weights of the graph `G`. Thus `Graph::getVertexWeights(G)` returns the weight of all vertices in `G`.

Note If FAIL is returned, no weights were defined (this way both, network and graph algorithms handle this situation correct.)

Examples

Example 1

First lets define a graph without vertex weights:

```
G1 := Graph::createCircleGraph(3):  
Graph::getVertexWeights(G1)
```

FAIL

FAIL was returned, because no vertex weights were defined.

```
Graph::getVertices(G1);  
G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]):  
Graph::getVertexWeights(G1)
```

[1, 2, 3]

```
┌───┐  
1 | 5  
3 | 1/2
```

The first output shows all the vertices and the second one the assigned vertex weights.

Parameters**G**

A graph

Return Values

Table

Graph::getVertices

Purpose Returns a list with all vertices

Syntax Graph::getVertices(G)

Description Graph::getVertices(G) returns the list of all vertices of the Graph G.

Examples **Example 1**

A small creation of two different graphs and the output `getVertices` generates:

```
G1 := Graph::createCompleteGraph(10):  
Graph::getVertices(G1)
```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
```

```
G2 := Graph::createCircleGraph([x.i $ i = 1..12]):  
Graph::getVertices(G2)
```

```
[x1, x2, x3, x4, x5, x6, x7, x8, x9, x10, x11, x12]
```

Parameters **G**

A graph

Return Values List

Purpose Returns the indegree of one or more vertices.

Syntax `Graph::inDegree(G, <Vertex>)`

Description `Graph::inDegree(G, Vertex)` returns the indegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges `[u, Vertex]`.

`Graph::inDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1, v2, ..., vn` and the corresponding values are the indegrees.

`Graph::inDegree(G)` returns a table in which each node of `G` is mapped to its indegree. `Graph::inDegree(G)` is equivalent to `Graph::inDegree(G, Graph::getVertices(G))`.

Examples **Example 1**

In a complete graph of n vertices, each vertex has indegree $n - 1$:

```
G := Graph::createCompleteGraph(5):  
Graph::inDegree(G, [2, 4, 5]), Graph::inDegree(G),  
Graph::inDegree(G, Graph::getVertices(G))
```

```
  1 4  1 4  
2 4 2 4 2 4  
4 4 3 4 3 4  
5 4 4 4 4 4  
  5 4  5 4
```

The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

Example 2

Remember that also only one vertex needs to be specified as a list!

```
G := Graph::createCompleteGraph(5):  
Graph::inDegree(G, [2])
```

Graph::inDegree

2/4

Parameters

G

A Graph

Vertex

A list containing one or more vertices.

Return Values

Table containing all the indegrees of the specified vertices.

Purpose Finds out if the graph is connected

Syntax Graph::isConnected(G)

Description Graph::isConnected(G) returns TRUE if G is connected, FALSE otherwise.

Examples **Example 1**

A circle graph is made to create a connected Graph:

```
G1 := Graph::createCircleGraph(3):  
Graph::isConnected(G1)
```

TRUE

After adding a single vertex to the graph, it is not connected any more:

```
G2 := Graph::addVertices(G1, [4]):  
Graph::isConnected(G2)
```

FALSE

Parameters **G**

A graph

Return Values TRUE or FALSE

Graph::isDirected

Purpose	Finds out if the graph is directed
Syntax	Graph::isDirected(G)
Description	Graph::isDirected(G) returns TRUE if G is directed, FALSE otherwise.
Examples	<p>Example 1</p> <p>A circle graph is made to create a directed Graph:</p> <pre>G1 := Graph::createCircleGraph(3): Graph::isDirected(G1)</pre> <p>TRUE</p> <p>Example 2</p> <p>Now a complete graph is created in order to get an undirected graph:</p> <pre>G1 := Graph::createCompleteGraph(3): Graph::isDirected(G1)</pre> <p>FALSE</p>
Parameters	G A graph
Return Values	TRUE or FALSE

Purpose Finds out if the edges exists

Syntax Graph::isEdge(G, Edge)

Description Graph::isEdge(G) returns TRUE if ALL specified edges exist in G, FALSE otherwise.

Examples **Example 1**

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]  
Edges: [[1, 2], [2, 3], [3, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]  
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]  
Graph is directed.
```

First let us check for an existing single edge:

```
Graph::isEdge(G1, [[1, 2]] )
```

```
TRUE
```

Now we check if several edges exist:

```
Graph::isEdge(G1, [[1, 2], [2, 3]] )
```

Graph::isEdge

TRUE

What about a non existing edge?

```
Graph::isEdge(G1, [[3, 2]] )
```

FALSE

Finally a list of some existing and non existing edges is checked:

```
Graph::isEdge(G1, [[1, 2], [2, 3], [3, 2]])
```

FALSE

Parameters

G

A graph

Edge

A list containing one or more edges

Return Values

TRUE or FALSE

Purpose	Finds out if special vertices exist in the Graph
Syntax	Graph::isVertex(G, Vertex)
Description	Graph::isVertex(G) returns TRUE if ALL specified vertices exist in G, FALSE otherwise.

Examples **Example 1**

A circle graph is made to create a directed Graph:

```
G1 := Graph::createCircleGraph(3):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]  
Edges: [[1, 2], [2, 3], [3, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]  
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]  
Graph is directed.
```

First, let us check for an existing vertex:

```
Graph::isVertex(G1, [1])
```

```
TRUE
```

Now we check if several vertices exist:

```
Graph::isVertex(G1, [1, 2])
```

Graph::isVertex

TRUE

What about a non existing vertex?

```
Graph::isVertex(G1, [4])
```

FALSE

Finally a list of some existing and non existing vertices is checked:

```
Graph::isVertex(G1, [1, 2, 4])
```

FALSE

Parameters

G

A graph

Vertex

A list containing one or more vertices

Return Values

TRUE or FALSE

Purpose

Longest paths from one single node

Syntax

`Graph::longestPath(G, v, <w>, <Length>, <Path>)`

Description

`Graph::longestPath(G, v)` returns a table with the length of longest paths from `v` to all other nodes in the Graph with respect to the edge weight.

`Graph::longestPath(G, v, w)` returns the length of a longest path from `v` to `w`.

If the optional argument `Path` is given, a table with longest paths is returned. If both `Length` and `Path` are given, then both the length of the longest paths and the paths are returned. Paths are given as lists of nodes in reverse order.

If `Path` is not given, the option `Length` has no effect.

Note The Graph `G` must be directed and should not contain cycles.

Examples

Example 1

We construct a Graph and try a few calls to `Graph::longestPath`:

```
V := [1, 2, 3, 4, 5]:  
Ed := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:  
Ew := [7, 6, 5, 4, 2, 2, 1]:  
G := Graph(V, Ed, EdgeWeights = Ew, Directed):  
Graph::longestPath(G, 1)
```

```
1 | 0  
2 | 7  
3 | 12  
4 | 14  
5 | 15
```

Graph::longestPath

Graph::longestPath(G, 1, Path)

```
2 | [2, 1]
3 | [3, 2, 1]
4 | [4, 3, 2, 1]
5 | [5, 4, 3, 2, 1]
```

Parameters

G

A Graph

v, w

Vertices in G

Options

Length

Return a table with the lengths of shortest paths

Path

Return a table with the paths themselves

Return Values

Table, an integer or a list of nodes

Algorithms

The implemented algorithm is a variation of the algorithm of Bellman.

Purpose Computes a maximal flow through a graph

Syntax `Graph::maxFlow(G, s, t)`

Description `Graph::maxFlow(G, s, t)` computes a maximal flow from `s` to `t` in `G` with respect to the edge capacities. `s` and `t` must be nodes in `G`.

`Graph::maxFlow(G, s, t)` returns a sequence containing the flow value, that is the inflow of `s`, which equals the outflow of `s`, and the flow itself in form of table `tbl` with the flow from vertex `v` to vertex `w` is `tbl[[v,w]]`.

Examples **Example 1**

In the complete Graph with four vertices and default capacities of 1, the maximum flow from one vertex to another one consists of sending one unit through each of the remaining vertices and one directly, which makes three units altogether:

```
G1 := Graph::createCompleteGraph(4):  
Graph::maxFlow(G1, [1], [4])
```

```
[1, 2] 1  
[2, 1] 0  
[1, 3] 1  
[3, 1] 0  
[1, 4] 1  
3, [2, 3] 0  
[3, 2] 0  
[4, 1] 0  
[2, 4] 1  
[4, 2] 0  
[3, 4] 1  
[4, 3] 0
```

Graph::maxFlow

Example 2

As a more complex example, the following graph shows that this function also finds flows through multiple edges, unlike `Graph::admissibleFlow`, which only works on completely described flows:

```
V := [1, 2, 3, s, t]:  
Edge := [[s, 1], [t, 2], [1, 2], [1, 3], [2, 3], [3, t]]:  
up := [5, 5, 2, 6, 6, 1]:  
G2 := Graph(V, Edge, EdgeCosts = up, Directed):  
Graph::maxFlow(G2, [s], [t])
```

```
  [1, 2] 0  
  [1, 3] 1  
1, [2, 3] 0  
  [s, 1] 1  
  [t, 2] 0  
  [3, t] 1
```

Parameters

G

Graph

s, t

Expressions (vertices in G)

Return Values

List, containing a number and a table

Algorithms

The implemented algorithm is the preflow-push algorithm of Goldberg & Tarjan with the FIFO selection strategy and an exact distance labeling (“A new approach to the maximum-flow problem”, Journal of the ACM 35(4), 1988).

The running time is $O(n^3)$, where n is the number of vertices in the Graph.

Graph::minCost

Purpose Computes a minimal cost flow

Syntax `Graph::minCost(G)`

Description `Graph::minCost(G)` computes a minimal cost flow in `G` with respect to the edge capacities, the edge weights and the vertex weights of `G`.

The vertex weights are interpreted as supply and demand. The edge weights give restrictions for the flow on every edge. The edge costs are the cost for one unit flow over an edge.

The algorithm computes a flow, if there is any, which is possible and satisfactory, i.e., it is within the supply and demand range, which respects the capacities and which has minimal cost.

Examples

Example 1

We construct a `Graph` with five vertices and seven edges. One of the vertices is a pure source (1), another one is a pure sink (5). No other vertices supply or demand any goods, they only serve as transportation junctions:

```
V := [1, 2, 3, 4, 5]:
Vw := [25, 0, 0, 0, -25]:
edges := [[1, 2], [1, 3], [2, 3], [2, 4], [3, 4], [3, 5], [4, 5]]:
Ec := [7, 6, 5, 4, 2, 2, 1]:
Ew := [30, 20, 25, 10, 20, 25, 20]:
G1 := Graph(V, edges, EdgeCosts = Ec, EdgeWeights = Ew,
            VertexWeights = Vw, Directed):
Graph::minCost(G1)
```

[1, 2]	5	[1, 2]	35	
[1, 3]	20	[1, 3]	120	
[2, 3]	0	[2, 3]	0	
[2, 4]	5	[2, 4]	20	220,
[3, 4]	0	[3, 4]	0	1
[3, 5]	20	[3, 5]	40	2
[4, 5]	5	[4, 5]	5	3
				4
				5
				0

All 25 units could be transported from vertex 1 to vertex 5, for a total cost of 220. The cost for each edge can be found in the first table, the accumulated costs in the second and the last table holds the dual prices. For example 6 units flow over edge [1, 3] since $6 \cdot 20 = 120$ and 7 units flow over edge [1, 2] since $7 \cdot 5 = 35$.

Parameters

G

Graph

Return Values

Sequence, consisting of three tables and a number. The first table holds the amount flowing over the edge, the second the accumulated costs for each used edge and the number is the sum of all edge-costs for the flow. The last table holds the dual prices for each vertex.

Algorithms

The implemented algorithm is the relaxation algorithm due to Bertsekas (taken from Bertsekas, "Linear Network Optimization", MIT Press, Cambridge(Mass.)-London, 1991) which is known to be one of the fastest algorithms in practice.

Graph::minCut

Purpose Computes a minimal cut

Syntax Graph::minCut(G, q, s)

Description Graph::minCut(G, q, s) computes a minimal cut in G that separates q from s, i.e., a subset T of the set S of edges of G such that every path from q to s contains at least one edge in T. The cut is minimal with respect to the capacities of the edges.

Graph::minCut(G, q, s) returns a sequence consisting of the cut value (the sum of the edge weights of the cut edges) and a list with the edges of the cut.

Note that q is separated from s, not vice versa.

Examples

Example 1

In a complete graph, a vertex can be separated from another one only by cutting all edges starting at the first vertex:

```
G1 := Graph::createCompleteGraph(4):  
Graph::minCut(G1, [1], [4])
```

```
3, [[1, 2], [1, 3], [1, 4]]
```

Example 2

In the following example, the edge from vertex q to vertex 1 could have been used as well, but its edge capacity is higher than that of the edge used, so the minimality condition precludes this choice:

```
V := [1, 2, 3, q, s]:  
Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]:  
up := [5, 2, 6, 6, 1]:  
G2 := Graph(V, Edge, EdgeWeights = up, Directed):  
Graph::minCut(G2, [q], [s])
```

```
1, [[3, s]]
```

There is no path from vertex s to vertex q (or any other vertex of the Graph), so no cut is necessary to separate s from q :

```
Graph::minCut(G2, [s], [q])
```

```
0, []
```

Parameters

q, s

Vertices that have to be defined within G

G

Graph

Return Values

Sequence, consisting of the “cut value” and a list of edges cut

Graph::minimumSpanningTree

Purpose Creates a MST

Syntax `Graph::minimumSpanningTree(G, <SearchFor = Weights
| Costs>, <ReturnAsTable>)`

Description `Graph::minimumSpanningTree(G)` creates a minimum spanning tree according to the weights of the edges and returns a Graph consisting only of them. The same result would be achieved using `Graph::minimumSpanningTree(G, SearchFor = Weights)`

`Graph::minimumSpanningTree(G, SearchFor = Costs)` creates a minimum spanning tree according to the costs of the edges and returns a Graph consisting only of them.

`Graph::minimumSpanningTree(G, ReturnAsTable)` creates a minimum spanning tree according to the weights of the edges and returns a list with two objects. The first is a table consisting of the used edges and their weights. The second object is a number containing the sum of all the edge weights.(The same result can be achieved using: `Graph::minimumSpanningTree(G, SearchFor=Weights, ReturnAsTable)`.)

`Graph::minimumSpanningTree(G, SearchFor=Costs, ReturnAsTable)` creates a minimum spanning tree according to the costs of the edges and returns a list with two objects. The first is a table consisting of the used edges and their costs. The second object is a number containing the sum of all the edge costs.

Examples

Example 1

The following graph will be used throughout all the following examples. MuPAD does not allow placement of any text at a specified coordinate. Thus the output of this description was not created with MuPAD. (Have a look at the edge $[c, f]$. This edge is responsible for the different outputs whether Costs or Weights was chosen.)

```
G := Graph([a, b, c, d, e, f, g, h, i],  
          [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d, e],
```

Graph::minimumSpanningTree

```
[f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c,
EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6
EdgeCosts     = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6
```

We will plot this graph and all graphs derived from it using `Graph::plotGridGraph` with the following options:

```
plotOptions :=
  VerticesPerLine=7,
  VertexOrder = [
    None, b,    None, c,    None, d,    None,
    a,    None, i,    None, None, None, e,
    None, h,    None, g,    None, f,    None]:

plot(Graph::plotGridGraph(G, plotOptions))
```

Graph::minimumSpanningTree

Now we use this Graph to create a minimum spanning tree according to the weights of the edges and have a look which edges were used:

```
Graph::minimumSpanningTree(G, SearchFor = Weights, ReturnAsTable),  
Graph::minimumSpanningTree(G, ReturnAsTable)
```

σ_1, σ_1

where

$$\sigma_1 = \left[\begin{array}{l} [a, b] 4 \\ [b, a] 4 \\ [b, c] 8 \\ [c, b] 8 \\ [c, d] 7 \\ [d, c] 7 \\ [c, f] 4 \\ [d, e] 9, 37 \\ [e, d] 9 \\ [f, c] 4 \\ [c, i] 2 \\ [i, c] 2 \\ [f, g] 2 \\ [g, f] 2 \\ [g, h] 1 \\ [h, g] 1 \end{array} \right]$$

Both calls return exactly the same tables. That was expected and just to show that it is of no importance if the additional SearchFor=Weights is omitted.

Graph::minimumSpanningTree

Now we want to get the minimum spanning tree returned as a Graph so we can have a look how it looks like

```
weightMST := Graph::minimumSpanningTree(G):  
plot(Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Red))
```

There are two ways of displaying both graphs at the same time:

```
plot(  
  Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black),  
  Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Red)  
)
```

Graph::minimumSpanningTree

```
edgesWeightMST := Graph::getEdges(weightMST):  
plot(Graph::plotGridGraph(G, plotOptions,  
    EdgeColor = RGB::Black,  
    SpecialEdges = edgesWeightMST,  
    SpecialEdgeColor = RGB::Green))
```

Example 2

Maybe instead of the weights there is an interest in getting the MST for the costs of the edges.

```
G := Graph([a, b, c, d, e, f, g, h, i],
           [[a, b], [a, h], [b, h], [b, c], [c, d], [d, f], [d,
            [f, e], [h, g], [g, f], [c, i], [h, i], [g, i], [c,
            EdgeWeights = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6
            EdgeCosts    = [4, 8, 11, 8, 7, 14, 9, 10, 1, 2, 2, 7, 6
```

```
Graph::minimumSpanningTree(G, SearchFor = Costs, ReturnAsTable)
```

Graph::minimumSpanningTree

[a, b]	4
[b, a]	4
[b, c]	8
[c, b]	8
[c, d]	7
[d, c]	7
[d, e]	9
[e, d]	9, 39
[c, i]	2
[i, c]	2
[f, g]	2
[g, f]	2
[g, h]	1
[h, g]	1
[g, i]	6
[i, g]	6

Plotting this spanning tree is just as easy as above:

```
costMST := Graph::minimumSpanningTree(G, SearchFor = Costs):  
plot(Graph::plotGridGraph(costMST, plotOptions, EdgeColor = RGB::B1
```

Graph::minimumSpanningTree

To combine both spanning trees, we use different line widths, to avoid one graph being completely covered by the other:

```
plot(  
  plot::Group2d(  
    Graph::plotGridGraph(costMST, plotOptions, EdgeColor = RGB::Red,  
      LineWidth = 2.5  
  ),  
  plot::Group2d(  
    Graph::plotGridGraph(G, plotOptions, EdgeColor = RGB::Black)  
    Graph::plotGridGraph(weightMST, plotOptions, EdgeColor = RGB::Red,  
      PointSize = 5,  
      LineWidth = 1  
  )  
)
```

Graph::minimumSpanningTree

Parameters

G

Graph

Options

SearchFor

Can either be Costs or Weights. Default is Weights

ReturnAsTable

If omitted, a Graph is returned, otherwise a list containing a table and the sum of the edge weights/costs.

Return Values

Graph consisting of the MST. Only if `ReturnAsTable` was specified, a list containing a table and a number are returned. The table holds the edges with either the weights or costs of each edge and the number is the sum of all edges.

Purpose

Creates new graph

Syntax

```
Graph(V, E, <VertexWeights = vw>, <EdgeDescriptions
= ed>, <EdgeWeights = ew>, <EdgeCosts = ec>,
<Directed | Undirected>)
```

Description

Graph(V, E) creates a graph.

Graph([v1, ..., vn], [e1, ..., em]) generates a new undirected graph with n vertices and m edges.

Graph([1,a,3], [[1,a],[1,3]], Directed) generates a new directed graph with the vertices 1, a, 3 and the edges [1,a], [1,3].

Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], EdgeWeights = [4,5]) generates a new directed graph where the vertices have the values a=1, b=2, 3=3 and the edges [a,b]=4, [b,3]=5.

Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,None,3], EdgeWeights = [4, None]) generates a new directed graph where the vertices have the values a=1, 3=3 and the edges [a,b]=4. The difference to the example directly above is that the keyword None can be used to not assign a value to a vertex or edge.

Examples**Example 1**

An (undirected) graph with four vertices:

```
G1 := Graph([1,a,3], [[1,a],[1,3]]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 3, a]
Edges: [[1, 3], [1, a], [3, 1], [a, 1]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, a], a = [1], 3 = [1]
```

Graph

```
Adjacency list (in): 1 = [3, a], a = [1], 3 = [1]
Graph is undirected.
```

Example 2

The same graph but this time with parameter Directed:

```
G1 := Graph([1,a,3], [[1,a],[1,3]], Directed):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 3, a]
Edges: [[1, 3], [1, a]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: no edge weights.
Edge costs: no edge costs.
Adjacency list (out): 1 = [3, a], a = [], 3 = []
Adjacency list (in): 1 = [], a = [1], 3 = [1]
Graph is directed.
```

Example 3

The circle graph with predefined vertices:

```
G3 := Graph([a,b,3], [[a,b],[b,3]], VertexWeights = [1,2,3], EdgeWeights = [4,5,4,5]):
Graph::printGraphInformation(G3)
```

```
Vertices: [3, a, b]
Edges: [[3, b], [a, b], [b, 3], [b, a]]
Vertex weights: a = 1, b = 2, 3 = 3 (other existing vertices have no weights)
Edge descriptions: no edge descriptions.
Edge weights: [a, b] = 4, [b, 3] = 5, [b, a] = 4, [3, b] = 5 (other edges have no weights)
Edge costs: no edge costs.
Adjacency list (out): a = [b], b = [3, a], 3 = [b]
Adjacency list (in): a = [b], b = [3, a], 3 = [b]
```

Graph is undirected.

Example 4

The circle graph with predefined vertices:

```
G3 := Graph([a,b,3,7], [[a,b],[b,3],[3,7]],  
VertexWeights = [1,2,3,4], EdgeWeights = [-1,-2,-5],  
EdgeDescriptions = ["Small", None, "Smallest"]):  
Graph::printGraphInformation(G3)
```

```
Vertices: [3, 7, a, b]  
Edges: [[3, 7], [3, b], [7, 3], [a, b], [b, 3], [b, a]]  
Vertex weights: a = 1, b = 2, 3 = 3, 7 = 4 (other existing verti  
Edge descriptions: [a, b] = "Small", [3, 7] = "Smallest", [b, a]  
Edge weights: [a, b] = -1, [b, 3] = -2, [3, 7] = -5, [b, a] = -1  
o weight)  
Edge costs: no edge costs.  
Adjacency list (out): a = [b], b = [3, a], 3 = [7, b], 7 = [3]  
Adjacency list (in): a = [b], b = [3, a], 3 = [7, b], 7 = [3]  
Graph is undirected.
```

If you look at the edge descriptions, the keyword `None` can be used for every edge which is not supposed to have a description.

Parameters

V

List of vertices

E

List of edges

vw, ew, ec

List of numbers

ed

Graph

List of strings

Options

Directed

The Graph is created as a directed graph.

Undirected

The Graph is created as an undirected graph. Default.

Purpose Returns the outdegree of one or more vertices.

Syntax `Graph::outDegree(G, <Vertex>)`

Description `Graph::outDegree(G)` returns the number of edges leaving each vertex `Vertex` of the Graph `G`.

`Graph::outDegree(G, Vertex)` returns the outdegree of the vertex `Vertex` in the Graph `G`, i.e., the number of edges [`Vertex`, `u`].

`Graph::outDegree(G, [v1, v2, ..., vn])` returns a table in which the keys are `v1`, `v2`, ..., `vn` and the corresponding values are the outdegrees.

`Graph::outDegree(G)` returns a table in which each node of `G` is mapped to its outdegree. `Graph::outDegree(G)` is equivalent to `Graph::outDegree(G, Graph::getVertices(G))`.

Examples

Example 1

In a complete graph of n vertices, each vertex has outdegree $n - 1$:

```
G := Graph::createCompleteGraph(5):
Graph::outDegree(G, [2, 4, 5]), Graph::outDegree(G),
Graph::outDegree(G, Graph::getVertices(G))
```

```

  1 4 1 4
2 4 2 4 2 4
4 4 3 4 3 4
5 4 4 4 4 4
   5 4 5 4
```

The first table shows what happens, if some vertices are specified. The second and third table return all indegrees, but with two different calls (the second is redundant).

Example 2

Remember that also only one vertex needs to be specified as a list !

Graph::outDegree

```
G := Graph::createCompleteGraph(5) :
```

```
Graph::outDegree(G, [2])
```

```
2|4
```

Parameters

G

A Graph

Options

Vertex

A list containing one or more vertices.

Return Values

Table containing all the outdegrees of the specified vertices.

Purpose

Plots a Graph in a bipartite layout

Syntax

```
Graph::plotBipartiteGraph(G, <PointSize = n>,
<SpecialVertices = [v1, ..., vn]>, <SpecialEdges =
[e1, ..., en]>, <EdgeColor = RGB>, <SpecialEdgeColor =
RGB>, <SpecialVertexColor = RGB>, <Vertex1Color =
RGB>, <Vertex2Color = RGB>)
```

Description

Graph::plotBipartiteGraph(G) returns a plot::Group2d object in which the vertices are ordered in two rows (from bottom to top). The first vertex in the left row is drawn in blue and the second (the first vertex in the right row) in green. All other vertices are drawn in red. The width of the points is predefined with 40.

Examples**Example 1**

A random graph is created and plotted (your output may differ due to random creation):

```
G1 := Graph::createRandomGraph(110, 10, Undirected):
plot(Graph::plotBipartiteGraph(G1)):
```

Graph::plotBipartiteGraph

Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5, 6],  
           [[1, 2], [2, 3], [3, 4], [4, 5], [1, 6]]):  
Graph::bipartite(G2, Lists)  
  
[[2, 4, 6], [1, 3, 5]]  
  
edges := [[6, 1], [1, 2]]:  
plot(Graph::plotBipartiteGraph(G2, SpecialEdges = edges,  
                               SpecialEdgeColor = RGB::Blue))
```

Parameters

G

Graph

n

a positive integer.

[v₁, ..., v_n]

a list of vertices.

[e₁, ..., e_n]

a list of edges.

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

SpecialVertices

Graph::plotBipartiteGraph

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

SpecialEdges

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

EdgeColor

Defines a color with which to draw the edges. Default is `RGB::Red`.

SpecialEdgeColor

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`.

VertexColor

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They can be given different colors via `Vertex1Color` and `Vertex2Color`. Default is `RGB::Red`.

SpecialVertexColor

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`.

Vertex1Color

Defines a color with which to draw the first vertex with (the starting vertex at the bottom of the first set). Default is `RGB::Blue`.

Vertex2Color

Defines a color with which to draw the second vertex with (the starting vertex at the bottom of the second set). Default is `RGB::Green`.

Return Values

`plot::Group2d`

Purpose

Plots a Graph in a circle layout

Syntax

```
Graph::plotCircleGraph(G, <PointSize = n>, <SpecialVertices = [v1, ..., vn]>, <SpecialEdges = [e1, ..., en]>, <EdgeColor = RGB>, <SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>, <Vertex1Color = RGB>, <Vertex2Color = RGB>)
```

Description

Graph::plotCircleGraph(G) returns a plot::Group2d object in which the vertices are ordered in a circle (rightmost position upwards). The first vertex is drawn in blue and the second in green. All other vertices are drawn in red. The edges are drawn in red. The width of the points is predefined with 40. If a vertex points to itself it will be drawn outside

Examples**Example 1**

A random graph is created and plotted (your output may differ due random creation):

```
G1 := Graph::createRandomGraph(20, 10, Undirected):  
plot(Graph::plotCircleGraph(G1))
```

Graph::plotCircleGraph

Next, a complete graph will be plotted.

```
G1 := Graph::createCompleteGraph(20):  
plot(Graph::plotCircleGraph(G1))
```

Example 2

If some edges are to be emphasized they can be drawn in a special color:

```
G2 := Graph([1, 2, 3, 4, 5],  
            [[1, 2], [2, 3], [3, 4], [4, 5],  
             [1, 3], [1, 4], [1, 5]]):  
edges := [[1, 3], [1, 4]]:  
plot(Graph::plotCircleGraph(G2,  
                             SpecialEdges = edges, SpecialEdgeColor = RGB::BL
```

Graph::plotCircleGraph

Parameters

G

Graph

n

a positive integer.

[v₁, ..., v_n]

a list of vertices.

[e₁, ..., e_n]

a list of edges.

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

SpecialVertices

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

SpecialEdges

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

EdgeColor

Defines a color with which to draw the edges. Default is `RGB::Red`

SpecialEdgeColor

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

VertexColor

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is `RGB::Red`

SpecialVertexColor

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

Vertex1Color

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). Default is `RGB::Blue`

Vertex2Color

Defines a color with which to draw the second vertex with. Default is `RGB::Green`

Return Values

`plot::Group2d`

Graph::plotGridGraph

Purpose Plots a Graph in a grid layout

Syntax `Graph::plotGridGraph(G, <PointSize = n>, <VerticesPerLine = n>, <VertexOrder = [n1, ..., nm]>, <SpecialVertices = [v1, ..., vn]>, <SpecialEdges = [e1, ..., en]>, <EdgeColor = RGB>, <SpecialEdgeColor = RGB>, <SpecialVertexColor = RGB>, <Vertex1Color = RGB>, <Vertex2Color = RGB>)`

Description `Graph::plotGridGraph(G)` returns a `plot::Scene` object in which the vertices are square ordered (topmost left to downmost right). The number of vertices per line is the floor of the squareroot of the number of the vertices. The first vertex is drawn in `RGB::Blue` and the second in `RGB::Green`. All other vertices are drawn in `RGB::Red`. The edges are drawn in `RGB::Red`. The width of the points is predefined with 40. If the last line contains only one vertex, it will be drawn centered in the middle of the line.

`Graph::plotGridGraph(G, VerticesPerLine=n)` returns a `plot::Scene` object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on their name. If the last row consists of only one vertex, this one will be centered.

`Graph::plotGridGraph(G, VerticesPerLine=[v1..vn])` returns a `plot::Scene` object like described above with one exception. In line 1 there are exactly `v1` vertices placed. In line 2 there are `v2` vertices and so on. The last line contains `vn` vertices. They appear in sorted order depending on their name. The sum of the numbers specified in `VerticesPerLine` must equal the number of vertices in the graph.

`Graph::plotGridGraph(G, VerticesPerLine=n, VertexOrder=[v1..vn])` returns a `plot::Scene` object like described above with one exception. In every line there are exactly `n` vertices. They appear in sorted order depending on the order that was specified in `VertexOrder`. `vi` can consist of any vertex defined as well as the substitute `None`. Nevertheless the number of vertices in `G` must not exceed the number of `VerticesPerLine`. If the last line holds only one vertex, it will be centered.

Examples

Example 1

First, a small graph is created and plotted with the default values:

```
G := Graph([a, b, c, d], [[a, b], [b, c], [c, d], [d, a]]):  
plot(Graph::plotGridGraph(G))
```

Now, we exchange the two vertices c and d. The order given above was [a, b, c, d]:

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c]))
```

Graph::plotGridGraph

If only one vertex is placed in the last line, it will be centered:

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c],  
                          VerticesPerLine = 3))
```

The same result can be gained by defining the Vertices per line specifically (in this case the number of vertices must be no less than the number of vertices in the graph):

```
plot(Graph::plotGridGraph(G, VertexOrder = [a, b, d, c],  
                          VerticesPerLine = [3, 1]))
```

Graph::plotGridGraph

Now we get to the point, why the plot routine got the name Grid. The substitute None can be used whenever a place should be skipped. Think of some drawing paper with caskets. The layout is exactly the same. In this case it would consist of 3 caskets in each row. None leaves it blank, while a vertex from the Graph is drawn. Because the first casket is empty, the first color is omitted, too. The vertex a which is placed in the second casket is drawn as predefined in Vertex2Color (RGB::Green):

```
plot(Graph::plotGridGraph(G,  
      VertexOrder = [None, a,  None,  
                    b,  None, c,  
                    None, d,  None],  
      VerticesPerLine = 3))
```

Example 2

With the knowledge obtained so far, it is possible to get deeper into the art of creating objects. One of the most usefull outputs is that of a tree. Thus a Graph is created to be used for the tree output:

```
TreeGraph := Graph([a, b, c, d, e, f, g, h, i, j, k, l],
  [[a, b], [a, c], [b, d], [b, e], [c, f], [c, g],
  [d, h], [e, i], [e, j], [f, k], [g, l]], Directed)
```

Next we define a special vertex order, because the vertices are not drawn the way they were defined:

```
vOrder :=
[None, None, None, None, None, None, a, None, None, None, Non
None, None, b, None, None, None, None, None, None, c, Non
None, d, None, None, e, None, None, f, None, None, g,
h, None, None, i, None, j, None, None, k, None, Non
```

Graph::plotGridGraph

Now it is time to have a look at how the tree looks:

```
plot(Graph::plotGridGraph(TreeGraph,  
    VerticesPerLine = 12, VertexOrder = vOrder))
```

Now we want to see the path from vertex a to Vertexb. For this example it will be given explicitly. For bigger graphs one of the `shortestPath` procedures is recommended:

```
specialPath := [[a, c], [c, f], [f, k]]:
```

Finally we draw the path inside the Graph and have a good overview about the path it takes:

```
plot(Graph::plotGridGraph(TreeGraph,  
    VerticesPerLine = 12, VertexOrder = vOrder,  
    SpecialEdges = specialPath, SpecialEdgeColor = RGB::Blue))
```

Example 3

To show what can be done with more detailed and complex examples a small outer face is being drawn (have a close look at the Vertices which are not drawn, because the color is set to RGB::White and thus equals the background-color). Additionally, the “eyes” have been colored differently, so the usage of `SpecialVertexColor` could be presented:

```
Smile := Graph([1,2,4,5,7,8,9,10,11,12,13,14,15,16,17,18,19,20,
                21,22,23,24,25,26,27,28,29,30,31,32,33,34,35,36],
               [[1,4],[2,5],[4,5],[7,4],[5,8],[7,10],[9,10],[10,14],[9
                [13,19],[19,20],[20,14],[14,15],[15,16],[16,17],[17,11
                [ 8,11],[11,12],[12,18],[18,22],[22,21],[21,17],[21,24
                [24,28],[28,32],[32,36],[36,35],[35,34],[34,33],[33,29
                [29,25],[25,23],[23,20],[26,30],[30,31],[31,27]]):
plot(
  Graph::plotGridGraph(Smile, VerticesPerLine = 10,
    VertexOrder = [
```

Graph::plotGridGraph

```
None, None, None, 1, None, None, 2, None, None, None,
None, None, None, None, 4, 5, None, None, None, None,
None, None, None, 7, None, None, 8, None, None, None,
None, 9, 10, None, None, None, None, 11, 12, None,
13, None, None, 14, 15, 16, 17, None, None, 18,
None, 19, 20, None, None, None, None, 21, 22, None,
None, None, 23, None, None, None, None, 24, None, None,
None, None, 25, 26, None, None, 27, 28, None, None,
None, None, 29, None, 30, 31, None, 32, None, None,
None, None, None, 33, 34, 35, 36, None, None, None],
SpecialEdges = [[13,9],[9,10],[10,14],[14,20],[20,19],[19,13],
[14,15],[15,16],[16,17],[17,21],[21,22],[22,18],[18,12],[12,
[11,17]],
SpecialVertices = [1,2,4,5,7,8,23,24,25,26,27,28,29,30,31,
32,33,34,35,36],
VertexColor = RGB::White,
SpecialVertexColor = RGB::Green, EdgeColor = RGB::Green,
SpecialEdgeColor = RGB::Black)
)
```

Example 4

The next example is a complete graph drawn with the vertices ordered in a square so that all vertices can be connected inside the square:

```
CG := Graph::createCompleteGraph(30):  
plot(Graph::plotGridGraph(CG,  
    VerticesPerLine = [8, 2, 2, 2, 2, 2, 2, 2, 8],  
    Vertex1Color = RGB::Red, Vertex2Color = RGB::Red))
```

Graph::plotGridGraph

Using the default values in every line vertices are drawn and the graph looks not as “dense” as the above one:

```
plot(Graph::plotGridGraph(CG, Vertex1Color = RGB::Red,  
                          Vertex2Color = RGB::Red))
```

Example 5

The last example shows a small kite inside a frame:

```
Shield := Graph([1, 2, 3, 4, 5, 6, 7, 8, 9],
  [[1, 2], [1, 8], [2, 9], [8, 9], [3, 5], [4, 5],
   [5, 6], [5, 7], [3, 6], [6, 7], [3, 4], [4, 7]]):
plot(Graph::plotGridGraph(Shield, Vertex1Color = RGB::White,
  Vertex2Color = RGB::White, VertexColor = RGB::White,
  VerticesPerLine = 7,
  VertexOrder = [
    1, None, None, None, None, None, 2,
    None, None, None, 3, None, None, None,
    None, None, None, None, None, None, None,
    None, None, None, None, None, None, None,
    None, None, None, None, None, None, None,
    None, 4, None, 5, None, 6, None,
    None, None, None, None, None, None, None,
```

Graph::plotGridGraph

```
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, None, None, None, None,
None, None, None, 7, None, None, None,
      8, None, None, None, None, None, 9],
SpecialVertices = [3, 4, 5, 6, 7],
SpecialVertexColor = RGB::Blue,
SpecialEdges = [[3, 5], [4, 5], [5, 6], [5, 7],
                [3, 6], [6, 7], [3, 4], [4, 7]],
SpecialEdgeColor = RGB::Blue))
```

Parameters

G

Graph

n

a positive integer.

[n₁, ..., n_m]

a list of positive integers.

[v₁, ..., v_n]

a list of vertices.

[e₁, ..., e_n]

a list of edges.

Options

PointSize

Defines the thickness in which the points are drawn. Default is 40.

VerticesPerLine

If specified as single number, this many vertices are placed in every row. If specified as list, the number of vertices per line are read out of the list. If the vertices are specified as list, the number of vertices must match either the number of vertices defined in the graph, or, if specified, the number defined in `VertexOrder`.

VertexOrder

Defines an order in which the vertices are to be placed. It starts in the upper left and ends in the lower right. The number of specified vertices must match the number of vertices defined in the graph or the sum of the vertices specified in `VerticesPerLine`.

SpecialVertices

Defines a set of vertices. This option makes only sense if used with the option `SpecialVertexColor`.

SpecialEdges

Graph::plotGridGraph

Defines a set of edges. This option makes only sense if used with the option `SpecialEdgeColor`.

EdgeColor

Defines a color with which to draw the edges. Default is `RGB::Red`

SpecialEdgeColor

Defines a color to be used to draw the set of edges specified. This option makes only sense if used with the option `SpecialEdges`

VertexColor

Defines a color with which to draw the vertices. If this option is specified, the first two vertices are set to this color, too. They must be specified via `Vertex1Color` and `Vertex2Color` to distinct them again. Default is `RGB::Red`

SpecialVertexColor

Defines a color to be used to draw the set of vertices specified. This option makes only sense if used with the option `SpecialVertices`

Vertex1Color

Defines a color with which to draw the uppermost left (first) vertex with (the starting vertex). If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is `RGB::Blue`

Vertex2Color

Defines a color with which to draw the second vertex with. If `VertexOrder` holds a `None` for this vertex, it will be skipped. Default is `RGB::Green`

Return Values

`Plot::Scene`.

Graph::printEdgeCostInformation

Purpose Prints the edge costs of a graph

Syntax `Graph::printEdgeCostInformation(G)`

Description `Graph::printEdgeCostInformation` prints the edge costs of a graph.
`Graph::printEdgeCostInformation(G)` prints the edge costs of the graph *G*

Examples **Example 1**

A circle graph is created and the edge costs of it printed to screen:

```
G := Graph::createCircleGraph(3):  
Graph::printEdgeCostInformation(G)
```

```
No edge costs defined.
```

```
G := Graph::setEdgeCosts(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30])  
Graph::printEdgeCostInformation(G)
```

```
Edge costs existing in the graph:
```

```
-----  
Edge [1, 2] has cost 10  
Edge [2, 3] has cost 20  
Edge [3, 1] has cost 30
```

Parameters **G**

Graph

Return Values Text containing information about the edge costs of a graph.

Graph::printEdgeDescInformation

Purpose Prints the edge descriptions of a graph

Syntax Graph::printEdgeDescInformation(G)

Description Graph::printEdgeDescInformation prints the edge descriptions of a graph.
Graph::printEdgeDescInformation(G) prints the edge descriptions of the graph *G*

Examples **Example 1**

A circle graph is created and the edge descriptions of it printed to screen:

```
G := Graph::createCircleGraph(3):  
Graph::printEdgeDescInformation(G)
```

```
No edge descriptions defined.
```

```
G := Graph::setEdgeDescriptions(G, [[1, 2], [2, 3], [3, 1]],  
                                  ["Shortcut", "Highway", "Speedup"]):  
Graph::printEdgeDescInformation(G)
```

```
Edge descriptions existing in the graph:
```

```
-----  
Edge [1, 2] = "Shortcut"  
Edge [2, 3] = "Highway"  
Edge [3, 1] = "Speedup"
```

Parameters **G**

Graph

Graph::printEdgeDescInformation

Return Values

Text containing information about the edge descriptions of a graph.

Graph::printEdgeInformation

Purpose Prints the edges of a graph

Syntax `Graph::printEdgeInformation(G)`

Description `Graph::printEdgeInformation` prints the edges of a graph.
`Graph::printEdgeInformation(G)` prints the edges used in the graph *G*.

Examples **Example 1**

A circle graph is created and the edges of it printed to screen:

```
G := Graph::createCircleGraph(3):  
Graph::printEdgeInformation(G)
```

```
Edges existing in the graph:
```

```
-----  
[1, 2], [2, 3], [3, 1]
```

Example 2

A complete graph is created and the edges of it printed to screen:

```
G := Graph::createCompleteGraph(3):  
Graph::printEdgeInformation(G)
```

```
Edges existing in the graph:
```

```
-----  
[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]
```

Parameters **G**

Graph

Return Values

Text containing information about the edges of a graph.

Graph::printEdgeWeightInformation

Purpose Prints the edge weights of a graph

Syntax `Graph::printEdgeWeightInformation(G)`

Description `Graph::printEdgeWeightInformation` prints the edge weights of a graph.

`Graph::printEdgeWeightInformation(G)` prints the edge weights of the graph G

Examples **Example 1**

A circle graph is created and the edge weights of it printed to screen:

```
G := Graph::createCircleGraph(3):  
Graph::printEdgeWeightInformation(G)
```

```
No edge weights defined.
```

```
G := Graph::setEdgeWeights(G, [[1, 2], [2, 3], [3, 1]], [10, 20, 30])  
Graph::printEdgeWeightInformation(G)
```

```
Edge weights existing in the graph:
```

```
-----  
Edge [1, 2] has weight 10  
Edge [2, 3] has weight 20  
Edge [3, 1] has weight 30
```

Parameters **G**

Graph

Graph::printEdgeWeightInformation

Return Values

Text containing information about the edge weights of a graph.

Graph::printGraphInformation

Purpose

Prints the edges of a graph

Syntax

```
Graph::printGraphInformation(G)
```

Description

Graph::printGraphInformation prints a summary of various information about a graph.

Graph::printGraphInformation(G) prints a summary of the graph *G*

Examples

Example 1

A circle graph is created and a summary of it printed to screen:

```
G := Graph::createCircleGraph(3):  
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]  
Edges: [[1, 2], [2, 3], [3, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]  
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]  
Graph is directed.
```

Example 2

A complete graph is created and a summary of it printed to screen:

```
G := Graph::createCompleteGraph(3):  
Graph::printGraphInformation(G)
```

```
Vertices: [1, 2, 3]  
Edges: [[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]  
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [1, 2]  
Graph is undirected.
```

Parameters

G

Graph

Return Values

Text containing information about the graph.

Graph::printVertexInformation

Purpose	Prints vertex information of a graph
Syntax	<code>Graph::printVertexInformation(G)</code>
Description	<code>Graph::printVertexInformation</code> prints the edges of a graph. <code>Graph::printVertexInformation(G)</code> prints the edges of the graph <i>G</i>

Examples

Example 1

A circle graph is created and information of the vertices printed to screen:

```
G := Graph::createCircleGraph(3):  
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
```

```
-----
```

```
Vertex 1 has weight None  
Vertex 2 has weight None  
Vertex 3 has weight None
```

Example 2

A complete graph is created and information of the vertices printed to screen:

```
G := Graph::createCompleteGraph(3):  
Graph::printVertexInformation(G)
```

```
Vertices existing in the graph:
```

```
-----
```

```
Vertex 1 has weight None  
Vertex 2 has weight None  
Vertex 3 has weight None
```

Graph::printVertexInformation

Parameters

G

Graph

Return Values

Text containing information about the vertices of a graph.

Graph::removeEdge

Purpose	Removes one or several edges from a graph
Syntax	Graph::removeEdge(G, e) Graph::removeEdge(G, l)
Description	<p>Graph::removeEdge(G, [e1, ..., en]) removes edges e1...en from graph G.</p> <p>Graph::removeEdge deletes one or several edges from a graph. An edge is represented by a list containing two vertices of the graph. A warning is printed if the specified edge is not contained in the graph.</p> <p>Graph::removeEdge(G, e) removes the edge e from the graph G.</p> <p>Graph::removeEdge(G, l) removes all edges in list l from graph G.</p>

Examples

Example 1

Removing an edge from a cyclic graph results in a (degenerated) tree:

```
G1 := Graph::createCircleGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G1))
```

```
G2 := Graph::removeEdge(G1, [[5, 1]]):  
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = []  
Adjacency list (in): 1 = [], 2 = [1], 3 = [2], 4 = [3], 5 = [4]  
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G2))
```

Graph::removeEdge

If more than one edge is to be removed they must also be specified in a list:

```
edges := [[2, 3], [4, 5]]:  
G3 := Graph::removeEdge(G1, edges):  
Graph::printGraphInformation(G3)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [3, 4], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [], 3 = [4], 4 = [], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [], 4 = [3], 5 = []  
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G3))
```

Parameters

I

A list of edges

e

An edge

G

A graph

Return Values

Graph

Graph::removeVertex

Purpose Removes one or several vertices from a graph

Syntax `Graph::removeVertex(G, v)`
`Graph::removeVertex(G, l)`

Description `Graph::removeVertex(G, v)` removes vertex `v` from graph `G`.
`Graph::removeVertex(G, [v1, ..., vn])` removes vertices `v1...vn` from graph `G`.

`Graph::removeVertex` deletes one or several vertices from a graph. A warning is printed if the specified vertex is not contained in the graph.

Note If a vertex is connected to other vertices with edges, they will be removed from the graph, too!

`Graph::removeVertex(G, v)` removes the vertex `v` from the graph `G`.

`Graph::removeVertex(G, l)` removes all vertices in list `l` from graph `G`.

Examples

Example 1

Removing a vertex from a cyclic graph removes also two edges:

```
G1 := Graph::createCircleGraph(5):  
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3, 4, 5]  
Edges: [[1, 2], [2, 3], [3, 4], [4, 5], [5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [2], 2 = [3], 3 = [4], 4 = [5], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [1], 3 = [2], 4 = [3], 5 = [4]
```

Graph is directed.

```
plot(Graph::plotCircleGraph(G1))
```

```
G2 := Graph::removeVertex(G1, [1]):  
Graph::printGraphInformation(G2)
```

```
Vertices: [2, 3, 4, 5]  
Edges: [[2, 3], [3, 4], [4, 5]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.  
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 2 = [3], 3 = [4], 4 = [5], 5 = []  
Adjacency list (in): 2 = [], 3 = [2], 4 = [3], 5 = [4]
```

Graph::removeVertex

Graph is directed.

```
plot(Graph::plotCircleGraph(G2))
```

If more than one vertex is to be removed they must also be specified in a list:

```
vertices := [2, 4]:  
G3 := Graph::removeVertex(G1, vertices):  
Graph::printGraphInformation(G3)
```

```
Vertices: [1, 3, 5]  
Edges: [[5, 1]]  
Vertex weights: no vertex weights.  
Edge descriptions: no edge descriptions.
```

```
Edge weights: no edge weights.  
Edge costs: no edge costs.  
Adjacency list (out): 1 = [], 2 = [], 3 = [], 5 = [1]  
Adjacency list (in): 1 = [5], 2 = [], 3 = [], 5 = []  
Graph is directed.
```

```
plot(Graph::plotCircleGraph(G3))
```

Parameters

I

A list of vertices

v

A vertex

G

Graph::removeVertex

A graph

**Return
Values**

Graph

Purpose Computes the residual graph

Syntax `Graph::residualGraph(G, f, <Extended>)`

Description `Graph::residualGraph(G, flow)` computes the residual of the graph `G` with respect to the flow `flow`, meaning the graph that remains when the flow `flow` is “subtracted” from `G`.

`Graph::residualGraph` computes the residual graph with respect to a given flow. A flow in a `Graph` is a table `tbl`, where `tbl[[i,j]]` gives the number of units flowing from vertex `i` to vertex `j`.

If the optional argument `Extended` is given, then also those edges with a zero residual capacity are considered, otherwise these edges are omitted.

Examples **Example 1**

In the following call, `G2` is the graph consisting of the remaining transport capacities after a given flow:

```
G1 := Graph::createCompleteGraph(3):
G2 := Graph::residualGraph(G1,
    table( [1, 2] = 1, [2, 1] = 1/2,
           [1, 3] = 0, [3, 1] = 0.5,
           [2, 3] = 1, [3, 2] = 0 ) ):
Graph::getEdgeWeights(G2)
```

[2, 1]	$\frac{1}{2}$
[1, 3]	1
[3, 1]	0.5
[3, 2]	1

The algorithm detects the lack of edge weights and edge costs and sets all edge weights and costs to default values of 1.

Graph::residualGraph

Example 2

The resulting graph depends on whether the option `Extended` is used:

```
V := [1, 2, 3, q, s]:
Edge := [[q, 1], [1, 2], [1, 3], [2, 3], [3, s]]:
up := [5, 4, 4, 2, 5]:
G := Graph(V,Edge,EdgeWeights = up, Directed):
flow := table([q, 1] = 5, [3, s] = 5, [1, 2] = 1,
              [1, 3] = 4, [2, 3] = 1):
G1 := Graph::residualGraph(G, flow):
Graph::printGraphInformation(G1);
```

```
Vertices: [1, 2, 3, q, s]
Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [2, 3]]
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [1, 2] = 3, [2, 3] = 1, [2, 1] = 1, [3, 1] = 4, [3, 2]
have no weight)
Edge costs: [1, 2] = 1, [2, 3] = 1, [2, 1] = -3, [3, 1] = 0, [3, 2]
have costs zero)
Adjacency list (out): 1 = [2, q], 2 = [1, 3], 3 = [1, 2], q = [], s
Adjacency list (in): 1 = [2, 3], 2 = [1, 3], 3 = [2, s], q = [1], s
Graph is directed.
```

Edge Weights contain the residual graph with all the flows. Edge Costs show the flow that was subtracted or added. For example edge [1, 2] had weight 4. After a flow of 3 was sent over it, the residual edge [2, 1] contains the flow of -3 and the residual edge [1, 2] contains the flow of 1. Since the negative flow of the reverted edge plus the flow of the edge in the residual graph have to sum up to the flow it shows that the flow is calculated correctly. $(-3) + 1 = 4$

```
G1 := Graph::residualGraph(G, flow, Extended):
Graph::printGraphInformation(G1);
```

```
Vertices: [1, 2, 3, q, s]
Edges: [[2, 1], [3, 1], [3, 2], [s, 3], [1, q], [1, 2], [1, 3],
Vertex weights: no vertex weights.
Edge descriptions: no edge descriptions.
Edge weights: [q, 1] = 5, [1, 2] = 4, [1, 3] = 4, [2, 3] = 2, [3, 1]
= -5, [1, q] = -5 (other existing edges have no weight)
Edge costs: [1, 2] = 3, [1, 3] = 0, [2, 3] = 1, [3, s] = 0, [q,
[1, q] = 5 (other existing edges have costs zero)
Adjacency list (out): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], q = [1, q]
Adjacency list (in): 1 = [2, 3, q], 2 = [1, 3], 3 = [1, 2, s], s = [3, s]
Graph is directed.
```

Parameters

G

Graph

flow

The predefined flow

Options

Extended

Include edges with zero capacities

Return Values

Graph

Graph::revert

Purpose	Reverts the edges of a graph.
Syntax	Graph::revert(G)
Description	Graph::revert(G) returns a graph in which all edges $[u, v]$ and their properties belong to edges $[v, u]$. Graph::revert overloads the system function revert.

Examples

Example 1

First, a circle graph is defined with some additional settings:

```
G1 := Graph::createCircleGraph(3):
G1 := Graph::setEdgeWeights(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeCosts(G1, [[1, 2]], [20]):
G1 := Graph::setEdgeDescriptions(G1, [[1, 2]], ["Shortcut"]):
Graph::printGraphInformation(G1)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 2], [2, 3], [3, 1]]
Vertex weights: no vertex weights.
Edge descriptions: [1, 2] = "Shortcut"
Edge weights: [1, 2] = 20 (other existing edges have no weight)
Edge costs: [1, 2] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [2], 2 = [3], 3 = [1]
Adjacency list (in): 1 = [3], 2 = [1], 3 = [2]
Graph is directed.
```

Now we revert the graph:

```
G2 := revert(G1):
Graph::printGraphInformation(G2)
```

```
Vertices: [1, 2, 3]
Edges: [[1, 3], [2, 1], [3, 2]]
Vertex weights: no vertex weights.
Edge descriptions: [2, 1] = "Shortcut"
Edge weights: [2, 1] = 20 (other existing edges have no weight)
Edge costs: [2, 1] = 20 (other existing edges have costs zero)
Adjacency list (out): 1 = [3], 2 = [1], 3 = [2]
Adjacency list (in): 1 = [2], 2 = [3], 3 = [1]
Graph is directed.
```

Parameters

G

A graph

Return Values

Graph

Graph::setEdgeCosts

Purpose Assigns edge costs to edges.

Syntax `Graph::setEdgeCosts(G, Edge, EdgeCosts, <OnlySpecifiedEdges>)`

Description `Graph::setEdgeCosts(G, Edges, EdgeCosts)` returns a graph where Edges have the edge costs EdgeCosts.

Note If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeCosts(G, [[u,v]], [1])` is invoked, only the edge $[u, v]$ gets 1. The edge $[v, u]$ will not be changed.

Note The substitute `None` can be used when a specified edge should not get the assigned costs.

Examples

Example 1

First lets define a graph without edge costs:

```
G1 := Graph::createCircleGraph(3):  
Graph::getEdgeCosts(G1)
```

FAIL

FAIL was returned, because no edge costs werde defined.

```
Graph::getEdges(G1);  
G1 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):  
Graph::getEdgeCosts(G1)
```

[[1, 2], [2, 3], [3, 1]]

```
[1, 2] | 5
[3, 1] | 1/2
```

The first output shows all the edges and the second one the assigned edge costs.

```
G1 := Graph::setEdgeCosts(G1, [[2, 3]], [infinity]):
Graph::getEdgeCosts(G1)
```

```
[1, 2] | 5
[3, 1] | 1/2
[2, 3] | ∞
```

It is easy to see that only the edge cost of [2,3] was changed.

Example 2

First lets define a graph without edge costs:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeCosts(G1)
```

FAIL

FAIL was returned, because no edge costs were defined.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeCosts(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

Graph::setEdgeCosts

```
[1, 2] | 5
[2, 1] | 5
[1, 3] | 1/2
[3, 1] | 1/2
```

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge costs. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeCosts(G1, [[1, 2], [3, 1]], [5, 1/2],
                          OnlySpecifiedEdges):
```

```
Graph::getEdgeCosts(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
[1, 2] | 5
[3, 1] | 1/2
```

It is easy to see that only the specified edge costs were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the costs via a table instead of a list.

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl):
```

```
Graph::getEdgeCosts(G2)
```

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges:

```
tbl := table([1, 2] = 15, [1, 3] = 20):  
G2 := Graph::createCompleteGraph(3):  
  
G2 := Graph::setEdgeCosts(G2, [[1, 2], [3, 1]], tbl,  
                           OnlySpecifiedEdges):  
Graph::getEdgeCosts(G2)
```

[1, 2]	15
[3, 1]	20

Parameters

G

A graph

Edge

A list of one or more edges

EdgeCosts

A list of one or more numbers, or a table consisting of the edges with their costs.

Options

OnlySpecifiedEdges

Only the edges specified in Edge will be set.

Graph::setEdgeCosts

Return Values

New graph with the corrected edge costs.

Purpose Assigns edge Descriptions to edges.

Syntax `Graph::setEdgeDescriptions(G, Edge, EdgeDescriptions, <OnlySpecifiedEdges>)`

Description `Graph::setEdgeDescriptions(G, Edges, EdgeDescriptions)` returns a graph where Edges have the edge descriptions EdgeDescriptions.

Note If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call `Graph::setEdgeDescriptions(G, [[u,v]], [1])` is invoked, only the edge `[u, v]` gets 1. The edge `[v, u]` will not be changed.

Note The substitute `None` can be used when a specified edge should not get the assigned description.

Examples

Example 1

First lets define a graph without edge descriptions:

```
G1 := Graph::createCircleGraph(3):  
Graph::getEdgeDescriptions(G1)
```

FAIL

FAIL was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1);  
G1 := Graph::setEdgeDescriptions(G1, [[1, 2],[3, 1]],  
                                ["Route 66", "Speedway"]):
```

Graph::setEdgeDescriptions

```
Graph::getEdgeDescriptions(G1)
```

```
[[1, 2], [2, 3], [3, 1]]
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"

The first output shows all the edges and the second one the assigned edge descriptions.

```
G1 := Graph::setEdgeDescriptions(G1, [[2, 3]], ["Shortcut"]):  
Graph::getEdgeDescriptions(G1)
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"
[2, 3]	"Shortcut"

It is easy to see that only the edge description of [2,3] was changed.

Example 2

First lets define a graph without edge Descriptions:

```
G1 := Graph::createCompleteGraph(3):  
Graph::getEdgeDescriptions(G1)
```

FAIL

FAIL was returned, because no edge descriptions werde defined.

```
Graph::getEdges(G1);  
G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],  
                                ["Route 66", "Speedway"]):  
Graph::getEdgeDescriptions(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]	"Route 66"
[2, 1]	"Route 66"
[1, 3]	"Speedway"
[3, 1]	"Speedway"

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge Descriptions. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);  
G2 := Graph::setEdgeDescriptions(G1, [[1, 2], [3, 1]],  
                                  ["Route 66", "Speedway"],  
                                  OnlySpecifiedEdges):  
Graph::getEdgeDescriptions(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

[1, 2]	"Route 66"
[3, 1]	"Speedway"

It is easy to see that only the specified edge Descriptions were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the Descriptions via a table instead of a list.

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere");  
G2 := Graph::createCompleteGraph(3):  
Graph::getEdgeDescriptions(G2):
```

Graph::setEdgeDescriptions

```
G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl):  
Graph::getEdgeDescriptions(G2)
```

[1, 2]	"Highway"
[2, 1]	"Highway"
[1, 3]	"Road to nowhere"
[3, 1]	"Road to nowhere"

And again, but this time only the specified edges:

```
tbl := table([1, 2] = "Highway", [1, 3] = "Road to nowhere"):  
G2 := Graph::createCompleteGraph(3):  
Graph::getEdgeDescriptions(G2):  
G2 := Graph::setEdgeDescriptions(G2, [[1, 2], [3, 1]], tbl,  
    OnlySpecifiedEdges):  
Graph::getEdgeDescriptions(G2)
```

[1, 2]	"Highway"
[3, 1]	"Road to nowhere"

Parameters

G

A graph

Edge

A list of one or more edges

EdgeDescriptions

A list of one or more numbers, or a table consisting of the edges with their descriptions.

Options

OnlySpecifiedEdges

Only the edges specified in Edge will be set.

**Return
Values**

New graph with the corrected edge Descriptions.

Graph::setEdgeWeights

Purpose Assigns edge weights to edges.

Syntax Graph::setEdgeWeights(G, Edge, EdgeWeights, <OnlySpecifiedEdges>)

Description Graph::setEdgeWeights(G, Edges, EdgeWeights) returns a graph where Edges have the edge weights EdgeWeights.

Note If *OnlySpecifiedEdges* is stated and an undirected graph is to be changed, only the edges specified are used and not the inverted ones. For example if a call Graph::setEdgeWeights(G, [[u,v]], [1]) is invoked, only the edge [u, v] gets 1. The edge [v, u] will not be changed.

Note The substitute None can be used when a specified edge should not get the assigned weights.

Examples

Example 1

How to set edge weights with a list:

```
G1 := Graph::createCircleGraph(3):  
Graph::getEdgeWeights(G1)
```

FAIL

FAIL was returned, because no edge weights were defined.

```
Graph::getEdges(G1);  
G1 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):  
Graph::getEdgeWeights(G1)
```

[[1, 2], [2, 3], [3, 1]]

```
[1, 2] | 5
[3, 1] | 1/2
```

The first output shows all the edges and the second one the assigned edge weights.

```
G1 := Graph::setEdgeWeights(G1, [[2, 3]], [infinity]):
Graph::getEdgeWeights(G1)
```

```
[1, 2] | 5
[3, 1] | 1/2
[2, 3] | ∞
```

It is easy to see that only the edge weight of [2, 3] was changed.

Example 2

How to set edge weights with a table:

```
G1 := Graph::createCompleteGraph(3):
Graph::getEdgeWeights(G1)
```

FAIL

FAIL was returned, because no edge weights were defined.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2]):
Graph::getEdgeWeights(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

Graph::setEdgeWeights

```
[1, 2] | 5
[2, 1] | 5
[1, 3] | 1/2
[3, 1] | 1/2
```

The first output shows all the edges (the graph is undirected !) and the second one the assigned edge weights. Not only the specified edges were set, but also the reverted edges.

```
Graph::getEdges(G1);
G2 := Graph::setEdgeWeights(G1, [[1, 2], [3, 1]], [5, 1/2],
                             OnlySpecifiedEdges):
```

```
Graph::getEdgeWeights(G2)
```

```
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]
```

```
[1, 2] | 5
[3, 1] | 1/2
```

It is easy to see that only the specified edge Weights were changed and not the reverted edges, too.

Example 3

There exist also the possibility to set the weights via a table instead of a list.

```
tbl := table([1, 2] = 15, [1, 3] = 20):
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl):
```

```
Graph::getEdgeWeights(G2)
```

[1, 2]	15
[2, 1]	15
[1, 3]	20
[3, 1]	20

And again, but this time only the specified edges:

```
tbl := table([1, 2] = 15, [1, 3] = 20):
```

```
G2 := Graph::createCompleteGraph(3):
```

```
G2 := Graph::setEdgeWeights(G2, [[1, 2], [3, 1]], tbl,  
                             OnlySpecifiedEdges):
```

```
Graph::getEdgeWeights(G2)
```

[1, 2]	15
[3, 1]	20

Parameters

G

A graph

Edge

A list of one or more edges

EdgeWeights

A list of one or more numbers, or a table consisting of the edges with their weights.

Options

OnlySpecifiedEdges

Only the edges specified in Edge will be set.

Graph::setEdgeWeights

Return Values

New graph with the corrected edge weights.

Purpose

Assigns vertex weights to vertices.

Syntax

```
Graph::setVertexWeights(G, Vertex, VertexWeights)
```

Description

`Graph::setVertexWeights(G, Vertex, VertexWeights)` returns a graph where the vertices in `Vertex` have the vertex weights `VertexWeights`.

Note The substitute `None` can be used when a specified edge should not get the assigned weights.

Examples

Example 1

How to set vertex weights with a list:

```
G1 := Graph::createCircleGraph(3):  
Graph::getVertexWeights(G1)
```

FAIL

FAIL was returned, because no vertex weights were defined.

```
Graph::getVertices(G1);  
G1 := Graph::setVertexWeights(G1, [1, 3], [5, 1/2]):  
Graph::getVertexWeights(G1)
```

[1, 2, 3]

```
1 | 5  
3 | 1/2
```

Graph::setVertexWeights

The first output shows all vertices and the second the assigned vertex weights.

Example 2

How to set vertex weights with a table:

```
G1 := Graph::createCompleteGraph(3):  
Graph::getVertexWeights(G1)
```

FAIL

FAIL was returned, because no vertex weights were defined.

```
G2 := Graph::createCompleteGraph(3):  
tbl := table(1 = 15, 3 = 20):  
G2 := Graph::setVertexWeights(G2, [1, 3], tbl):  
Graph::getVertexWeights(G2)
```

```
1 | 15  
3 | 20
```

Parameters

G

A graph

Vertex

A list of one or more vertices

VertexWeights

A list of one or more numbers, or a table consisting of the vertices with their weights.

Return Values

New graph with the corrected vertex weights.

Purpose

Shortest paths from and to all vertices

Syntax

```
Graph::shortestPathAllPairs(G, <SearchFor =  
Weights | Costs>)
```

Description

`Graph::shortestPathAllPairs(G)` returns a table with all paths between all vertices.

`Graph::shortestPathAllPairs(G, SearchFor=Costs)` returns a table with all paths according to the edge costs.

`Graph::shortestPathAllPairs(G, SearchFor=Weights)` returns a table with all paths according to the edge weights. (Default)

Examples

Example 1

A small graph to be used for the algorithms:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],  
           EdgeWeights = [2, 1, 3, 2],  
           EdgeCosts = [1, 3, 1, 2],  
           Directed):
```

Now the shortest path between all vertices is found according to the edge weights, because no specification was given and defaults are used.

```
Graph::shortestPathAllPairs(G)
```

Graph::shortestPathAllPairs

a, a	0		
a, b	2		
b, a	∞	a, b	a
a, c	1	b, a	∞
b, b	0	a, c	a
c, a	∞	c, a	∞
a, d	3	a, d	c
b, c	3	b, c	b
c, b	∞	c, b	∞
d, a	∞	d, a	∞
b, d	5	b, d	c
c, c	0	d, b	∞
d, b	∞	c, d	c
c, d	2	d, c	∞
d, c	∞		
d, d	0		

The interpretation of the table is as follows:

The first table holds each path: (FromVertex, ToVertex) = weight/cost. The second table is a bit more tricky. The left hand side again is the path itself. On the right hand side though, the vertex that was found before the final vertex was reached is stated. If for example the path from a to d is to be found with all vertices that are used within this path it is done in the following way: First take the path itself (a, d). The predecessor is c. Now have a look for the path (a, c). It's predecessor is a. Since the predecessor equals the first vertex in the path to be found, the search is over and the path a -> c -> d is found. To search the graph for costs the option SearchFor=Costs has to be added.

Graph::shortestPathAllPairs(G, SearchFor = Costs)

a, a	0		
a, b	1		
b, a	∞	a, b	a
a, c	2	b, a	∞
b, b	0	a, c	b
c, a	∞	c, a	∞
a, d	4	a, d	c
b, c	1	b, c	b
c, b	∞	c, b	∞
d, a	∞	d, a	∞
b, d	3	b, d	c
c, c	0	d, b	∞
d, b	∞	c, d	c
c, d	2	d, c	∞
d, c	∞		
d, d	0		

Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. You will see that this does not influence the correctness of the results the algorithm returns (like for example Dijkstra).

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],
           EdgeWeights = [2, 1, 3, 2],
           EdgeCosts = [1, 3, 1, 2],
           Directed):
```

```
G := Graph::setEdgeWeights(G, Graph::getEdges(G), [2, 1, -3, 2])
```

```
Graph::shortestPathAllPairs(G)
```

Graph::shortestPathAllPairs

a, a	0		
a, b	2		
b, a	∞	a, b	a
a, c	-1	b, a	∞
b, b	0	a, c	b
c, a	∞	c, a	∞
a, d	1	a, d	c
b, c	-3	b, c	b
c, b	∞	c, b	∞
d, a	∞	d, a	∞
b, d	-1	b, d	c
c, c	0	d, b	∞
d, b	∞	c, d	c
c, d	2	d, c	∞
d, c	∞		
d, d	0		

Parameters **G**

Graph

Options **SearchFor**

Defines whether the weights of the graph are considered or the costs. Default is Weights.

Return Values

List consisting of two tables. The first table holds the sum of the path weights or costs and the second the predecessors for every path (to find the complete path).

Algorithms

The algorithm is also known as Floyd-Warshall or Roy-Warshall algorithm. The idea behind it is to solve the problem by continuous

matrix multiplication. The only difference is that Floyd uses the assignment $a_{i,j} := \min(a_{i,j}, a_{i,k} + a_{k,j})$.

Graph::shortestPathSingleSource

Purpose Shortest paths from one single vertex

Syntax `Graph::shortestPathSingleSource(G, StartVertex, <EndVertex = v>, <SearchWith = Dijkstra | Bellman>, <SearchFor = Weights | Costs>, <ReturnAsGraph>)`

Description `Graph::shortestPathSingleSource(G, StartVertex=vertex)` gives the length of a shortest path from `StartVertex` to every other vertex in `G`.

`Graph::shortestPathSingleSource(G, StartVertex=sv)` returns a table with all paths from `sv` to any other.

`Graph::shortestPathSingleSource(G, StartVertex=sv, ReturnAsGraph)` returns a table with all paths from `sv` to any other because `EndVertex` has to be set in order to get a `Graph` as return value.

With `Graph::shortestPathSingleSource(G, StartVertex=sv, EndVertex=ev, SearchWith=Dijkstra, SearchFor=Costs)` returns a table from vertex `sv` to vertex `ev` according to Dijkstra which used the edge-costs for its algorithm.

Note Using Dijkstra for shortest path can be erroneous if the graph contains negative edges.

Note If `ReturnAsGraph` is stated and `EndVertex` omitted, a table is returned nevertheless.

Examples

Example 1

A small graph to be used for the algorithms:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],  
           EdgeWeights = [2, 1, 3, 2],
```

```
EdgeCosts = [1, 3, 1, 2], Directed):
```

Now the shortest path is found according to Bellman using edge weights, because no specification was given and defaults are used:

```
Graph::shortestPathSingleSource(G, StartVertex = [a])
```

a	0	b	a
b	2	c	a
c	1	d	c
d	3		

To search the graph with Bellman for costs the option SearchFor=Costs has to be added:

```
Graph::shortestPathSingleSource(G, StartVertex = [a],  
                                SearchFor=Costs)
```

a	0	b	a
b	1	c	b
c	2	d	c
d	4		

Example 2

Now the weights of the graph are changed, so that negative edge weights are assigned. After this the procedure is called again with Bellman and afterwards with Dijkstra to compare the results:

```
G := Graph([a, b, c, d], [[a, b], [a, c], [b, c], [c, d]],  
           EdgeWeights = [2, 1, 3, 2],  
           EdgeCosts = [1, 3, 1, 2], Directed):
```

```
G := Graph::setEdgeWeights(G, Graph::getEdges(G),  
                           [2, 1, -3, 2]):
```

```
Graph::shortestPathSingleSource(G, StartVertex = [a],
```

Graph::shortestPathSingleSource

```
SearchWith = Bellman),  
Graph::shortestPathSingleSource(G, StartVertex = [a],  
SearchWith = Dijkstra)
```

$$\left[\begin{array}{c|c|c|c} a & 0 & b & a \\ b & 2 & c & b \\ c & -1 & d & c \\ d & 1 & & \end{array} \right], \left[\begin{array}{c|c|c|c} a & 0 & b & a \\ b & 2 & c & a \\ c & -1 & d & c \\ d & 3 & & \end{array} \right]$$

This is a typical example where Dijkstra can make a mistake because he does not correct earlier solutions (a so called greedy strategy). Although vertex c gets the correct value -1, at the time d got the value 3, vertex c still held the value 1. This happens because Dijkstra first searches the best solutions (a->c = 1) then traverses further (c->d = 1 + 2 = 3). In spite of changing the value of vertex c the value for d is never to be changed again (because no other path ever reaches it again):

It might be interesting to see a shortest path inside the graph. Here are two steps that accomplish this task:

First step (creation of a shortest path graph [in this case with Dijkstra]):

```
dijk := Graph::shortestPathSingleSource(G, StartVertex = [a],  
EndVertex = [d],  
SearchWith = Dijkstra,  
ReturnAsGraph):
```

Second step (combination of the graphs using plotGridGraph):

```
plot(Graph::plotGridGraph(G, VerticesPerLine = 4,  
VertexOrder = [None, b, None, d, a, None, c, None],  
VertexColor = RGB::Red,  
SpecialEdges = Graph::getEdges(dijk),  
SpecialEdgeColor = RGB::Blue))
```

Graph::shortestPathSingleSource

The same with Bellman to show the differences:

First step (creation of a shortest path graph [in this case with Dijkstra]):

```
bellm := Graph::shortestPathSingleSource(G, StartVertex = [a],  
                                         EndVertex = [d],  
                                         SearchWith = Bellman,  
                                         ReturnAsGraph):
```

Second step (combination of the graphs using plotGridGraph):

```
plot(Graph::plotGridGraph(G, VerticesPerLine = 4,  
                          VertexOrder = [None, b, None, d, a, None, c, None],  
                          VertexColor = RGB::Red,  
                          SpecialEdges = Graph::getEdges(bellm),  
                          SpecialEdgeColor = RGB::Blue))
```

Graph::shortestPathSingleSource

Parameters

G

Graph

vertex

A vertex in G

Options

EndVertex

Specifies a single vertex to which the shortest path is to be found.

SearchWith

Defines the algorithm to use. Dijkstra can be erroneous if the graph consists of negative edges. Default is Bellman

SearchFor

Defines whether the weights of the graph are considered or the costs. Default is `Weights`.

ReturnAsGraph

If `stated` and `EndVertex` is set, the path is returned as a `Graph`. If `stated` and `EndVertex` is not set, this option is omitted.

Return Values

Either a list consisting of two tables or a `Graph`. The first table holds the weights or cost for each vertex and the second the predecessors for every vertex (to find the path)

Algorithms

Both, Bellman and Dijkstra expect a `Graph` without negative circles. Only Dijkstra may return erroneous results when negative edges (either weights or costs) are specified.

The Bellman algorithm originated from: Ahuja, Magnanti, Orlin: `Graph Flows`, Prentice-Hall, 1993 Section 5.4

Graph::stronglyConnectedComponents

Purpose Finds the strongly connected components

Syntax Graph::stronglyConnectedComponents(G)

Description Graph::stronglyConnectedComponents(G) finds the strongly connected components of G

Graph::stronglyConnectedComponents returns all the strongly connected components of a graph. Single vertices form a component of themselves.

Examples **Example 1**

Two obvious components pointing to a single vertex:

```
G1 := Graph([a, b, c, d, e, f, g],
            [[a, b], [b, g], [g, a], [b, c],
             [d, c], [e, d], [d, f], [f, e]], Directed):

plot(Graph::plotGridGraph(G1,
    VertexOrder = [a, None, None, None, e,
                  None, b, c, d, None,
                  g, None, None, None, f],
    VerticesPerLine=5))
```

Graph::stronglyConnectedComponents

The graphical output reveals the two "big" components [a, b, g] and [d, e, f]. The single vertex [c] forms a component of itself:

```
G2 := Graph::stronglyConnectedComponents(G1)
```

```
[Graph(...), Graph(...), Graph(...)]
```

A list containing three Graphs is returned. Now we find out which vertices belong to each component:

```
Graph::getVertices(op(G2, 1))
```

```
[d, e, f]
```

```
Graph::getVertices(op(G2, 2))
```

Graph::stronglyConnectedComponents

[a, b, g]

```
Graph::getVertices(op(G2, 3))
```

[c]

Example 2

A complete graph is returned as a single component:

```
G3 := Graph::createCompleteGraph(5):  
plot(Graph::plotCircleGraph(G3))
```

```
G4 := Graph::stronglyConnectedComponents(G3):  
plot(Graph::plotCircleGraph(op(G4)))
```

Graph::stronglyConnectedComponents

It was necessary to use `op(G4)`, because `G4` is a list containing a graph!

Parameters

G

A graph

Return Values

List of graphs containing the strongly connected components.

Graph::topSort

Purpose Topological sorting of the vertices

Syntax Graph::topSort(G)

Description Graph::topSort(G) computes a topological sorting of the graph G, i.e., a numbering T of the vertices, such that $T_i < T_j$ whenever there is an edge $[i, j]$ in the graph. Single vertices are positioned at the beginning.

Graph::topSort returns a list containing two tables. The first table holds the ordering of the vertices. The second table shows the predecessors of each vertex. If several vertex u_i precede a vertex v , the first vertex in the ordering of u_i is the predecessor of v . If no predecessor exist, the value will be *infinity*.

Note If G contains any cycle then a topological sorting does not exist and the call of Graph::topSort results in an error.

Examples

Example 1

A "butterfly" graph that is decomposed in three strongly connected components:

```
G1 := Graph([a, b, c, d, e, f],  
            [[a, b], [a, c], [a, d], [c, e], [d, e]],  
            Directed):  
Graph::topSort(G1)
```

1	f	a	a
2	a	b	a
3	b,	c	a
4	c	d	a
5	d	e	c
6	e	f	∞

The first table shows the ordering of the vertices. The left side holds the order for each vertex, whereas the right side holds the name of the vertex. The second table shows the predecessors of each vertex. If no predecessor exist, the right side holds *infinity*. Otherwise the right side holds the vertex that is the direct predecessor of the vertex on the left side. To see how the graph looks a graphical plotting helps:

```
plot(Graph::plotGridGraph(G1,  
    VertexOrder = [None, b,  f,  
                  a,  c,  None,  
                  None, None, e,  
                  None, d,  None],  
    VerticesPerLine=3))
```

Parameters G

A graph

Graph::topSort

Return Values

List containing two tables.

groebner – Gröbner bases

groebner::dimension
groebner::eliminate
groebner::gbasis
groebner::normalf
groebner::spoly
groebner::stronglyIndependentSets

groebner::dimension

Purpose Dimension of the affine variety generated by polynomials

Syntax `groebner::dimension(polys, <order>)`

Description `groebner::dimension(polys)` computes the dimension of the affine variety generated by the polynomials in the set or list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

Examples **Example 1**

An example from the book of Cox, Little and O'Shea (see below):

```
groebner::dimension([y^2*z^3, x^5*z^4, x^2*y*z^2])
```

```
2
```

Parameters **polys**

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Return Values Nonnegative integer

Algorithms

First, the Gröbner basis of the given polynomials with respect to the given monomial ordering is computed using `groebner::gbasis`. This Gröbner basis is then used to compute the dimension of the affine variety generated by the polynomials.

References

The implemented algorithm is described in Cox, Little, O’Shea: “Ideals, Varieties and Algorithms”, Springer, 1992, Chapter 9.

MuPAD Functions

`groebner::gbasis` | `poly`

groebner::eliminate

Purpose Eliminate variables

Syntax `groebner::eliminate(sys, vars)`

Description `groebner::eliminate(sys, vars)` returns a list of polynomial expressions obtained by eliminating the elements of `vars` from `sys`. In other words, the return value does not contain the variables in `vars`, every zero of the original system `sys` must be a zero of the return value, and every tuple of numbers that makes the return value zero can be extended to a solution of `sys`.

Examples **Example 1**

Suppose that $x^2 + y = 0$ and $x + y = 0$, what does this imply for y ?

```
groebner::eliminate({x^2 + y, y+x}, {x})
```

```
[y^2 + y]
```

We infer that for every pair (x, y) solving the system, y must satisfy $y^2 + y = 0$, that is, $y = 0$ or $y = -1$. Indeed:

```
solve({x^2 + y, y+x}, {x, y})
```

```
{[x = 0, y = 0], [x = 1, y = -1]}
```

Parameters **sys**

A set or list of polynomial expressions. The coefficients in these polynomial expressions can be arbitrary arithmetical expressions.

vars

A set or list of identifiers

Return Values List of polynomial expressions

Algorithms

`groebner::eliminate` proceeds by computing a lexical-order Gröbner basis. Hence the computation complexity grows fast when increasing the number of variables.

See Also

MuPAD Functions

`groebner::gbasis`

groebner::gbasis

Purpose Computation of a reduced Gröbner basis

Syntax `groebner::gbasis(polys, <order>, options)`

Description `groebner::gbasis(polys)` computes a reduced Gröbner basis of the ideal generated by the polynomials in the list `polys`.

The rules laid down in the introduction to the `groebner` package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

The ordering strategy indicated by `Reorder` is used automatically when polynomial expressions are used.

Examples

Example 1

We demonstrate the effect of various input formats. First, we use polynomial expressions to define the polynomial ideal. The Gröbner basis is returned as a list of polynomial expressions:

```
groebner::gbasis([x^2 - y^2, x^2 + y], LexOrder)
```

```
[x^2 + y, x^4 - x^2]
```

Next, the same polynomials are defined via `poly`. Note that `poly` fixes the ordering of the variables.

```
groebner::gbasis([poly(x^2 - y^2, [x, y]),  
                 poly(x^2 + y, [x, y])], LexOrder)
```

```
[poly(x^2 + y, [x, y]), poly(y^2 + y, [x, y])]
```

Changing the ordering of the variables in `poly` changes the lexicographical ordering. This results in a different basis:

```
groebner::gbasis([poly(x^2 - y^2, [y, x]),
                 poly(x^2 + y, [y, x])], LexOrder)
```

```
[poly(y + x^2, [y, x]), poly(x^4 - x^2, [y, x])]
```

With Reorder the ordering of the variables may be changed internally:

```
groebner::gbasis([poly(x^2 - y^2, [x, y]),
                 poly(x^2 + y, [x, y])], LexOrder, Reorder)
```

```
[poly(y + x^2, [y, x]), poly(x^4 - x^2, [y, x])]
```

Example 2

Polynomials over arbitrary fields are allowed. In particular, you can use the field of rational functions in some given variable(s):

```
F := Dom::Fraction(Dom::DistributedPolynomial([y])):
F::Name := "Q(y)":
groebner::gbasis(
[poly(y*z^2 + 1, [x, z], F),
 poly((y^2 + 1)*x^2 - y - z^3, [x, z], F)])
```

```
[poly(x^2 + z/(y + y^3) - y/(y^2 + 1), [x, z], Q(y)),
 poly(z^2 + 1/y, [x, z], Q(y))]
```

```
delete F:
```

Parameters

polys

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions. If polys are polynomials over an arbitrary domain, then their coefficients must be domain elements and the domain must be a field.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Options

Factor

With this option, `groebner::gbasis` returns a set of lists, such that each list is the Gröbner basis of an ideal. The union of these ideals is a superset of the ideal given as input, and a subset of the radical of that ideal. In other words, it has the same variety (only the multiplicity of points can change).

IgnoreSpecialCases

With this option, `groebner::gbasis` handles all coefficients in all intermediate results as nonzero unless these coefficients are equal to zero for all parameter values. In other words, if the coefficients are rational functions of the free parameters, then results are correct on all of the parameter space except on an algebraic variety of lower dimension.

Reorder

With this option `groebner::gbasis` internally may change the lexicographical ordering of variables to decrease running time.

With this option the variables are sorted internally such that they have a “heuristic optimal” ordering. Consequently, the ordering of the variables in the output polynomials may differ from their ordering in the input polynomials. For details on the ordering strategy, see W. Boege, R. Gebauer und H. Kredel: “Some Examples for Solving Systems of Algebraic Equations by Calculating Groebner Bases” im *J. Symbolic Comp.* (1986) Vol. 1, 83-98.

Re-ordering is always applied when polynomial expressions are used for input.

Monic

Option, specified as `Monic = N`

This option sets the normalizing routine to `N`. For every polynomial `f` in the polynomial ring, `N(f, o)` must return some associate of `f`, where `o` is the chosen order.

The method `N` should be chosen such that it produces simple output.

By default, `polylib::primpart` is used for polynomials with integer coefficients; other polynomials are divided by their leading coefficient.

Order

Option, specified as `Order = order`

This option is equivalent to passing `order` as an argument.

Return Values

List of polynomials. The output polynomials have the same type as the polynomials of the input list.

Algorithms

In most cases, `groebner::gbasis` computes the basis via the Buchberger algorithm with the “sugar” selection strategy being used.

References

For general information, see T. Becker and V. Weispfenning: “Gröbner Bases”, Springer (1993). For details on the sugar selection strategy, see A. Giovini, T. Mora, G. Niesi, L. Robbiano, C. Traverso: “One sugar cube, please — or Selection strategies in the Buchberger algorithm”, Proc. ISSAC '91, Bonn, 49-54 (1991).

MuPAD Functions

`poly`

groebner::normalf

Purpose Complete reduction modulo a polynomial ideal

Syntax `groebner::normalf(p, polys, <order>)`

Description `groebner::normalf(p, polys)` computes a normal form of the polynomial `p` by complete reduction modulo all polynomials in the list `polys`.

The rules laid down in the introduction to the groebner package concerning the polynomial types and the ordering apply.

The polynomials in the list `polys` must all be of the same type as `p`. In particular, do not mix polynomials created via `poly` and polynomial expressions.

Examples **Example 1**

We consider the ideal generated by the following polynomials:

```
p1 := poly(x^2 - x + 2*y^2, [x,y]):  
p2 := poly(x + 2*y - 1, [x,y]):
```

We compute the normal form of the following polynomial `p` modulo the ideal generated by `p1`, `p2` with respect to lexicographical ordering:

```
p := poly(x^2*y - 2*x*y + 1, [x,y]):  
groebner::normalf(p, [p1, p2], LexOrder);
```

```
poly(-2 y^3 + 2 y^2 - y + 1, [x, y])
```

Note that `p1`, `p2` do not form a Gröbner basis. The corresponding Gröbner basis leads to a different normal form of `p`:

```
groebner::normalf(p, groebner::gbasis([p1, p2]), LexOrder)
```

$$\text{poly}\left(-\frac{5y}{9} + 1, [x, y]\right)$$

delete p1, p2, p:

Parameters

p

A polynomial or a polynomial expression. The coefficients in this polynomial and polynomial expression can be arbitrary arithmetical expressions.

polys

A list of polynomials of the same type as *p*. In particular, if *p* is a polynomial expression, *polys* must be a list of polynomial expressions.

order

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

Algorithms

A polynomial *g* is a reduced form of a polynomial *p* modulo a list of polynomials p_1, \dots, p_n , if $g \equiv p$ and none of the leading terms of the p_i divides the leading term of *p*, or if — for some *i* — *g* is a reduced form of $p - qp_i$, where *q* is the quotient of the leading monomial of *p* and the leading monomial of p_i . A reduced form always exists, but need not be unique. It is unique, if the p_i form a Gröbner basis.

In the implementation of `groebner::normalf`, reduction modulo some p_i of largest possible total degree is preferred, if reduction modulo several p_i is possible.

groebner::normalf

MuPAD Functions

`groebner::gbasis` | `poly`

Purpose The S-polynomial of two polynomials

Syntax `groebner::spoly(p1, p2, <order>)`

Description `groebner::spoly(p1, p2)` computes the S-polynomial of the polynomials p1 and p2.

The rules laid down in the introduction to groebner concerning the polynomial types and the ordering apply.

The polynomials must be of the same type. In particular, do not mix polynomials created via `poly` and polynomial expressions!

Examples **Example 1**

The polynomials

```
p1 := poly(x^2 - x + 2*y^2, [x, y]):
p2 := poly(x + 2*y - 1, [x, y]):
```

generate the following S-polynomial with respect to lexicographical ordering:

```
groebner::spoly(p1, p2, LexOrder)
```

```
poly(-2 x y + 2 y^2, [x, y])
```

```
delete p1, p2:
```

Parameters **p₁, p₂**

A list or set of polynomials or polynomial expressions of the same type. The coefficients in these polynomials and polynomial expressions can be arbitrary arithmetical expressions.

order

groebner::spoly

One of the identifiers `DegInvLexOrder`, `DegreeOrder`, and `LexOrder`, or a user-defined term ordering of type `Dom::MonomOrdering`. The default ordering is `DegInvLexOrder`.

Return Values

Polynomial of the same type as the input polynomials. If polynomial expressions are used as input, then a polynomial expression is returned.

Algorithms

The S-polynomial of two polynomials p_1, p_2 is defined to be

$$\frac{\text{lcm}(\text{lterm}(p_1), \text{lterm}(p_2))}{\text{lmonomial}(p_1)} p_1 - \frac{\text{lcm}(\text{lterm}(p_1), \text{lterm}(p_2))}{\text{lmonomial}(p_2)} p_2$$

where `lterm` and `lmonomial` are used in the same sense as the MuPAD functions of the same name. This formula is constructed such that the leading terms of the two summands cancel.

MuPAD Functions

`poly`

Purpose Strongly independent set of variables

Syntax `groebner::stronglyIndependentSets(G)`

Description `groebner::stronglyIndependentSets(G)` computes a strongly independent set of variables modulo the ideal generated by G .

A set of variables S is strongly independent modulo an ideal I if no leading term of an element of the Gröbner basis of I consists entirely of elements of S . A set is maximally strongly independent if no proper superset of it is strongly independent. Two maximally strongly independent set may be of different size.

`groebner::stronglyIndependentSets` accepts Gröbner bases in the format returned by `groebner::gbasis`.

Examples **Example 1**

The following example has been given by Moeller and Mora in 1983.

```
G:=map([X0^8*X2, X0*X3, X1^8*X3, X1^7*X3^2, X1^6*X3^3,
        X1^5*X3^4, X1^4*X3^5, X1^3*X3^6, X1^2*X3^7, X1*X3^8],
        poly, [X3, X2, X1, X0]):
groebner::stronglyIndependentSets(G)
```

```
[2, {X0, X1}, {{X2, X3}, {X0, X1}, {X1, X2}}]
```

```
delete G:
```

Parameters **G**

The Gröbner basis of an ideal: a list.

Return Values

List of the form $[d, S, M]$, where d is an integer equal to the dimension of the ideal generated by G , S is the greatest strongly independent set of variables, and M is a set consisting of all maximal strongly independent sets of variables or a piecewise consisting of such lists.

groebner::stronglyIndependentSets

MuPAD Functions

groebner::gbasis

import – Import Data

```
import::csv  
import::readbitmap  
import::readdata  
import::readlisp
```

import::csv

Purpose Read CSV data from an ASCII file

Syntax `import::csv(filename, <separator>, <NonNested>, <Trim>, <DecimalComma>)`
`import::csv(n, <separator>, <NonNested>, <Trim>, <DecimalComma>)`

Description `import::csv` is used to read CSV (“Comma Separated Values” or “Character Separated Values”) data files produced by external programs, like Microsoft Excel[®]. CSV is an ASCII based tabular data file format, formally defined in RfC 4180, that has fields separated by the comma character.

Note Some localized versions of Microsoft Excel use semicolons instead of commas! Set the parameter `separator` to change the default separator.

`import::csv(filename)` reads the data in the file `filename`. File data separated by a comma are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::csv(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

In contrast to `finput`, the data must not be ended by a colon or semicolon. Data separated by `separator` are interpreted as single data items. The default separator is a comma.

Empty lines are ignored.

All data elements in the file that cannot be converted to valid MuPAD numbers are imported as MuPAD strings.

`import::csv` tries to convert a number contained in the CSV file to a valid MuPAD number. For example: 1,234.56 or 1 234.56 are converted to the MuPAD number 1234.56. Many countries use a comma to separate the integral and fractional part instead of the dot used in England and the US. For example: 1234,56 or 1.234,56 are converted to 1234.56. `import::csv` expects this number format if the option `DecimalComma` is given.

Note A comma as CSV separator doesn't make sense if the comma is used to separate thousands in a number or the decimal comma is used. In most cases, the CSV file uses a semicolon to separate data. So, a semicolon should be used as separator.

Note All numbers contained in the CSV file must use the same radix separator, mixed formats cannot be converted.

With `NonNested`, the result will be a list containing all data. Otherwise, the result is a list of list, each "inner" list representing a line of the CSV file.

With `Trim`, leading and trailing blanks in strings are removed.

If the file is specified by a string, the corresponding file is opened and closed, automatically. If the user has opened a text file in `Read` mode and passes the file descriptor to `import::readdata`, the file remains open and needs to be closed by the user.

Files compressed with `gzip` or in a compatible format, whose names end in ".gz", are automatically decompressed while being read by `import::csv`.

`import::csv(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory”.
- Last, the file name is concatenated to the directory path.

If a file can be opened with one of these names, then the file is read.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

A path separator (“/”) is inserted as necessary when concatenating a given path and filename.

If a file is specified by a file name, there is no need to open or close the file via `fopen` and `fclose`, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Note that the file must have been opened in `Read` mode by `fopen`. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via `fclose`.

Examples

Example 1

We wish to read CSV data into a MuPAD session. Assume that the file “`datafile.csv`” contains the following two columns of ASCII data:

```
a ,12.5
a-b ,1234.56
```

`import::csv` returns the following list representing the data in the file:

```
data := import::csv("datafile.csv")
```

```
[[ "a ", 12.5 ], [ " a-b ", 1234.56 ]]
```

```
data := import::csv("datafile.csv", Trim)
```

```
[[ "a", 12.5 ], [ "a-b", 1234.56 ]]
```

```
data := import::csv("datafile.csv", NonNested)
```

```
[ "a ", 12.5, " a-b ", 1234.56 ]
```

Example 2

Let us assume that the file “datafile.csv” contains the following ASCII data:

```
a ;12.5  
a-b;1,234.56  
a b; -12345.6789E-02
```

We specify the data separator ";" for reading the data:

```
import::csv("datafile.csv", ";")
```

```
[[ "a ", 12.5 ], [ "a-b", 1234.56 ], [ "a b", -123.456789 ]]
```

Example 3

Let us assume that the file “datafile.csv” contains the following ASCII data:

import::csv

```
abc;12,5
a-b;1.234,56
a b; -12345.6789E-02
```

We specify the data separator ";" and the option `DecimalComma` for reading the data:

```
import::csv("datafile.csv", ";", DecimalComma)
```

```
[[ "a ", 12.5], [ "a-b", 1234.56], [ "a b", - 123.456789]]
```

Parameters

filename

The file name: a non-empty character string

n

A file descriptor provided by `fopen`: a positive integer

separator

The separator between data elements: a character string of length 1 (a single character). The default separator is a comma (the single character string ",").

Options

NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

Trim

Leading and trailing blanks in strings are removed.

DecimalComma

A decimal comma instead of a decimal point is used as the radix separator in the CSV file.

Return Values

Nested list of lists. The sublists contain the data of the individual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

MuPAD Functions

`FILEPATH` | `fopen` | `import::readdata` | `readbytes` | `READPATH`

import::readbitmap

Purpose Read bitmap data

Syntax `import::readbitmap(filename, <ReturnType = DOM_HFARRAY
| DOM_ARRAY | DOM_LIST>)`

Description `import::readbitmap` is used for reading ASCII or binary data files storing bitmap images of pictures. The following standard graphical formats can be read: BMP, DCX, DDS, WAD, GIF, ICO, JPG, LIF, MDL, PCD, PCX, PIC, PIX, PNG, PNM, PSD, PSP, PXR, RAW, SGI, TGA, TIF, WAL, XPM. The format of the pixel data is determined automatically from the contents of the file. The return value [w, h, colordata] provides the pixel height h, the pixel width w, and the color data of the bitmap image.

Either the complete return value or just the third element, `colordata`, can be passed to the function `plot::Raster` to generate a plot object that can be used in a MuPAD graphics. E.g., the command

```
plot(plot::Raster(import::readbitmap("mypicture.jpeg")))
```

creates a MuPAD graphics of the bitmap stored in the JPG file "mypicture.jpeg".

Note Most of the standard graphical formats store the pixel data row by row in the usual reading order starting with the upper left corner of the image. The pixel data in the returned array `colordata` (if requesting `ReturnType = DOM_ARRAY`), however, are to be interpreted as follows:

`colordata[1, 1]` is the RGB color of the lower left corner.

`colordata[h, 1]` is the RGB color of the upper left corner.

`colordata[1, w]` is the RGB color of the lower right corner.

`colordata[h, w]` is the RGB color of the upper right corner.

The interpretation of the other return types is analogous, see below for details on the return types.

This is consistent with the interpretation of a color array by `plot::Raster`.

`import::readbitmap(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory.”
- Last, the file name is concatenated to the directory path.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X

import::readbitmap

systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

A path separator (“/”) is inserted as necessary when concatenating a given path and filename.

`import::readbitmap` does not accept file handles returned by `fopen`. Nor can it handle files which have been compressed by `gzip`, but since most bitmap formats employ high quality compression in any case, there is little reason to try compressing them again in any case.

Examples

Example 1

We import a PGM (portable graymap) picture:

```
[w, h, Norton] := import::readbitmap("Norton.pgm");
```

The bitmap image is to be embedded in a MuPAD graphics. We use the width `w` and the height `h` to place the bitmap in a rectangle whose sides have the same ratio as the original bitmap. With `Scaling = Constrained` we make sure that this aspect ratio is also used in the final graphics:

```
xmin := 2: xmax := xmin + w/100:  
ymin := 0.5: ymax := ymin + h/100:  
plot(plot::Function2d(x*sin(PI/x), x = -1..4.5, AdaptiveMesh = 2),  
      plot::Raster(Norton, x = xmin ..xmax, y = ymin .. ymax),  
      Scaling = Constrained, Footer = "Work And Play");
```

Work And Play

Parameters

filename

The file name: a non-empty character string

Options

ReturnType

Option, specified as `ReturnType = DOM_HFARRAY | DOM_ARRAY | DOM_LIST`

Set the type of the actual color data returned as `colordata`.

If set to `DOM_LIST`, `colordata` is a nested list, the outermost list containing `h` lists, each of which represents one row of image data and contains `w` lists of three floating-point numbers, each of which represents an “RGB Colors” color.

If set to `DOM_ARRAY`, `colordata` is an array containing lists with color information, as in `array(2, 1..h, 1..w, [color1,`

import::readbitmap

`color2,]`). The interpretation is analogous to the nested lists described above.

If set to `DOM_HFARRAY`, which is the default setting, `colordata` is a `DOM_HFARRAY` of dimensions `hfarray(3, 1..h, 1..w, 1..3, [actual data])`. The interpretation of these floating-point values is as described above for the `DOM_LIST` case.

Return Values

`list[w, h, colordata]`. The integer `w` is the pixel width of the bitmap. The integer `h` is the pixel height of the bitmap. `colordata` provides the RGB colors of the bitmap. Its type depends on the setting of the option `ReturnTypes`.

MuPAD Functions

`import::readdata` | `readbytes` | `READPATH`

MuPAD Graphical Primitives

`plot::Raster`

Purpose Read data from an ASCII file

Syntax `import::readdata(filename | n, <separator>, <NonNested>)`

Description `import::readdata(filename)` reads the data in the file `filename`. File data separated by whitespace are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator)` reads the data in the file `filename`. File data separated by the character `separator` are regarded as different data elements. The result is a list of lists, each sublist representing one line of the file.

`import::readdata(filename, separator, NonNested)` reads the data in the file `filename` as a single data record. File data separated by the character `separator` are regarded as different data elements. The result is a plain non-nested list containing the data of all lines of the file.

`import::readdata(filename)` searches for the file in various directories:

- First, the name is interpreted as a relative file name: `filename` is concatenated to each directory given by the environment variable `READPATH`.
- Then the file name is interpreted as an absolute path name.
- Then the file name is interpreted relative to the “working directory.”
- Last, the file name is concatenated to the library directory.

If a file can be opened with one of this names, then the file is read.

Note that the meaning of “working directory” depends on the operating system. On Microsoft Windows systems and on Apple Mac OS X systems, the “working directory” is the folder where MuPAD is installed. On UNIX systems, it is the current working directory in which MuPAD was started; when started from a menu or desktop item, this is typically the user’s home directory.

import::readdata

A path separator (“/”) is inserted as necessary when concatenating a given path and filename.

If a file is specified by a file name, there is no need to open or close the file via `fopen` and `fclose`, respectively. This is done automatically by `import::readdata`.

Instead of a file name, also a file descriptor of a file opened via `fopen` can be used. Note that the file must have been opened in `Read` mode by `fopen`. If a file descriptor is used, the corresponding file is not closed automatically but must be closed by the user via `fclose`.

Files compressed by `gzip` or a compatible program (having a name ending in “.gz”) are decompressed automatically upon reading.

All data elements in the file are interpreted as MuPAD objects. If a data element cannot be interpreted as a MuPAD object, it is imported as a MuPAD string. Otherwise, the corresponding MuPAD object is inserted into the list returned by `import::readdata`.

Note Note that the MuPAD objects corresponding to the data elements are evaluated after reading. E.g., the data element “sin(0)” in the file is evaluated and imported as the MuPAD integer 0. Beware: the characters “;” and “:” have a specific meaning if not specified as separators in `import::readdata`: they separate MuPAD commands. Hence, if a read data element contains one of this characters, MuPAD interprets this data element as a sequence of statements and, upon evaluation, returns the value of the *last* statement as the MuPAD object corresponding to the data element. Cf. “Example 3” on page 12-17.

In contrast to `finput`, the data elements in the file do not have to be ended by a colon or a semicolon.

Empty lines in the file are ignored.

Examples

Example 1

We wish to read statistical data into a MuPAD session to test the correlation of two data samples. Assume that the file “datafile” contains the following two columns of ASCII data (each column representing a data sample):

```
0.12    0.2534
2.324   5.72
1.02    2.2232
4.02    7.321
7.4     14.9
-7.4    -15.1
```

`import::readdata` returns the following list representing the data in the file:

```
data := import::readdata("datafile")
```

```
[[0.12, 0.2534], [2.324, 5.72], [1.02, 2.2232], [4.02, 7.321], [7.4, 14.9], [-7.4, -15.1]]
```

The data structure `stats::sample` converts this nested list into two data columns:

```
s := stats::sample(data)
```

```
0.12    0.2534
2.324   5.72
1.02    2.2232
4.02    7.321
7.4     14.9
-7.4    -15.1
```

import::readdata

The following computation shows that there is a very strong correlation between the data in the first column and the data in the second column:

```
stats::correlation(s, 1, 2)
```

```
0.9982703003
```

If the data in the file are supposed to represent a single sample (data record), we may ignore the fact that the numbers are arranged on several lines. With `NonNested`, the data are read as a single sample:

```
data := import::readdata("datafile", NonNested)
```

```
[0.12, 0.2534, 2.324, 5.72, 1.02, 2.2232, 4.02, 7.321, 7.4, 14.9, -7.4, -15.1]
```

Mean and standard deviation of the data are:

```
stats::mean(data), stats::stdev(data)
```

```
1.900133333, 7.568789783
```

```
delete data, s:
```

Example 2

Let us assume that the file “datafile” contains the following ASCII data:

```
1 | 2 | 3
4 | 5 | 6.65786
7 | 8 | 9 | 5 | "ahfjd" | ab100|-23
```

We specify the data separator "|" for reading the data:

```
import::readdata("datafile", "|")  
  
[[1, 2, 3], [4, 5, 6.65786], [7, 8, 9, 5, "ahfjd", ab100, -23]]
```

Note that whitespace inside the data elements as well as the empty line in the file are ignored.

Example 3

We first create the ASCII data files that will be used in this example.

We recall that x degrees Celsius are $\frac{9x}{5} + 32$ degrees Fahrenheit. First, two data files are created containing the matching temperatures from -5 degrees Celsius to 30 degrees Celsius in steps of 5 degrees Celsius:

```
n1 := fopen(Text, "data1", Write):  
n2 := fopen(Text, "data2", Write):  
for celsius from -5 to 20 step 5 do  
  fahrenheit := 9/5*celsius + 32:  
  fprintf(Unquoted, n1, celsius, " ", fahrenheit):  
  fprintf(n2, celsius, fahrenheit):  
end_for:  
fclose(n1):  
fclose(n2):
```

The file “data1” now contains the following data:

```
-5 23  
0 32  
5 41  
10 50  
15 59  
20 68
```

The file “data2” contains the following data:

import::readdata

```
-5:23:  
0:32:  
5:41:  
10:50:  
15:59:  
20:68:
```

Now, we import the data:

```
import::readdata("data1")
```

```
[[ -5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]
```

Reading data from the file “data2” yields an unexpected result:

```
import::readdata("data2")
```

```
[[23], [32], [41], [50], [59], [68]]
```

What went wrong? Remember that the default data separator is whitespace. Consequently, MuPAD reads the expression `-5:23:` as the only data element in the first line. When MuPAD evaluates this data element, it interprets it as a sequence of two MuPAD statements. The result of the statement sequence is the result of the last of the two statements, i.e., the number 23. This is the first datum in the resulting list. For getting the data as desired, an appropriate separator must be specified. The file “data2” should be read as follows:

```
import::readdata("data2", ":")
```

```
[[ -5, 23], [0, 32], [5, 41], [10, 50], [15, 59], [20, 68]]
```

We use the option `NonNested` to get a plain list containing all data elements without putting each record (line) in a sublist of its own:

```
import::readdata("data2", ":", NonNested)
```

```
[-5, 23, 0, 32, 5, 41, 10, 50, 15, 59, 20, 68]
```

```
delete n1, n2:
```

Example 4

Here we can see that the data are evaluated after reading. First, we create the data file:

```
n1 := fopen(Text, "data3", Write) :  
fprint(Unquoted, n1, a, " 12 ", b):  
fclose(n1):
```

Now, the data are read:

```
import::readdata("data3")
```

```
[[a, 12, b]]
```

If `a` and `b` have values, we get:

```
a := 3: b := 34: import::readdata("data3")
```

```
[[3, 12, 34]]
```

```
delete n1, a, b:
```

Example 5

First, we create a data file with random floating-point data that are separated by blank characters:

import::readdata

```
n := fopen(Text, "data4", Write):
for i from 1 to 3 do
  fprintf(Unquoted, n, (frandom(), " ") $ j = 1..4);
end_for;
fclose(n):
```

This file is reopened for reading with fopen:

```
n := fopen(Text, "data4", Read)
```

```
64
```

The file descriptor `n` returned by `fopen` can be passed to `import::readdata`:

```
import::readdata(n)
```

```
[[0.2703567032, 0.8142678572, 0.1145977439, 0.247668289],
 [0.436855213, 0.7507294917, 0.5143284818, 0.47002619],
 [0.06956333824, 0.5063265159, 0.4145331467, 0.365909575]]
```

Note, however, that the file was opened explicitly by the user with `fopen` and is not closed automatically by `import::readdata`. Consequently, the user is supposed to close the file explicitly via `fclose`:

```
fclose(n):
delete i, n:
```

Parameters

filename

The file name: a non-empty character string

n

A file descriptor provided by `fopen`: a positive integer

separator

The separator between data elements: a character string of length 1 (a single character). The default separator is whitespace.

Options

NonNested

Return all file data as a single data record in a non-nested list. The data of all lines are ordered sequentially in this list.

Return Values

Nested list of lists. The sublists contain the data of the individual lines. With the option `NonNested`, a plain list containing all data elements from every line in the file.

MuPAD Functions

`finput` | `fopen` | `fread` | `ftextinput` | `import::csv` | `import::readbitmap` | `pathname` | `read`

import::readlisp

Purpose Parse Lisp-formatted string

Syntax `import::readlisp(s)`

Description `import::readlisp(s)` parses the Lisp-formatted string `s` and returns the corresponding MuPAD expression.

`import::readlisp` returns the constructed MuPAD expression as an unevaluated call. So the result of `import::readlisp` is in every case of type `DOM_EXPR`.

If the parsed string `s` contains only white spaces, then the unevaluated `null()` expression is returned.

Examples

Example 1

A first example:

```
import::readlisp("(INTEGRATE (EXPT X -1) X)")
```

$$\int \frac{1}{X} dX$$

```
import::readlisp("(EXP 2.0)")
```

$$e^{2.0}$$

Example 2

In “Example 1” on page 12-22 above we can see that the corresponding MuPAD expression is not evaluated. Let us have a closer look at this behavior:

```
domtype(import::readlisp("(INTEGRATE (EXPT X -1) X))),  
eval(import::readlisp("(INTEGRATE (EXPT X -1) X))),  
domtype(import::readlisp("(EXP 2.0))),  
eval(import::readlisp("(EXP 2.0)))
```

DOM_EXPR, $\ln(X)$, DOM_EXPR, 7.389056099

Example 3

Another example demonstrating that `import::readlisp` returns an unevaluated call:

```
x := 2: import::readlisp>(* x (/ 2 y))
```

$x \frac{2}{y}$

```
eval(import::readlisp(* x (/ 2 y)))
```

$\frac{4}{y}$

Example 4

An empty string is converted into an unevaluated call of `null()`:

```
type(import::readlisp(""))
```

"null"

We try to convert an illegal Lisp string:

```
import::readlisp(* 2(EXP 3))
```

Error: The closing parenthesis is missing. [import::parseLambda]

Parameters

s

A string

import::readlisp

Return Values

MuPAD expression of type DOM_EXPR

intlib – Integration Utilities

intlib::byparts
intlib::changevar
intlib::intOverSet
intlib::printWarnings

intlib::byparts

Purpose Integration by parts

Syntax `intlib::byparts(integral, du)`

Description `intlib::byparts(integral, du)` performs on `integral` the integration by parts, where `du` is the part to be integrated and returns an expression containing the unevaluated partial integral.

Mathematically, the rule of integration by parts is formally defined for indefinite integrals as

$$\int u'(x) v(x) dx = u(x) v(x) - \int u(x) v'(x) dx$$

and for definite integrals as

$$\int_a^b u'(x) v(x) dx = u(b) v(b) - u(a) v(a) - \int_a^b u(x) v'(x) dx$$

`intlib::byparts` works for indefinite as well as for definite integrals.

If MuPAD cannot solve the integral for `du` in case of definite integration, the function call is returned unevaluated.

The first argument should contain a symbolic integral of type "int". Such an expression can be obtained with `hold` or `freeze` (cf. "Example 1" on page 13-2).

The second argument `du` should typically be a partial expression of the integrand in `integral`.

Examples

Example 1

As a first example we apply the rule of integration by parts to the integral $\int_a^b x e^x dx$. By using the function `hold` we ensure that the first argument is of type "int":

```
intlib::byparts(hold(int)(x*exp(x), x = a..b), exp(x))
```

$$b e^b - a e^a - \int_a^b e^x dx$$

In this case the ansatz is chosen as $u'(x) = e^x$ and thus $v(x) = x$.

Example 2

In the following we give a more advanced example using the method of integration by parts for solving the integral $\int e^{ax} \sin(bx) dx$. For this we have to prevent that the integrator already evaluates the integrals. Thus we first inactivate the requested integral with the function freeze

```
F := freeze(int)(exp(a*x)*sin(b*x), x)
```

$$\int e^{ax} \sin(bx) dx$$

and apply afterwards partial integration with $u'(x) = e^{ax}$:

```
F1 := intlib::byparts(F, exp(a*x))
```

$$\frac{e^{ax} \sin(bx)}{a} - \int \frac{b e^{ax} \cos(bx)}{a} dx$$

This result contains another symbolic integral, which MuPAD can solve directly:

```
eval(F1)
```

$$\frac{e^{ax} \sin(bx)}{a} - \frac{b e^{ax} (a \cos(bx) + b \sin(bx))}{a(a^2 + b^2)}$$

intlib::byparts

Example 3

Here we demonstrate the difference between indefinite and definite integration by parts. If in the indefinite case the partial part cannot be solved, simply the unevaluated integral is plugged into the integration rule:

```
intlib::byparts(hold(int)(x*f(x), x), f(x))
```

$$x \int f(x) dx - \int \int f(x) dx dx$$

This is no longer true for the definite case:

```
intlib::printWarnings(TRUE):  
intlib::byparts(hold(int)(x*f(x), x=a..b), f(x))
```

Warning: No closed form for 'int(f(x), x)' is found. [intlib::byparts]

$$\text{intlib::byparts} \left(\int_a^b x f(x) dx, f(x) \right)$$

Parameters

integral

Integral: an arithmetical expression containing a symbolic "int" call of the form `int(du*v, x)` or `int(du*v, x = a..b)`

du

The part to be integrated: an arithmetical expression

Return Values

Arithmetical expression.

**MuPAD
Functions**

subs | intlib::changevar

intlib::changevar

Purpose Change of variable

Syntax `intlib::changevar(integral, eq, <var>)`

Description `intlib::changevar(integral, eq)` performs a change of variable for indefinite and definite integrals.

Mathematically, the substitution rule is formally defined for indefinite integrals as

$$\int f(g(x)) g'(x) dx = \left(\left(\int f(t) dt \right) \Big|_{t=g(x)} \right)$$

and for definite integrals as

$$\int_a^b f(g(x)) g'(x) dx = \int_{g(a)}^{g(b)} f(t) dt$$

`intlib::changevar(integral, eq)` performs in `integral` the change of variable defined by `eq` and returns an unevaluated new integral. You can use the `eval` command to find the closed form of this new integral providing that the closed form exists.

`intlib::changevar` works for indefinite as well as for definite integrals.

The first argument should contain a symbolic integral of type "int". Such an expression can be obtained with `hold` or `freeze`. See "Example 1" on page 13-7.

If more than two variables occur in `eq`, the new variable must be given as third argument.

If MuPAD cannot solve the given equation `eq` an error will occur.

Examples**Example 1**

As a first example we perform a change of variable for the integral

$\int_a^b f(x+c) dx$. By using the hold function we ensure that the first argument is of type "int":

```
intlib::changevar(hold(int)(f(x + c), x = a..b),
                  t = x + c, t)
```

$$\int_{a+c}^{b+c} f(t) dt$$

Note that in this case the substitution equation has two further variables besides x . Thus it is necessary to specify the new integration variable as third argument.

Example 2

In the following example we use the change of variable method for solving the integral $\int \cos(\ln(x)) dx$. First we perform the transformation $t = \ln(x)$:

```
f1 := intlib::changevar(hold(int)(cos(ln(x)), x),
                        t = ln(x), t)
```

$$\int e^t \cos(t) dt$$

Now we can evaluate the integral with the MuPAD integrator:

```
f2:=eval(f1)
```

$$\frac{e^t (\cos(t) + \sin(t))}{2}$$

intlib::changevar

Finally we change the variable t back to x and get the result:

```
F := simplify(f2 | t = ln(x))
```

$$\frac{x (\cos(\ln(x)) + \sin(\ln(x)))}{2}$$

We can also verify the solution of the integral:

```
simplify(diff(F,x) - cos(ln(x)))
```

```
0
```

Parameters

integral

The integral: an arithmetical expression containing a symbolic "int" call

eq

Equation defining the new integration variable in terms of the old one: an equation

var

The new integration variable: an identifier

Return Values

Arithmetical expression.

See Also

MuPAD Functions

subs | intlib::byparts

Purpose Integration over a set

Syntax `intlib::intOverSet(f, x, S)`

Description `intlib::intOverSet(f, x, S)` computes the integral

$\int_{-\infty}^{\infty} f(x) i_S(x) dx$ where $i_S(x)$ is the indicator function of the set S .

If S is an interval (a, b) with $a \leq b$, the call is equivalent to `int(f, x=a..b)`. However, by definition, interchanging the borders to `int(f, x=b..a)` just reverses the sign of the latter while (b, a) is empty and any integral over the empty set is zero.

The function may return unevaluated if the integral could not be computed.

Examples **Example 1**

For intervals, calling `intlib::intOverSet` is just equivalent to calling definite integration:

```
int(1/x, x=1..2), intlib::intOverSet(1/x, x, Dom::Interval(1, 2))
ln(2), ln(2)
```

If the lower border is greater than the upper, this does not hold anymore:

```
int(1/x, x=2..1), intlib::intOverSet(1/x, x, Dom::Interval(2, 1))
-ln(2), 0
```

Example 2

In more complex cases, the function returns unevaluated:

```
intlib::intOverSet(1/x^2, x, solve(t > sin(t), t))
```

intlib::intOverSet

$$\int_{x \in \text{solve}(\sin(t) < t, t)} \frac{1}{x^2} dx$$

Parameters

f

Arithmetical expression

x

Identifier

S

Set-theoretic expression

Return Values

Arithmetical expression.

MuPAD Functions

int

Purpose Enable or disable warnings

Syntax `intlib::printWarnings(TRUE)`
`intlib::printWarnings(FALSE)`
`intlib::printWarnings()`

Description `intlib::printWarnings` lets you enable or disable warnings.

By default, MuPAD does not display warnings during integration. To enable warnings, use the `intlib::printWarnings(TRUE)` function call. If later you want to disable warnings, use the `intlib::printWarnings(FALSE)` function call. See “Example 1” on page 13-11.

The `intlib::printWarnings()` function call shows whether warnings are enabled or disabled. See “Example 1” on page 13-11.

The output of `intlib::printWarnings` displays the previous setting. You can save this previous setting and switch to a new setting in a single function call. See “Example 2” on page 13-12.

Examples **Example 1**

Enable the warnings by setting the value of `intlib::printWarnings` to TRUE:

```
intlib::printWarnings(TRUE):
```

Compute the integral of $|x|$ under the assumption that x is an integer. MuPAD cannot integrate the expression over a discrete subset of the real numbers. The system issues a warning and integrates over the set \mathbb{R} of real numbers:

```
int(abs(x), x) assuming x in Z_
```

```
Warning: Cannot integrate when 'x' has property 'Z_'. The assumption
```

intlib::printWarnings

$$\frac{x^2 \operatorname{sign}(x)}{2}$$

If you evaluate the same integral again, MuPAD does not recalculate the integral. The system remembers the previous result and returns it, skipping the warning:

```
int(abs(x), x) assuming x in Z_
```

$$\frac{x^2 \operatorname{sign}(x)}{2}$$

To check whether the warnings are enabled or disabled, use the `intlib::printWarnings()` function call:

```
intlib::printWarnings()
```

```
TRUE
```

Disable the warnings for further computations:

```
intlib::printWarnings(FALSE):
```

Example 2

Enable the warnings and save the previous setting in a single function call:

```
old := intlib::printWarnings(TRUE):
```

Assume that x is positive. Then, integrate x over the interval $[-2, 1]$. In this case, the system issues a warning, temporarily disregards the assumption $x > 0$, and integrates over the interval $[-2, 1]$:

```
assume(x > 0):  
int(x, x = -2..1)
```

Warning: The assumption that 'x' has property '[-2, 1]' instead

$$-\frac{3}{2}$$

Restore the setting of intlib::printWarnings:

```
intlib::printWarnings(old):
```

The warnings are disabled now:

```
intlib::printWarnings()
```

```
FALSE
```

For further computations, clear the assumption on the variable x:

```
unassume(x):
```

Return Values

Previously set value TRUE or FALSE

linalg::addCol

Purpose Linear combination of matrix columns

Syntax `linalg::addCol(A, c1, c2, s1)`
`linalg::addCol(A, c1, c2, s1, s2)`

Description `linalg::addCol(A, c1, c2, s1)` adds s_1 times column c_1 to column c_2 in the matrix A .

`linalg::addCol(A, c1, c2, s)` returns a copy of the matrix A in which column c_2 of A is replaced by $s \cdot \text{col}(A, c_1) + \text{col}(A, c_2)$.

`linalg::addCol(A, c1, c2, s1, s2)` returns a copy of the matrix A in which column c_2 of A is replaced by $s_1 \cdot \text{col}(A, c_1) + s_2 \cdot \text{col}(A, c_2)$.

Examples **Example 1**

The following defines a 3×3 matrix over the integers:

```
A := Dom::Matrix(Dom::Integer)(  
  [[1, 2, 3], [4, 5, 6], [7, 8, 9]]  
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd column by $-\text{col}(A, 1) + \text{col}(A, 2)$, i.e., we subtract the first column from the second:

```
linalg::addCol(A, 1, 2, -1)
```

$$\begin{pmatrix} 1 & 1 & 3 \\ 4 & 1 & 6 \\ 7 & 1 & 9 \end{pmatrix}$$

Example 2

The following defines a 2×3 matrix over the reals:

```
B := Dom::Matrix(Dom::Real)(
  [[sin(2), 0, 1], [1, PI, 0]]
)
```

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If s is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st column by $xcol(B, 3) + col(B, 1)$, where x is an identifier which cannot be converted to the component ring $Dom::Real$ of B :

```
delete x: linalg::addCol(B, 3, 1, x)
```

```
Error: Cannot convert 'x'. [linalg::addCol]
```

Example 3

If symbolic expressions are involved, then one may define matrices over a component ring created by $Dom::ExpressionField$. The following example defines a matrix over this default component ring:

```
delete a11, a12, a21, a22, x:
C := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:

```
linalg::addCol(C, 2, 1, x)
```

$$\begin{pmatrix} a11 + a12 x & a12 \\ a21 + a22 x & a22 \end{pmatrix}$$

linalg::addCol

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c_1, c_2

The column indices: positive integers less or equal to n

s_1, s_2

Expressions that can be converted to the component ring of A

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Domains

`Dom::Matrix`

MuPAD Functions

`linalg::addRow` | `linalg::col` | `linalg::multCol` |
`linalg::multRow`

Purpose

Linear combination of matrix rows

Syntax

```
linalg::addRow(A, r1, r2, s)  
linalg::addRow(A, r1, r2, s1, s2)
```

Description

`linalg::addRow(A, r1, r2, s1)` adds s_1 times row r_1 to row r_2 , in the matrix A .

`linalg::addRow(A, r1, r2, s)` returns a copy of the matrix A in which row r_2 of A is replaced by $s \text{row}(A, r_1) + \text{row}(A, r_2)$.

`linalg::addRow(A, r1, r2, s1, s2)` returns a copy of the matrix A in which row r_2 of A is replaced by $s_1 \text{row}(A, r_1) + s_2 \text{row}(A, r_2)$.

Examples

Example 1

The following defines a 3×3 matrix over the integers:

```
A := Dom::Matrix(Dom::Integer)(  
  [[1, 2, 3], [4, 5, 6], [7, 8, 9]]  
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

We replace the 2nd row by $-\text{row}(A, 1) + \text{row}(A, 2)$, i.e., we subtract the first row from the second:

```
linalg::addRow(A, 1, 2, -1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 3 & 3 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

Example 2

The following defines a 2×3 matrix over the reals:

linalg::addRow

```
B := Dom::Matrix(Dom::Real)(
  [[sin(2), 0, 1], [1, PI, 0]]
)
```

$$\begin{pmatrix} \sin(2) & 0 & 1 \\ 1 & \pi & 0 \end{pmatrix}$$

If s is an expression that does not represent a real number then an error message is reported. The following tries to replace the 1st row by $xrow(B, 2) + row(B, 1)$, where x is an identifier which cannot be converted to the component ring `Dom::Real` of B :

```
delete x: linalg::addRow(B, 2, 1, x)
```

```
Error: Cannot convert 'x'. [linalg::addRow]
```

Example 3

If symbolic expressions are involved, then one may define matrices over the component ring created by `Dom::ExpressionField`. The following example defines a matrix over this default component ring:

```
delete a11, a12, a21, a22, x:
C := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a11 & a12 \\ a21 & a22 \end{pmatrix}$$

We retry the input from the previous example:

```
linalg::addRow(C, 2, 1, x)
```

$$\begin{pmatrix} a11 + a21 x & a12 + a22 x \\ a21 & a22 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r₁, r₂

The row indices: positive integers less or equal to m

s, s₁, s₂

Expressions that can be converted to the component ring of A

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Functions

`linalg::addCol` | `linalg::row` | `linalg::multCol` |
`linalg::multRow`

linalg::adjoint

Purpose Adjoint of a matrix

Syntax `linalg::adjoint(A)`

Description `linalg::adjoint(A)` computes the adjoint $Adj(A)$ of the $n \times n$ matrix A . The adjoint matrix satisfies the equation $A Adj(A) = \det A I_n$, where I_n is the $n \times n$ identity matrix.

The component ring of A must be of category `Cat::CommutativeRing`.

Examples **Example 1**

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):  
A := MatQ([[0, 2, 1], [2, 1, 0], [1, 0, 2]])
```

$$\begin{pmatrix} 0 & 2 & 1 \\ 2 & 1 & 0 \\ 1 & 0 & 2 \end{pmatrix}$$

Then the adjoint matrix of A is given by:

```
Ad := linalg::adjoint(A)
```

$$\begin{pmatrix} 2 & -4 & -1 \\ -4 & -1 & 2 \\ -1 & 2 & -4 \end{pmatrix}$$

We check the property of the adjoint matrix Ad mentioned above:

```
A * Ad = det(A) * MatQ::identity(3)
```

$$\begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix} = \begin{pmatrix} -9 & 0 & 0 \\ 0 & -9 & 0 \\ 0 & 0 & -9 \end{pmatrix}$$

Parameters**A**A square matrix of a domain of category `Cat::Matrix`**Return Values**Matrix of the same domain type as `A`.**Algorithms**The adjoint of a square matrix A is the matrix whose (i, j) -th entry is the (j, i) -th cofactor of A .

The (j, i) -th *cofactor* of A is defined by $a'_{ji} = (-1)^{i+j} \det(A_{ji})$, where A_{ji} is the submatrix of A obtained from A by deleting the i -th row and j -th column.

See Also**MuPAD Functions**

det

linalg::angle

Purpose Angle between two vectors

Syntax `linalg::angle(u, v)`

Description `linalg::angle(u, v)` computes the angle φ between the two vectors u and v , defined by

$$\varphi = \arccos\left(\frac{\langle \vec{u}, \vec{v} \rangle}{\|\vec{u}\|_2 \|\vec{v}\|_2}\right),$$

where $\langle \vec{u}, \vec{v} \rangle$ denotes the scalar product of two vectors given by `linalg::scalarProduct`, and $\|\cdot\|_2$ the 2-norm of a vector, i.e., $\|\vec{u}\|_2 = \sqrt{\langle \vec{u}, \vec{u} \rangle}$.

`linalg::angle` does not check if the computation is defined in the corresponding component ring. This can lead to an error message, as shown in “Example 2” on page 14-13.

The following relationship between the angle between \vec{u} and \vec{v} and the angle between \vec{u} and $-\vec{v}$ holds: $\varphi(\vec{u}, \vec{v}) = \pi - \varphi(\vec{u}, -\vec{v})$.

An error message is returned if the vectors are not defined over the same component ring.

Examples

Example 1

We compute the angle between the two vectors $\begin{pmatrix} 2 \\ 5 \end{pmatrix}$ and $\begin{pmatrix} -3 \\ 3 \end{pmatrix}$:

```
phi := linalg::angle(  
  matrix([2, 5]), matrix([-3, 3])  
)
```

$$\arccos\left(\frac{\sqrt{18}\sqrt{29}}{58}\right)$$

We use the function `float` to get a floating-point approximation of this number:

```
float(phi)
```

```
1.165904541
```

We give two further examples:

```
linalg::angle(
  matrix([1, -1]), matrix([1, 1])
)
```

```
 $\frac{\pi}{2}$ 
```

```
linalg::angle(
  matrix([1, 1]), matrix([-1, -1])
)
```

```
 $\pi$ 
```

Example 2

`linalg::angle` does not check whether the term $\frac{\langle \vec{u}, \vec{v} \rangle}{\|\vec{u}\|_2 \|\vec{v}\|_2}$ is defined in the corresponding component ring.

As an example, we try to compute the angle between two vectors with components in τ :

```
MatZ7 := Dom::Matrix(Dom::IntegerMod(7))
```

linalg::angle

`Dom::Matrix(Dom::IntegerMod(7))`

The following call leads to an error because the 2-norm cannot be computed:

```
linalg::angle(MatZ7([1, 1]), MatZ7([-1, -1]))
```

`Error: An integer exponent is expected. [(Dom::IntegerMod(7))::_pow`

Note that the domain `Dom::IntegerMod(7)` does not implement the square root of an element, therefore in MuPAD you cannot compute the angle of any two vectors over \mathbb{Z}_7 .

Parameters

`u, v`

Vectors of the same dimension; a vector is a $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Arithmetical expression.

See Also

MuPAD Functions

`arccos` | `linalg::scalarProduct` | `linalg::vecdim`

Purpose Basis for a vector space

Syntax `linalg::basis(S)`

Description `linalg::basis(S)` returns a basis for the vector space spanned by the vectors in the set or list S .

`linalg::basis(S)` removes those vectors in S that are linearly dependent on other vectors in S . The result is a basis for the vector space spanned by the vectors in S .

For an ordered basis of vectors, S should be a list of vectors.

The vectors in S must be defined over the same component ring.

The component ring of the vectors in S must be a field, i.e., it must be of category `Cat::Field`.

Examples **Example 1**

We define the domain of matrices over :

```
MatQ := Dom::Matrix(Dom::Rational):
```

and compute a basis for the vector space spanned by the vectors

$$\begin{pmatrix} 3 \\ -2 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix} \text{ and } \begin{pmatrix} 5 \\ -3 \end{pmatrix}:$$

```
v1 := MatQ([3, -2]):
```

```
v2 := MatQ([1, 0]):
```

```
v3 := MatQ([5, -3]):
```

```
linalg::basis([v1, v2, v3])
```

$$\left[\begin{pmatrix} 3 \\ -2 \end{pmatrix}, \begin{pmatrix} 1 \\ 0 \end{pmatrix} \right]$$

If not a list but a set of vectors is given, then the basis returned may not consist of the same vectors as above. The order of the vectors in the

linalg::basis

set depends on the internal order (see `sysorder` and `DOM_SET`), i.e., the order of the vectors appears to be random:

```
b := linalg::basis({v1, v2, v3}):  
op(b, 1)
```

$$\begin{pmatrix} 3 \\ -2 \end{pmatrix}$$

Parameters

s

A set or list of n -dimensional vectors; a vector is a $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Set or a list of vectors, respectively.

See Also

MuPAD Functions

`linalg::intBasis` | `linalg::sumBasis` | `l1l1int`

Purpose Characteristic matrix

Syntax `linalg::charmat(A, x)`

Description `linalg::charmat(A, x)` returns the characteristic matrix $xI_n - A$ of the $n \times n$ matrix A , where I_n denotes the $n \times n$ identity matrix.

The component ring of A must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

The characteristic matrix $M = xI_n - A$ of A can be evaluated at a point $x = u$ via `evalp(M, x = u)`. See “Example 2” on page 14-18.

Examples **Example 1**

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

and compute the characteristic matrix of A in the variable x :

```
MA := linalg::charmat(A, x)
```

$$\begin{pmatrix} x-1 & -2 \\ -3 & x-4 \end{pmatrix}$$

The determinant of the matrix MA is a polynomial in x , the characteristic polynomial of the matrix A :

```
pA := det(MA)
```

$$x^2 - 5x - 2$$

linalg::charmat

`domtype(pA)`

`Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)`

Of course, we can compute the characteristic polynomial of A directly via `linalg::charpoly`:

`linalg::charpoly(A, x)`

$x^2 - 5x - 2$

The result is of the same domain type as the polynomial pA .

Example 2

We define a matrix over the complex numbers:

`B := Dom::Matrix(Dom::Complex)([[1 + I, 1], [1, 1 - I]])`

$$\begin{pmatrix} 1+i & 1 \\ 1 & 1-i \end{pmatrix}$$

The characteristic matrix of B in the variable z is:

`MB := linalg::charmat(B, z)`

$$\begin{pmatrix} z-1-i & -1 \\ -1 & z-1+i \end{pmatrix}$$

We evaluate MB at $z = i$ and get the matrix:

`evalp(MB, z = I)`

$$\begin{pmatrix} -1 & -1 \\ -1 & -1+2i \end{pmatrix}$$

Note that this is a matrix of the domain type
`Dom::Matrix(Dom::Complex):`

`domtype(%)`

`Dom::Matrix(Dom::Complex)`

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

x

An identifier

Return Values

Matrix of the domain

`Dom::Matrix(Dom::DistributedPolynomial([x], R))` or of
`Dom::DenseMatrix(Dom::DistributedPolynomial([x], R))`,
 where R is the component ring of A.

See Also

MuPAD Functions

`linalg::charpoly`

linalg::charpoly

Purpose Characteristic polynomial of a matrix

Syntax `linalg::charpoly(A, x)`

Description `linalg::charpoly(A, x)` computes the characteristic polynomial of the matrix A . The characteristic polynomial of a $n \times n$ matrix is defined by $p_A(x) := \det(xI_n - A)$, where I_n denotes the $n \times n$ identity matrix. The component ring of A must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

Examples **Example 1**

We define a matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Then the characteristic polynomial $p_A(x)$ is given by:

```
linalg::charpoly(A, x)
```

$$x^2 - 5x - 2$$

It is of the domain type:

```
domtype(%)
```

```
Dom::DistributedPolynomial([x], Dom::Rational, LexOrder)
```

Example 2

We define a matrix over \mathbb{Z}_7 :

```
B := Dom::Matrix(Dom::IntegerMod(7))([[1, 2], [3, 0]])
```

$$\begin{pmatrix} 1 \bmod 7 & 2 \bmod 7 \\ 3 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

The characteristic polynomial $p_B(x)$ of B is given by:

```
p := linalg::charpoly(B, x)
```

$$(1 \bmod 7) x^2 + (6 \bmod 7) x + (1 \bmod 7)$$

We compute the zeros of $p_B(x)$, i.e., the eigenvalues of the matrix B :

```
solve(p)
```

$$\{[x = 3 \bmod 7], [x = 5 \bmod 7]\}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

x

An identifier

Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where R is the component ring of A .

Algorithms

`linalg::charpoly` implements Hessenberg's algorithm to compute the characteristic polynomial of a square matrix A . See: Henri Cohen: *A Course in Computational Algebraic Number Theory*, GTM 138, Springer Verlag.

This algorithm works for any field and requires only $O(n^3)$ field operations, in contrast to $O(n^4)$ when computing the determinant of the characteristic matrix of A .

linalg::charpoly

Since the size of the components of A in intermediate computations of Hessenberg's algorithm can swell extremely, it is only applied for matrices over `Dom::Float` and `Dom::IntegerMod`.

For any other component ring, the characteristic polynomial is computed using the Berkowitz algorithm.

MuPAD Functions

`linalg::charmat` | `det` | `linalg::hessenberg` | `linalg::minpoly`

Purpose Extract columns of a matrix

Syntax `linalg::col(A, c)`
`linalg::col(A, c1 .. c2)`
`linalg::col(A, list)`

Description `linalg::col(A, c)` extracts the c -th column vector of the matrix A .

`linalg::col(A, c1.. c2)` returns a list of column vectors whose indices are in the range $c_1.. c_2$. If $c_2 < c_1$ then the empty list `[]` is returned.

`linalg::col(A, list)` returns a list of column vectors whose indices are contained in `list` (in the same order).

Examples **Example 1**

We define a matrix over :

```
A := Dom::Matrix(Dom::Rational)(
  [[1, 1/5, 2], [-3/2, 0, 5]]
)
```

$$\begin{pmatrix} 1 & \frac{1}{5} & 2 \\ -\frac{3}{2} & 0 & 5 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::col`:

```
linalg::col(A, 2)
```

$$\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}$$

```
linalg::col(A, [2, 1, 3])
```

linalg::col

$$\left[\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} 1 \\ -\frac{3}{2} \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \end{pmatrix} \right]$$

`linalg::col(A, 2..3)`

$$\left[\begin{pmatrix} \frac{1}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \end{pmatrix} \right]$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c

The column index: a positive integer less or equal to n

c₁ .. c₂

A range of column indices (positive integers less or equal to n)

list

A list of column indices (positive integers less or equal to n)

Return Values

Single column vector or a list of column vectors; a column vector is an $m \times 1$ matrix of category `Cat::Matrix(R)`, where R is the component ring of A .

MuPAD Functions

`linalg::row` | `linalg::delCol` | `linalg::delRow` | `linalg::setCol`
| `linalg::setRow`

Purpose	Companion matrix of a univariate polynomial
Syntax	<code>linalg::companion(p, <x>)</code>
Description	<p><code>linalg::companion(p)</code> returns the companion matrix associated with the polynomial p.</p> <p>p must be monic and of degree one at least.</p> <p>If p is a polynomial, i.e., an object of type <code>DOM_POLY</code>, then specifying x has no effect.</p> <p>If p is a polynomial, then the component ring of the returned matrix is the coefficient ring of p, except in two cases for built-in coefficient rings: if the coefficient ring of p is <code>Expr</code> then the domain <code>Dom::ExpressionField()</code> is the component ring of the companion matrix. If it is <code>IntMod(m)</code> then the companion matrix is defined over the ring <code>Dom::IntegerMod(m)</code> (see “Example 2” on page 14-27).</p> <p>If p is a polynomial expression, then the companion matrix is defined over <code>Dom::ExpressionField()</code>.</p> <p>If p is a polynomial expression containing several symbolic indeterminates then x must be specified and distinguishes the indeterminate x from the other symbolic parameters.</p>

Examples

Example 1

We start with the following polynomial expression:

```
delete a_0, a_1, a_2, a_3:  
p := x^4 + a_3*x^3 + a_2*x^2 + a_1*x + a_0
```

$$x^4 + a_3 x^3 + a_2 x^2 + a_1 x + a_0$$

To compute the companion matrix of p with respect to x we must specify the second parameter x , because the expression p contains the indeterminates a_0 , a_1 , a_2 , a_3 and x :

`linalg::companion`

```
linalg::companion(p)
```

```
Error: The polynomial expression is multivariate. Specify the indet
```

```
linalg::companion(p, x)
```

$$\begin{pmatrix} 0 & 0 & 0 & -a_0 \\ 1 & 0 & 0 & -a_1 \\ 0 & 1 & 0 & -a_2 \\ 0 & 0 & 1 & -a_3 \end{pmatrix}$$

Of course, we can compute the companion matrix of p with respect to a_0 as well:

```
linalg::companion(p, a_0)
```

$$\left(-x^4 - a_3 x^3 - a_2 x^2 - a_1 x \right)$$

The following fails with an error message, because the polynomial p is not monic with respect to a_1 :

```
linalg::companion(p, a_1)
```

```
Error: Polynomial is not monic. [linalg::companion]
```

Example 2

If we enter a polynomial over the built-in coefficient domain Expr, then the companion matrix is defined over the standard component ring for matrices (the domain Dom::ExpressionField()):

```
C := linalg::companion(poly(x^2 + 10*x + PI, [x]))
```

$$\begin{pmatrix} 0 & -\pi \\ 1 & -10 \end{pmatrix}$$

```
domtype(C)
```

```
Dom::Matrix()
```

If we define a polynomial over the build-in coefficient domain IntMod(m), then the companion matrix is defined over the corresponding component ring Dom::IntegerMod(m), as shown in the next example:

```
p := poly(x^2 + 10*x + 7, [x], IntMod(3))
```

```
poly(x^2 + x + 1, [x], IntMod(3))
```

```
C := linalg::companion(p)
```

$$\begin{pmatrix} 0 \bmod 3 & 2 \bmod 3 \\ 1 \bmod 3 & 2 \bmod 3 \end{pmatrix}$$

```
domtype(C)
```

```
Dom::Matrix(Dom::IntegerMod(3))
```

Parameters

p

linalg::companion

An univariate polynomial, or a polynomial expression

x

An identifier

Return Values

Matrix of the domain `Dom::Matrix(R)`.

Algorithms

The companion matrix of the polynomial $x^n + a_n x^{n-1} + \dots + a_1 x + a_0$ is the matrix:

$$C = \begin{pmatrix} 0 & \dots & 0 & -a_0 \\ 1 & & & -a_1 \\ & \ddots & & \vdots \\ & & \ddots & \vdots \\ & & & 0 & -a_{n-1} \\ & & & 1 & -a_n \end{pmatrix}.$$

The companion matrix of a univariate polynomial p of degree n is an $n \times n$ matrix C with $p_C = p$, where p_C is the characteristic polynomial of C .

Purpose

Join matrices horizontally

Syntax

```
linalg::concatMatrix(A, B1, <B2, >)
```

Description

`linalg::concatMatrix(A, B1, B2, dots)` returns the matrix formed by joining the matrices A, B_1, B_2, \dots horizontally.

The matrices B_1, B_2, \dots are converted into the matrix domain $\text{Dom}::\text{Matrix}(R)$, where R is the component ring of A .

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of rows as the matrix A .

A short form of `linalg::concatMatrix` is available through the dot operator `.`, i.e., instead of `linalg::concatMatrix(A, B)` one may use the short form `A . B`.

Examples

Example 1

We define the matrix:

```
A := matrix([[sin(x), x], [-x, cos(x)]])
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2×2 identity matrix to the right of A:

```
I2 := matrix::identity(2):  
linalg::concatMatrix(A, I2)
```

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

The short form for this operation is:

```
A . I2
```

linalg::concatMatrix

$$\begin{pmatrix} \sin(x) & x & 1 & 0 \\ -x & \cos(x) & 0 & 1 \end{pmatrix}$$

Example 2

We define a matrix from the ring of 2×2 square matrices:

```
SqMatQ := Dom::SquareMatrix(2, Dom::Rational):  
A := SqMatQ([[1, 2], [3, 4]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note the following operation:

```
AA := A . A
```

$$\begin{pmatrix} 1 & 2 & 1 & 2 \\ 3 & 4 & 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:

```
domtype(AA)
```

```
Dom::Matrix(Dom::Rational)
```

Parameters

A, B₁, B₂, ...

Matrices of a domain of category `Cat::Matrix`

Return Values

Matrix of the domain type `Dom::Matrix(R)`, where R is the component ring of A.

See Also

MuPAD Functions

`linalg::stackMatrix`

linalg::cond

Purpose Condition number of a matrix

Syntax `linalg::cond(M, <1 | 2 | Spectral | Infinity | Frobenius>)`

Description `linalg::cond(M)` computes the condition number of a matrix, defined by $\|M\|_{\infty} \left\| \frac{1}{M} \right\|_{\infty}$. By default the matrix norm Infinity is used by `linalg::cond`.

`linalg::cond(M)` is the short form of `linalg::cond(M, Infinity)`.

`linalg::cond(M, k)` computes the condition number of the matrix M, defined by $\|M\|_k \left\| \frac{1}{M} \right\|_k$.

For further details see the help page of `norm`.

Examples

Example 1

We define the 3×3 matrix A.

```
A := matrix(3,3, [[1,0,3],[-4,2,0],[0,3,-2]])
```

$$\begin{pmatrix} 1 & 0 & 3 \\ -4 & 2 & 0 \\ 0 & 3 & -2 \end{pmatrix}$$

Now we calculate the condition number of A for some matrix norms.

```
linalg::cond(A)
```

$$\frac{33}{10}$$

```
linalg::cond(A, Infinity)
```

$$\frac{33}{10}$$

```
linalg::cond(A, 1)
```

```
3
```

```
linalg::cond(A, Frobenius)
```

$$\frac{\sqrt{2} \sqrt{43} \sqrt{251}}{40}$$

The result for the spectral norm is too complex, so we want the floating valuation. The tiny imaginary part is a rounding artifact:

```
linalg::cond(A, 2);
float(%)
```

$$\sqrt{\frac{343}{9\sigma_1} + \sigma_1 + \frac{43}{3}} \sqrt{\frac{11401}{5760000\sigma_2} + \sigma_2 + \frac{251}{2400}}$$

where

$$\sigma_1 = \left(\frac{3970}{27} + \frac{\sqrt{27} \sqrt{910841} i}{27} \right)^{1/3}$$

$$\sigma_2 = \left(\frac{705851}{13824000000} + \frac{\sqrt{910841} \sqrt{1769472000000000} i}{17694720000000} \right)^{1/3}$$

$$2.223147175 + 1.386849201 \cdot 10^{-18} i$$

If A contains at least one floating-point number, the result will be computed numerically.

```
B := A;
B[1,1] := float(B[1,1]):
```

linalg::cond

```
linalg::cond(B, 2)
```

```
2.223147175
```

Example 2

We define the 2×2 matrix C .

```
C := matrix([[1, -2], [3, -4]])
```

$$\begin{pmatrix} 1 & -2 \\ 3 & -4 \end{pmatrix}$$

Now we calculate the condition number of C for some matrix norms.

```
linalg::cond(C, 1)
```

```
21
```

```
linalg::cond(C, Infinity)
```

```
21
```

```
linalg::cond(C, Frobenius); Simplify(%);
```

$$\frac{\sqrt{2} \sqrt{15} \sqrt{30}}{2}$$

```
15
```

Example 3

Hilbert matrices are very ill-conditioned:

```
linalg::cond( linalg::hilbert(3) )
```

748

```
linalg::cond( linalg::hilbert(5) )
```

943656

```
linalg::cond( linalg::hilbert(7) )
```

$\frac{1970389773}{2}$

Parameters

M

Square matrix of domain type Dom::Matrix

Options

Frobenius, Infinity, Spectral

The index of the matrix norm.

Return Values

Arithmetical expression.

See Also

MuPAD Functions

norm

linalg::crossProduct

Purpose Cross product of three-dimensional vectors

Syntax `linalg::crossProduct(u, v)`

Description `linalg::crossProduct(u, v)` computes the cross product of the three-dimensional vectors \vec{u} and \vec{v} . This is the vector

$$\vec{u} \times \vec{v} = \begin{pmatrix} u_2 v_3 - u_3 v_2 \\ u_3 v_1 - u_1 v_3 \\ u_1 v_2 - u_2 v_1 \end{pmatrix}.$$

The vectors must be defined over the same component ring.

Examples

Example 1

We define two vectors:

```
a := matrix([[1, 2, 3]]);  
b := matrix([[ -1, 0, 1]])
```

```
( 1 2 3 )
```

```
( -1 0 1 )
```

The cross product of these two vectors is a vector \vec{c} which is orthogonal to \vec{a} and \vec{b} :

```
c := linalg::crossProduct(a, b)
```

```
( 2 -4 2 )
```

```
linalg::scalarProduct(a, c), linalg::scalarProduct(b, c)
```

```
0, 0
```

Parameters

u, v

3-dimensional vectors, i.e., either two 3×1 or two 1×3 matrices of a domain of category `Cat::Matrix`

Return Values

Vector of the same domain type as u.

See Also**MuPAD Functions**

`linalg::scalarProduct`

linalg::curl

Purpose Curl of a vector field

Note `linalg::curl` will be removed in a future release. Use `curl` instead.

Syntax
`linalg::curl(v, x)`
`linalg::curl(v, x, ogCoord, <c>)`

Description `linalg::curl(v, x)` computes the curl of the three-dimensional vector field \vec{v} with respect to the three-dimensional vector \vec{x} in Cartesian coordinates. This is the vector field

$$\text{curl}(\vec{v}) = \begin{pmatrix} \frac{\partial}{\partial x_2} v_3 - \frac{\partial}{\partial x_3} v_2 \\ \frac{\partial}{\partial x_3} v_1 - \frac{\partial}{\partial x_1} v_3 \\ \frac{\partial}{\partial x_1} v_2 - \frac{\partial}{\partial x_2} v_1 \end{pmatrix}.$$

`linalg::curl` and `curl` are equivalent. See details and examples on the `curl` help page.

Parameters

v

A list of three arithmetical expressions, or a three-dimensional vector (a 3×1 or 1×3 matrix of a domain of category `Cat::Matrix`)

x

A list of three identifiers or indexed identifiers

ogCoord

The name of a three-dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic

expressions representing the scale factors of an orthogonal coordinate system.

c

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is $c = 1$.

Return Values

Column vector.

linalg::delCol

Purpose Delete matrix columns

Syntax `linalg::delCol(A, c)`
`linalg::delCol(A, c1 .. c2)`
`linalg::delCol(A, list)`

Description `linalg::delCol(A, c)` returns a copy of the matrix A in which the column with index c is deleted.

`linalg::delCol(A, c1.. c2)` deletes those columns whose indices are in the range $c_1.. c_2$. If $c_2 < c_1$ then the input matrix A is returned.

`linalg::delCol(A, list)` deletes those columns whose indices are contained in `list`.

If all columns are deleted then NIL is returned.

Examples

Example 1

We define the following matrix:

```
A := matrix([[1, 2, 3, 4], [5, 6, 7, 8]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix}$$

and demonstrate the three different input formats for `linalg::delCol`:

```
linalg::delCol(A, 2)
```

$$\begin{pmatrix} 1 & 3 & 4 \\ 5 & 7 & 8 \end{pmatrix}$$

```
linalg::delCol(A, [1, 3])
```

$$\begin{pmatrix} 2 & 4 \\ 6 & 8 \end{pmatrix}$$

```
linalg::delCol(A, 2..4)
```

$$\begin{pmatrix} 1 \\ 5 \end{pmatrix}$$

Example 2

We compute the inverse of the 2×2 matrix:

```
MatQ := Dom::Matrix(Dom::Rational):
A := MatQ([[3, 2], [5, -4]])
```

$$\begin{pmatrix} 3 & 2 \\ 5 & -4 \end{pmatrix}$$

by appending the 2×2 identity matrix to the right side of A and applying the Gauss-Jordan algorithm provided by the function `linalg::gaussJordan`:

```
B := linalg::gaussJordan(A . MatQ::identity(2))
```

$$\begin{pmatrix} 1 & 0 & \frac{2}{11} & \frac{1}{11} \\ 0 & 1 & \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

We get the inverse of A by deleting the first two columns of the matrix B:

```
AI := linalg::delCol(B, 1..2)
```

$$\begin{pmatrix} \frac{2}{11} & \frac{1}{11} \\ \frac{5}{22} & -\frac{3}{22} \end{pmatrix}$$

Finally, we check the result:

linalg::delCol

$A * AI, AI * A$

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Note: The inverse of A can be computed directly by entering $1/A$.

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c

The column index: a positive integer less or equal to n

c₁ .. c₂

A range of column indices (positive integers less or equal to n)

list

A list of column indices (positive integers less or equal to n)

Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where R is the component ring of A, or NIL.

See Also

MuPAD Functions

`linalg::col` | `linalg::delRow` | `linalg::row`

Concepts

Purpose Delete matrix rows

Syntax `linalg::delRow(A, r)`
`linalg::delRow(A, r1 .. r2)`
`linalg::delRow(A, list)`

Description `linalg::delRow(A, r)` returns a copy of the matrix A in which the row with index r is deleted.

`linalg::delRow(A, r1 .. r2)` deletes those rows whose indices are in the range $r_1 .. r_2$. If $r_2 < r_1$ then the input matrix A is returned.

`linalg::delRow(A, list)` deletes those rows whose indices are contained in `list`.

If all rows are deleted then NIL is returned.

Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, 2], [3, 4], [5, 6], [7, 8]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::delRow`:

```
linalg::delRow(A, 2)
```

$$\begin{pmatrix} 1 & 2 \\ 5 & 6 \\ 7 & 8 \end{pmatrix}$$

```
linalg::delRow(A, [1, 4])
```

linalg::delRow

$$\begin{pmatrix} 3 & 4 \\ 5 & 6 \end{pmatrix}$$

```
linalg::delRow(A, 2..4)
```

$$(1 \ 2)$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r

The row index: a positive integer less or equal to m

r₁ .. r₂

A range of row indices (positive integers less or equal to m)

list

A list of row indices (positive integers less or equal to m)

Return Values

Matrix of a domain of category `Cat::Matrix(R)`, where R is the component ring of A or `NIL`.

`linalg::col` | `linalg::delCol` | `linalg::row`

Concepts

- “Swap and Delete Rows and Columns”

Purpose Determinant of a matrix

Note `linalg::det` will be removed in a future release. Use `det` instead.

Syntax `linalg::det(A, options)`

Description

`linalg::det(A)` computes the determinant of the square matrix A .

A floating-point approximation of the determinant is computed with `numeric::det`, if A is defined over the component ring `Dom::Float`. In this case, it is recommended to call `numeric::det` directly for a better efficiency.

The component ring of A must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

The `MinorExpansion` option is useful for small matrices (typically, matrices of dimension up to 10) containing many symbolic entries. By default, `linalg::det` tries to recognize matrices that can benefit from using `MinorExpansion`, and uses this option when computing their determinants. Nevertheless, `linalg::det` does not always recognize these matrices. Also, identifying that a matrix is small enough and contains many symbolic entries takes time. To improve performance, use the `MinorExpansion` option explicitly.

By default, `linalg::det` calls `normal` before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. It also affects the result returned by `linalg::det` only if a matrix contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::det` also can return normalized results, but does not guarantee such normalization. See “Example 2” on page 14-46 and “Example 3” on page 14-47.

linalg::det

Examples

Example 1

Compute the determinant of the following matrix:

```
A := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

`linalg::det` returns the well-known formula for the determinant of an arbitrary 2×2 matrix:

```
linalg::det(A)
```

$$a_{11} a_{22} - a_{12} a_{21}$$

Example 2

If you use the `Normal` option, `linalg::det` calls the `normal` function for final results. This call ensures that `linalg::det` returns results in normalized form:

```
linalg::det(matrix([[x, x^2], [x/(x + 2), 1/x]]))
```

$$\frac{-x^3 + x + 2}{x + 2}$$

If you specify `Normal = FALSE`, `linalg::det` does not call `normal` for the final result:

```
linalg::det(matrix([[x, x^2], [x/(x + 2), 1/x]]), Normal = FALSE)
```

$$1 - \frac{x^3}{x + 2}$$

Example 3

Using `Normal` can significantly decrease the performance of `linalg::det`. For example, computing the determinant of this matrix takes a long time:

```
n := 5:
det5 := linalg::det(matrix([[x[i*j]^(i + j) + x[i+j]^j)/(i + j)]))
```

For better performance, specify `Normal = FALSE`:

```
n := 5:
det5 := linalg::det(matrix([[x[i*j]^(i + j) + x[i+j]^j)/(i + j)]))
```

Parameters**A**

Square matrix of a domain of category `Cat::Matrix`

Options**MinorExpansion**

Compute the determinant by a recursive minor expansion along the first column.

Normal

Option, specified as `Normal = b`

Return normalized results. The value `b` must be `TRUE` or `FALSE`. By default, `Normal = TRUE`, meaning that `linalg::det` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

Return Values

Element of the component ring of `A`.

Algorithms

For an $n \times n$ matrix $A = (a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$ over a commutative ring its determinant is defined as:

linalg::det

$$\det A := \sum_{\sigma \in S_n} \text{sign}(\sigma) \left(\prod_{j=1}^n a_{\sigma(j), j} \right)$$

(S_n is the symmetric group of all permutations of $\{1, \dots, n\}$.)

For a component ring of A that is an integral domain (i.e., a domain of category `Cat::IntegralDomain`) and not defined over the domain `Dom::Float`, Gaussian elimination is used to compute the determinant of A .

For any other commutative ring that is not an integral domain, a modification of the Berkowitz algorithm is used.

MuPAD Functions

`linalg::gaussElim` | `linalg::permanent` | `linalg::rank` |
`numeric::det`

Purpose Divergence of a vector field

Note `linalg::divergence` will be removed in a future release. Use `divergence` instead.

Syntax `linalg::divergence(v, x)`
`linalg::divergence(v, x, ogCoord, <c>)`

Description `linalg::divergence(v, x)` computes the divergence of the vector field \vec{v} with respect to \vec{x} in Cartesian coordinates. This is the sum

$$\operatorname{div}(\vec{v}) = \sum_{i=1}^n \frac{\partial}{\partial x_i} v_i$$

`linalg::divergence` and `divergence` are equivalent. See details and examples on the `divergence` help page.

Parameters

v

A list of arithmetical expressions, or a vector (an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

x

A list of identifiers or indexed identifiers

ogCoord

The name of a three-dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the scale factors of an orthogonal coordinate system.

c

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is `c = 1`.

linalg::divergence

Return Values

Arithmetical expression, or an element of the component ring of v .

Purpose

Eigenvalues of a matrix

Syntax

```
linalg::eigenvalues(A, <Multiple>)
```

Description

`linalg::eigenvalues(A)` returns a list of the eigenvalues of the matrix A .

A floating-point approximation of the eigenvalues is computed with `numeric::eigenvalues`, if the matrix A is defined over the component ring `Dom::Float` (see “Example 1” on page 14-51). In this case it is recommended to call `numeric::eigenvalues` directly for a better efficiency.

The eigenvalues are obtained by computing the zeros of the characteristic polynomial of A . The solver `solve` must be able to compute the roots of the characteristic polynomial over the component ring of A .

Examples

Example 1

We compute the eigenvalues of the matrix

$$A = \begin{pmatrix} 1 & 4 & 2 \\ 1 & 4 & 2 \\ 2 & 5 & 3 \end{pmatrix};$$

```
A := matrix([[1, 4, 2], [1, 4, 2], [2, 5, 3]]):  
linalg::eigenvalues(A)
```

```
{0, 4 - √15, √15 + 4}
```

If we consider the matrix over the domain `Dom::Float`, then the call of `linalg::eigenvalues(A)` results in a numerical computation of the eigenvalues of A via `numeric::eigenvalues`:

```
B := Dom::Matrix(Dom::Float)(A):  
linalg::eigenvalues(B)
```

linalg::eigenvalues

$\{-1.370431546 \cdot 10^{-15}, 0.1270166538, 7.872983346\}$

Example 2

With the option `Multiple` we get the information about the algebraic multiplicity of each eigenvalue:

```
C := Dom::Matrix(Dom::Rational)(4, 4, [[-3], [0, 6]])
```

$$\begin{pmatrix} -3 & 0 & 0 & 0 \\ 0 & 6 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

```
linalg::eigenvalues(C, Multiple)
```

```
[[ -3, 1], [0, 2], [6, 1]]
```

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Options

Multiple

Returns a list of sublists, where each sublist contains an eigenvalue of `A` and its algebraic multiplicity. Note that due to rounding errors, this may lead to wrong results in cases where multiple eigenvalues exist and `numeric::eigenvalues` is used.

Return Values

Set of the eigenvalues of `A`, or a list of inner lists when the option `Multiple` is given (see below).

linalg::eigenvectors

Purpose	Eigenvectors of a matrix
Syntax	<code>linalg::eigenvectors(A)</code>
Description	<p><code>linalg::eigenvectors(A)</code> computes the eigenvalues and eigenvectors of the matrix A.</p> <p>A floating-point approximation of the eigenvalues and the eigenvectors is computed using <code>numeric::eigenvectors</code>, if the matrix A is defined over the component ring <code>Dom::Float</code> (see “Example 1” on page 14-54). In this case it is recommended to call <code>numeric::eigenvalues</code> directly for a better efficiency.</p> <p><code>linalg::eigenvectors</code> works as follows: For each eigenvalue λ of the $n \times n$ matrix A, a basis for the kernel of $(\lambda I_n - A)$, the eigenspace of A with respect to the eigenvalue λ, is computed using the Gauss-Jordan algorithm (see <code>linalg::gaussJordan</code>). Here, I_n denotes the $n \times n$ identity matrix.</p> <p>The eigenvectors are of the domain <code>Dom::Matrix(R)</code>, where R is the component ring of A.</p> <p>The component ring of the matrix A must be a field, i.e., a domain of category <code>Cat::Field</code>, for which the solver <code>solve</code> is able to compute the zeros of a polynomial.</p> <p>It can happen that a basis for the eigenspace of A with respect to a certain eigenvalue cannot be computed (e.g., if the component ring does not have a canonical representation of the zero element). In this case <code>linalg::eigenvectors</code> answers with a warning message and returns <code>FAIL</code>.</p>

Examples

Example 1

We compute the eigenvalues and the eigenvectors of the matrix

$$A = \begin{pmatrix} 1 & -3 & 3 \\ 6 & -10 & 6 \\ 6 & 6 & 4 \end{pmatrix};$$

```
A := Dom::Matrix(Dom::Rational)(
  [[1, -3, 3], [6, -10, 6], [6, 6, 4]]
):
Ev:= linalg::eigenvectors(A)
```

$$\left[\left[-11, 1, \begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix} \right] \right], \left[-2, 1, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \right], \left[8, 1, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix} \right]$$

The matrix A is diagonalizable. Hence, we extract the eigenvectors and combine them to a matrix P such that $P^{-1} * A * P$ is the diagonal matrix whose diagonal entries are given by the corresponding eigenvalues:

```
Eigenvectors:= Ev[1][3][1], Ev[2][3][1], Ev[3][3][1]
```

$$\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix}$$

```
P:= Eigenvectors[1].Eigenvectors[2].Eigenvectors[3]
```

$$\begin{pmatrix} -\frac{7}{10} & -1 & \frac{1}{4} \\ -\frac{9}{5} & 0 & \frac{5}{12} \\ 1 & 1 & 1 \end{pmatrix}$$

linalg::eigenvectors

$P^{-1} * A * P$

$$\begin{pmatrix} -11 & 0 & 0 \\ 0 & -2 & 0 \\ 0 & 0 & 8 \end{pmatrix}$$

A more skillful way of extracting the above eigenvectors from the output generated by `linalg::eigenvectors` is the following:

`map(Ev, op@op, 3)`

$$\left[\left(\begin{pmatrix} -\frac{7}{10} \\ -\frac{9}{5} \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix}, \begin{pmatrix} \frac{1}{4} \\ \frac{5}{12} \\ 1 \end{pmatrix} \right) \right]$$

If we consider the matrix `A` over the domain `Dom::Float`, the call of `linalg::eigenvectors(A)` results in a numerical computation of the eigenvalues and the eigenvectors of `A` via the function `numeric::eigenvectors`:

`B := Dom::Matrix(Dom::Float)(A):`
`linalg::eigenvectors(B)`

$$\left[\left[8.0, 1, \left[\begin{pmatrix} 0.2248595067 \\ 0.3747658445 \\ 0.8994380268 \end{pmatrix} \right] \right], \left[-2.0, 1, \left[\begin{pmatrix} 0.7071067812 \\ 0.0 \\ -0.7071067812 \end{pmatrix} \right] \right], \right. \\ \left. \left[-11.0, 1, \left[\begin{pmatrix} 0.3218603429 \\ 0.8276408818 \\ -0.4598004899 \end{pmatrix} \right] \right] \right]$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

List of sublists, where each sublist consists of an eigenvalue λ of **A**, its algebraic multiplicity and a basis for the eigenspace of λ . If a basis of an eigenspace cannot be computed, `FAIL` is returned.

linalg::expr2Matrix

Purpose Construct a matrix from equations

Syntax `linalg::expr2Matrix(eqns, <vars, R>, <Include>)`

Description `linalg::expr2Matrix(eqns, vars)` constructs the extended coefficient matrix $\begin{pmatrix} A & \vec{b} \end{pmatrix}$ of the system of m linear equations in eqns with respect to the n indeterminates in vars. The vector \vec{b} is the right-hand side of this system.

`linalg::expr2Matrix` returns the extended coefficient matrix

$M = \begin{pmatrix} A & \vec{b} \end{pmatrix}$. The right-hand side vector \vec{b} can be extracted from the matrix M by `linalg::col(M, n + 1)`.

The coefficient matrix A can be extracted by `linalg::delCol(M, n + 1)`.

Arithmetical expressions in eqns are considered as equations with right hand-sides zero.

If no variables are given, then the indeterminates of the equations are determined with the function `indets` and the option `PolyExpr`, i.e., the left-hand sides of the equations are considered as polynomial expressions.

If no component ring R is given then the standard domain `Dom::ExpressionField()` is chosen as the component ring of the extended coefficient matrix.

The coefficients of the linear equations are converted into elements of the component ring R . An error message is returned if this is not possible.

Examples

Example 1

The extended coefficient matrix of the system $x + y + z = 1$, $2y - z + 5 = 0$ of linear equations in the variables x, y, z is the following 2×4 matrix:

```
delete x, y, z:
```

```
Ab := linalg::expr2Matrix(  
  [x + y + z = 1, 2*y - z + 5], [x, y, z], Dom::Real  
)
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 2 & -1 & -5 \end{pmatrix}$$

We use `linalg::matlinsolve` to compute the general solution of this system:

```
linalg::matlinsolve(Ab)
```

$$\left[\left(\begin{pmatrix} \frac{7}{2} \\ -\frac{5}{2} \\ 0 \end{pmatrix} \right), \left[\left(\begin{pmatrix} -\frac{3}{2} \\ \frac{1}{2} \\ 1 \end{pmatrix} \right) \right] \right]$$

The coefficient matrix or the right-hand side vector can be extracted from the matrix `Ab` in the following way:

```
A := linalg::delCol(Ab, 4); b := linalg::col(Ab, 4)
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 2 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ -5 \end{pmatrix}$$

Example 2

The following two inputs lead to different linear systems:

```
delete x, y, z:  
linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x]),
```

linalg::expr2Matrix

```
linalg::expr2Matrix([x + y + z = 1, 2*y - z + 5 = x], [x, y])
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ -1 & 2 & -1 & -5 \end{pmatrix}, \begin{pmatrix} 1 & 1 & 1 & -z \\ -1 & 2 & z & -5 \end{pmatrix}$$

Example 3

Note the difference between calling `linalg::expr2Matrix` with and without option `Include`:

```
delete x, y:  
linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y])
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 2 & -1 & 3 \end{pmatrix}$$

```
linalg::expr2Matrix([x + y = 1, 2*x - y = 3], [x, y], Include)
```

$$\begin{pmatrix} 1 & 1 & -1 \\ 2 & -1 & -3 \end{pmatrix}$$

Parameters

eqns

The system of linear equations, i.e. a set or list of expressions of type `"_equal"`

vars

A set or list of indeterminates

R

A commutative ring, i.e., a domain of category `Cat::CommutativeRing`

Options

Include

Appends the negative of the right-hand side vector \vec{b} to the coefficient matrix A of the given system of linear equations. The result is the $m \times (n + 1)$ matrix $\left(A, -\vec{b} \right)$.

Return Values

$m \times (n + 1)$ matrix of the domain `Dom::Matrix(R)`.

See Also

MuPAD Functions

`linalg::matlinsolve` | `linsolve` | `indets`

linalg::factorCholesky

Purpose The Cholesky decomposition of a matrix

Syntax `linalg::factorCholesky(A, <NoCheck>, <Real>)`

Description `linalg::factorCholesky(A)` computes the Cholesky factorization of a Hermitian positive definite matrix A and returns a lower triangular matrix L , such that $LL^H = A$. Here, L^H is the Hermitian conjugate of L (the complex conjugate of the transpose).

The component ring of A must be a field (a domain of category `Cat::Field`).

If A is not a Hermitian positive definite matrix, then `linalg::factorCholesky` throws an error. If you use `NoCheck`, `linalg::factorCholesky` does not check whether the matrix is Hermitian positive definite. See “Example 2” on page 14-63.

If you use `Real`, then `linalg::factorCholesky` assumes that A is real and symmetric and, therefore, does not apply complex conjugate in the course of the algorithm.

`linalg::factorCholesky` returns `FAIL` if it fails to compute the matrix L over the component ring of A . (The algorithm requires the computation of square roots of some elements in L).

Environment Interactions Properties of identifiers are taken into account.

Examples **Example 1**

Define matrix S as follows:

```
S := Dom::Matrix(Dom::Rational)(
  [[4, -2, 4, 2], [-2, 10, -2, -7], [4, -2, 8, 4], [2, -7, 4, 7]]
)
```

$$\begin{pmatrix} 4 & -2 & 4 & 2 \\ -2 & 10 & -2 & -7 \\ 4 & -2 & 8 & 4 \\ 2 & -7 & 4 & 7 \end{pmatrix}$$

Compute the Cholesky factorization of S:

```
L := linalg::factorCholesky(S)
```

$$\begin{pmatrix} 2 & 0 & 0 & 0 \\ -1 & 3 & 0 & 0 \\ 2 & 0 & 2 & 0 \\ 1 & -2 & 1 & 1 \end{pmatrix}$$

Verify the result:

```
is(L * htranspose(L) = S)
```

```
TRUE
```

Example 2

Define matrix H as follows:

```
H := matrix([[a, b], [b, a]])
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

`linalg::factorCholesky` cannot compute the Cholesky factorization because it cannot prove that H is a Hermitian matrix:

```
linalg::factorCholesky(H)
```

linalg::factorCholesky

Error: A Hermitian matrix is expected. [linalg::factorCholesky]

If you assume that a and b are real, then matrix H is Hermitian. Still, linalg::factorCholesky cannot compute the Cholesky factorization:

`linalg::factorCholesky(H)` assuming a in R_ and b in R_

Error: Cannot check whether the matrix component is positive. [linalg::factorCholesky]

Use the NoCheck option to skip checking whether this matrix is Hermitian positive definite. Now, linalg::factorCholesky computes the factorization:

`L := linalg::factorCholesky(H, NoCheck)`

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \frac{\sqrt{a|a|-|b|^2}}{\sqrt{|a|}} \end{pmatrix}$$

This result is not generally valid:

`L*htranspose(L) = H`

$$\begin{pmatrix} \sqrt{a} \sqrt{a} & \frac{\sqrt{a} \bar{b}}{\sqrt{a}} \\ \frac{b \sqrt{a}}{\sqrt{a}} & \frac{\sqrt{a|a|-|b|^2}}{|a|} \sqrt{a|a|-|b|^2} + \frac{b \bar{b}}{\sqrt{a} \sqrt{a}} \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

It is valid for $0 < a < b$:

`simplify(L*htranspose(L) = H) assuming 0 < b < a`

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

Example 3

Compute the Cholesky factorization of matrix H using NoCheck to skip checking whether it is Hermitian positive definite. By default, `linalg::factorCholesky` computes a Hermitian factorization $A = LL^H$. Thus, the result contains complex conjugates (implied by $|a| = a\bar{a}$).

```
H := matrix([[a, b], [b, a]]):
L := linalg::factorCholesky(H, NoCheck)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \frac{\sqrt{a|a|-|b|^2}}{\sqrt{|a|}} \end{pmatrix}$$

To avoid complex conjugates in the result, use Real:

```
L := linalg::factorCholesky(H, NoCheck, Real)
```

$$\begin{pmatrix} \sqrt{a} & 0 \\ \frac{b}{\sqrt{a}} & \sqrt{\frac{a^2-b^2}{a}} \end{pmatrix}$$

With this option, `linalg::factorCholesky` computes a symmetric factorization $A = LL^t$ instead of a Hermitian factorization $A = LL^H$:

```
simplify(L*transpose(L) = H)
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

linalg::factorCholesky

Parameters

A

Square matrix of a domain of category `Cat::Matrix`.

Options

NoCheck

Skip checking whether A is Hermitian positive definite. When you use this option, the identity $LL^H = A$ is guaranteed to hold only if A is a Hermitian positive definite matrix.

Real

Compute the Cholesky factorization assuming that matrix A is symmetric and all its symbolic parameters are real. In this case, the transpose of the matrix is its Hermitian transpose. Use this option if A contains symbolic parameters, and you want to avoid complex conjugates. When using this option, the identity $LL^T = A$ is guaranteed to hold.

Return Values

Matrix of the same domain type as A , or the value `FAIL`.

Algorithms

The Cholesky factorization of a Hermitian positive definite $n \times n$ matrix A is a decomposition of A in a product $LL^H = A$, such that L is a lower triangular matrix with positive entries on the main diagonal. L is called the “Cholesky factor” of A .

If $L = (l_{ij})$, where $1 \leq i \leq n$, $1 \leq j \leq n$, is the Cholesky factor of A , then

$$\det A = \left(\prod_{i=1}^n l_{ii} \right)^2.$$

See Also

MuPAD Functions

`linalg::isHermitian` | `linalg::isPosDef`

Related Examples

- “Compute Cholesky Factorization”

Purpose LU-decomposition of a matrix

Syntax `linalg::factorLU(A)`

Description `linalg::factorLU(A)` computes an LU-decomposition of an $m \times n$ matrix A , i.e., a decomposition of the A into an $m \times m$ lower triangular matrix L and an $m \times n$ upper triangular matrix U such that $PA = LU$, where P is a permutation matrix.

The diagonal entries of the lower triangular matrix L are equal to one (*Doolittle*-decomposition). The diagonal entries of U are the pivot elements used during the computation.

The matrices L and U are unique.

`pivindex` is a list $[r_1, r_2, \dots]$ representing the row exchanges of A in the pivoting steps, i.e., $B = PA = LU$, where $b_{ij} = a_{r_i, j}$.

A floating-point approximation of the decomposition is computed using `numeric::factorLU`, if the matrix A is defined over the component ring `Dom::Float`. In this case it is recommended to call `numeric::factorLU` directly for a better efficiency.

The algorithm also works for singular A . In this case either L or U is singular.

L and U are nonsingular if and only if A is nonsingular.

The component ring of the matrix A must be a field, i.e., a domain of category `Cat::Field`.

Examples **Example 1**

We compute an LU-decomposition of the real matrix:

```
A := Dom::Matrix(Dom::Real)(
  [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
)
```

linalg::factorLU

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

`[L, U, pivlist] := linalg::factorLU(A)`

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3] \right]$$

The lower triangular matrix L is the first element and the upper triangular matrix U is the second element of the list LU. The product of these two matrices is equal to the input matrix A:

`L * U`

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

Example 2

An LU-decomposition of the 3×2 matrix:

`A := Dom::Matrix(Dom::Real)([[2, -3], [1, 2], [2, 3]])`

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

gives a 3×3 lower triangular matrix and a 3×2 upper triangular matrix:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\left(\begin{array}{ccc} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 1 & \frac{12}{7} & 1 \end{array} \right), \left(\begin{array}{cc} 2 & -3 \\ 0 & \frac{7}{2} \\ 0 & 0 \end{array} \right), [1, 2, 3] \right]$$

```
L * U
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

Example 3

To compute the LU-decomposition of the matrix:

```
A := matrix([[1, 2, -1], [0, 0, 3], [0, 2, -1]])
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

one row interchange is needed, and we therefore get a non-trivial permutation list:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\left(\begin{array}{ccc} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{array} \right), \left(\begin{array}{ccc} 1 & 2 & -1 \\ 0 & 2 & -1 \\ 0 & 0 & 3 \end{array} \right), [1, 3, 2] \right]$$

The corresponding permutation matrix is the following:

linalg::factorLU

```
P := linalg::swapRow(matrix::identity(3), 3, 2)
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

Hence, we have a decomposition of A into the product of the three matrices $\frac{1}{P}$, L and U as follows:

```
P^(-1) * L * U
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 0 & 0 & 3 \\ 0 & 2 & -1 \end{pmatrix}$$

Example 4

You may compute an LU-decomposition of a matrix with symbolic components, such as:

```
delete a, b, c, d:  
A := matrix([[a, b], [c, d]])
```

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

The diagonal entries of the matrix U are the pivot elements used during the computation. They must be non-zero, if the inverse of U is needed:

```
[L, U, pivlist] := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 \\ \frac{c}{a} & 1 \end{pmatrix}, \begin{pmatrix} a & b \\ 0 & d - \frac{bc}{a} \end{pmatrix}, [1, 2] \right]$$

For example, if we use this decomposition to solve the linear system $A \vec{x} = \vec{b}$ for arbitrary vectors $\vec{b} = (b_1, b_2)^t$, then the following result is only correct for $a \neq 0$ and $d - \frac{bc}{a} \neq 0$:

```
delete b1, b2:
linalg::matlinsolveLU(L, U, matrix([b1, b2]))
```

$$\begin{pmatrix} \frac{b_1 - \frac{b(a b_2 - b_1 c)}{a d - b c}}{a} \\ \frac{a b_2 - b_1 c}{a d - b c} \end{pmatrix}$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

List `[L, U, pivindex]` with the two matrices L and U of the domain `Dom::Matrix(R)` and a list `pivindex` of positive integers. R is the component ring of A .

Algorithms

The following algorithm for solving the system $A \vec{x} = \vec{b}$ with a nonsingular matrix A uses LU-decomposition:

1 Compute a LU-decomposition of A : $A = LU$.

2 Solve $\vec{y} = \frac{\vec{b}}{L}$ by forward substitution.

3 Solve $\vec{x} = \frac{\vec{y}}{R}$ by backward substitution.

The LU-decomposition of a matrix A is useful for solving several systems of linear equations $A \vec{x} = \vec{b}$ with the same coefficient matrix

linalg::factorLU

A and several right-hand side vectors \vec{b} , because then step one of the algorithm above needs to be done only once.

| `linalg::matlinsolveLU` | `lllint` | `numeric::factorLU`

Related Examples

- “Compute LU Factorization”

Purpose QR-decomposition of a matrix

Syntax `linalg::factorQR(A)`

Description `linalg::factorQR(A)` computes an QR-decomposition of an $m \times n$ matrix A , i.e., a decomposition of A into an $m \times m$ unitary matrix Q and an $m \times n$ upper triangular matrix R such that $QR = A$.

`linalg::factorQR` uses Gram-Schmidt orthonormalization to compute the decomposition.

For a singular or non-square matrix A the QR-decomposition of A is not unique.

The columns of Q form an orthonormal basis with respect to the scalar product of two vectors, defined by `linalg::scalarProduct`, and the 2-norm of two vectors (see the method "norm" of the domain constructor `Dom::Matrix`).

If the component ring of A does not define the method "conjugate", then the factor Q is orthogonal instead of unitary.

If the columns of A cannot be orthonormalized then FAIL is returned.

If A is a matrix over the domain `Dom::Float` and the computations are based on the standard scalar product, then the use of the corresponding function from the numeric library (`numeric::factorQR`) is recommended.

Even if A is defined over the real or the complex numbers the call of `numeric::factorQR` with the option `Symbolic` is recommended for better efficiency.

The component ring of the matrix A must be a field, i.e., a domain of category `Cat::Field`.

Examples **Example 1**

We compute the QR-decomposition of a real matrix:

```
A := Dom::Matrix(Dom::Real)(
```

linalg::factorQR

```
) [[2, -3, -1], [1, 1, -1], [0, 1, -1]]
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
QR := linalg::factorQR(A)
```

$$\left[\begin{pmatrix} \frac{2\sqrt{5}}{5} & -\frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{30} \\ \frac{\sqrt{5}}{5} & \frac{\sqrt{6}}{3} & \frac{\sqrt{2}\sqrt{15}}{15} \\ 0 & \frac{\sqrt{6}}{6} & -\frac{\sqrt{2}\sqrt{15}}{6} \end{pmatrix}, \begin{pmatrix} \sqrt{5} & -\sqrt{5} & -\frac{3\sqrt{5}}{5} \\ 0 & \sqrt{6} & -\frac{\sqrt{6}}{3} \\ 0 & 0 & \frac{2\sqrt{2}\sqrt{15}}{15} \end{pmatrix} \right]$$

The orthogonal matrix Q is the first element und the upper triangular matrix R is the second element of the list QR . The product of these two matrices is equal to the input matrix A :

```
QR[1] * QR[2]
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

Example 2

The QR-decomposition of the 3×2 matrix:

```
B := Dom::Matrix(Dom::Real)(  
  [[2, -3], [1, 2], [2, 3]]  
)
```

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

yields a 3×3 orthogonal matrix and a 3×2 upper triangular matrix:

`QR := linalg::factorQR(B)`

$$\left[\begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix} \right]$$

`QR[1] * QR[2]`

$$\begin{pmatrix} 2 & -3 \\ 1 & 2 \\ 2 & 3 \end{pmatrix}$$

For this example we may call `numeric::factorQR(B, Symbolic)` instead, which in general is faster than `linalg::factorQR`:

`QR := numeric::factorQR(B, Symbolic)`

$$\left[\begin{pmatrix} \frac{2}{3} & -\frac{31\sqrt{194}}{582} & \frac{\sqrt{194}}{194} \\ \frac{1}{3} & \frac{8\sqrt{194}}{291} & \frac{6\sqrt{194}}{97} \\ \frac{2}{3} & \frac{23\sqrt{194}}{582} & -\frac{7\sqrt{194}}{194} \end{pmatrix}, \begin{pmatrix} 3 & \frac{2}{3} \\ 0 & \frac{\sqrt{194}}{3} \\ 0 & 0 \end{pmatrix} \right]$$

linalg::factorQR

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

List [Q, R] of the two matrices Q and R (of the same domain type as A), or the value FAIL.

Algorithms

The QR-decomposition can be used to generate a least square solution to an overdetermined system of linear equations. If $A \vec{x} = \vec{b}$, then $R \vec{x} = Q^t \vec{b}$ can be solved via backward substitution.

Related Examples

- “Compute QR Factorization”

Purpose Frobenius form of a matrix

Syntax `linalg::frobeniusForm(A, <All>)`

Description `linalg::frobeniusForm(A)` returns the Frobenius form of the matrix A , also called the Rational Canonical form of A .

`linalg::frobeniusForm(A, All)` computes the Frobenius form R of A and a transformation matrix P such that PRP^{-1} .

The Frobenius form as computed by `linalg::frobeniusForm` is unique (see below).

The component ring of A must be a field, i.e., a domain of category `Cat::Field`.

Examples **Example 1**

The Frobenius form of the following matrix over :

```
A := Dom::Matrix(Dom::Complex)(  
  [[1, 2, 3], [4, 5, 6], [7, 8, 9]]  
)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

is the matrix:

```
R := linalg::frobeniusForm(A)
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 18 \\ 0 & 1 & 15 \end{pmatrix}$$

The transformation matrix P can be selected from the list `[R, P]`, which is the result of `linalg::frobeniusForm` with option `All`:

linalg::frobeniusForm

```
P := linalg::frobeniusForm(A, All)[2]
```

$$\begin{pmatrix} 1 & 1 & 30 \\ 0 & 4 & 66 \\ 0 & 7 & 102 \end{pmatrix}$$

We check the result:

```
P * R * P^(-1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Options

All

Returns the list $[R, P]$ with the Frobenius form R of A and a transformation matrix P such that $A = PRP^{-1}$.

Return Values

Matrix of the same domain type as A , or the list $[R, P]$ when the option `All` is given.

Algorithms

The Frobenius form of a square matrix A is the matrix

$$R = \begin{pmatrix} R_1 & & & \\ & \ddots & & \\ & & \ddots & \\ & & & R_r \end{pmatrix},$$

where R_1, \dots, R_r are known as companion matrices and have the form:

$$R_i = \begin{pmatrix} 0 & \dots & 0 & -a_0 \\ 1 & & & -a_1 \\ & \ddots & & \vdots \\ & & \ddots & \vdots \\ & & & -0 & \vdots \\ & & & & 1 & -a_{n_i-1} \end{pmatrix}, i = 1, \dots, r$$

In the last column of the companion matrix R_i , you see the coefficients of its minimal polynomial in ascending order, i.e., the polynomial $m_i := X^{n_i} + a_{n_i-1}X^{n_i-1} + \dots + a_1X + a_0$ is the minimal polynomial of the matrix R_i .

For these polynomials the following holds: m_{i+1} divides m_i for $i = 1, \dots, r - 1$, and the product of all m_i for $i = 1, \dots, r$ gives a factorization of the characteristic polynomial of the matrix A . The Frobenius form defined in this way is unique.

MuPAD Functions

`linalg::jordanForm` | `linalg::hermiteForm` | `linalg::smithForm`
| `linalg::minpoly`

linalg::gaussElim

Purpose Gaussian elimination

Syntax `linalg::gaussElim(A, <All>)`

Description `linalg::gaussElim(A)` performs Gaussian elimination on the matrix A to reduce A to a similar matrix in upper row echelon form.

A row echelon form of A returned by `linalg::gaussElim` is not unique. See `linalg::gaussJordan` for computing the *reduced* row echelon form.

The component ring R of A must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If R is a field, i.e., a domain of category `Cat::Field`, ordinary Gaussian elimination is used. Otherwise, `linalg::gaussElim` applies fraction-free Gaussian elimination to A .

`linalg::gaussElim` serves as an interface function for the method "gaussElim" of the matrix domain of A , i.e., one may call `A::dom::gaussElim(A)` directly instead of `linalg::gaussElim(A, All)`

Refer to the help page of `Dom::Matrix` for details about the computation strategy of `linalg::gaussElim`.

Examples

Example 1

We apply Gaussian elimination to the following matrix:

```
A := Dom::Matrix(Dom::Rational)(  
  [[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]]  
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

which reduces A to the following row echelon form:

```
linalg::gaussElim(A)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 0 & 2 & 4 & 4 \\ 0 & 0 & -1 & -1 \end{pmatrix}$$

Example 2

We apply Gaussian elimination to the matrix:

```
B := Dom::Matrix(Dom::Integer)(
  [[1, 2, -1], [1, 0, 1], [2, -1, 4]]
)
```

$$\begin{pmatrix} 1 & 2 & -1 \\ 1 & 0 & 1 \\ 2 & -1 & 4 \end{pmatrix}$$

and get the following result:

```
linalg::gaussElim(B, All)
```

$$\left[\begin{pmatrix} 1 & 2 & -1 \\ 0 & -2 & 2 \\ 0 & 0 & -2 \end{pmatrix}, 3, -2, \{1, 2, 3\} \right]$$

We see that $\text{rank}(B) = 3$ and $\det B = -2$.

Parameters

A

A matrix of a domain of category `Cat::Matrix`

linalg::gaussElim

Options

All

Returns a list $[T, \text{rank}(A), \det A, \{j_1, \dots, j_r\}]$ where T is a row echelon form of A and $\{j_1, \dots, j_r\}$ is the set of characteristic column indices of T .

If A is not square, then the value FAIL is given instead of $\det A$.

Return Values

a matrix of the same domain type as A , or the list $[T, \text{rank}(A), \det(A), \{j_1, \dots, j_r\}]$ when the option All is given (see below).

Algorithms

Let $T = (t_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$ be an $m \times n$ matrix. Then T is a matrix in an upper row echelon form, if $r \in \{0, 1, \dots, n\}$ and indices $j_1, j_2, \dots, j_r \in \{1, \dots, n\}$ exist with:

1 $j_1 < j_2 < \dots < j_r$.

2 For each $i \in \{1, \dots, r\}$: $t_{i,1} = t_{i,2} = \dots = t_{i,j_i-1} = 0$.

3 For each $i \in \{r+1, \dots, m\}$: $t_{i,j} = 0$ for each $j \in \{1, \dots, n\}$.

The indices j_1, j_2, \dots, j_r are the *characteristic column indices* of the matrix T .

See Also

MuPAD Functions

`linalg::gaussJordan` | `linalg::llint`

Purpose Gauss-Jordan elimination

Syntax `linalg::gaussJordan(A, <All>)`

Description `linalg::gaussJordan(A)` performs Gauss-Jordan elimination on the matrix A , i.e., it returns the reduced row echelon form of A .

The component ring R of A must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

If R is a field, i.e., a domain of category `Cat::Field`, then the leading entries of the matrix T in reduced row echelon form are equal to one.

If R is a ring providing the method "gcd", then the components of each row of T do not have a non-trivial common divisor.

If the component ring of A is a field, then the reduced row echelon form is unique.

Examples **Example 1**

We apply Gauss-Jordan elimination to the following matrix:

```
A := Dom::Matrix(Dom::Rational)(  
  [[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]  
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -5 & 0 & 3 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

```
linalg::gaussJordan(A, All)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 & \frac{1}{2} \\ 0 & 1 & 0 & \frac{1}{2} \\ 0 & 0 & 1 & \frac{5}{6} \end{pmatrix}, 3, \text{FAIL}, \{1, 2, 3\} \right]$$

linalg::gaussJordan

We see that $\text{rank}(B) = 3$. Because the determinant of a matrix is only defined for square matrices, the third element of the returned list is the value FAIL.

Example 2

If we consider the matrix from “Example 1” on page 14-83 as an integer matrix and apply the Gauss-Jordan elimination we get the following matrix:

```
B := Dom::Matrix(Dom::Integer)(
  [[1, 2, 3, 4], [-5, 0, 3, 0], [3, 5, 6, 9]]
):
linalg::gaussJordan(B)
```

$$\begin{pmatrix} 2 & 0 & 0 & 1 \\ 0 & -2 & 0 & -1 \\ 0 & 0 & -6 & -5 \end{pmatrix}$$

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Options

All

Returns a list $[T, \text{rank}(A), \text{det } A, \{j_1, \dots, j_r\}]$ where T is the reduced row echelon form of A and $\{j_1, \dots, j_r\}$ is the set of characteristic column indices of T .

If A is not square, then the value FAIL is given instead of **det A**.

Return Values

a matrix of the same domain type as A , or the list $[T, \text{rank}(A), \text{det}(A), \{j_1, \text{dots}, j_r\}]$ when the option **All** is given (see below).

Algorithms

Let $T = (t_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$ be an $m \times n$ matrix. Then T is a matrix in *reduced row echelon form*, if $r \in \{0, 1, \dots, n\}$ and indices $j_1, j_2, \dots, j_r \in \{1, \dots, n\}$ exist with:

- 1** $j_1 < j_2 < \dots < j_r$.
- 2** For each $i \in \{1, \dots, r\}$: $t_{i,1} = t_{i,2} = \dots = t_{i,j_i-1} = 0$. In addition, if A is defined over a field: $t_{i,j_i} = 1$.
- 3** For each $i \in \{r+1, \dots, m\}$: $t_{i,j} = 0$ for each $j \in \{1, \dots, n\}$.
- 4** For each $i \in \{1, \dots, r\}$: $t_{k,j_i} = 0$ for each $k \in \{1, \dots, i-1\}$.

The indices j_1, j_2, \dots, j_r are the *characteristic column indices* of the matrix T .

MuPAD Functions

`linalg::gaussElim`

Related Examples

- “Compute Reduced Row Echelon Form”

linalg::gradient

Purpose Vector gradient

Note `linalg::gradient` will be removed in a future release. Use `gradient` instead.

Syntax
`linalg::gradient(f, x)`
`linalg::gradient(f, x, ogCoord, <c>)`

Description `linalg::gradient(f, x)` computes the vector gradient of the scalar function $f(\vec{x})$ with respect to \vec{x} in Cartesian coordinates. This is the

vector $\text{grad}(f) = \left(\frac{\partial}{\partial x_1} f, \dots, \frac{\partial}{\partial x_n} f \right)$.

`linalg::gradient`, `linalg::grad`, and `gradient` are equivalent. See details and examples on the `gradient` help page.

Parameters **f**

An arithmetical expression in the variables given in **x**

x

A list of identifiers or indexed identifiers

ogCoord

The name of a three-dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the scale factors of an orthogonal coordinate system.

c

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is `c = 1`.

Return Values

Column vector of the domain `Dom::Matrix()`.

linalg::grad

Purpose Vector gradient

Note `linalg::grad` will be removed in a future release. Use `gradient` instead.

Syntax `linalg::grad(f, x)`
`linalg::grad(f, x, ogCoord, <c>)`

Description `linalg::grad(f, x)` computes the vector gradient of the scalar function $f(\vec{x})$ with respect to \vec{x} in Cartesian coordinates. This is the vector $\text{grad}(f) = \left(\frac{\partial}{\partial x_1} f, \dots, \frac{\partial}{\partial x_n} f \right)$. `linalg::grad`, `linalg::gradient`, and `gradient` are equivalent. See details and examples on the `gradient` help page.

Parameters **f**
An arithmetical expression in the variables given in `x`

x
A list of (indexed) identifiers

ogCoord
The name of a three-dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the scale factors of an orthogonal coordinate system.

c
The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is `c = 1`.

Return Values

Column vector of the domain `Dom::Matrix()`.

linalg::hermiteForm

Purpose Hermite normal form of a matrix

Syntax `linalg::hermiteForm(A, <All>)`

Description `linalg::hermiteForm(A)` computes the Hermite normal form of a non-singular integer square matrix A . This is an upper-triangular matrix H such that $H_{jj} \geq 0$ and $-\frac{H_{ij}}{H_{jj}} < H_{ij} \leq \frac{H_{ij}}{H_{jj}}$ for $j > i$. In the case, A is not a square matrix or a singular matrix, the matrix H is simply an upper-triangular matrix.

If the matrix A is not of the domain `Dom::Matrix(Dom::Integer)` then A is converted into a matrix of this domain for intermediate computations.

If this conversion fails, then an error message is returned.

`linalg::hermiteForm(A, All)` computes a transformation matrix U and a matrix H such that $H = UA$.

Examples

Example 1

We compute the Hermite normal form of the matrix:

```
A := Dom::Matrix(Dom::Rational)(  
  [[9, -36, 30], [-36, 192, -180], [30, -180, 180]]  
)
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

```
linalg::hermiteForm(A)
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

We may also compute the transformation matrix by giving the option `All`:

```
linalg::hermiteForm(A, All)
```

$$\left[\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}, \begin{pmatrix} 13 & 9 & 7 \\ 6 & 4 & 3 \\ 20 & 15 & 12 \end{pmatrix} \right]$$

Let us check the result:

```
U := linalg::hermiteForm(A, All)[2]:
```

```
U * A
```

$$\begin{pmatrix} 3 & 0 & 30 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

Parameters

A

An integer matrix of category `Cat::Matrix`

Options

All

Returns the list `[H, U]` with the hermite normal form H of A and the corresponding transformation matrix U

Return Values

Either a matrix of the same domain type as A or the list `[H, U]` when the option `All` is given.

Algorithms

Let A be an $n \times n$ matrix with coefficients in \mathbb{Z} . Then there exists an $n \times n$ matrix $H = (h_{ij})$ in Hermite normal form such that $H = AU$ with $|U| = \pm 1$.

linalg::hermiteForm

Note that H is unique, if A has full row rank. The matrix U is not unique. U may be computed by using the option `All`.

If A is a square matrix, then the product of the diagonal elements of its Hermite normal form is, up to the sign, the determinant of A .

MuPAD Functions

`linalg::frobeniusForm` | `linalg::jordanForm` | `linalg::smithForm`
| `lllint`

Purpose Hessenberg matrix

Syntax `linalg::hessenberg(A, <All>)`

Description `linalg::hessenberg(A)` returns an (upper) Hessenberg matrix H .
`linalg::hessenberg` uses Gaussian elimination without pivoting. There is no special implementation for matrices with floating-point components.

The component ring of A must be a field, i.e., a domain of category `Cat::Field`.

Examples **Example 1**

Consider the matrix:

```
A := Dom::Matrix(Dom::Rational)(
  [[0, 1, 0, -1], [-4/3, 2/3, 5/3, -1/3],
   [-1, 2, 0, 0], [-5/3, 4/3, 1/3, 1/3]]
)
```

$$\begin{pmatrix} 0 & 1 & 0 & -1 \\ -\frac{4}{3} & \frac{2}{3} & \frac{5}{3} & -\frac{1}{3} \\ -1 & 2 & 0 & 0 \\ -\frac{5}{3} & \frac{4}{3} & \frac{1}{3} & \frac{1}{3} \end{pmatrix}$$

The following Hessenberg matrix is similar to A :

```
H := linalg::hessenberg(A)
```

linalg::hessenberg

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

If the corresponding transformation matrix is needed as well, call `linalg::hessenberg` with option `All`:

```
[H, P] := linalg::hessenberg(A, All)
```

$$\left[\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & -\frac{3}{4} & 1 & 0 \\ 0 & -\frac{8}{7} & -\frac{1}{7} & 1 \end{pmatrix} \right]$$

Then P is a nonsingular matrix such that the product PAP^{-1} is equal to H :

```
P * A * P^(-1)
```

$$\begin{pmatrix} 0 & -\frac{1}{4} & -\frac{1}{7} & -1 \\ -\frac{4}{3} & \frac{3}{2} & \frac{34}{21} & -\frac{1}{3} \\ 0 & \frac{7}{8} & -\frac{17}{14} & \frac{1}{4} \\ 0 & 0 & -\frac{72}{49} & \frac{5}{7} \end{pmatrix}$$

Parameters	A A square matrix of a domain of category <code>Cat::Matrix</code>
Options	All Returns the list [H, P] with a Hessenberg matrix H similar to A and the corresponding nonsingular transformation matrix P such that $H = PAP^{-1}$.
Return Values	Matrix of the same domain type as A , or the list [H, P] when the option <code>All</code> is given.
Algorithms	An $n \times n$ matrix $A = (a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$ is called an (upper) <i>Hessenberg matrix</i> , if the following holds: $a_{i,j} = 0$ for all $i, j \in \{1, \dots, n\}$ with $i > j$. For each square matrix A over a field there exists a Hessenberg matrix similar to A . In general, the upper Hessenberg matrix is not unique.

MuPAD Functions	<code>linalg::charpoly</code>

linalg::hessian

Purpose Hessian matrix of a scalar function

Note `linalg::hessian` will be removed in a future release. Use `hessian` instead.

Syntax `linalg::hessian(f, x)`

Description `linalg::hessian(f, x)` computes the Hesse matrix (the Hessian) of the scalar function $f(\vec{x})$ in Cartesian coordinates, i.e., the square matrix of second partial derivatives of $f(\vec{x})$.

`hessian` and `linalg::hessian` are equivalent. See details and examples on the `hessian` help page.

Parameters **f**
An arithmetical expression (the scalar function)

x
A list of (indexed) identifiers

Return Values Matrix of the domain `Dom::Matrix()`.

Purpose Hilbert matrix

Syntax `linalg::hilbert(n, <R>)`

Description `linalg::hilbert(n)` returns the $n \times n$ Hilbert matrix $H = (h_{i,j})_{1 \leq i \leq$

$m, 1 \leq j \leq n$ defined by $h_{i,j} = \frac{1}{(i+j-1)}$.

The entries of Hilbert matrices are rational numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Rational`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::hilbert(n, Dom::Rational)` to define the $n \times n$ Hilbert matrix over the field of rational numbers.

Examples **Example 1**

We construct the 3×3 Hilbert matrix:

```
H := linalg::hilbert(3)
```

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the Hilbert matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

linalg::hilbert

```
H := linalg::hilbert(3, Dom::Float)
```

```
( 1.0      0.5      0.3333333333
  0.5      0.3333333333  0.25
  0.3333333333  0.25      0.2 )
```

```
domtype( H )
```

```
Dom::Matrix(Dom::Float)
```

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Hilbert matrices are symmetric and positive definite.

Hilbert matrices of large dimension are notoriously ill-conditioned challenging any numerical inversion scheme. However, their inverse can also be computed by a closed formula (see `linalg::invhilbert`).

linalg::invhilbert | linalg::invpascal |
linalg::invvandermonde | linalg::pascal | linalg::toeplitz
| linalg::toeplitzSolve | linalg::vandermonde |
linalg::vandermondeSolve
```

Purpose Hermitian transpose of a matrix

Syntax `linalg::htranspose(M)`

Description `linalg::htranspose(M)` computes the Hermitian transpose of the matrix M .

The Hermitian transpose of M is computed. The result is an $n \times m$ matrix.

The $[i, j]$ th element of the result is equal to the conjugate of the $[j, i]$ th element of M .

Examples **Example 1**

We define a 3×4 matrix:

```
A := matrix([[1, 2, 3, 4], [-I, 0, 1+I, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -i & 0 & 1+i & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the Hermitian transpose of A is the 4×3 matrix:

```
linalg::htranspose(A)
```

$$\begin{pmatrix} 1 & i & 3 \\ 2 & 0 & 5 \\ 3 & 1-i & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

Parameters **M**

$m \times n$ matrix of domain `Dom::Matrix`

linalg:htranspose

Return Values $n \times m$ matrix of domain `Dom::Matrix`.

Overloaded By `M`

Algorithms Let $A = (a_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$ be an $m \times n$ matrix. Then the Hermitian transpose of A is the $n \times m$ matrix:

$$A^t = \begin{pmatrix} \overline{a_{1,1}} & \overline{a_{1,2}} & \cdots & \overline{a_{m,1}} \\ \overline{a_{1,2}} & \overline{a_{2,2}} & \cdots & \overline{a_{m,2}} \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ \overline{a_{1,n}} & \overline{a_{1,n}} & \cdots & \overline{a_{m,n}} \end{pmatrix}$$

See Also

MuPAD Functions `conjugate` | `linalg::transpose`

Purpose

Basis for the intersection of vector spaces

Syntax

`linalg::intBasis(S1, S2, ...)`

Description

`linalg::intBasis(S1, S2, ...)` returns a basis for the intersection of the vector spaces spanned by the vectors in S₁, S₂, ...

The domain type of the vectors of the returned set is the domain type of the first parameter S₁.

A basis for the zero-dimensional space is the empty set or empty list, respectively.

The given vectors must be defined over the same component ring which must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We define three vectors $\vec{v}_1, \vec{v}_2, \vec{v}_3$ in \mathbb{R}^2 :

```
MatQ := Dom::Matrix(Dom::Rational):
```

```
v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])
```

$$\begin{pmatrix} 3 & -2 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 \end{pmatrix}$$

$$\begin{pmatrix} 5 & -3 \end{pmatrix}$$

A basis for the vector space $V_1 \cap V_2 \cap V_3$ with

- V_1 generated by $\vec{v}_1, \vec{v}_2, \vec{v}_3$
- V_2 generated by \vec{v}_1, \vec{v}_3
- V_3 generated by $\vec{v}_1 + \vec{v}_2, \vec{v}_2, \vec{v}_1 + \vec{v}_3$

linalg::intBasis

is:

```
linalg::intBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])  
[(4 -2), (1 0)]
```

Example 2

The intersection of the two vector spaces spanned by the vectors in S_1 and S_2 , respectively:

```
S1 := {matrix([[1, 0, 1, 0]]), matrix([[0, 1, 0, 1]])};  
S2 := {matrix([[1, 2, 1, 1]]), matrix([[ -1, -2, 1, 0]])}  
  
{(0 1 0 1), (1 0 1 0)}  
  
{(-1 -2 1 0), (1 2 1 1)}
```

is the zero-dimensional space:

```
linalg::intBasis(S1, S2)  
  
∅
```

Parameters

S_1, S_2, \dots

Either sets or lists of n -dimensional vectors (a vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

Return Values

Set or a list of vectors, according to the domain type of the parameter S_1 .

MuPAD Functions

`linalg::basis` | `linalg::sumBasis`

linalg::inverseLU

Purpose Computing the inverse of a matrix using LU-decomposition

Syntax `linalg::inverseLU(A)`
`linalg::inverseLU(L, U, pivindex)`

Description `linalg::inverseLU(A)` computes the inverse $\frac{1}{A}$ of the square matrix A using LU-decomposition.

`linalg::inverseLU(L, U, pivindex)` computes the inverse of the matrix $A = P^{-1}LU$ where L , U and pivindex are the result of an LU-decomposition of the (nonsingular) Matrix A , as computed by `linalg::factorLU`.

The matrix A must be nonsingular.

`pivindex` is a list $[r[1], r[2], \dots]$ representing a permutation matrix P such that $B = PA = LU$, where $b_{ij} = a_{r_i, j}$.

It is not checked whether `pivindex` has such a form.

The component ring of the input matrices must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We compute the inverse of the matrix:

```
A := Dom::Matrix(Dom::Real)(  
  [[2, -3, -1], [1, 1, -1], [0, 1, -1]]  
)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

using LU-decomposition:

```
Ai := linalg::inverseLU(A)
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

We check the result:

`A * Ai, Ai * A`

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We can also compute the inverse of A in the usual way:

`1/A`

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

`linalg::inverseLU` should be used for efficiency reasons in the case where an LU decomposition of a matrix already is computed, as the next example illustrates.

Example 2

If we already have an LU decomposition of a (nonsingular) matrix, we can compute the inverse of the matrix $A = P^{-1}LU$ as follows:

`LU := linalg::factorLU(linalg::hilbert(3))`

`linalg::inverseLU`

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} \\ 0 & \frac{1}{12} & \frac{1}{12} \\ 0 & 0 & \frac{1}{180} \end{pmatrix}, [1, 2, 3] \right]$$

`linalg::inverseLU(op(LU))`

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

`linalg::inverseLU` then only needs to perform forward and backward substitution to compute the inverse matrix (see also `linalg::matlinsolveLU`).

Parameters

A, L, U

A square matrix of a domain of category `Cat::Matrix`

pivindex

A list of positive integers

Return Values

Matrix of the same domain type as A or L, respectively.

See Also

MuPAD Functions

`_invert` | `linalg::factorLU` | `linalg::matlinsolveLU`

Purpose Inverse of a Hilbert matrix

Syntax `linalg::invhilbert(n, <R>)`

Description `linalg::invhilbert(n)` returns the inverse of the $n \times n$ Hilbert matrix H . The $n \times n$ Hilbert matrix $H = (h_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$ is defined by

$$h_{i,j} = \frac{1}{(i+j-1)}.$$

`linalg::invhilbert` uses an explicit formula for the inverse.

Note that the entries of the inverse of a Hilbert matrix are integers. But the returned matrix is defined over the standard component domain `Dom::ExpressionField()` so that no conversion is necessary when working with other functions that expect or return matrices over that component domain.

`linalg::invhilbert(n, Dom::Integer)` returns the inverse of the $n \times n$ Hilbert matrix defined over the integers.

Examples **Example 1**

We compute the inverse of the 3×3 Hilbert matrix:

```
A := linalg::invhilbert(3)
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted into the desired domain afterwards (see `coerce`, for example).

Alternatively, one can specify the component ring when calling `linalg::invhilbert`, for example the domain `Dom::Float`:

```
A := linalg::invhilbert(3, Dom::Float)
```

linalg::invhilbert

$$\begin{pmatrix} 9.0 & -36.0 & 30.0 \\ -36.0 & 192.0 & -180.0 \\ 30.0 & -180.0 & 180.0 \end{pmatrix}$$

`domtype(A)`

`Dom::Matrix(Dom::Float)`

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Hilbert matrices of large dimension are notoriously ill-conditioned, challenging any numerical inversion scheme.

`linalg::invhilbert` uses the formula

$$\left(\frac{1}{H}\right)_{i,j} = \frac{(-1)^{i+j} (c_i c_j)}{i+j-1}$$

where

$$c_i = \frac{(n+i-1)!}{(n-i)! ((i-1)!)^2}$$

for the inverse of the $n \times n$ Hilbert matrix H . All entries of $\frac{1}{H}$ are integers.

`linalg::vandermonde` | `linalg::vandermondeSolve`

linalg::invpascal

Purpose Inverse of a Pascal matrix

Syntax `linalg::invpascal(n, <R>)`

Description `linalg::invpascal(n)` returns the inverse of the $n \times n$ Pascal matrix. The entries of inverse Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Integer`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

The runtime to compute the inverse $n \times n$ Pascal matrix via `linalg::invpascal` is $O(n^2)$. This is much faster than inverting the Pascal matrix by a generic inversion algorithm.

The Pascal matrices are provided by `linalg::pascal`.

Examples

Example 1

We construct the inverse 3×3 Pascal matrix:

```
linalg::invpascal(3)
```

$$\begin{pmatrix} 3 & -3 & 1 \\ -3 & 5 & -2 \\ 1 & -2 & 1 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the inverse Pascal matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
linalg::invpascal(3, Dom::Float)
```

$$\begin{pmatrix} 3.0 & -3.0 & 1.0 \\ -3.0 & 5.0 & -2.0 \\ 1.0 & -2.0 & 1.0 \end{pmatrix}$$

`domtype(%)`

`Dom::Matrix(Dom::Float)`

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Pascal matrices and their inverses are symmetric and positive definite.

The determinant of a Pascal matrix and its inverse is 1.

The inverse of a Pascal matrix has integer entries.

If λ is an eigenvalue of a Pascal matrix/inverse Pascal matrix, then $\frac{1}{\lambda}$ is also an eigenvalue of the matrix.

The entries Q_{ij} of the inverse $n \times n$ Pascal matrix Q satisfy the linear relation

$$Q_{i,j} = Q_{i,j+1} + Q_{i+1,j} + (-1)^{i+j} \binom{n}{i} \binom{n}{j}.$$

This relation is used by `linalg::invpascal` to compute the matrix.

linalg::invpascal

`linalg::vandermonde` | `linalg::vandermondeSolve`

Purpose Checks whether a matrix is Hermitian

Syntax `linalg::isHermitian(A)`

Description `linalg::isHermitian(A)` determines whether the matrix A is Hermitian, i.e., whether $A = \overline{A}^t$, where \overline{A} denotes the conjugate matrix. If the component ring of the matrix A does not provide the method "conjugate", then A is tested for symmetry, i.e., `linalg::isHermitian` returns `TRUE` if and only if A satisfies the equation $A = A^t$.

Examples **Example 1**

Here is an example of a Hermitian matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, I], [-I, 1]])
```

$$\begin{pmatrix} 1 & i \\ -i & 1 \end{pmatrix}$$

```
linalg::isHermitian(A)
```

```
TRUE
```

The following matrix is not Hermitian:

```
B := Dom::Matrix(Dom::Complex)([[1, -I], [-I, 1]])
```

$$\begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

```
linalg::isHermitian(B)
```

```
FALSE
```

linalg::isHermitian

The reason is the following:

```
linalg::transpose(conjugate(B)) <> B
```

$$\begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \neq \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix}$$

Example 2

Here is an example of a symmetric matrix over the integers:

```
C := Dom::Matrix(Dom::Integer)([[1, 2], [2, -1]])
```

$$\begin{pmatrix} 1 & 2 \\ 2 & -1 \end{pmatrix}$$

```
linalg::isHermitian(C)
```

```
TRUE
```

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Either TRUE or FALSE.

See Also

MuPAD Functions

`linalg::isPosDef`

Purpose Test a matrix for positive definiteness

Syntax `linalg::isPosDef(A)`

Description `linalg::isPosDef(A)` checks whether the matrix A is positive definite, so that $\vec{x}^t A \vec{x} > 0$ for arbitrary vectors $\vec{x} \neq \vec{0}$.

The component ring of A must be a field, i.e., a domain of category `Cat::Field`.

An error message is returned, if a result of an intermediate computation cannot be checked for being positive (which could happen, for example, if components of A are symbolic).

Environment Interactions Properties of identifiers are taken into account.

Examples **Example 1**

Here is an example of a positive definite matrix:

```
MatR := Dom::Matrix( Dom::Real ):  
A := MatR([[14, 6, 9], [6, 17, -4], [9, -4, 13]])
```

$$\begin{pmatrix} 14 & 6 & 9 \\ 6 & 17 & -4 \\ 9 & -4 & 13 \end{pmatrix}$$

```
linalg::isPosDef(A)
```

```
TRUE
```

The following matrix is not positive definite:

```
B := MatR([[1, 2, 3], [2, 3, 4], [5, 6, 7]])
```

linalg::isPosDef

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 3 & 4 \\ 5 & 6 & 7 \end{pmatrix}$$

```
linalg::isPosDef(B)
```

```
FALSE
```

Example 2

`linalg::isPosDef` in general does not work for matrices with symbolic entries. It may respond with an error message (because the system in general cannot decide whether a symbolic component is positive), such as for the following matrix:

```
delete a, b:  
C := matrix([[a, b], [b, a]])
```

$$\begin{pmatrix} a & b \\ b & a \end{pmatrix}$$

```
linalg::isPosDef(C)
```

```
Error: Cannot check whether the matrix component is positive. [linalg::isPosDef]
```

However, properties of identifiers are taken into account, so that, for example, `linalg::isPosDef` is able to perform the test correctly for the following matrix:

```
assume(a > 1): C := matrix([[a, 1], [1, a]]):
```

```
linalg::isPosDef(C)
```

```
TRUE
```

Note that such computations depend on the power of the underlying property mechanism implemented in the property library.

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Either TRUE or FALSE.

See Also

MuPAD Functions

`linalg::factorCholesky` | `linalg::isHermitian`

linalg::isUnitary

Purpose Test whether a matrix is unitary

Syntax `linalg::isUnitary(A)`

Description `linalg::isUnitary` tests whether the matrix A is a unitary matrix. An $n \times n$ matrix A is unitary, if $A \overline{A}^t = I_n$, where I_n is the $n \times n$ identity matrix.

The square matrix A is a unitary matrix, if and only if the columns of A form an orthonormal basis with respect to the scalar product `linalg::scalarProduct` of two vectors.

The correctness of the result `FALSE` of `linalg::isUnitary` can only be guaranteed if the elements of the component ring R of the matrix A are canonically represented, i.e., if each element of R has only one unique representation.

The axiom `Ax::canonicalRep` states that a domain has this property. Hence, `linalg::isUnitary` returns `FALSE` or `UNKNOWN`, respectively, depending on whether the component ring of A has the axiom `Ax::canonicalRep`.

If the component ring of A does not define the method "conjugate" then it is checked whether A is an orthogonal matrix such that $AA^t = E_n$, where E_n is the $n \times n$ identity matrix.

Examples

Example 1

The following matrix is unitary:

```
A := 1/sqrt(5) * matrix([[1, 2], [2, -1]])
```

$$\begin{pmatrix} \frac{\sqrt{5}}{5} & \frac{2\sqrt{5}}{5} \\ \frac{2\sqrt{5}}{5} & -\frac{\sqrt{5}}{5} \end{pmatrix}$$

```
linalg::isUnitary(A)
```

`TRUE`

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Either `TRUE`, `FALSE`, or `UNKNOWN`.

See Also

MuPAD Functions

`linalg::orthog` | `linalg::scalarProduct`

linalg::jacobian

Purpose Jacobian matrix of a vector function

Note `linalg::jacobian` will be removed in a future release. Use `jacobian` instead.

Syntax `linalg::jacobian(v, x)`

Description `linalg::jacobian(v, x)` computes the Jacobian matrix of the vector function \vec{v} with respect to \vec{x} .

`jacobian` and `linalg::jacobian` are equivalent. See details and examples on the `jacobian` help page.

Parameters **v**

A list of arithmetical expressions, or a vector (i.e., an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

x

A list of (indexed) identifiers

Return Values

Matrix of the domain `Dom::Matrix(R)`, where `R` is the component ring of `v` or the domain `Dom::ExpressionField()`.

Purpose Jordan normal form of a matrix

Syntax `linalg::jordanForm(A, <All>)`

Description `linalg::jordanForm(A)` returns the Jordan normal form J of the matrix A .

`linalg::jordanForm` computes a nonsingular transformation matrix P and a matrix J such that $A = PJP^{-1}$ with $J = \text{diag}(J_1, \dots, J_r)$ and Jordan matrices J_1, \dots, J_r .

The Jordan normal form of a square matrix A over a field F exists if the characteristic polynomial of A splits over F into linear factors. If this is not the case for the matrix A , then `linalg::jordanForm` returns FAIL.

The Jordan normal form is unique up to permutations of the Jordan matrices J_1, \dots, J_r .

The implemented method computes the eigenvalues of A . It returns FAIL if this is not possible (see `linalg::eigenvalues`).

The component ring of A must be a field, i.e., a domain of category `Cat::Field`.

Examples **Example 1**

The Jordan normal form of the matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, 2], [4, 5]])
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

is the following matrix:

```
J := linalg::jordanForm(A)
```

linalg::jordanForm

$$\begin{pmatrix} -2\sqrt{3}+3 & 0 \\ 0 & 2\sqrt{3}+3 \end{pmatrix}$$

The corresponding transformation matrix P can be obtained from the result $[J, P]$ of `linalg::jordanForm` with the option `All`:

```
P := linalg::jordanForm(A, All)[2]
```

$$\begin{pmatrix} -\frac{\sqrt{3}}{2} - \frac{1}{2} & \frac{\sqrt{3}}{2} - \frac{1}{2} \\ 1 & 1 \end{pmatrix}$$

We check the result:

```
map(P * J * P^(-1), radsimp)
```

$$\begin{pmatrix} 1 & 2 \\ 4 & 5 \end{pmatrix}$$

To get this result we must apply the function `radsimp` to each component of the matrix that is returned by the matrix product PJP^{-1} .

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Options

All

Returns the list $[J, P]$ with the Jordan normal form J of A and the corresponding transformation matrix P such that $A = PJP^{-1}$.

Return Values

Either a matrix of the same domain type as A , the list $[J, P]$ when the option `All` is given, or the value `FAIL`.

`linalg::smithForm` | `linalg::hermiteForm`

linalg::kroneckerProduct

Purpose Kronecker product of matrices

Syntax `linalg::kroneckerProduct(A, <B, >)`

Description `linalg::kroneckerProduct(A, B)` computes the Kronecker product of two matrices A and B.

The Kronecker product (direct matrix product) of an $m \times n$ matrix A and a $p \times q$ matrix B is the $(mp) \times (nq)$ matrix $A \otimes B$ given in block form as

$$A \otimes B = \begin{pmatrix} a_{1,1} B & \dots & a_{1,n} B \\ \vdots & & \vdots \\ a_{m,1} B & \dots & a_{m,n} B \end{pmatrix}$$

Componentwise: $(A \otimes B)_{I,J} = a_{i,j} B_{k,l}$ with $I = p(i - 1) + k$, $J = q(j - 1) + l$.

If A and B are matrices of the same matrix domain with the same component ring, the result is a matrix of the same type as A and B. If the domains or the component rings of A and B differ, `linalg::kroneckerProduct` tries to convert B into the domain type of A by `A::dom::coerce`. If this fails, conversion of A to the domain type of B is attempted. If no conversion is possible, an error is raised.

Note Note that the Kronecker product is only implemented for matrices over the domains `Dom::Matrix`, `Dom::SquareMatrix` or `Dom::MatrixGroup`. In particular, this includes matrices created by `matrix`.

A call with more than two arguments produces
`linalg::kroneckerProduct(A, B, C) =`

`linalg::kroneckerProduct(linalg::kroneckerProduct(A, B), C)` etc.

A call with only one argument is possible. It returns the input matrix.

Examples

Example 1

We consider two matrices A and B with symbolic components:

```
A:= matrix([[a11, a12], [a21, a22]]);  
B:= matrix([[b11, b12, b13], [b21, b22, b23]]);
```

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

$$\begin{pmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \end{pmatrix}$$

The Kronecker product of A and B is computed by multiplying the matrix B with each of the components of the matrix A. The resulting block matrix is returned as a matrix of larger dimension:

```
linalg::kroneckerProduct(A, B);
```

$$\begin{pmatrix} a_{11} b_{11} & a_{11} b_{12} & a_{11} b_{13} & a_{12} b_{11} & a_{12} b_{12} & a_{12} b_{13} \\ a_{11} b_{21} & a_{11} b_{22} & a_{11} b_{23} & a_{12} b_{21} & a_{12} b_{22} & a_{12} b_{23} \\ a_{21} b_{11} & a_{21} b_{12} & a_{21} b_{13} & a_{22} b_{11} & a_{22} b_{12} & a_{22} b_{13} \\ a_{21} b_{21} & a_{21} b_{22} & a_{21} b_{23} & a_{22} b_{21} & a_{22} b_{22} & a_{22} b_{23} \end{pmatrix}$$

```
delete A, B;
```

Example 2

An $n \times n$ matrix H with components in $\{-1, 1\}$ is called a *Hadamard matrix* if H multiplied with its transpose equals n times the $n \times n$ identity matrix. The matrix H defined below is a Hadamard matrix:

linalg::kroneckerProduct

```
H:= matrix([[1, 1], [1, -1]]);  
H * linalg::transpose(H) = 2 * matrix::identity(2);
```

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} = \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix}$$

Hadamard matrices play a role in the field of error correcting codes. A basic property of this type of matrices is that the Kronecker product of two Hadamard matrices is again a Hadamard matrix. We verify this statement for the matrix H:

```
H2:= linalg::kroneckerProduct(H, H);
```

$$\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \end{pmatrix}$$

Indeed, the matrix H2 is a again a Hadamard matrix:

```
H2 * linalg::transpose(H2) = 4 * matrix::identity(4);
```

$$\begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{pmatrix} = \begin{pmatrix} 4 & 0 & 0 & 0 \\ 0 & 4 & 0 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 4 \end{pmatrix}$$

```
delete H, H2;
```

Parameters **A, B, ...**

Matrices of the domains `Dom::Matrix`, `Dom::SquareMatrix` or `Dom::MatrixGroup`

Return Values

Matrix of the same type as A or B.

linalg::laplacian

Purpose The Laplacian

Note `linalg::laplacian` will be removed in a future release. Use `laplacian` instead.

Syntax `linalg::laplacian(f, [x1, x2, ...])`
`linalg::laplacian(f, [x1, x2, ...], ogCoord, <c>)`

Description `linalg::laplacian(f, [x1, x2, ...])` computes the Laplacian

$\Delta f = \sum_i \frac{\partial^2}{\partial x_i^2} f$ of the function f .

`linalg::laplacian` and `laplacian` are equivalent. See details and examples on the `laplacian` help page.

Parameters **f**

An arithmetical expression in the variables x_1, x_2 etc.

x₁, x₂, ...

identifiers or indexed identifiers

ogCoord

The name of a three-dimensional orthogonal coordinate system predefined in the table `linalg::ogCoordTab`, or a list of algebraic expressions representing the scale factors of an orthogonal coordinate system.

c

The parameter of the coordinate systems `EllipticCylindrical` and `Torus`, respectively: an arithmetical expression. The default value is $c = 1$.

Return Values

Arithmetical expression.

Purpose Dimension of a matrix

Syntax `linalg::matdim(A)`

Description `linalg::matdim(A)` returns the dimension of the matrix A , i.e., the number of rows and columns of A .

`linalg::matdim` is an interface function for the method "matdim" of the matrix domain of A , i.e., instead of `linalg::matdim(A)` one may call `A::dom::matdim(A)` directly.

Examples **Example 1**

The dimension of the matrix:

```
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

can be determined by:

```
linalg::matdim(A)
```

```
[3, 4]
```

Parameters **A**

An $m \times n$ matrix of a domain of category `Cat::Matrix`

Return Values List $[m, n]$, where m is the number of rows and n is the number of columns of A .

linalg::matdim

- “Compute Dimensions of a Matrix”

Purpose

Solving systems of linear equations

Syntax

```
linalg::matlinsolve(A, b, <list>, options)
linalg::matlinsolve(A, B, options)
linalg::matlinsolve(A, options)
```

Description

`linalg::matlinsolve(A, b)` computes the general solution of the equation $A \vec{x} = \vec{b}$.

`linalg::matlinsolve(A, b)` returns the solution vector \vec{x} of the system $A \vec{x} = \vec{b}$ if it is a unique solution.

`linalg::matlinsolve(A, b)` returns a list $[\vec{w}, [\vec{v}_1, \dots, \vec{v}_r]]$ if the system $A \vec{x} = \vec{b}$ has more than one solution, where \vec{w} is one particular solution, i.e., $A \vec{w} = \vec{b}$ and $\vec{v}_1, \dots, \vec{v}_r$ form a basis of the kernel of A, i.e., the solution space of the homogenous system $A \vec{x} = \vec{0}$.

Each solution \vec{x} has the form $\vec{x}_s + s_1 \vec{v}_1 + \dots + s_r \vec{v}_r$ ($r \leq n$) with certain scalars s_1, \dots, s_r .

A list of n scalars $[s_1, \dots, s_n]$ may be passed as the additional

parameter list. This extracts the solution $\vec{x}_s + s_{i_1} \vec{v}_1 + \dots + s_{i_r} \vec{v}_r$ with $\{i_1, \dots, i_r\} = \{1, \dots, n\} \setminus \{j_1, \dots, j_l\}$ from the solution space of the system $A \vec{x} = \vec{b}$, where j_1, \dots, j_l are the characteristic column indices of A (see `linalg::gaussJordan`).

The entries of `list` are converted to elements of the component ring of A (an error message is returned if this is not possible).

linalg::matlinsolve

Note This option should only be used for exact and symbolic computations. In the case that A or b contains floating-point entries, it should not be used.

If the system $A \vec{x} = \vec{b}$ has no solution, then the empty list `[]` is returned.

`linalg::matlinsolve(A)` solves the matrix equation $C \vec{x} = \vec{b}$, where \vec{b} is the last column of A and C is A with the last column deleted.

`linalg::matlinsolve(A, B)` returns the solution X of the matrix equation $AX = B$, if it has exactly one solution. Otherwise the empty list `[]` is returned.

The vector b and the matrix B respectively, are converted into the domain `Dom::Matrix(R)`, where R is the component ring of A . Solution vectors also belong to this domain.

The component ring of A must be an integral domain, i.e., a domain of category `Cat::IntegralDomain`.

`linalg::matlinsolve` can compute the general solution for systems with more than one solution only over fields, i.e., component rings of category `Cat::Field`. If in this case the component ring of A does not have a canonical representation of the zero element, then it may happen that `linalg::matlinsolve` does not find a basis for the null space. In such a case, a wrong result is returned.

`linalg::matlinsolve` does exploit a sparse structure of A . (A matrix is *sparse* if it has many zero components). See “Example 5” on page 14-138.

Use the function `numeric::matlinsolve` to solve a linear system numerically.

Examples

Example 1

Solve the linear system:

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix} \vec{x} = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

over the reals. First, enter the coefficient matrix and the right side:

```
MatR := Dom::Matrix(Dom::Real):  
A := MatR([[1, 2], [-1, 2]]); b := MatR([1, -1])
```

$$\begin{pmatrix} 1 & 2 \\ -1 & 2 \end{pmatrix}$$

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:

```
x := linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

The system has exactly one solution. The vector x satisfies the matrix equation given above:

```
A * x
```

$$\begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

Example 2

The system:

linalg::matlinsolve

$$\begin{pmatrix} 1 & 2 \\ -1 & -2 \end{pmatrix} \vec{x} = (1)$$

does not have a solution over (in fact, over no component domain):

```
MatR := Dom::Matrix(Dom::Real):  
A := MatR([[1, 2], [-1, -2]]): b := MatR([1, 0]):  
linalg::matlinsolve(A, b)
```

□

Example 3

Solve the linear system:

$$\begin{pmatrix} 1 & 1 & -4 & -7 & -6 \\ 1 & 1 & -3 & -5 & -7 \end{pmatrix} \vec{x} = \begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

over the rational numbers. First, enter the coefficient matrix and the right side:

```
MatQ := Dom::Matrix(Dom::Rational):  
A := MatQ([[1, 1, -4, -7, -6], [0, 1, -3, -5, -7]]):  
b := MatQ([30, 17])
```

$$\begin{pmatrix} 1 & 1 & -4 & -7 & -6 \\ 0 & 1 & -3 & -5 & -7 \end{pmatrix}$$

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

Next, call `linalg::matlinsolve` to solve the system:

```
sol := linalg::matlinsolve(A, b)
```

$$\left[\begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 \\ 3 \\ 1 \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 2 \\ 5 \\ 0 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 7 \\ 0 \\ 0 \\ 1 \end{pmatrix} \right]$$

The result is to be interpreted as follows: The first vector of the list `sol` is a particular solution of the linear system:

$$A * \text{sol}[1]$$

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

The second entry of the list contains a basis for the null space of A , i.e., the solution space of the corresponding homogenous system $A \vec{x} = \vec{0}$ (the kernel of A). The basis returned is given as a list of vectors.

The following input checks this fact by computing the product $A \vec{x}$ for each vector \vec{x} of the list `sol[2]`:

$$\text{map}(\text{sol}[2], x \rightarrow A * x)$$

$$\left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right]$$

Any solution of the linear system can be represented as a sum of a particular solution (here: `sol[1]`) and a linear combination of the basis vectors of the kernel of A . Hence the input system has an infinite number of solutions.

For example, another solution of the system is given by:

$$x := \text{sol}[1] + 1 * \text{sol}[2][1] + 1/2 * \text{sol}[2][2] - 2 * \text{sol}[2][3]$$

linalg::matlinsolve

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

A * x

$$\begin{pmatrix} 30 \\ 17 \end{pmatrix}$$

If you identify the columns of the coefficient matrix A of the linear system with the variables x_1, x_2, x_3, x_4, x_5 , then you see from the general solution that the variables x_3, x_4, x_5 act as free parameters. They can be assigned arbitrary rational values to obtain a unique solution.

By giving a list of values for these variables as a third parameter to `linalg::matlinsolve`, you can select a certain vector from the set of all solutions of the linear system. For example, to select the same vector x as chosen in the previous input, enter:

```
linalg::matlinsolve(A, b, [0, 0, 1, 1/2, -2])
```

$$\begin{pmatrix} 17 \\ \frac{17}{2} \\ 1 \\ \frac{1}{2} \\ -2 \end{pmatrix}$$

If you are only interested in a particular solution and do not need the general solution of the linear system, enter:

```
linalg::matlinsolve(A, b, Special)
```

$$\begin{pmatrix} 13 \\ 17 \\ 0 \\ 0 \\ 0 \end{pmatrix}$$

This call suppresses the computation of the kernel of A.

Example 4

If the linear system is given in the form of equations the function `linalg::expr2Matrix` can be used to form the corresponding matrix equation:

```
delete x, y, z:  
Ab := linalg::expr2Matrix(  
  [x + y + z = 6, 2*x + y + 2*z = 10, x + 3*y + z = 10]  
)
```

$$\begin{pmatrix} 1 & 1 & 1 & 6 \\ 2 & 1 & 2 & 10 \\ 1 & 3 & 1 & 10 \end{pmatrix}$$

The result here is the extended coefficient matrix of the input system, that is, the right side vector \vec{b} is the 4th column vector of the matrix Ab. Since you did not specify a component ring for this matrix, the standard component ring for matrices, the domain `Dom::ExpressionField()`, was chosen.

To solve the linear system, call:

```
linalg::matlinsolve(Ab)
```

linalg::matlinsolve

$$\left[\begin{pmatrix} 4 \\ 2 \\ 0 \end{pmatrix}, \left[\begin{pmatrix} -1 \\ 0 \\ 1 \end{pmatrix} \right] \right]$$

The system has an infinite number of solutions. The third variable z acts as a free parameter and therefore can have any (complex) value.

To get the general solution in parameter form, you can use parameters for the variables x, y, z of the input system:

```
delete u, v, w:  
sol := linalg::matlinsolve(Ab, [u, v, w])
```

$$\begin{pmatrix} 4 - w \\ 2 \\ w \end{pmatrix}$$

This is possible here because you perform the matrix computations over `Dom::ExpressionField()` which lets you compute with symbolical (arithmetical) expressions.

To select a certain vector from the set of solutions, for example, the solution for $w = 1$, enter:

```
x := subs(sol, w = 1)
```

$$\begin{pmatrix} 3 \\ 2 \\ 1 \end{pmatrix}$$

Example 5

Consider a system of linear equations with a sparse structure, that is, the coefficient matrix has many zero components:

```
eqs := {x1 + x5 = 0, x2 - x4 = 1, x3 + 2*x5 = 2, x4 - x5 = -1}:  
Ab := linalg::expr2Matrix(eqs, [x1, x2, x3, x4, x5])
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & -1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 2 & 2 \\ 0 & 0 & 0 & 1 & -1 & -1 \end{pmatrix}$$

`linalg::matlinsolve` exploits the sparsity of the coefficient matrix if it is passed as a matrix of type `Dom::Matrix`. Alternatively, you can use the function `linsolve` which allows sparse input and output via symbolic equations:

```
linsolve(eqs)
```

```
[x1 = -x5, x2 = x5, x3 = 2 - 2 x5, x4 = x5 - 1]
```

You also can use the function `numeric::matlinsolve` with the option `Symbolic` instead of `linalg::matlinsolve`:

```
A := linalg::delCol(Ab, 6):
b := linalg::col(Ab, 6):
numeric::matlinsolve(A, b, Symbolic)
```

$$\left[\begin{pmatrix} 0 \\ 0 \\ 2 \\ -1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ -2 \\ 1 \\ 1 \end{pmatrix} \right]$$

Note that the function `numeric::matlinsolve` always works over a subfield of the complex numbers and does not let you specify the domain of computation. Without the option `Symbolic`, `numeric::matlinsolve` converts input data to floating-point numbers.

Example 6

Check whether the matrix equation

linalg::matlinsolve

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix} \vec{x} = \begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

has a unique solution over the integers.

Start by entering the coefficient matrix and the right side matrix:

```
MatZ := Dom::Matrix(Dom::Integer):  
A := MatZ([[1, 2], [-2, 3]]); B := MatZ([[4, 2], [6, 3]])
```

$$\begin{pmatrix} 1 & 2 \\ -2 & 3 \end{pmatrix}$$

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Next, solve the matrix equation:

```
X := linalg::matlinsolve(A, B)
```

$$\begin{pmatrix} 0 & 0 \\ 2 & 1 \end{pmatrix}$$

The equation indeed has a unique solution (otherwise the answer of `linalg::matlinsolve` would be the empty list []). Check the result:

```
A * X
```

$$\begin{pmatrix} 4 & 2 \\ 6 & 3 \end{pmatrix}$$

Example 7

If you use the Normal option, `linalg::matlinsolve` calls the normal function for final results. This call ensures that `linalg::matlinsolve` returns results in normalized form:

```
A := matrix([[1, s], [t, -1]]):
b := matrix([s + 1, t - 1]):
x := linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

If you specify `Normal = FALSE`, `linalg::matlinsolve` does not call `normal` for the final result:

```
x := linalg::matlinsolve(A, b, Normal = FALSE)
```

$$\begin{pmatrix} s - \frac{s(t(s+1)-t+1)}{st+1} + 1 \\ \frac{t(s+1)-t+1}{st+1} \end{pmatrix}$$

Example 8

Solve this system:

```
A := matrix([[1, s], [1, t]]):
b := matrix([1, 1]):
```

```
linalg::matlinsolve(A, b)
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$

Note that more solutions exist for $t = s$. `linalg::matlinsolve` omits these solutions because it makes some additional assumptions on symbolic parameters of this system. To see the assumptions that `linalg::matlinsolve` made while solving this system, use the `ShowAssumptions` option:

```
linalg::matlinsolve(A, b, ShowAssumptions)
```

linalg::matlinsolve

$$\left[\begin{pmatrix} 1 \\ 0 \end{pmatrix}, [], [], [t-s \neq 0] \right]$$

Parameters

A

$m \times n$ matrix of a domain of category `Cat::Matrix`

B

$m \times k$ matrix of a domain of category `Cat::Matrix`

b

m -dimensional column vector, i.e., a $m \times 1$ matrix of a domain of category `Cat::Matrix`

list

List of n elements of the component ring of A

Options

Normal

Option, specified as `Normal = b`

Return normalized results. The value `b` must be `TRUE` or `FALSE`. By default, `Normal = TRUE`, meaning that `linalg::matlinsolve` guarantees normalization of the returned results. Normalizing results can be computationally expensive.

By default, `linalg::matlinsolve` calls `normal` before returning results. This additional internal call ensures that the final result is normalized. This call can be computationally expensive. This option affects the output only if the solution contains variables or exact expressions, such as `sqrt(5)` or `sin(PI/7)`.

To avoid this additional call, specify `Normal = FALSE`. In this case, `linalg::matlinsolve` also can return normalized results, but does not guarantee such normalization. See “Example 7” on page 14-140.

ShowAssumptions

Return information about internal assumptions that `linalg::matlinsolve` made on symbolic parameters in eqs.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `A` and `b` (or `B`). Internally, these were assumed to hold true when solving the system. See “Example 8” on page 14-141.

When Gaussian elimination produces an equation $0 = c$ with nonzero `c`, `linalg::matlinsolve` without `ShowAssumptions` returns `[]`. If `c` involves symbolic parameters, try using `linalg::matlinsolve` with `ShowAssumptions` to solve such systems. If the system is solvable, you will get the solution. In this case, an equation $0 = c$ is returned in the `Constraints` list. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

Special

Only one particular solution w of the system $A\vec{x} = \vec{b}$ is returned. This suppresses the computation of a basis for the kernel of `A`.

Unique

Checks whether the system has a unique solution and returns it. The return value `NIL` means that the system has more than one solution.

Return Values

Without `ShowAssumptions`, `linalg::matlinsolve` can return a vector or a list `[S, KernelBasis]` (possibly empty), where `S` is a solution vector and `KernelBasis` is a list of basis vectors for the kernel of `A`. It also can return a matrix or the value `NIL`.

The matrix and the vectors, respectively, are of the domain type `Dom::Matrix(R)`, where `R` is the component ring of `A`.

With `ShowAssumptions`, `linalg::matlinsolve` returns a list `[S, KernelBasis, Constraints, Pivots]`. The lists `Constraints`

and Pivots contain equations and inequalities involving symbolic parameters in A and b (or B). Internally, these were assumed to hold true when solving the system. If the system is not solvable, `linalg::matlinsolve` with `ShowAssumptions` returns `[[], [], [], []]`.

Algorithms

Let A be an $m \times n$ matrix with components from a field F and \vec{b} an m -dimensional vector over F . Let $\left(A, \vec{b}\right)$ be the extended coefficient matrix of the linear system $A \vec{x} = \vec{b}$.

Then the following holds:

- The linear system $A \vec{x} = \vec{b}$ has a solution, if and only if $\text{rank}\left(A, \vec{b}\right) = \text{rank}(A)$.
- It has exactly one solution, if and only if $\text{rank}\left(A, \vec{b}\right) = \text{rank}(A) = n$.
- If \vec{x} is a solution of the system $A \vec{x} = \vec{b}$ and $\{\vec{v}_1, \dots, \vec{v}_r\}$ a basis of the kernel of A , then

$$L\left(A, \vec{b}\right) = \left\{ \vec{w} + \lambda_1 \vec{v}_1 + \lambda_2 \vec{v}_2 + \dots + \lambda_r \vec{v}_r \mid \lambda_1, \dots, \lambda_r \in K \right\}$$

is the set of all solutions of the linear system $A \vec{x} = \vec{b}$, the *general solution* of the (inhomogeneous) linear system.

The *kernel of the matrix* A is defined as:

$$\ker(A) = \left\{ \vec{w} \mid A \vec{w} = \vec{0} \right\}$$

The kernel of A is a vector space over F of dimension $n - \text{rank}(A)$.

Concepts

- “Solve Algebraic Systems”

linalg::matlinsolveLU

Purpose Solving the linear system given by an LU decomposition

Syntax `linalg::matlinsolveLU(L, U, b)`
`linalg::matlinsolveLU(L, U, B)`

Description `linalg::matlinsolveLU(L, U, b)` solves the linear system $LU\vec{x} = \vec{b}$, where the matrices L and U form an LU-decomposition, as computed by `linalg::factorLU`.

If the third parameter is an $n \times k$ matrix B then the result is an $n \times k$ matrix X satisfying the matrix equation $LUX = B$.

The system to be solved always has a unique solution.

The diagonal entries of the lower diagonal matrix L must be equal to one (*Doolittle*-decomposition, see `linalg::factorLU`).

`linalg::matlinsolveLU` expects L and U to be nonsingular.

`linalg::matlinsolveLU` does not check on any of the required properties of L and U .

The component ring of the matrices L and U must be a field, i.e., a domain of category `Cat::Field`.

The parameters must be defined over the same component ring.

Examples

Example 1

We solve the system

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ & 1 & -1 \end{pmatrix} X = \begin{pmatrix} 1 & & \\ & 1 & \\ & & 1 \end{pmatrix} :$$

```
MatR := Dom::Matrix(Dom::Real):  
A := MatR([[2, -3, -1], [1, 1, -1], [0, 1, -1]]);  
I3 := MatR::identity(3)
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

We start by computing an LU-decomposition of A:

```
LU := linalg::factorLU(A)
```

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{2} & 1 & 0 \\ 0 & \frac{2}{5} & 1 \end{pmatrix}, \begin{pmatrix} 2 & -3 & -1 \\ 0 & \frac{5}{2} & -\frac{1}{2} \\ 0 & 0 & -\frac{4}{5} \end{pmatrix}, [1, 2, 3] \right]$$

Now we solve the system $AX = I_3$, which gives us the inverse of A:

```
Ai := linalg::matlinsolveLU(LU[1], LU[2], I3)
```

$$\begin{pmatrix} 0 & 1 & -1 \\ -\frac{1}{4} & \frac{1}{2} & -\frac{1}{4} \\ -\frac{1}{4} & \frac{1}{2} & -\frac{5}{4} \end{pmatrix}$$

```
A * Ai, Ai * A
```

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

linalg::matlinsolveLU

Parameters

L

An $n \times n$ lower triangular matrix of a domain of category `Cat::Matrix`

U

An $n \times n$ upper triangular form matrix of the same domain as L

B

An $n \times k$ matrix of a domain of category `Cat::Matrix`

b

An n -dimensional column vector, i.e., an $n \times 1$ matrix of a domain of category `Cat::Matrix`

Return Values

n -dimensional solution vector or $n \times k$ dimensional solution matrix, respectively, of the domain type `Dom::Matrix(R)`, where R is the component ring of A.

See Also

MuPAD Functions

`linalg::factorLU` | `linalg::inverseLU` | `linalg::matlinsolve`

Purpose Minimal polynomial of a matrix

Syntax `linalg::minpoly(A, x)`

Description `linalg::minpoly(A, x)` computes the minimal polynomial of the square matrix A in x , i.e., the monic polynomial of lowest degree annihilating the matrix A .

The minimal polynomial of A divides the characteristic polynomial of A , by Cayley-Hamilton theorem.

If the matrix is defined over `Dom::Float`, then due to numerical errors the computed polynomial can have a degree higher than the dimension of the matrix. In such cases, `linalg::minpoly` returns the value `FAIL`. See “Example 3” on page 14-151.

The component ring of A must be a field, i.e., a domain of category `Cat::Field`.

Examples **Example 1**

We define the following matrix over the rational numbers:

```
A := Dom::Matrix(Dom::Rational)(
  [[0, 2, 0], [0, 0, 2], [2, 0, 0]]
)
```

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 0 & 2 \\ 2 & 0 & 0 \end{pmatrix}$$

The minimal polynomial of the matrix A in the variable x is then given by:

```
delete x: linalg::minpoly(A, x)
```

$$x^3 - 8$$

linalg::minpoly

In this case, the minimal polynomial is in fact equal to the characteristic polynomial of A :

```
linalg::charpoly(A, x)
```

$$x^3 - 8$$

Example 2

The minimal polynomial of the matrix:

```
B := matrix([[0, 1, 0], [0, 0, 0], [0, 0, 0]])
```

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

is a polynomial of degree 2:

```
m := linalg::minpoly(B, x)
```

$$x^2$$

The characteristic polynomial of B has degree 3 and is divided by the minimal polynomial of B :

```
p := linalg::charpoly(B, x)
```

$$x^3$$

```
p / m
```

$$x$$

Example 3

For the following example, MuPAD is not able to compute the minimal polynomial, and thus FAIL is returned:

```
C := Dom::Matrix(Dom::Float)([
  [7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0],
  [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]
])
```

$$\begin{pmatrix} 7.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 0.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 0.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 3.0 & 0.0 & 0.0 \\ 1.0 & 2.0 & 3.0 & 4.0 & 7.0 \end{pmatrix}$$

```
delete x: linalg::minpoly(C, x)
```

Warning: Cannot compute the minimal polynomial. [linalg::minpoly

FAIL

In fact, for this example MuPAD is not able to check for zero equivalence during Gaussian elimination and therefore chose a wrong pivot element.

If you perform the computation over the coefficient domain `Dom::ExpressionField(normal)` instead, then in most cases the minimal polynomial can be computed:

```
C := matrix([
  [7, 0, 0, 0, 0], [1, 0, 0, 0, 0], [1, 2, 0, 0, 0],
  [1, 2, 3, 0, 0], [1, 2, 3, 4, 7]
])
```

linalg::minpoly

$$\begin{pmatrix} 7 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 \\ 1 & 2 & 0 & 0 & 0 \\ 1 & 2 & 3 & 0 & 0 \\ 1 & 2 & 3 & 4 & 7 \end{pmatrix}$$

`linalg::minpoly(C, x)`

$$x^5 - 14x^4 + 49x^3$$

However, in general this problem regarding zero recognition cannot be avoided.

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

x

An indeterminate

Return Values

Polynomial of the domain `Dom::DistributedPolynomial([x],R)`, where R is the component ring of A, or the value FAIL.

MuPAD Functions

`linalg::charpoly` | `linalg::frobeniusForm`

Purpose Multiply columns with a scalar

Syntax

```
linalg::multCol(A, c, s)
linalg::multCol(A, c1 .. c2, s)
linalg::multCol(A, list, s)
```

Description `linalg::multCol(A, c, s)` returns a copy of the matrix A resulting from A by multiplying the c -th column of A with the scalar s .

`linalg::multCol(A, c1.. c2, s)` returns a copy of the matrix A obtained from A by multiplying those columns whose indices are in the range $c_1.. c_2$ with the scalar s .

`linalg::multCol(A, list, s)` returns a copy of the matrix A obtained from matrix A by multiplying those columns whose indices are contained in `list` with the scalar s .

The scalar s is converted into an element of the component ring of the matrix A . An error message is returned if the conversion fails.

Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multCol`:

```
linalg::multCol(A, 2, -1)
```

$$\begin{pmatrix} 1 & -2 & 3 \\ 4 & -5 & 6 \\ 7 & -8 & 9 \end{pmatrix}$$

linalg::multCol

```
linalg::multCol(A, 1..2, 2)
```

$$\begin{pmatrix} 2 & 4 & 3 \\ 8 & 10 & 6 \\ 14 & 16 & 9 \end{pmatrix}$$

```
linalg::multCol(A, [3, 1], 0)
```

$$\begin{pmatrix} 0 & 2 & 0 \\ 0 & 5 & 0 \\ 0 & 8 & 0 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c

The column index: a positive integer less or equal to n

c₁ .. c₂

A range of column indices (positive integers less or equal to n)

list

A list of column indices (positive integers less or equal to n)

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Functions

`linalg::addCol` | `linalg::addRow` | `linalg::multRow`

Purpose Multiply rows with a scalar

Syntax

```
linalg::multRow(A, r, s)
linalg::multRow(A, r1 .. r2, s)
linalg::multRow(A, list, s)
```

Description `linalg::multRow(A, r, s)` returns a copy of the matrix A resulting from A by multiplying the r -th row of A with the scalar s .

`linalg::multRow(A, r1.. r2, s)` returns a copy of the matrix A obtained from A by multiplying those rows whose indices are in the range $r_1.. r_2$ with the scalar s .

`linalg::multRow(A, list, s)` returns a copy of the matrix A obtained from matrix A by multiplying those rows whose indices are contained in `list` with the scalar s .

The scalar s is converted into an element of the component ring of the matrix A . An error message is returned if the conversion fails.

Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

and illustrate the three different input formats for `linalg::multRow`:

```
linalg::multRow(A, 2, -1)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ -4 & -5 & -6 \\ 7 & 8 & 9 \end{pmatrix}$$

linalg::multRow

```
linalg::multRow(A, 1..2, 2)
```

$$\begin{pmatrix} 2 & 4 & 6 \\ 8 & 10 & 12 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::multRow(A, [3, 1], 0)
```

$$\begin{pmatrix} 0 & 0 & 0 \\ 4 & 5 & 6 \\ 0 & 0 & 0 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r

The row index: a positive integer less or equal to m

r₁ .. r₂

A range of row indices (positive integers less or equal to m)

list

A list of row indices (positive integers less or equal to m)

Return Values

Matrix of the same domain type as A .

MuPAD Functions

`linalg::addCol` | `linalg::addRow` | `linalg::multCol`

Purpose	Number of columns of a matrix
Syntax	<code>linalg::ncols(A)</code>
Description	<code>linalg::ncols(A)</code> returns the number of columns of the matrix A .
Examples	<p>Example 1</p> <p>The matrix:</p> <pre>A:= matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])</pre> $\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$ <p>has four columns:</p> <pre>linalg::ncols(A)</pre> <pre>4</pre>
Parameters	<p>A</p> <p>A matrix of a domain of category <code>Cat::Matrix</code></p>
Return Values	Positive integer.
See Also	
MuPAD Functions	<code>linalg::matdim</code> <code>linalg::nrows</code> <code>linalg::vecdim</code>

linalg::nonZeros

Purpose Number of non-zero elements of a matrix

Syntax `linalg::nonZeros(A)`

Description `linalg::nonZeros(A)` returns the number of non-zero components of the matrix A .

Examples **Example 1**

The matrix

```
MZ7 := Dom::Matrix(Dom::IntegerMod(7)):
A := MZ7([[18, -1], [4, 81]])
```

$$\begin{pmatrix} 4 \bmod 7 & 6 \bmod 7 \\ 4 \bmod 7 & 4 \bmod 7 \end{pmatrix}$$

has four non-zero entries:

```
linalg::nonZeros(A)
```

4

The matrix:

```
B := MZ7([[21, 2], [-1, 14]])
```

$$\begin{pmatrix} 0 \bmod 7 & 2 \bmod 7 \\ 6 \bmod 7 & 0 \bmod 7 \end{pmatrix}$$

has only two non-zero entries:

```
linalg::nonZeros(B)
```

2

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

Nonnegative integer

linalg::normalize

Purpose Normalize a vector

Syntax `linalg::normalize(v)`

Description `linalg::normalize(v)` normalizes the vector \vec{v} with respect to the 2-norm ($\|\vec{v}\|_2 = \sqrt{\langle \vec{v}, \vec{v} \rangle}$).

The result of `linalg::normalize(v)` is a vector that has norm 1 and the same direction as v .

The scalar product $\langle \vec{v}, \vec{v} \rangle$ for a vector \vec{v} is implemented by the function `linalg::scalarProduct`.

The norm of a vector is computed with the function `norm`, which is overloaded for vectors. See the method "norm" of the domain constructor `Dom::Matrix` for details.

If the norm is an object that cannot be converted into an element of the component ring of v , then an error occurs (see "Example 2" on page 14-161).

Examples

Example 1

We define the following vector:

```
u := matrix([[1, 2]])
```

$$\begin{pmatrix} 1 & 2 \end{pmatrix}$$

Then the vector of norm 1 with the same direction as u is given by:

```
linalg::normalize(u)
```

$$\begin{pmatrix} \frac{\sqrt{5}}{5} & \frac{2\sqrt{5}}{5} \end{pmatrix}$$

Example 2

The following computation fails because the vector (1, 2) cannot be normalized over the rationals:

```
v := Dom::Matrix(Dom::Rational)([[1, 2]]):  
linalg::normalize(v)
```

Error: Cannot normalize the given vector over its component ring

If we define v over the real numbers, then we get the normalized vector of v as follows:

```
w := Dom::Matrix(Dom::Real)(v): linalg::normalize(w)
```

$$\left(\frac{\sqrt{5}}{5} \quad \frac{2\sqrt{5}}{5} \right)$$

Parameters

v

A vector, i.e., an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`

Return Values

Vector of the same domain type as v.

See Also

MuPAD Functions

norm | linalg::scalarProduct

linalg::nrows

Purpose Number of rows of a matrix

Syntax `linalg::nrows(A)`

Description `linalg::nrows(A)` returns the number of rows of the matrix A .

Examples **Example 1**

The matrix:

```
A := matrix([[1, 2, 3, 4], [3, 1, 4], [5, 6]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 1 & 4 & 0 \\ 5 & 6 & 0 & 0 \end{pmatrix}$$

has three rows:

```
linalg::nrows(A)
```

```
3
```

Parameters **A**

A matrix of a domain of category `Cat::Matrix`

Return Values Positive integer.

See Also

MuPAD Functions `linalg::matdim` | `linalg::ncols` | `linalg::vecdim`

Purpose Basis for the null space of a matrix

Syntax `linalg::nullspace(A)`

Description `linalg::nullspace(A)` returns a basis for the null space of the matrix A , i.e., a list B of linearly independent vectors such that $A \vec{x} = \vec{0}$ if and only if \vec{x} is a linear combination of the vectors in B .

The component ring of the matrix A must be a field, i.e., a domain of category `Cat::Field`.

If the component ring of A does not have a canonical representation of the zero element, it can happen that `linalg::nullspace` does not find a basis for the null space. In such a case, a wrong result is returned.

Examples **Example 1**

The kernel of the matrix:

```
A := Dom::Matrix(Dom::Real)(
  [[3^(1/2)*2 - 2, 2], [4, 3^(1/2)*2 + 2]]
)
```

$$\begin{pmatrix} 2\sqrt{3}-2 & 2 \\ 4 & 2\sqrt{3}+2 \end{pmatrix}$$

is one-dimensional, and a basis is $\left\{ \begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix} \right\}$:

```
linalg::nullspace(A)
```

$$\left[\begin{pmatrix} -\frac{1}{\sqrt{3}-1} \\ 1 \end{pmatrix} \right]$$

linalg::nullspace

Parameters

A

A matrix of a domain of category `Cat::Matrix`

Return Values

List of (column) vectors of the domain `Dom::Matrix(R)`, where R is the component ring of A.

Purpose

Table of orthogonal coordinate transformations

Syntax

```
linalg::ogCoordTab[ogName](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
    Transformation](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
    InverseTransformation](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
    UnitVectors](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName,
    Scales](u1, u2, u3, <c>)
linalg::ogCoordTab[ogName, Ranges](<c>)
linalg::ogCoordTab[ ogName , Dimension]
```

Description

`linalg::ogCoordTab` is a table of predefined orthogonal coordinate transformations in \mathbb{R}^3 .

The entry associated with `ogName` defines a coordinate transformation $\vec{x} = \vec{x}(\vec{u})$ which maps the orthogonal parameters $\vec{u} = (u_1, u_2, u_3)$ to a vector $\vec{x} = (x_1, x_2, x_3)$ in Cartesian coordinates.

The coordinate systems `EllipticCylindrical` and `Torus` are defined with a constant parameter `c` which has to be passed as an additional argument. See “Example 2” on page 14-170.

The following coordinate transformations are stored in `linalg::ogCoordTab`. They are invertible for the indicated parameter values:

- Cartesian:

$$u_1, u_2, u_3 :$$

$$x_1 = u_1, x_2 = u_2, x_3 = u_3 .$$

- Spherical and its equivalent Spherical[RightHanded]:

$$0 < u_1 < \infty, 0 \leq u_2 \leq \pi, 0 \leq u_3 < 2\pi:$$

$$x_1 = u_1 \sin(u_2) \cos(u_3), x_2 = u_1 \sin(u_2) \sin(u_3), x_3 = u_1 \cos(u_2)$$

- Spherical[LeftHanded]:

$$0 < u_1 < \infty, 0 \leq u_2 < 2\pi, 0 \leq u_3 \leq \pi:$$

$$x_1 = u_1 \cos(u_2) \sin(u_3), x_2 = u_1 \sin(u_2) \sin(u_3), x_3 = u_1 \cos(u_3)$$

- Cylindrical:

$$0 < u_1 < \infty, 0 \leq u_2 < 2\pi, u_3 :$$

$$x_1 = u_1 \cos(u_2), x_2 = u_1 \sin(u_2), x_3 = u_3$$

- EllipticCylindrical:

$$0 < u_1 < \infty, 0 \leq u_2 < 2\pi, u_3 \text{ (with a real constant } c\text{):}$$

$$x_1 = c \cos(u_1) \cos(u_2), x_2 = c \sinh(u_1) \sin(u_2), x_3 = u_3$$

- ParabolicCylindrical:

$$0 < u_1 < \infty, u_2, u_3 :$$

$$x_1 = \frac{(u_1^2 - u_2^2)}{2}, x_2 = u_1 u_2, x_3 = u_3$$

- RotationParabolic:

$$0 < u_1 < \infty, 0 < u_2 < \infty, 0 \leq u_3 < 2\pi:$$

$$x_1 = u_1 u_2 \cos(u_3), x_2 = u_1 u_2 \sin(u_3), x_3 = \frac{(u_1^2 - u_2^2)}{2}$$

- Torus:

$$0 < u_1 < c, 0 \leq u_2 < 2\pi, 0 \leq u_3 < 2\pi \text{ (with a positive constant } c\text{):}$$

$$x_1 = (c - u_1 \cos(u_2)) \cos(u_3), x_2 = (c - u_1 \cos(u_2)) \sin(u_3), x_3 = u_1 \sin(u_2)$$

`linalg::ogCoordTab` is used by functions such as `curl`, `divergence`, `gradient`, and `laplacian` to perform computations in non-Cartesian coordinates.

Examples

Example 1

The following call returns the Cartesian vector $\vec{x} = [x, y, z]$ in terms of the right-handed spherical coordinates $\vec{u} = [u_1, u_2, u_3]$:

```
linalg::ogCoordTab[Spherical[RightHanded], Transformation](u1, u2, u3)
```

```
[u1 cos(u3) sin(u2), u1 sin(u2) sin(u3), u1 cos(u2)]
```

linalg::ogCoordTab

The spherical coordinates expressed by the Cartesian coordinates:

```
linalg::ogCoordTab[Spherical[RightHanded], InverseTransformation](x
```

$$\left[\sqrt{x^2 + y^2 + z^2}, \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right), \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right) + \text{sign}(y) (\text{sign}(y) - 1) \left(\pi - \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right)\right) \right]$$

Note the `sign(y)` in the expression for u_3 . This ensures that the correct angle is returned for any value of y :

```
assume(y > 0):
```

```
linalg::ogCoordTab[Spherical[RightHanded], InverseTransformation](x
```

$$\left[\sqrt{x^2 + y^2 + z^2}, \arccos\left(\frac{z}{\sqrt{x^2 + y^2 + z^2}}\right), \arccos\left(\frac{x}{\sqrt{x^2 + y^2}}\right) \right]$$

```
linalg::ogCoordTab[Spherical[RightHanded], InverseTransformation](1
```

```
linalg::ogCoordTab[Spherical[RightHanded], InverseTransformation](-
```

```
linalg::ogCoordTab[Spherical[RightHanded], InverseTransformation](1
```

```
linalg::ogCoordTab[Spherical[RightHanded], InverseTransformation](1
```

$$\left[\sqrt{2}, \frac{\pi}{2}, \frac{\pi}{4} \right], \left[\sqrt{2}, \frac{\pi}{4}, \pi \right], \left[\sqrt{5}, \arccos\left(\frac{2\sqrt{5}}{5}\right), 0 \right], \left[\sqrt{11}, \arccos\left(\frac{3\sqrt{11}}{11}\right), \frac{7\pi}{4} \right]$$

These parameter values are from the following ranges:

```
linalg::ogCoordTab[Spherical[RightHanded], Ranges]()
```

```
[0..∞, 0..π, 0..2 π]
```

The following orthonormal vectors are tangent to the spherical parameter lines:

```
linalg::ogCoordTab[Spherical[RightHanded], UnitVectors](u1, u2,
```

```
[[cos(u3) sin(u2), sin(u2) sin(u3), cos(u2)], [cos(u2) cos(u3), cos(u2) sin(u3), -sin(u2)],
 [-sin(u3), cos(u3), 0]]
```

The ‘scaling factors’ are:

```
linalg::ogCoordTab[Spherical[RightHanded], Scales](u1, u2, u3)
```

```
[1, u1, u1 sin(u2)]
```

There is the following relationship between the Jacobian of the transformation $\vec{u} \rightarrow \vec{x}$ from the orthogonal coordinates to the Cartesian coordinates:

```
xyz:= linalg::ogCoordTab[Spherical[RightHanded], Transformation](
unitvectors:= linalg::ogCoordTab[Spherical[RightHanded], UnitVec
scales:= linalg::ogCoordTab[Spherical[RightHanded], Scales](u1,

linalg::transpose(jacobian(xyz, [u1, u2, u3])) =
    matrix(3, 3, scales, Diagonal)* matrix(unitvectors)
```

linalg::ogCoordTab

$$\sigma_1 = \sigma_1$$

where

$$\sigma_1 = \begin{pmatrix} \cos(u_3) \sin(u_2) & \sin(u_2) \sin(u_3) & \cos(u_2) \\ u_1 \cos(u_2) \cos(u_3) & u_1 \cos(u_2) \sin(u_3) & -u_1 \sin(u_2) \\ -u_1 \sin(u_2) \sin(u_3) & u_1 \cos(u_3) \sin(u_2) & 0 \end{pmatrix}$$

delete y, xyz, unitvectors, scales:

Example 2

The following call returns the Cartesian vector $\vec{x} = [x, y, z]$ in terms of elliptic cylindrical coordinates $\vec{u} = [u, v, w]$ involving a parameter c :

```
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, z, c)
```

$$[c \cosh(u) \cos(v), c \sinh(u) \sin(v), z]$$

We compute the gradient of the function $f(u, v, w) = x(u, v, w)$ in elliptic cylindrical coordinates $\vec{u} = [u, v, w]$.

```
f := (c*cos(v)*cosh(u))^2:
```

For computing the components of the gradient with respect to an orthogonal system, it is sufficient to know the 'scale parameters':

```
linalg::ogCoordTab[EllipticCylindrical, Scales](u, v, w, c)
```

$$\left[c \sqrt{\cosh(u)^2 - \cos(v)^2}, c \sqrt{\cosh(u)^2 - \cos(v)^2}, 1 \right]$$

```
gradf := gradient(f, [u, v, w], %)
```

$$\begin{pmatrix} \frac{2c \cosh(u) \cos(v)^2 \sinh(u)}{\sqrt{\cosh(u)^2 - \cos(v)^2}} \\ -\frac{2c \cosh(u)^2 \cos(v) \sin(v)}{\sqrt{\cosh(u)^2 - \cos(v)^2}} \\ 0 \end{pmatrix}$$

These are the coefficients of the gradient with respect to the orthonormal basis $\vec{e}_u, \vec{e}_v, \vec{e}_w$ returned via the option UnitVectors:

```
[e_u, e_v, e_w] :=
linalg::ogCoordTab[EllipticCylindrical, UnitVectors](u, v, w, c)
```

```
[[σ1, σ2, 0], [-σ2, σ1, 0], [0, 0, 1]]
```

where

$$\sigma_1 = \frac{\cos(v) \sinh(u)}{\sqrt{\cosh(u)^2 - \cos(v)^2}}$$

$$\sigma_2 = \frac{\cosh(u) \sin(v)}{\sqrt{\cosh(u)^2 - \cos(v)^2}}$$

We convert the lists e_u, e_v, e_w into column vectors via `matrix`. Thus, in the standard basis of \mathbb{R}^3 , the gradient vector field is:

```
G := gradf[1]*matrix(e_u)
      + gradf[2]*matrix(e_v)
      + gradf[3]*matrix(e_w)
```

linalg::ogCoordTab

$$\begin{pmatrix} \frac{2 c \cosh(u) \cos(v)^3 \sinh(u)^2}{\cosh(u)^2 - \cos(v)^2} + \frac{2 c \cosh(u)^3 \cos(v) \sin(v)^2}{\cosh(u)^2 - \cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} \frac{2 c \cosh(u) \cos(v)^3 \sinh(u)^2}{\cosh(u)^2 - \cos(v)^2} + \frac{2 c \cosh(u)^3 \cos(v) \sin(v)^2}{\cosh(u)^2 - \cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} \frac{2 c \cosh(u) \cos(v)^3 \sinh(u)^2}{\cosh(u)^2 - \cos(v)^2} + \frac{2 c \cosh(u)^3 \cos(v) \sin(v)^2}{\cosh(u)^2 - \cos(v)^2} \\ 0 \\ 0 \end{pmatrix}$$

We simplify this expression using the identities $\sin^2(v) = 1 - \cos^2(v)$,
 $\sinh^2(u) = \cosh^2(u) - 1$:

```
normal(subs(G, sin(v)^2 = 1 - cos(v)^2,  
sinh(u)^2 = cosh(u)^2 - 1))
```

$$\begin{pmatrix} 2 c \cosh(u) \cos(v) \\ 0 \\ 0 \end{pmatrix}$$

This is the gradient of the function $f(x, y, z) = x^2$ with x expressed by elliptic cylindrical coordinates:

```
G := gradient(x^2, [x, y, z])
```

$$\begin{pmatrix} 2x \\ 0 \\ 0 \end{pmatrix}$$

```
[x, y, z] :=
linalg::ogCoordTab[EllipticCylindrical, Transformation](u, v, w,
```

```
[c cosh(u) cos(v), c sinh(u) sin(v), w]
```

```
map(G, eval)
```

$$\begin{pmatrix} 2c \cosh(u) \cos(v) \\ 0 \\ 0 \end{pmatrix}$$

```
delete f, gradf, e_u, e_v, e_w, G, x, y, z:
```

Parameters

ogName

The name of a predefined coordinate system. The following 3 dimensional coordinate systems are available: Cartesian, Spherical (equivalent to Spherical[RightHanded]), Spherical[LeftHanded], Cylindrical, EllipticCylindrical, ParabolicCylindrical, RotationParabolic, Torus.

u_1, u_2, u_3

The coordinates of the orthogonal system: identifiers, indexed identifiers, or arithmetical expressions.

x_1, x_2, x_3

Cartesian coordinates: identifiers, indexed identifiers, or arithmetical expressions.

c

An arithmetical expression. The default value is $c = 1$.

linalg::ogCoordTab

Options

Transformation

`linalg::ogCoordTab [ogName, Transformation](u1, u2, u3, c)` returns a list of arithmetical expressions [$x_1(u_1, u_2, u_3)$, $x_2(u_1, u_2, u_3)$, $x_3(u_1, u_2, u_3)$] defining the transformation from the orthogonal coordinates u_i to the Cartesian coordinates x_j . The transformation is invertible if the coordinates u_i are from the range $a_i < u_i < b_i$ where [a1..b1, a2..b2, a3..b3] = `linalg::ogCoordTab [ogName, Ranges](c)`.

InverseTransformation

`linalg::ogCoordTab [ogName, InverseTransformation](x1, x2, x3, c)` returns a list of arithmetical expressions [$u_1(x_1, x_2, x_3)$, $u_2(x_1, x_2, x_3)$, $u_3(x_1, x_2, x_3)$] defining the inverse transformation. The inverse transformation produces parameter values u_i in the range $a_i \leq u_i \leq b_i$ given by [a1..b1, a2..b2, a3..b3] = `linalg::ogCoordTab [ogName, Ranges](c)`.

UnitVectors

`linalg::ogCoordTab [ogName, UnitVectors](u1, u2, u3, c)` returns a list of orthonormal vectors $\left[\vec{e}_1, \vec{e}_2, \vec{e}_3 \right]$, where each vector is represented by a list of three arithmetical expressions.

These vectors $\vec{e}_i = \frac{1}{s_i} \frac{\partial \vec{x}}{\partial u_i}$ with $s_i = \left| \frac{\partial \vec{x}}{\partial u_i} \right|$ are the unit vectors tangent to the parameter lines u_i .

Scales

`linalg::ogCoordTab [ogName, Scales](u1, u2, u3, c)` returns a list [s_1, s_2, s_3] of “scaling factors” of the transformation $\vec{u} \rightarrow \vec{x}$. The “scales” are the Euclidean lengths

$s_i = \left| \frac{\partial \vec{x}}{\partial u_i} \right|$ of the vectors $\frac{\partial \vec{x}}{\partial u_i}$ tangent to the parameter lines u_i .

Return Values

Most of the entries in `linalg::ogCoordTab` are functions:

`linalg::ogCoordTab [ogName, Transformation](u1, u2, u3, c)` returns a list of arithmetical expressions [$x_1(u_1, u_2, u_3)$, $x_2(u_1, u_2, u_3)$, $x_3(u_1, u_2, u_3)$] defining the transformation from the orthogonal coordinates u_i to the Cartesian coordinates x_j .

`linalg::ogCoordTab [ogName, InverseTransformation](x1, x2, x3, c)` returns a list of arithmetical expressions [$u_1(x_1, x_2, x_3)$, $u_2(x_1, x_2, x_3)$, $u_3(x_1, x_2, x_3)$] defining the inverse transformation.

`linalg::ogCoordTab [ogName, UnitVectors](u1, u2, u3, c)` returns a list of orthogonal unit “vectors.” The “vectors” are given as lists of arithmetical expressions.

`linalg::ogCoordTab [ogName, Scales](u1, u2, u3, c)` returns a list of arithmetical expressions.

`linalg::ogCoordTab [ogName, Ranges](c)` returns a list of ranges [$a_1.. b_1$, $a_2.. b_2$, $a_3.. b_3$]. The transformation is invertible for parameter values $a_i < u_i < b_i$.

`linalg::ogCoordTab [ogName, Dimension]` yields the dimension of the space parametrized by the orthogonal coordinates. Presently, all predefined systems parametrize ³, i.e., the dimension is 3 in all cases.

The call `linalg::ogCoordTab [ogName](u1, u2, u3, c)` is identical to the call `linalg::ogCoordTab [ogName, UnitVectors](u1, u2, u3, c)`.

linalg::orthog

Purpose Orthogonalization of vectors

Syntax `linalg::orthog(S, <Real>)`

Description `linalg::orthog(S)` orthogonalizes the vectors in S using the Gram-Schmidt orthogonalization algorithm.

The vectors in S are orthogonalized with respect to the scalar product `linalg::scalarProduct`.

If O is the returned set, then the vectors of O span the same subspace as the vectors in S , and they are pairwise orthogonal, i.e.: $\vec{v} \cdot \vec{w} = 0$ for all $\vec{v}, \vec{w} \in O$ with $\vec{v} \neq \vec{w}$.

The vectors returned are not normalized. To normalize them use `map(O, linalg::normalize)`.

For an ordered set of orthogonal vectors, S should be a list.

The vectors in S must be defined over the same component ring.

The component ring of the vectors in S must be a field, i.e., a domain of category `Cat::Field`.

If you use the `Real` option, `linalg::orthog` computes an orthogonal basis using a real scalar product in the orthogonalization process.

Examples

Example 1

The following list of vectors is a basis of the vector space ³:

```
MatR := Dom::Matrix(Dom::Real):  
S := [MatR([2, 1, 0]), MatR([-3, 1, 1]), MatR([-1, -1, -1])]
```

$$\left[\begin{pmatrix} 2 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -3 \\ 1 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ -1 \end{pmatrix} \right]$$

The Gram-Schmidt algorithm then returns an orthogonal basis for S . We get an orthonormal basis with the following input:

```
ON:= linalg::orthog(S)
```

$$\left[\begin{pmatrix} 2 \\ 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 2 \\ 1 \end{pmatrix}, \begin{pmatrix} -\frac{2}{15} \\ \frac{4}{15} \\ -\frac{2}{3} \end{pmatrix} \right]$$

The vectors can be normalized using `linalg::normalize`:

```
map(ON, linalg::normalize)
```

$$\left[\begin{pmatrix} \frac{2\sqrt{5}}{5} \\ \frac{\sqrt{5}}{5} \\ 0 \end{pmatrix}, \begin{pmatrix} -\frac{\sqrt{6}}{6} \\ \frac{\sqrt{6}}{3} \\ \frac{\sqrt{6}}{6} \end{pmatrix}, \begin{pmatrix} -\frac{\sqrt{2}\sqrt{15}}{30} \\ \frac{\sqrt{2}\sqrt{15}}{15} \\ -\frac{\sqrt{2}\sqrt{15}}{6} \end{pmatrix} \right]$$

We may also build a matrix from the vectors in S and apply `linalg::orthog` to this matrix. The result is the matrix whose columns are given by the above elements of the list `ON`:

```
A:= S[1].S[2].S[3]
```

$$\begin{pmatrix} 2 & -3 & -1 \\ 1 & 1 & -1 \\ 0 & 1 & -1 \end{pmatrix}$$

```
linalg::orthog(A)
```

linalg::orthog

$$\begin{pmatrix} 2 & -1 & -\frac{2}{15} \\ 1 & 2 & \frac{4}{15} \\ 0 & 1 & -\frac{2}{3} \end{pmatrix}$$

Example 2

The orthogonalization of the vectors:

```
T := {matrix([[ -2, 5, 3]], matrix([[0, 2, 1]])}
      {(0 2 1), (-2 5 3)}
```

gives:

```
linalg::orthog(T)
      {(0 2 1), (-2 -1/5 2/5)}
```

Example 3

The result of `linalg::orthog` is a list or set of linearly independent vectors, even if the input contains linearly dependent vectors:

```
MatQ := Dom::Matrix(Dom::Rational):
S := [MatQ([2, 1]), MatQ([3, 4]), MatQ([-1, 1])]
```

$$\left[\begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} 3 \\ 4 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix} \right]$$

```
linalg::orthog(S)
```

$$\left[\begin{pmatrix} 2 \\ 1 \end{pmatrix}, \begin{pmatrix} -1 \\ 2 \end{pmatrix} \right]$$

Example 4

Compute an orthogonal basis of this matrix:

```
A := matrix([[a, 1], [1, a]]):
linalg::orthog(A)
```

$$\begin{pmatrix} a - \frac{a^2-1}{a\bar{a}+1} \\ 1 - \frac{\bar{a}-a^2\bar{a}}{a\bar{a}+1} \end{pmatrix}$$

To avoid complex conjugates, use the `Real` option:

```
linalg::orthog(A, Real)
```

$$\begin{pmatrix} a - \frac{a^2-1}{a^2+1} \\ 1 - \frac{a(a^2-1)}{a^2+1} \end{pmatrix}$$

Parameters**S**

A set or list of vectors of the same dimension (a vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`) or a matrix

Options**Real**

Avoid using a complex scalar product in the orthogonalization process.

linalg::orthog

Return Values

Set or a list of vectors, respectively.

See Also

MuPAD Functions

`linalg::factorQR` | `linalg::isUnitary` | `linalg::normalize` |
`linalg::scalarProduct` | `llint` | `norm`

Purpose	Pascal matrix
Syntax	<code>linalg::pascal(n, <R>)</code>
Description	<code>linalg::pascal(n)</code> returns the $n \times n$ Pascal matrix P given by

$$P_{i,j} = \binom{i+j-2}{i-1}, 1 \leq i, j \leq n.$$

The entries of Pascal matrices are integer numbers. Note, however, that the returned matrix is not defined over the component domain `Dom::Integer`, but over the standard component domain `Dom::ExpressionField()`. Thus, no conversion is necessary when working with other functions that expect or return matrices over that component domain.

Use `linalg::pascal(n, Dom::Integer)` to define the $n \times n$ Pascal matrix over the ring of integer numbers.

Inverse Pascal matrices are provided by `linalg::invpascal`.

Examples

Example 1

We construct the 3×3 Pascal matrix:

```
linalg::pascal(3)
```

$$\begin{pmatrix} 1 & 1 & 1 \\ 1 & 2 & 3 \\ 1 & 3 & 6 \end{pmatrix}$$

This is a matrix of the domain `Dom::Matrix()`.

If you prefer a different component ring, the matrix may be converted to the desired domain after construction (see `coerce`, for example). Alternatively, one can specify the component ring when creating the Pascal matrix. For example, specification of the domain `Dom::Float` generates floating-point entries:

linalg::pascal

```
linalg::pascal(3, Dom::Float)
```

$$\begin{pmatrix} 1.0 & 1.0 & 1.0 \\ 1.0 & 2.0 & 3.0 \\ 1.0 & 3.0 & 6.0 \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix(Dom::Float)
```

Example 2

The Cholesky factor of a Pascal matrix consists of the elements of Pascal's triangle:

```
linalg::factorCholesky(linalg::pascal(4))
```

$$\begin{pmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 1 & 2 & 1 & 0 \\ 1 & 3 & 3 & 1 \end{pmatrix}$$

Parameters

n

The dimension of the matrix: a positive integer

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Pascal matrices are symmetric and positive definite.

The determinant of a Pascal matrix is 1.

The inverse of a Pascal matrix has integer entries.

If λ is an eigenvalue of a Pascal matrix, then $\frac{1}{\lambda}$ is also an eigenvalue of the matrix.

linalg::permanent

Purpose Permanent of a matrix

Syntax `linalg::permanent(A)`

Description `linalg::permanent(A)` computes the permanent of the square matrix A .

The component ring of the matrix A must be a commutative ring, i.e., a domain of category `Cat::CommutativeRing`.

Examples

Example 1

We compute the permanent of the following matrix:

```
delete a11, a12, a21, a22:  
A := matrix([[a11, a12], [a21, a22]])
```

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$$

which gives us the general formula for the permanent of an arbitrary 2×2 matrix:

```
linalg::permanent(A)
```

$$a_{11} a_{22} + a_{12} a_{21}$$

Example 2

The permanent of a matrix can be computed over arbitrary commutative rings. Let us create a random matrix defined over the ring \mathbb{Z}_6 , the integers modulo 6:

```
B := linalg::randomMatrix(5, 5, Dom::IntegerMod(6))
```

$$\begin{pmatrix} 3 \bmod 6 & 2 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 & 4 \bmod 6 \\ 2 \bmod 6 & 5 \bmod 6 & 2 \bmod 6 & 1 \bmod 6 & 1 \bmod 6 \\ 1 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 2 \bmod 6 & 2 \bmod 6 \\ 1 \bmod 6 & 0 \bmod 6 & 3 \bmod 6 & 3 \bmod 6 & 5 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 1 \bmod 6 & 3 \bmod 6 \end{pmatrix}$$

The permanent of this matrix is:

`linalg::permanent(B)`

`4 mod 6`

Its determinant is:

`det(B)`

`0 mod 6`

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Element of the component ring of A.

Algorithms

The permanent of an $n \times n$ matrix $A = (a_{i,j})_{1 \leq i \leq n, 1 \leq j \leq n}$ is defined similarly as the determinant of A, only the signs of the permutations do not enter the definition:

$$\text{perm}(A) := \sum_{\sigma \in S_n} \prod_{j=1}^n a_{\sigma(j),j}$$

linalg::permanent

(S_n is the symmetric group of all permutations of $\{1, \dots, n\}$.)

In contrast to the computation of the determinant, the computation of the permanent takes time $O(n^2 2^n)$.

See Also

MuPAD Functions

det

Purpose The (scalar) potential of a gradient field

Note `linalg::potential` will be removed in a future release. Use `potential` instead.

Syntax `linalg::potential(f, [x1, x2, ...], <[y1, y2, ...]>, <Test>)`

Description `linalg::potential(f, x)` determines whether the vector field $\vec{f} = \vec{f}(\vec{x})$ is a gradient field $\vec{f}(\vec{x}) = \text{grad}(p(\vec{x}))$ of some scalar potential p with respect to the variables \vec{x} , and computes that potential if it exists.

`linalg::potential` and `potential` are equivalent. See details and examples on the `potential` help page.

Parameters **f**

The vector field: a list of arithmetical expressions, or a vector of such expressions. A vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`.

x₁, x₂, ...

The variables: identifiers or indexed identifiers

y₁, y₂, ...

The components of the “base point:” arithmetical expressions.

If a base point \vec{y} is specified, the returned potential p satisfies

$$p(\vec{y}) = 0.$$

Options **Test**

`linalg::potential` only checks whether the vector field has a potential and returns `TRUE` or `FALSE`, respectively.

linalg::potential

Return Values

Arithmetical expression or a Boolean value.

Purpose	Moore-Penrose inverse of a matrix
Syntax	<code>linalg::pseudoInverse(A)</code>
Description	<code>linalg::pseudoInverse(A)</code> computes the Moore-Penrose inverse of A . If the Moore-Penrose inverse of A does not exist, then FAIL is returned. The component ring of the matrix A must be a field, i.e., a domain of category <code>Cat::Field</code> .

Examples

Example 1

The Moore-Penrose inverse of the 2×3 matrix:

```
A := Dom::Matrix(Dom::Complex)([[1, I, 3], [1, 3, 2]])
```

$$\begin{pmatrix} 1 & i & 3 \\ 1 & 3 & 2 \end{pmatrix}$$

is the 3×2 matrix:

```
Astar := linalg::pseudoInverse(A)
```

$$\begin{pmatrix} \frac{7}{96} + \frac{1}{32}i & \frac{1}{24} - \frac{1}{32}i \\ -\frac{7}{32} - \frac{5}{96}i & \frac{5}{16} + \frac{7}{96}i \\ \frac{7}{24} + \frac{1}{16}i & \frac{1}{96} - \frac{3}{32}i \end{pmatrix}$$

Note that in this example, only:

```
A * Astar
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

linalg::pseudoinverse

yields the identity matrix, but not (see “Backgrounds” below):

`Astar * A`

$$\begin{pmatrix} \frac{11}{96} & \frac{3}{32} - \frac{1}{48}i & \frac{29}{96} + \frac{1}{32}i \\ \frac{3}{32} + \frac{1}{48}i & \frac{95}{96} & -\frac{1}{32} - \frac{1}{96}i \\ \frac{29}{96} - \frac{1}{32}i & -\frac{1}{32} + \frac{1}{96}i & \frac{43}{48} \end{pmatrix}$$

Parameters **A**

A matrix of category `Cat::Matrix`

Return Values

Matrix of the same domain type as A, or the value FAIL.

Algorithms

For an invertible matrix A , the Moore-Penrose inverse A^* of A coincides with the inverse of A . In general, only $AA^*A = A$ and $A^*AA^* = A^*$ holds.

If A is of dimension $m \times n$, then A^* is of dimension $n \times m$.

The computation of the Moore-Penrose inverse requires the existence of a scalar product on the vector space K^n , where K is the coefficient field of the matrix A . This is only the case for some fields K in theory, but `linalg::scalarProduct` works also for vectors over other fields (e.g. finite fields). The computation of a Moore-Penrose inverse may fail in such cases.

See Also

MuPAD Functions

`_invert`

Purpose Generate a random matrix

Syntax `linalg::randomMatrix(m, n, <R>, <bound>, <Diagonal | Unimodular>)`

Description The call `linalg::randomMatrix(m, n)` returns a random $m \times n$ matrix over the default component ring for matrices, i.e., over the domain `Dom::ExpressionField()`.

The matrix components are generated by the method "random" of the domain R (see "Example 2" on page 14-192).

The parameter `bound` is given as a parameter to the method "random" of the domain R in order to bound the size of the components of the random matrix. The correct type of `bound` is determined by the method "random". The parameter has no effect if the slot "random" does not have a size argument.

Examples **Example 1**

We create a random square matrix over the integers. Because the matrix is random the created matrix can vary:

```
linalg::randomMatrix(2, 2, Dom::Integer)
```

$$\begin{pmatrix} 824 & -65 \\ -814 & -741 \end{pmatrix}$$

If you want to bound the size of its components, say between -2 and 2, enter:

```
linalg::randomMatrix(2, 2, Dom::Integer, -2..2)
```

$$\begin{pmatrix} -1 & 1 \\ -2 & 1 \end{pmatrix}$$

linalg::randomMatrix

Example 2

The following input creates a random vector over the component ring `Dom::FloatIV` of floating-point intervals. Because the vector is random the created vector can vary:

```
v := linalg::randomMatrix(1, 4, Dom::FloatIV)
```

```
[[0.2703581654 ... 0.831037179, 0.1531565158 ... 0.9948127811, 0.1801642274 ... 0.2662729024,  
0.4520830547 ... 0.6787819565]]
```

```
domtype(v)
```

```
Dom::Matrix(Dom::FloatIV)
```

The components of this matrix are random floating-point intervals created by the "random" method of the domain constructor `Dom::FloatIV`.

Example 3

To create a random diagonal matrix over the rationals we enter, for example:

```
linalg::randomMatrix(3, 3, Dom::Rational, Diagonal)
```

$$\begin{pmatrix} \frac{229}{220} & 0 & 0 \\ 0 & -\frac{535}{617} & 0 \\ 0 & 0 & -\frac{245}{397} \end{pmatrix}$$

Example 4

The following command creates a random unimodular matrix over the integers so that its determinant is either 1 or -1:

```
A := linalg::randomMatrix(3, 3, Dom::Integer, Unimodular)
```

$$\begin{pmatrix} -1 & -8 & 4 \\ 4 & 0 & -5 \\ -3 & 5 & 2 \end{pmatrix}$$

```
det(A)
```

```
-1
```

We can bound the size of the components. The following input returns a unimodular matrix $A = (a_{ij})$ with $|a_{ij}| \leq 2$ for $i, j = 1, 2, 3$:

```
A := linalg::randomMatrix(3, 3, 2, Unimodular)
```

$$\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 2 \\ 1 & 0 & 1 \end{pmatrix}$$

Since we did not specify the component ring, the matrix is defined over the standard component ring for matrices (the domain `Dom::ExpressionField()`):

```
domtype(A)
```

```
Dom::Matrix()
```

Parameters

m, n

Positive integers

R

The component ring, i.e., a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

linalg::randomMatrix

bound

An arithmetical expression

Options

Diagonal

Creates a random $m \times n$ diagonal matrix over R.

Unimodular

Creates a random $m \times m$ unimodular matrix over R, so that its determinant is a unit in R.

Note Note that this option is only available for square matrices.

The norm of each component of the matrix returned does not exceed bound, which must be a positive integer, if specified. The default value of bound is 10.

Return Values

Matrix of the domain `Dom::Matrix(R)`.

References

For generating random unimodular matrices, see Jürgen Hansen: *Generating Problems in Linear Algebra*, MapleTech, Volume 1, No.2, 1994.

MuPAD Domains

`Dom::Matrix`

MuPAD Functions

`random`

Purpose Rank of a matrix

Syntax `linalg::rank(A)`
`linalg::rank(S)`

Description `linalg::rank(A)` computes the rank of the matrix A .

`linalg::rank(S)` computes the rank of the matrix whose columns are the vectors in S .

The row rank of a matrix is the maximal number of linearly independent row vectors of that matrix. The column rank of a matrix is the maximal number of linearly independent column vectors of that matrix. For each matrix, its row rank is equal to its column rank. This number is called the rank of a matrix.

The component ring of A or of the vectors given in S must be an integral domain (a domain of category `Cat::IntegralDomain`).

`linalg::rank` replaces symbolic elements of a matrix by random integer numbers between 1 and 10^{10} . Then the function computes the rank of the resulting numeric matrix by Gaussian elimination (see `linalg::gaussElim`). This approach introduces a tiny chance of getting a wrong result.

Note `linalg::rank` does not simplify special functions and algebraic numbers. For some matrices, this approach leads to wrong results. See “Example 3” on page 14-196.

Examples

Example 1

Define the following matrix A over :

```
MatZ := Dom::Matrix(Dom::Integer):  
A := MatZ([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])
```

linalg::rank

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Compute the rank of the matrix A:

```
linalg::rank(A)
```

3

Example 2

Use the three vectors $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$ to define the columns of the matrix A. Compute the rank of A:

```
MatZ := Dom::Matrix(Dom::Integer):  
S := { MatZ([0,1,1]), MatZ([0,1,0]), MatZ([0,0,1]) }:  
linalg::rank(S)
```

2

Example 3

The `linalg::rank` function does not use any simplification rules for special functions, algebraic numbers (radicals), and so on. If `linalg::rank` computes intermediate expressions that can be simplified to zero, the function can return incorrect results. For example, create the following matrices:

```
A := matrix([[exp(x + y), exp(x)], [exp(y), 1]]);  
B := matrix([[sin(x)^2 + cos(x)^2, 1], [1, 1]]);  
C := matrix([[sqrt(6), sqrt(2)], [sqrt(3), 1]])
```

$$\begin{pmatrix} e^{x+y} & e^x \\ e^y & 1 \end{pmatrix}$$

$$\begin{pmatrix} \cos(x)^2 + \sin(x)^2 & 1 \\ 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \sqrt{6} & \sqrt{2} \\ \sqrt{3} & 1 \end{pmatrix}$$

There is only one independent row in each of these matrices. The rank of the matrices A, B, and C is 1. The `linalg::rank` function returns 2 because it does not simplify the expressions $e^{x+y} - e^x e^y$, $\sin^2 + \cos^2 - 1$, and $\sqrt{2} \sqrt{3} - \sqrt{6}$:

```
linalg::rank(A), linalg::rank(B), linalg::rank(C)
```

```
2, 2, 2
```

Parameters

A

A matrix of a domain of category `Cat::Matrix`

S

A list or set of column vectors of the same dimension (a column vector is an $n \times 1$ matrix of a domain of category `Cat::Matrix`)

Return Values

Nonnegative integer

linalg::rank

See Also

MuPAD Functions

Related Examples

- “Compute Rank of a Matrix”

Purpose Extract rows of a matrix

Syntax `linalg::row(A, r)`
`linalg::row(A, r1 .. r2)`
`linalg::row(A, list)`

Description `linalg::row(A, r)` extracts the r -th row vector of the matrix A .
`linalg::row(A, r1.. r2)` returns a list of row vectors whose indices are in the range $r_1.. r_2$. If $r_2 < r_1$ then the empty list `[]` is returned.
`linalg::row(A, list)` returns a list of row vectors whose indices are contained in `list` (in the same order).

Examples **Example 1**

We define a matrix over :

```
A := Dom::Matrix(Dom::Rational)(
  [[1, 1/5], [-3/2, 5], [2, -3]]
)
```

$$\begin{pmatrix} 1 & \frac{1}{5} \\ -\frac{3}{2} & 5 \\ 2 & -3 \end{pmatrix}$$

and illustrate the three different input formats for the function `linalg::row`:

```
linalg::row(A, 2)
```

$$\left(-\frac{3}{2} \ 5\right)$$

```
linalg::row(A, [2, 1, 3])
```

linalg::row

$$\left[\left(-\frac{3}{2} \ 5 \right), \left(1 \ \frac{1}{5} \right), (2 \ -3) \right]$$

`linalg::row(A, 2..3)`

$$\left[\left(-\frac{3}{2} \ 5 \right), (2 \ -3) \right]$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r

The row index: a positive integer less or equal to m

r₁ .. r₂

A range of row indices (positive integers less or equal to m)

list

A list of row indices (positive integers less or equal to m)

Return Values

Single row vector or a list of row vectors; a row vector is a $1 \times n$ matrix of category `Cat::Matrix(R)`, where R is the component ring of A .

| `linalg::setRow`

Purpose	Scalar product of vectors
Syntax	<code>linalg::scalarProduct(u, v, <Real>)</code>
Description	<p><code>linalg::scalarProduct(u, v)</code> computes the scalar product of the vectors $\vec{u} = (u_1, \dots, u_n)$ and $\vec{v} = (v_1, \dots, v_n)$ with respect to the standard basis, i.e., the sum $u_1 \overline{v_1} + \dots + u_n \overline{v_n}$.</p> <p>The scalar product is also called “inner product” or “dot product”.</p> <p>If the component ring of the vectors <code>u</code> and <code>v</code> does not define the entry “conjugate” or if the option <code>Real</code> is specified, then <code>linalg::scalarProduct</code> uses the definition $u_1 v_1 + \dots + u_n v_n$ of the scalar product.</p> <p>The vectors <code>u</code> and <code>v</code> must be defined over the same component ring.</p> <p><code>linalg::scalarProduct</code> can be redefined to a different scalar product. This also affects the behaviour of functions such as <code>linalg::angle</code>, <code>linalg::factorQR</code>, <code>linalg::isUnitary</code>, <code>norm</code> (for vectors and matrices), <code>linalg::orthog</code> and <code>linalg::pseudoInverse</code> depend on the definition of <code>linalg::scalarProduct</code>. See “Example 3” on page 14-202.</p>
Environment Interactions	Properties of identifiers are taken into account.
Examples	<p>Example 1</p> <p>We compute the scalar product of the vectors $(i, 1)$ and $(1, -i)$:</p> <pre>MatC := Dom::Matrix(Dom::Complex): u := MatC([I, 1]): v := MatC([1, -I]): linalg::scalarProduct(u, v)</pre> <p><code>2i</code></p>

linalg::scalarProduct

Example 2

We compute the scalar product of the vectors $\vec{u} = (u_1, u_2)$ and $\vec{v} = (v_1, v_2)$ with the symbolic entries u_1, u_2, v_1, v_2 over the standard component ring for matrices:

```
delete u1, u2, v1, v2:  
u := matrix([u1, u2]): v := matrix([v1, v2]):  
linalg::scalarProduct(u, v)
```

$u_1 \bar{v}_1 + u_2 \bar{v}_2$

You can use `assume` to tell the system that the symbolic components are to represent real numbers:

```
assume([u1, u2, v1, v2], Type::Real):
```

Then the scalar product of \vec{u} and \vec{v} simplifies to:

```
linalg::scalarProduct(u, v)
```

$u_1 v_1 + u_2 v_2$

Alternatively, the option `Real` can be specified:

```
unassume(u1, u2, v1, v2):  
linalg::scalarProduct(u, v, Real)
```

$u_1 v_1 + u_2 v_2$

Example 3

One particular scalar product in the real vector space of continuous functions on the interval $[0, 1]$ is defined by

$$(f, g) = \int_0^1 f(t) g(t) dt$$

To compute an orthogonal basis corresponding to the polynomial basis $1, t, t^2, t^3, \dots$ with respect to this scalar product, we replace the standard scalar product by the following procedure:

```
standardScalarProduct := linalg::scalarProduct:
unprotect(linalg):
linalg::scalarProduct := proc(u, v)
  local F, f, t;
begin
  // (0)
  f := expr(u[1] * v[1]);

  // (1)
  t := indets(f);
  if t = {} then t := genident("t") else t := op(t, 1) end_if;

  // (2)
  F := int(f, t = 0..1);

  // (3)
  u::dom::coeffRing::coerce(F)
end:
```

We start with step (0) to convert $f(t)g(t)$ to an expression of a basic domain type, such that the system function `int` in step (2) can handle its input (this is not necessary if the elements of the component ring of the vectors are already represented by elements of basic domains).

Step (1) extracts the indeterminate of the polynomials, step (2) computes the scalar product as defined above and step (3) converts the result back to an element of the component ring of vectors u and v .

linalg::scalarProduct

Note that we need to unprotect the write protected identifier `linalg`, otherwise the assignment would lead to an error message.

We next create the matrix which consists of the first five of the above polynomials:

```
P := matrix([[1, t, t^2, t^3, t^4]])
```

```
(1 t t^2 t^3 t^4)
```

If we now perform the Gram-Schmidt orthogonalization procedure on the columns of `P` with the function `linalg::orthog`, we get:

```
S := linalg::orthog(linalg::col(P, 1..4))
```

```
( (1), (t - 1/2), (t^2 - t + 1/6), (t^3 - 3/2 t^2 + 3/5 t - 1/20) )
```

Each vector in `S` is orthogonal to the other vectors in `S` with respect to the modified scalar product. We check this for the first vector:

```
linalg::scalarProduct(S[1], S[j]) $ j = 2..nops(S)
```

```
0, 0, 0
```

Finally, we undo the redefinition of the scalar product, so as not to run into trouble with subsequent computations:

```
linalg::scalarProduct := standardScalarProduct:  
protect(linalg, Error):
```

Parameters

u, v

Vectors of the same dimension (a vector is an $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

Options

Real

Use $u_1v_1 + \dots + u_nv_n$ as the definition of the scalar product, i.e., suppress the use of conjugate.

Return Values

Element of the component ring of u and v .

linalg::setCol

Purpose Change a column of a matrix

Syntax `linalg::setCol(A, p, c)`

Description `linalg::setCol(A, p, c)` returns a copy of matrix A with the p -th column replaced by the column vector \vec{c} .

If c is a list with at most m elements, then c is converted into a column vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of A ; see “Example 2” on page 14-206).

Examples **Example 1**

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):  
A := MatQ([[1, 2], [3, 2]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd column by the 2×1 zero vector:

```
linalg::setCol(A, 2, MatQ([0, 0]))
```

$$\begin{pmatrix} 1 & 0 \\ 3 & 0 \end{pmatrix}$$

Example 2

We create the 2×2 zero matrix over \mathbb{Z}_6 :

```
B := Dom::Matrix(Dom::IntegerMod(6))(2, 2)
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd column by the vector $\begin{pmatrix} 1 \\ -1 \end{pmatrix}$. We give the column vector in form of a list. Its elements are converted implicitly into objects of the component ring of B:

```
linalg::setCol(B, 2, [1, -1])
```

$$\begin{pmatrix} 0 \bmod 6 & 1 \bmod 6 \\ 0 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number 1/3 can not be converted into an object of type Dom::IntegerMod(6):

```
linalg::setCol(B, 1, [1/3, 0])
```

```
Error: The column vector is invalid. [linalg::setCol]
```

Parameters

A

An $m \times n$ matrix of a domain of category Cat::Matrix

c

A column vector, or a list that can be converted into a column vector of the domain Dom::Matrix(R), where R is the component ring of A (a column vector is an $m \times 1$ matrix)

Return Values

Matrix of the same domain type as A.

See Also

MuPAD Functions

linalg::col | linalg::delCol | linalg::delRow | linalg::row  
| linalg::setRow
```

linalg::setRow

Purpose Change a row of a matrix

Syntax `linalg::setRow(A, p, r)`

Description `linalg::setRow(A, p, r)` returns a copy of the matrix A with the p -th row replaced by the row vector \vec{r} .

If r is a list with at most n elements, then r is converted into a row vector. An error message is returned if the conversion is not possible (e.g., if an element of the list cannot be converted into an object of the component ring of A ; see “Example 2” on page 14-208).

Examples **Example 1**

We define a matrix over the rationals:

```
MatQ := Dom::Matrix(Dom::Rational):  
A := MatQ([[1, 2], [3, 2]])
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 2 \end{pmatrix}$$

and replace the 2nd row by the 1×2 zero vector:

```
linalg::setRow(A, 2, MatQ(1, 2, [0, 0]))
```

$$\begin{pmatrix} 1 & 2 \\ 0 & 0 \end{pmatrix}$$

Example 2

We create the 2×4 zero matrix over \mathbb{Z}_6 :

```
B := Dom::Matrix(Dom::IntegerMod(6))(2, 4)
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \end{pmatrix}$$

and replace the 2nd row by the vector (1, - 1, 1, - 1). We give the row vector in form of a list. Its elements are converted implicitly into objects of the component ring of B:

```
linalg::setRow(B, 2, [1, -1, 1, -1])
```

$$\begin{pmatrix} 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 & 0 \bmod 6 \\ 1 \bmod 6 & 5 \bmod 6 & 1 \bmod 6 & 5 \bmod 6 \end{pmatrix}$$

The following input leads to an error message because the number $\frac{1}{3}$ can not be converted into an object of type `Dom::IntegerMod(6)`:

```
linalg::setRow(B, 1, [1/3, 0, 1, 0])
```

```
Error: The row vector is invalid. [linalg::setRow]
```

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r

A row vector or a list that can be converted into a row vector the domain `Dom::Matrix(R)`, where R is the component ring of A (a row vector is a $1 \times n$ matrix)

Return Values

Matrix of the same domain type as A.

```

linalg::smithForm

Purpose Smith canonical form of a matrix

Syntax `linalg::smithForm(A)`

Description `linalg::smithForm(A)` computes the Smith canonical form of the n -dimensional square matrix A , i.e., an $n \times n$ diagonal matrix S such that $S_{i-1, i-1}$ divides $S_{i, i}$ for $i = 2, \dots, n$.

The Smith canonical form of a matrix A is unique.

The component ring of A must be a Euclidean ring, i.e., a domain of category `Cat::EuclideanDomain`.

Examples

Example 1

We define a matrix over the integers:

```
MatZ := Dom::Matrix(Dom::Integer):  
A := MatZ([[9, -36, 30], [-36, 192, -180], [30, -180, 180]])
```

$$\begin{pmatrix} 9 & -36 & 30 \\ -36 & 192 & -180 \\ 30 & -180 & 180 \end{pmatrix}$$

The Smith canonical form of A is then given by:

```
linalg::smithForm(A)
```

$$\begin{pmatrix} 3 & 0 & 0 \\ 0 & 12 & 0 \\ 0 & 0 & 60 \end{pmatrix}$$

Example 2

We compute the Smith canonical form of a matrix over a ring of polynomials:

```
MatPoly := Dom::Matrix(Dom::DistributedPolynomial([x], Dom::Rati
B := MatPoly(
  [[-(x - 3)^2*(x - 2), (x - 3)*(x - 2)*(x - 4)],
   [(x - 3)*(x - 2)*(x - 4), -(x - 3)^2*(x - 4)]
])
```

$$\begin{pmatrix} -x^3 + 8x^2 - 21x + 18 & x^3 - 9x^2 + 26x - 24 \\ x^3 - 9x^2 + 26x - 24 & -x^3 + 10x^2 - 33x + 36 \end{pmatrix}$$

The Smith canonical form of the matrix B is the following matrix:

```
linalg::smithForm(B)
```

$$\begin{pmatrix} x-3 & 0 \\ 0 & x^3 - 9x^2 + 26x - 24 \end{pmatrix}$$

Parameters

A

A square matrix of a domain of category `Cat::Matrix`

Return Values

Matrix of the same domain type as A.

Algorithms

An $n \times n$ matrix $S = (s_{ij})$ with coefficients in a Euclidean ring is said to be in Smith canonical form if S is a diagonal matrix (with nonnegative coefficients in case of the ring) such that $s_{i,i}$ divides $s_{i+1,i+1}$ for all $i < n$.

See Also

MuPAD Functions

`linalg::frobeniusForm` | `linalg::hermiteForm` |
`linalg::jordanForm`

linalg::sqrtMatrix

Purpose Square root of a matrix

Syntax `linalg::sqrtMatrix(A, <sqrtfunc>)`

Description `linalg::sqrtMatrix(A)` returns the square root of the matrix A .
If A has an eigenvalue 0 of algebraic multiplicity larger than its geometric multiplicity, then the square root of A does not exist.

Examples **Example 1**

A square root of a diagonal matrix is given by the diagonal matrix, whose diagonal entries are just the square roots of the original matrix.

Compute the square root of the matrix

$$A = \begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix};$$

```
A := matrix([[4, 0, 0], [0, 2, 0], [0, 0, -1]]):  
S := linalg::sqrtMatrix(A)
```

$$\begin{pmatrix} 2 & 0 & 0 \\ 0 & \sqrt{2} & 0 \\ 0 & 0 & i \end{pmatrix}$$

Check the correctness of the result:

```
S^2
```

$$\begin{pmatrix} 4 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & -1 \end{pmatrix}$$

Example 2

Compute the square root of the matrix

$$A = \begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix};$$

```
A := matrix([[2, -2, 0], [-1, 3, 0], [-1/3, 5/3, 2]]):
S := linalg::sqrtMatrix(A)
```

$$\begin{pmatrix} \frac{4}{3} & -\frac{2}{3} & 0 \\ -\frac{1}{3} & \frac{5}{3} & 0 \\ \frac{2\sqrt{2}}{3} - 1 & 1 - \frac{\sqrt{2}}{3} & \sqrt{2} \end{pmatrix}$$

If you compute the square of the matrix S and simplify the result, you obtain the matrix A:

```
simplify(S^2)
```

$$\begin{pmatrix} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{pmatrix}$$

Using the function $x \rightarrow -\sqrt{x}$ as second argument for the computation of the square root of the matrix A, obtain a different matrix, whose components are just the negative components of the original square root computed above:

```
S:= linalg::sqrtMatrix(A, x -> -sqrt(x)):
S, simplify(S^2);
```

linalg::sqrtMatrix

$$\left(\begin{array}{ccc} -\frac{4}{3} & \frac{2}{3} & 0 \\ \frac{1}{3} & -\frac{5}{3} & 0 \\ 1 - \frac{2\sqrt{2}}{3} & \frac{\sqrt{2}}{3} - 1 & -\sqrt{2} \end{array} \right), \left(\begin{array}{ccc} 2 & -2 & 0 \\ -1 & 3 & 0 \\ -\frac{1}{3} & \frac{5}{3} & 2 \end{array} \right)$$

Parameters **A**

A square matrix of a domain of category `Cat::Matrix`

sqrtfunc

A function satisfying $\text{sqrtfunc}(a)^2 = a$ for every element a of the coefficient ring of A (i.e. the square root function of the coefficient domain of A).

Return Values

Matrix B with $B^2 = A$ such that the eigenvalues of B are the square roots of the eigenvalues of A or FAIL if the square root of the matrix does not exist

See Also

MuPAD Functions

`linalg::eigenvalues` | `linalg::eigenvectors` |
`linalg::jordanForm` | `numeric::eigenvalues` |
`numeric::eigenvectors` | `solve`

Purpose Join matrices vertically

Syntax `linalg::stackMatrix(A, <B1, B2, ... >)`

Description `linalg::stackMatrix(A, B1, B2, ...)` returns the matrix formed by joining the matrices A, B₁, B₂, ... vertically.

The matrices B₁, B₂, ... are converted into the matrix domain `Dom::Matrix(R)`, where R is the component ring of A.

An error message is raised if one of these conversions fails, or if the matrices do not have the same number of columns as the matrix A.

Examples **Example 1**

We define a matrix:

```
A := matrix( [[sin(x),x], [-x,cos(x)]] )
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \end{pmatrix}$$

and append the 2x2 identity matrix to the lower end of the matrix A:

```
linalg::stackMatrix(A, matrix::identity(2))
```

$$\begin{pmatrix} \sin(x) & x \\ -x & \cos(x) \\ 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Example 2

We define a matrix from the ring of 2x2 square matrices:

```
SqMatQ := Dom::SquareMatrix(2,Dom::Rational):  
A := SqMatQ([[1, 2], [3, 4]])
```

linalg::stackMatrix

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \end{pmatrix}$$

Note that the following operation:

```
AA := linalg::stackMatrix(A, A)
```

$$\begin{pmatrix} 1 & 2 \\ 3 & 4 \\ 1 & 2 \\ 3 & 4 \end{pmatrix}$$

returns a matrix of a different domain type as the input matrix:

```
domtype(AA)
```

```
Dom::Matrix(Dom::Rational)
```

Parameters

A, <B₁, B₂, ...>

Matrices of a domain of category `Cat::Matrix`

Return Values

Matrix of the domain type `Dom::Matrix(R)`, where R is the component ring of A.

See Also

MuPAD Functions

`linalg::concatMatrix`

Purpose Extract a submatrix or a subvector from a matrix or a vector, respectively

Syntax

```
linalg::submatrix(A, r1 .. r2, c1 .. c2)
linalg::submatrix(A, rlist, clist)
linalg::submatrix(v, i1 .. i2)
linalg::submatrix(v, list)
```

Description

`linalg::submatrix(A, r1.. r2, c1.. c2)` returns a copy of the submatrix of the matrix A obtained by selecting the rows $r_1, r_1 + 1, \dots, r_2$ and the columns $c_1, c_1 + 1, \dots, c_2$.

`linalg::submatrix(v, i1.. i2)` returns a copy of the subvector of the vector \vec{v} obtained by selecting the components with indices $i_1, i_1 + 1, \dots, i_2$.

The index notation $A[r_1.. r_2, c_1.. c_2]$ and $v[i_1.. i_2]$, respectively, can be used instead of `linalg::submatrix(A, r1.. r2, c1.. c2)` and `linalg::submatrix(v, i1.. i2)`.

`linalg::submatrix(A, rlist, clist)` returns the submatrix of the matrix A whose (i, j) -th component is $a_{rlist_i, clist_j}$.

`linalg::submatrix(v, list)` returns the subvector of the vector v whose i -th component is v_{list_i} .

If v is a row vector or a column vector, then `linalg::submatrix(v, 1..1, i1.. i2)` and `linalg::submatrix(v, i1.. i2, 1..1)`, respectively, are valid inputs, and they both are equivalent to the call `linalg::submatrix(v, i1.. i2)`.

Examples **Example 1**

We define the following matrix:

```
A := matrix([[1, x, 0], [0, x^2, 1]])
```

$$\begin{pmatrix} 1 & x & 0 \\ 0 & x^2 & 1 \end{pmatrix}$$

linalg::submatrix

The submatrix $(a_{1,j})_{1 \leq j \leq 2}$ of A is given by:

```
linalg::submatrix(A, 1..1, 1..2)
```

$$\begin{pmatrix} 1 & x \end{pmatrix}$$

Equivalent to the use of the index operator we obtain:

```
A[1..1, 1..2]
```

$$\begin{pmatrix} 1 & x \end{pmatrix}$$

We extract the first and the third column of A and get the 2×2 identity matrix:

```
linalg::submatrix(A, [1, 2], [1, 3])
```

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Example 2

Vector components can be accessed by a single index or a range of indices. For example, to extract the first two components of the following vector:

```
v := matrix([1, 2, 3])
```

$$\begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix}$$

just enter the command:

```
v[1..2]
```

$$\begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

Of course, the same subvector can be extracted with the command `linalg::submatrix(v, 1..2)`.

The following input returns the vector comprising the first and the third component of `v`:

```
linalg::submatrix(v, [1, 3])
```

$$\begin{pmatrix} 1 \\ 3 \end{pmatrix}$$

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

v

A vector with k components, i.e., a $k \times 1$ or $1 \times k$ matrix of a domain of category `Cat::Matrix`

r₁ .. r₂, c₁ .. c₂

Ranges of row/column indices: positive integers less or equal to m and n , respectively

rlist, clist

Lists of row/column indices: positive integers less or equal to m and n , respectively

i₁ .. i₂

A range of vector indices: positive integers less or equal to k

list

A list of vector indices: positive integers less or equal to k

linalg::submatrix

Return Values

Matrix of the same domain type as A or a vector of the same domain type as v , respectively.

See Also

MuPAD Functions

`linalg::col` | `linalg::row` | `linalg::substitute`

Purpose Replace a part of a matrix by another matrix

Syntax `linalg::substitute(B, A, m, n)`

Description `linalg::substitute(B, A, m, n)` returns a copy of the matrix B, where entries starting at position $[m, n]$ are replaced by the entries of the matrix A, i.e., B_{mn} is A_{11} .

If the matrices are defined over different component domains, then the entries of A are converted into elements of the component domain of the matrix B. If one of these conversions fails, then an error message is returned.

Examples **Example 1**

We define the following matrix:

```
B := matrix(  
  [[1, 2, 3, 4], [5, 6, 7, 8],  
   [9, 10, 11, 12], [13, 14, 15, 16]]  
)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 16 \end{pmatrix}$$

and copy the 2×2 zero matrix into the matrix B, beginning at position [3, 3]:

```
A := matrix(2, 2):  
linalg::substitute(B, A, 3, 3)
```

linalg::substitute

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 0 & 0 \\ 13 & 14 & 0 & 0 \end{pmatrix}$$

Matrix entries out of range are ignored:

```
linalg::substitute(B, A, 4, 4)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \\ 9 & 10 & 11 & 12 \\ 13 & 14 & 15 & 0 \end{pmatrix}$$

Parameters

A, B

Matrices of a domain of category `Cat::Matrix`

m, n

Positive integers

Return Values

Matrix of the same domain type as B.

See Also

MuPAD Functions

`linalg::submatrix` | `linalg::concatMatrix` | `linalg::setCol` |
`linalg::setRow` | `linalg::stackMatrix`

Purpose

Basis for the sum of vector spaces

Syntax

`linalg::sumBasis(S1, S2, ...)`

Description

`linalg::sumBasis(S1, S2, ...)` returns a basis of the vector space $V_1 + V_2 + \dots$, where V_i denotes the vector space spanned by the vectors in S_i .

To obtain an ordered basis, S_1, S_2, \dots should be given as lists of vectors.

A basis of the zero-dimensional space is the empty set or list, respectively.

The given vectors must be defined over the same component ring, which must be a field, i.e., a domain of category `Cat::Field`.

Examples

Example 1

We define three vectors $\vec{v}_1, \vec{v}_2, \vec{v}_3$ over :

```
MatQ := Dom::Matrix(Dom::Rational):
```

```
v1 := MatQ([[3, -2]]); v2 := MatQ([[1, 0]]); v3 := MatQ([[5, -3]])
```

$$\begin{pmatrix} 3 & -2 \end{pmatrix}$$

$$\begin{pmatrix} 1 & 0 \end{pmatrix}$$

$$\begin{pmatrix} 5 & -3 \end{pmatrix}$$

A basis of the vector space $V_1 + V_2 + V_3$ with

- V_1 generated by $\vec{v}_1, \vec{v}_2, \vec{v}_3$
- V_2 generated by \vec{v}_1, \vec{v}_3

linalg::sumBasis

- V_3 generated by $\vec{v}_1 + \vec{v}_2, \vec{v}_2, \vec{v}_1 + \vec{v}_3$

is:

```
linalg::sumBasis([v1, v2, v3], [v1, v3], [v1 + v2, v2, v1 + v3])  
  
[(3 -2), (1 0)]
```

Example 2

The following set of two vectors:

```
MatQ := Dom::Matrix(Dom::Rational):  
S1 := {MatQ([1, 2, 3]), MatQ([-1, 0, 2])}
```

$$\left\{ \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \right\}$$

is a basis of a two-dimensional subspace of \mathbb{R}^3 :

```
linalg::rank(S1)  
  
2
```

The same holds for the following set:

```
S2 := {MatQ([0, 2, 3]), MatQ([2, 4, 6])};  
linalg::rank(S2)
```

$$\left\{ \begin{pmatrix} 0 \\ 2 \\ 3 \end{pmatrix}, \begin{pmatrix} 2 \\ 4 \\ 6 \end{pmatrix} \right\}$$

2

The sum of the corresponding two subspaces is the vector space ³:

```
Q3 := linalg::sumBasis(S1, S2)
```

$$\left\{ \begin{pmatrix} -1 \\ 0 \\ 2 \end{pmatrix}, \begin{pmatrix} 0 \\ 2 \\ 3 \end{pmatrix}, \begin{pmatrix} 1 \\ 2 \\ 3 \end{pmatrix} \right\}$$

Parameters

S_1, S_2, \dots

A set or list of vectors of the same dimension (a vector is a $n \times 1$ or $1 \times n$ matrix of a domain of category `Cat::Matrix`)

Return Values

Set or a list of vectors, according to the domain type of the parameter S_1 .

See Also

MuPAD Functions

`linalg::basis` | `linalg::intBasis` | `linalg::rank`

linalg::swapCol

Purpose Swap two columns in a matrix

Syntax `linalg::swapCol(A, c1, c2)`
`linalg::swapCol(A, c1, c2, r1 .. r2)`

Description `linalg::swapCol(A, c1, c2)` returns a copy of the matrix *A* with the columns with indices *c₁* and *c₂* interchanged.

The effect of `linalg::swapCol(A, c1, c2, r1.. r2)` is that only the components from row *r₁* to row *r₂* of column *c₁* are interchanged with the corresponding components of column *c₂*.

Examples **Example 1**

We consider the following matrix:

```
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second column of *A*. The result is the following matrix:

```
linalg::swapCol(A, 1, 2)
```

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 8 & 7 & 9 \end{pmatrix}$$

If only the components in the first two rows should be affected, we enter:

```
linalg::swapCol(A, 1, 2, 1..2)
```

$$\begin{pmatrix} 2 & 1 & 3 \\ 5 & 4 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third row remains unchanged.

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

c_1, c_2

The column indices: positive integers less or equal to n

$r_1 \dots r_2$

A range of row indices (positive integers less or equal to m)

Return Values

Matrix of the same domain type as A.

linalg::swapRow

Purpose Swap two rows in a matrix

Syntax `linalg::swapRow(A, r1, r2)`
`linalg::swapRow(A, r1, r2, c1 .. c2)`

Description `linalg::swapRow(A, r1, r2)` returns a copy of the matrix A with the rows with indices r_1 and r_2 interchanged.

The effect of `linalg::swapRow(A, r1, r2, c1.. c2)` is that only the components from column c_1 to column c_2 of row r_1 are interchanged with the corresponding components of row r_2 .

Examples **Example 1**

We consider the following matrix:

```
A := matrix(3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The following command interchanges the first and the second row of A . The result is the following matrix:

```
linalg::swapRow(A, 1, 2)
```

$$\begin{pmatrix} 4 & 5 & 6 \\ 1 & 2 & 3 \\ 7 & 8 & 9 \end{pmatrix}$$

If only the components in the first two columns should be affected, we enter:

```
linalg::swapRow(A, 1, 2, 1..2)
```

$$\begin{pmatrix} 4 & 5 & 3 \\ 1 & 2 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

The third column remains unchanged.

Parameters

A

An $m \times n$ matrix of a domain of category `Cat::Matrix`

r₁, r₂

The row indices: positive integers less or equal to m

c₁ .. c₂

A range of column indices (positive integers less or equal to n)

Return Values

Matrix of the same domain type as A.

Concepts

- “Swap and Delete Rows and Columns”

linalg::sylvester

Purpose Sylvester matrix of two polynomials

Syntax `linalg::sylvester(p, q)`
`linalg::sylvester(f, g, x)`

Description `linalg::sylvester(p, q)` returns the Sylvester matrix of the two polynomials p and q .

If no variable is specified, then the polynomials p and q must be either of the domain `DOM_POLY` or from a domain of category `Cat::Polynomial`. Polynomial expressions are not allowed.

If the polynomials p and q are of the domain `DOM_POLY`, then they must be univariate polynomials. The component ring of the Sylvester matrix is the common coefficient ring R of p and q , except in the following two cases for built-in coefficient rings: If R is `Expr` then the domain `Dom::ExpressionField()` is the component ring of the Sylvester matrix. If R is `IntMod(m)`, then the Sylvester matrix is defined over the ring `Dom::IntegerMod(m)` (see “Example 2” on page 14-231).

Otherwise, if the polynomials p and q are from a domain of category `Cat::Polynomial`, then the Sylvester matrix is computed with respect to the main variable of p and q (see the method “`mainvar`” of the category `Cat::Polynomial`). In the case of univariate polynomials the Sylvester matrix is defined over the common coefficient ring of p and q . In the case of multivariate polynomials, the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of p and q except x , and R is the common coefficient ring of the polynomials.

If f and g are polynomial expressions or multivariate polynomials of type `DOM_POLY`, then you must specify the variable x .

In the case of polynomial expressions, the component ring of the Sylvester matrix is the domain `Dom::ExpressionField()` (see “Example 3” on page 14-232).

In the case of multivariate polynomials the Sylvester matrix is defined over the component ring `Dom::DistributedPolynomial(ind, R)`, where `ind` is the list of all variables of f and g except x , and R is the

common coefficient ring of the polynomials (see “Example 4” on page 14-232).

At least one of the input polynomials must have positive degree with respect to the main variable or x , respectively, but it is not necessary that both of them have positive degree.

Examples

Example 1

The Sylvester matrix of the two polynomials $p = x^2 + 2x - 1$ and $q = x^4 + 1$ over \mathbb{Z} is the following 6×6 matrix:

```
delete x: Z := Dom::Integer:
S := linalg::sylvester(poly(x^2 + 2*x - 1, Z), poly(x^4 + 1, Z))
```

$$\begin{pmatrix} 1 & 2 & -1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -1 & 0 & 0 \\ 0 & 0 & 1 & 2 & -1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -1 \\ 1 & 0 & 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 & 1 \end{pmatrix}$$

Example 2

If the polynomials have the built-in coefficient ring $\text{IntMod}(m)$, then the Sylvester matrix is defined over the domain $\text{Dom}::\text{IntegerMod}(m)$:

```
delete x:
S:= linalg::sylvester(
  poly(x + 1, IntMod(7)), poly(x^2 - 2*x + 2, IntMod(7))
)
```

$$\begin{pmatrix} 1 \bmod 7 & 1 \bmod 7 & 0 \bmod 7 \\ 0 \bmod 7 & 1 \bmod 7 & 1 \bmod 7 \\ 1 \bmod 7 & 5 \bmod 7 & 2 \bmod 7 \end{pmatrix}$$

linalg::sylvester

```
domtype(S)
```

```
Dom::Matrix(Dom::IntegerMod(7))
```

Example 3

The Sylvester matrix of the following two polynomial expressions with respect to the variable x is:

```
delete x, y:  
S := linalg::sylvester(x + y^2, 2*x^3 - 1, x)
```

$$\begin{pmatrix} 1 & y^2 & 0 & 0 \\ 0 & 1 & y^2 & 0 \\ 0 & 0 & 1 & y^2 \\ 2 & 0 & 0 & -1 \end{pmatrix}$$

```
domtype(S)
```

```
Dom::Matrix()
```

The Sylvester matrix of these two polynomials with respect to y is the following 2×2 matrix:

```
linalg::sylvester(x + y^2, 2*x^3 - 1, y)
```

$$\begin{pmatrix} 2x^3 - 1 & 0 \\ 0 & 2x^3 - 1 \end{pmatrix}$$

Example 4

Here is an example for computing the Sylvester matrix of multivariate polynomials:

```
delete x, y: Q := Dom::Rational:  
T := linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), x)
```

$$\begin{pmatrix} 1 & -1 & y \\ 1 & 2 & 0 \\ 0 & 1 & 2 \end{pmatrix}$$

```
domtype( T )
```

```
Dom::Matrix(Dom::DistributedPolynomial([y], Dom::Rational, LexOrder))
```

The Sylvester matrix of these two multivariate polynomials with respect to y is:

```
linalg::sylvester(poly(x^2 - x + y, Q), poly(x + 2, Q), y)  
(x+2)
```

Parameters

p, q

Polynomials

f, g

Polynomials or polynomial expressions of positive degree

x

A variable

Return Values

Matrix of the domain `Dom::Matrix(R)`, where R is the coefficient domain of the polynomials (see below).

See Also

MuPAD Functions

`polylib::discrim` | `polylib::resultant`

linalg::tr

Purpose Trace of a matrix

Syntax `linalg::tr(A)`

Description `linalg::tr(A)` returns the trace of the square matrix A , i.e., the sum of the diagonal elements of A .

Examples **Example 1**

We compute the trace of the following matrix:

```
A := Dom::Matrix(Dom::Integer)
      (3, 3, (i, j) -> 3*(i - 1) + j)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{pmatrix}$$

```
linalg::tr(A)
```

```
15
```

Parameters **A**

A square matrix of a domain of category `Cat::Matrix`

Return Values Element of the component ring of A .

See Also

MuPAD Functions `det`

Concepts • “Compute Determinants and Traces of Square Matrices”

Purpose Toeplitz matrix

Syntax
`linalg::toeplitz(m, n, [t-k, ..., tk], <R>)`
`linalg::toeplitz(n, [t-k, ..., tk], <R>)`
`linalg::toeplitz(c, r)`
`linalg::toeplitz(r)`

Description `linalg::toeplitz(m, n, [t-k, ..., t-1, t0, t1, ..., tk])` returns the $m \times n$ Toeplitz matrix

$$\begin{pmatrix}
 t_0 & t_1 & t_2 & \dots & \dots & \dots & \dots & t_k \\
 t_{-1} & t_0 & t_1 & t_2 & \dots & \dots & \dots & t_{k-1} \\
 t_{-2} & t_{-1} & t_0 & t_1 & t_2 & \dots & \dots & t_{k-2} \\
 \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\
 \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & t_0 & t_1 & t_2 \\
 \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & t_{-1} & t_0 & t_1 \\
 t_{-k} & \dots & \dots & \dots & \dots & t_{-2} & t_{-1} & t_0 & t_1
 \end{pmatrix}$$

`linalg::toeplitz(n, [t-k, ..., tk])` returns the square Toeplitz matrix of dimension $n \times n$.

A number of entries $[t_{-k}, \dots, t_k]$ must be an odd number $2k + 1$. There must be at least k diagonal bands above the diagonal and k diagonal bands below the diagonal: k must satisfy $k \leq \min(m, n) - 1$. Entries with matrix indices (i, j) satisfying $|i - j| > k$ are set to 0.

Toeplitz matrices of dimension $n \times n$ can be inverted with $O(n^2)$ operations. See `linalg::toeplitzSolve`.

`linalg::toeplitz(c, r)` generates a nonsymmetric Toeplitz matrix having c as its first column and r as its first row. If the first elements of c and r differ, `toeplitz` issues a warning and uses the first element of the column.

`linalg::toeplitz(r)` generates a symmetric Toeplitz matrix if r is real. If r is complex, but its first element is real, then this syntax

generates the Hermitian Toeplitz matrix formed from r . If the first element of r is complex, then the resulting matrix is Hermitian off the main diagonal, meaning that $T_{ij} = \text{conjugate}(T_{ji})$ for $i \neq j$.

When you use matrices in MuPAD computations, both computational efficiency and memory use can depend on whether the matrix is sparse or dense. The first two syntaxes are optimized for generating sparse matrices and, therefore, these syntaxes are preferable. For details about improving performance when working with matrices, see “Use Sparse and Dense Matrices”.

Examples

Example 1

Construct a 4×4 Toeplitz matrix with three bands:

```
linalg::toeplitz(4, [-1, 2, 1])
```

$$\begin{pmatrix} 2 & 1 & 0 & 0 \\ -1 & 2 & 1 & 0 \\ 0 & -1 & 2 & 1 \\ 0 & 0 & -1 & 2 \end{pmatrix}$$

Construct a 3×5 Toeplitz matrix with symbolic entries:

```
linalg::toeplitz(3, 5, [a, b, c])
```

$$\begin{pmatrix} b & c & 0 & 0 & 0 \\ a & b & c & 0 & 0 \\ 0 & a & b & c & 0 \end{pmatrix}$$

Example 2

Construct a Toeplitz matrix by using a vector to specify its first row. For a real vector, the resulting matrix is symmetric:

```
r := matrix([1, 2, 3]):  
linalg::toeplitz(r)
```

$$\begin{pmatrix} 1 & 2 & 3 \\ 2 & 1 & 2 \\ 3 & 2 & 1 \end{pmatrix}$$

For a complex vector, the resulting matrix is Hermitian off the main diagonal:

```
r := matrix([1 + I, 2 + I, 3 + I]):
T := linalg::toeplitz(r);
htranspose(T)
```

$$\begin{pmatrix} 1+i & 2+i & 3+i \\ 2-i & 1+i & 2+i \\ 3-i & 2-i & 1+i \end{pmatrix}$$

$$\begin{pmatrix} 1-i & 2+i & 3+i \\ 2-i & 1-i & 2+i \\ 3-i & 2-i & 1-i \end{pmatrix}$$

Example 3

Construct a Toeplitz matrix by using two vectors to specify its first column and first row:

```
c := matrix([1, a/2, b/2]):
r := [1, a, b]:
linalg::toeplitz(c, r)
```

$$\begin{pmatrix} 1 & \frac{a}{2} & \frac{b}{2} \\ a & 1 & \frac{a}{2} \\ b & a & 1 \end{pmatrix}$$

linalg::toeplitz

If the first elements of the vectors differ, `linalg::toeplitz` issues a warning and uses the first element of the column:

```
c := matrix([1, a/2, b/2]):  
r := [2, a, b]:  
linalg::toeplitz(c, r)
```

Warning: First element of input column does not match first element

$$\begin{pmatrix} 2 & \frac{a}{2} & \frac{b}{2} \\ a & 2 & \frac{a}{2} \\ b & a & 2 \end{pmatrix}$$

Parameters

m, n

Row and column dimensions of the matrix: positive integers.

t₁, ..., t_k

Arithmetical expressions or elements of the component ring R.

R

Component ring: a domain of category `Cat::Rng`. The default ring is `Dom::ExpressionField()`.

c

Vector specifying the first column of a Toeplitz matrix.

r

Vector specifying the first row of a Toeplitz matrix.

Return Values

Matrix of the domain `Dom::Matrix(R)`.

`linalg::vandermondeSolve`

linalg::toeplitzSolve

Purpose Solve a linear Toeplitz system

Syntax `linalg::toeplitzSolve(t, y)`

Description `linalg::toeplitzSolve(t, y)` returns the solution \vec{x} of the linear

Toeplitz system $\sum_{j=1}^n t_{i-j} x_j = y_i$ with $i = 1, \dots, n$.

`linalg::toeplitzSolve(t, y)` with $t = [t_k, \dots, t_0, \dots, t_{-k}]$ and $y = [y_1, \dots, y_n]$ solves the $n \times n$ Toeplitz system

$$\begin{pmatrix} t_0 & t_{-1} & \cdot & \cdot & \cdot & t_{-k} \\ t_1 & t_0 & t_{-1} & \cdot & \cdot & t_{-k} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} \\ \cdot & t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} \\ \cdot & \cdot & t_k & t_{k-1} & \cdot & \cdot & \cdot & t_{-k} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{pmatrix} = \begin{pmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{pmatrix}$$

with $2k + 1$ bands.

`linalg::toeplitzSolve` implements the Levinson algorithm. It uses $O(n^2)$ elementary operations to solve the Toeplitz system. The memory requirements are $O(n)$. For dense Toeplitz systems, it is faster than the general solver `solve` and the linear solvers `linsolve`, `numeric::linsolve`, `linalg::matlinsolve` and `numeric::matlinsolve`.

Note Note that the Levinson algorithm requires that all principal minors

$$t_0, \begin{pmatrix} t_0 & t_{-1} \\ t_1 & t_0 \end{pmatrix}, \begin{pmatrix} t_0 & t_{-1} & t_{-2} \\ t_1 & t_0 & t_{-1} \\ t_2 & t_1 & t_0 \end{pmatrix}, \text{ etc}$$

are non-singular.

If `linalg::toeplitzSolve` does not manage to find the solution due to this limitation, or if the system is very sparse with k smaller than \sqrt{n} , we recommend to generate the corresponding Toeplitz matrix via `linalg::toeplitz` and compute the solution via `linalg::matlinsolve` or `numeric::matlinsolve`, respectively. Cf. “Example 2” on page 14-242

`linalg::toeplitzSolve` can solve Toeplitz systems over arbitrary coefficient rings. Just make sure that both the Toeplitz entries t as well as the components of the ‘right hand side’ y are elements of the desired coefficient ring. Cf. “Example 3” on page 14-243.

Examples

Example 1

The Toeplitz entries t and the right hand side y of the linear system are entered as row vectors:

```
t := matrix([4, 2, 1, 3, 5]):  
y := matrix([y1, y2, y3]):
```

The solution of the Toeplitz system is returned as a vector of the same type as the input vector y :

```
x := linalg::toeplitzSolve(t, y): x, domtype(x)
```

linalg::toeplitzSolve

$$\begin{pmatrix} \frac{7y_2}{25} - \frac{y_1}{5} + \frac{4y_3}{25} \\ \frac{2y_1}{5} - \frac{19y_2}{25} + \frac{7y_3}{25} \\ \frac{2y_2}{5} - \frac{y_3}{5} \end{pmatrix}, \text{Dom::Matrix()}$$

If the input vector is a list, the output is a list, too:

```
x := linalg::toeplitzSolve(t, [y1, y2, y3]): x, domtype(x)
```

$$\left[\frac{7y_2}{25} - \frac{y_1}{5} + \frac{4y_3}{25}, \frac{2y_1}{5} - \frac{19y_2}{25} + \frac{7y_3}{25}, \frac{2y_2}{5} - \frac{y_3}{5} \right], \text{DOM_LIST}$$

```
delete t, y, x:
```

Example 2

The Levinson algorithm cannot solve the following Toeplitz system because the first principal minor of the Toeplitz matrix (the central element of the Toeplitz entries) vanishes:

```
linalg::toeplitzSolve([1, 0, 1], [y1, y2, y3, y4])
```

FAIL

This does not necessarily imply that the Toeplitz system is not solvable. We generate the corresponding Toeplitz matrix and use a generic linear solver such as `linalg::matlinsolve`:

```
T := linalg::toeplitz(4, 4, [1, 0, 1])
```

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}$$

```
linalg::matlinsolve(T, matrix([y1, y2, y3, y4]))
```

$$\begin{pmatrix} y2 - y4 \\ y1 \\ y4 \\ y3 - y1 \end{pmatrix}$$

Example 3

We solve a Toeplitz system over the field \mathbb{F}_7 (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:

```
R := Dom::IntegerMod(7):
t := [R(5), R(3), R(2), R(5), R(1)]:
y := [R(1), R(2), R(3)]:
linalg::toeplitzSolve(t, y)
```

```
[1 mod 7, 5 mod 7, 2 mod 7]
```

```
delete R, t, y:
```

Parameters

t

A vector or a list with $2k + 1$ elements. (A vector is a $(2k + 1) \times 1$ or a $1 \times (2k + 1)$ matrix of category `Cat::Matrix`).

y

A vector or a list with n elements

linalg::toeplitzSolve

Return Values

Vector or list with n elements of the same domain type as the elements of y . FAIL is returned if the algorithm does not succeed in finding a solution.

`numeric::matlinsolve` | `solve`

Purpose Transpose of a matrix

Syntax `linalg::transpose(A)`

Description `linalg::transpose(A)` returns the transpose A^t of the matrix A .
`linalg::transpose` is an interface function for the method "transpose" of the matrix domain of A , i.e., instead of `linalg::transpose(A)` one may call `A::dom::transpose(A)` directly.

Examples **Example 1**

We define a 3×4 matrix:

```
A := matrix([[1, 2, 3, 4], [-1, 0, 1, 0], [3, 5, 6, 9]])
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ -1 & 0 & 1 & 0 \\ 3 & 5 & 6 & 9 \end{pmatrix}$$

Then the transpose of A is the 4×3 matrix:

```
linalg::transpose(A)
```

$$\begin{pmatrix} 1 & -1 & 3 \\ 2 & 0 & 5 \\ 3 & 1 & 6 \\ 4 & 0 & 9 \end{pmatrix}$$

Parameters **A**
A matrix of a domain of category `Cat::Matrix`

Return Values Matrix of the same domain type as A .

linalg::transpose

Algorithms

Let $A = (a_{i,j})_{1 \leq i \leq m, 1 \leq j \leq n}$ be an $m \times n$ matrix. Then the transpose of A is the $n \times m$ matrix:

$$A^t = \begin{pmatrix} a_{1,1} & a_{1,2} & \cdots & a_{m,1} \\ a_{1,2} & a_{2,2} & \cdots & a_{m,2} \\ \cdot & \cdot & \cdots & \cdot \\ \cdot & \cdot & \cdots & \cdot \\ a_{1,n} & a_{2,n} & \cdots & a_{m,n} \end{pmatrix} .$$

Purpose Vandermonde matrices and their inverses

Syntax `linalg::vandermonde([v1, v2, ...], <R>)`

Description `linalg::vandermonde(v1, v2, ..., vn)` returns the $n \times n$ Vandermonde matrix V with entries $V_{ij} = v_i^{j-1}$.

Use `linalg::vandermonde([v1, ..., vn], R)` to define the $n \times n$ Vandermonde matrix over the field R . Note that the Vandermonde nodes v_i must be elements of R or must be convertible to elements of R . The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension $n \times n$ can be inverted with $O(n^2)$ operations. Linear equations with a Vandermonde coefficient matrix can be solved via `linalg::vandermondeSolve`.

Examples **Example 1**

We construct a 3×3 Vandermonde matrix:

```
V := linalg::vandermonde([v1, v2, v3])
```

$$\begin{pmatrix} 1 & v_1 & v_1^2 \\ 1 & v_2 & v_2^2 \\ 1 & v_3 & v_3^2 \end{pmatrix}$$

The inverse of this matrix is:

```
linalg::invvandermonde([v1, v2, v3])
```

linalg::vandermonde

$$\begin{pmatrix} \frac{v_2 v_3}{\sigma_3} & -\frac{v_1 v_3}{\sigma_2} & \frac{v_1 v_2}{\sigma_1} \\ -\frac{v_2+v_3}{\sigma_3} & \frac{v_1+v_3}{\sigma_2} & -\frac{v_1+v_2}{\sigma_1} \\ \frac{1}{\sigma_3} & -\frac{1}{\sigma_2} & \frac{1}{\sigma_1} \end{pmatrix}$$

where

$$\sigma_1 = (v_1 - v_3)(v_2 - v_3)$$

$$\sigma_2 = (v_1 - v_2)(v_2 - v_3)$$

$$\sigma_3 = (v_1 - v_2)(v_1 - v_3)$$

V and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} 1.0 & 2.0 & 4.0 \\ 1.0 & 3.141592654 & 9.869604401 \\ 1.0 & 0.3333333333 & 0.1111111111 \end{pmatrix}$$

```
domtype(V)
```

```
Dom::Matrix(Dom::Float)
```

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix} = \begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix}$$

```
delete V:
```

Parameters

v_1, v_2, \dots

The Vandermonde nodes: arithmetical expressions

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

Purpose

Vandermonde matrices and their inverses

Syntax

```
linalg::invvandermonde([v1, v2, ...], <R>)
```

Description

`linalg::invvandermonde(v1, v2, ..., vn)` returns the inverse of the Vandermonde matrix with nodes v_i .

Use `linalg::vandermonde([v1, ..., vn], R)` to define the $n \times n$ Vandermonde matrix over the field R . Note that the Vandermonde nodes v_i must be elements of R or must be convertible to elements of R . The same holds true for the inverse Vandermonde matrix.

Vandermonde matrices of dimension $n \times n$ can be inverted with $O(n^2)$ operations. Linear equations with a Vandermonde coefficient matrix can be solved via `linalg::vandermondeSolve`.

Examples

Example 1

We construct a 3×3 Vandermonde matrix:

```
V := linalg::vandermonde([v1, v2, v3])
```

$$\begin{pmatrix} 1 & v_1 & v_1^2 \\ 1 & v_2 & v_2^2 \\ 1 & v_3 & v_3^2 \end{pmatrix}$$

The inverse of this matrix is:

```
linalg::invvandermonde([v1, v2, v3])
```

linalg::invvandermonde

$$\begin{pmatrix} \frac{v_2 v_3}{\sigma_3} & -\frac{v_1 v_3}{\sigma_2} & \frac{v_1 v_2}{\sigma_1} \\ -\frac{v_2+v_3}{\sigma_3} & \frac{v_1+v_3}{\sigma_2} & -\frac{v_1+v_2}{\sigma_1} \\ \frac{1}{\sigma_3} & -\frac{1}{\sigma_2} & \frac{1}{\sigma_1} \end{pmatrix}$$

where

$$\sigma_1 = (v_1 - v_3) (v_2 - v_3)$$

$$\sigma_2 = (v_1 - v_2) (v_2 - v_3)$$

$$\sigma_3 = (v_1 - v_2) (v_1 - v_3)$$

V and its inverse are matrices of the domain `Dom::Matrix()`. One can specify a special component ring for the matrices, provided the nodes can be converted to elements of the ring. For example, specification of the domain `Dom::Float` generates floating-point entries:

```
V := linalg::vandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} 1.0 & 2.0 & 4.0 \\ 1.0 & 3.141592654 & 9.869604401 \\ 1.0 & 0.3333333333 & 0.1111111111 \end{pmatrix}$$

```
domtype(V)
```

```
Dom::Matrix(Dom::Float)
```

It is faster to compute the inverse via `linalg::invvandermonde` than inverting the Vandermonde matrix by a generic inversion algorithm (as implemented by `V^(-1)`):

```
V^(-1) = linalg::invvandermonde([2, PI, 1/3], Dom::Float)
```

$$\begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix} = \begin{pmatrix} -0.5503876788 & 0.2079506905 & 1.342436988 \\ 1.826356876 & -0.7278274166 & -1.098529459 \\ -0.5255815182 & 0.3119260357 & 0.2136554825 \end{pmatrix}$$

```
delete V:
```

Parameters

v_1, v_2, \dots

The Vandermonde nodes: arithmetical expressions

R

The component ring: a domain of category `Cat::Rng`; default: `Dom::ExpressionField()`

Return Values

$n \times n$ matrix of the domain `Dom::Matrix(R)`.

Algorithms

Vandermonde matrices are notoriously ill-conditioned. The inverses of large floating-point Vandermonde matrices are subject to severe round-off effects.

| `linalg::invpascal` | `linalg::pascal` | `linalg::toeplitz` |
`linalg::toeplitzSolve` | `linalg::vandermondeSolve`

Purpose	Solve a linear Vandermonde system
Syntax	<code>linalg::vandermondeSolve(v, y, <Transposed>)</code>
Description	<p><code>linalg::vandermondeSolve(v, y)</code> returns the solution \vec{x} of the linear Vandermonde system $\sum_{j=1}^n v_i^{j-1} x_j = y_i$ with $i = 1, \dots, n$.</p> <p><code>linalg::vandermondeSolve</code> uses $O(n^2)$ elementary operations to solve the Vandermonde system. It is faster than the general solver <code>solve</code> and the linear solvers <code>linsolve</code>, <code>numeric::linsolve</code>, <code>linalg::matlinsolve</code> and <code>numeric::matlinsolve</code>.</p> <p>The solution $\vec{x} = (x_1, \dots, x_n)$ returned by <code>linalg::vandermondeSolve([v[i] \$ i=1..n], [y[i] \$ i=1..n])</code> yields the coefficients of the polynomial $p(v) = x_1 + x_2 v + \dots + x_n v^{n-1}$ interpolating the data table $(v_1, y_1), \dots, (v_n, y_n)$, i.e.,</p> $p(v_1) = y_1, \dots, p(v_n) = y_n.$ <p>See “Example 1” on page 14-255.</p>

Examples

Example 1

The Vandermonde points v and the right hand side y of the linear system are entered as vectors:

```
delete y0, y1, y2:  
v := matrix([[0, 1, 2]]);  
y := matrix([[y0, y1, y2]])
```

```
( 0 1 2 )
```

```
(y0 y1 y2)
```

linalg::vandermondeSolve

The solution vector is:

```
x := linalg::vandermondeSolve(v, y)
```

$$\left(y_0 \quad 2 y_1 - \frac{3 y_0}{2} - \frac{y_2}{2} \quad \frac{y_0}{2} - y_1 + \frac{y_2}{2} \right)$$

The solution yields the coefficients of the interpolating polynomial:

```
P := v -> _plus(x[i+1]*v^i $ i=0..2):
```

through the points $(0, y_0)$, $(1, y_1)$, $(2, y_2)$:

```
P(v[1]), P(v[2]), P(v[3])
```

```
y0, y1, y2
```

With the optional argument `Transposed`, the linear system with the transposed Vandermonde matrix corresponding to v is solved:

```
linalg::vandermondeSolve(v, y, Transposed)
```

$$\left(y_0 - \frac{3 y_1}{2} + \frac{y_2}{2} \quad 2 y_1 - y_2 \quad \frac{y_2}{2} - \frac{y_1}{2} \right)$$

```
delete v, y, x, P:
```

Example 2

The Vandermonde points v and the right hand side y of the linear system are entered as 2×1 matrices:

```
Mat := Dom::Matrix(Dom::ExpressionField(normal)):
```

```
delete v1, v2, y1, y2:
```

```
v := Mat([v1, v2]):
```

```
y := Mat([y1, y2]):
```

We define the vectors over the domain `Dom::ExpressionField(normal)` in order to simplify intermediate computations.

Next, we compute the solution of the corresponding Vandermonde system:

```
x := linalg::vandermondeSolve(v, y)
```

$$\begin{pmatrix} \frac{v_1 y_2 - v_2 y_1}{v_1 - v_2} \\ \frac{y_1 - y_2}{v_1 - v_2} \end{pmatrix}$$

We construct the Vandermonde matrix `V` and verify the result:

```
V := Mat([[1, v[1]], [1, v[2]]])
```

$$\begin{pmatrix} 1 & v_1 \\ 1 & v_2 \end{pmatrix}$$

```
V * x
```

$$\begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$$

```
delete Mat, v, y, x, V:
```

Example 3

We solve a Vandermonde system over the field \mathbb{Z}_7 (the integers modulo 7) represented by the domain `Dom::IntegerMod(7)`:

```
MatZ7 := Dom::Matrix(Dom::IntegerMod(7)):
v := MatZ7([1, 2, 3]): y := MatZ7([0, 1, 2]):

linalg::vandermondeSolve(v, y)
```

linalg::vandermondeSolve

$$\begin{pmatrix} 6 \bmod 7 \\ 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix}$$

delete MatZ7, v, y:

Parameters

v

A vector with distinct elements (a vector is an $n \times 1$ or $1 \times n$ matrix of category `Cat::Matrix`). Alternatively, a list with n distinct elements is also accepted.

y

A vector of the same dimension and domain type as `v`. Alternatively, a list with n elements is also accepted.

Options

Transposed

Returns the solution \vec{x} of the transposed system $\sum_{j=1}^n v_j^{i-1} x_j = y_i$ with $i = 1, \dots, n$.

Return Values

Vector of the same domain type as `y`.

Algorithms

The Vandermonde matrix

$$V = \begin{pmatrix} 1 & v_1 & v_1^2 & \dots & v_1^{n-1} \\ 1 & v_2 & v_2^2 & \dots & v_2^{n-1} \\ \dots & \dots & \dots & \dots & \dots \\ 1 & v_n & v_n^2 & \dots & v_n^{n-1} \end{pmatrix}$$

generated by $v = [v_1, \dots, v_n]$ is invertible if and only if the v_i are distinct.

The vector \vec{x} returned by `linalg::vandermondeSolve(x, y)` is the unique solution of $V \vec{x} = \vec{y}$.

The vector x returned by `linalg::vandermondeSolve(x, y, Transposed)` is the unique solution of $V^t \vec{x} = \vec{y}$.

linalg::vecdim

Purpose Number of components of a vector

Syntax `linalg::vecdim(v)`

Description `linalg::vecdim(v)` returns the number of elements of the vector \vec{v} .

Examples **Example 1**

We define a column vector with two elements and a row vector with four elements:

```
v1 := matrix([1, 0]); v2 := matrix([[1, 2, 3, 4]])
```

$$\begin{pmatrix} 1 \\ 0 \end{pmatrix}$$
$$(1\ 2\ 3\ 4)$$

`linalg::vecdim` gives us the number of elements, i.e., the dimension of these vectors:

```
linalg::vecdim(v1), linalg::vecdim(v2)
```

$$2, 4$$

In contrast, the function `linalg::matdim` returns the number of rows and columns of these vectors:

```
linalg::matdim(v1), linalg::matdim(v2)
```

$$[2, 1], [1, 4]$$

Parameters

v

A vector, i.e., an $n \times 1$ or $1 \times n$ matrix of a domain of category
`Cat::Matrix`

Return Values

Positive integer.

See Also

MuPAD Functions

`linalg::matdim` | `linalg::ncols` | `linalg::nrows`

linalg::vectorOf

Purpose Type specifier for vectors

Syntax `linalg::vectorOf(R)`
`linalg::vectorOf(R, n)`

Description `linalg::vectorOf(R)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with component ring `R` and number of rows or number of columns equal to one.

`linalg::vectorOf(R,n)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

`linalg::vectorOf(Type::AnyType,n)` is a type specifier representing all objects of a domain of category `Cat::Matrix` with an arbitrary component ring `R` and number of rows equal to `n` and number of columns equal to one, or vice versa.

Examples

Example 1

`linalg::vectorOf` can be used together with `testtype` to check whether a MuPAD object is a vector:

```
MatZ := Dom::Matrix(Dom::Integer):  
v := MatZ([1, 0, -1])
```

$$\begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix}$$

The following yields `FALSE` because `v` is 3-dimensional vector:

```
testtype(v, linalg::vectorOf(Dom::Integer, 4))
```

`FALSE`

The following yields `FALSE` because `v` is defined over the integers:

```
testtype(v, linalg::vectorOf(Dom::Rational))
```

```
FALSE
```

Of course, `v` can be converted into a vector over the rationals, as shown by the following call:

```
bool(coerce(v, Dom::Matrix(Dom::Rational)) <> FAIL)
```

```
TRUE
```

This shows that `testtype` in conjunction with `linalg::vectorOf(R)` does not check whether an object can be converted into a vector over the specified component ring `R`. It checks only if the object is a vector whose component ring is `R`.

The following test returns `TRUE` because `v` is a 3-dimensional vector:

```
testtype(v, linalg::vectorOf(Type::AnyType, 3))
```

```
TRUE
```

Example 2

`linalg::vectorOf` can also be used for checking parameters of procedures. The following procedure computes the orthogonal complement of a 2-dimensional vector:

```
orth := proc(v:linalg::vectorOf(Type::AnyType, 2))
begin
    [v[1], v[2]] := [-v[2],v[1]];
    return(v)
end:

u := matrix([[1, 2]]); u_ := orth(u)
```

linalg::vectorOf

```
(1 2)
```

```
(-2 1)
```

Calling the procedure `orth` with an invalid parameter leads to an error message:

```
orth([1, 2])
```

```
Error: The type of argument number 1 must be 'slot(Type, vectorOf)(
Evaluating: orth
```

Parameters

R

The component ring: a library domain

n

A positive integer

Return Values

Type expression of the domain type `Type`.

See Also

MuPAD Functions

`testtype`

Purpose

Vector potential of a three-dimensional vector field

Note `linalg::vectorPotential` will be removed in a future release. Use `vectorPotential` instead.

Syntax

`linalg::vectorPotential(j, [x1, x2, x3], <Test>)`

Description

`linalg::vectorPotential(j, x)` returns the vector potential of the vector field $\vec{j}(\vec{x})$ with respect to \vec{x} . This is a vector field \vec{v} with

$$\text{curl}_{\vec{v}}(\vec{x}) = \vec{j}.$$

`linalg::vectorPotential` and `vectorPotential` are equivalent. See details and examples on the `vectorPotential` help page.

Parameters

j

A list of three arithmetical expressions, or a 3-dimensional vector (i.e., a 3×1 or 1×3 matrix of a domain of category `Cat::Matrix`)

x₁, x₂, x₃

(indexed) identifiers

Options

Test

`linalg::vectorPotential` only checks whether the vector field j has a vector potential and returns `TRUE` or `FALSE`, respectively.

Return Values

Vector with three components, i.e., an 3×1 or $1 \times n$ matrix of a domain of category `Cat::Matrix`, or a boolean value.

linalg::wiedemann

Purpose Solving linear systems by Wiedemann's algorithm

Syntax `linalg::wiedemann(A, b, <mult>, <prob>)`

Description `linalg::wiedemann(A, b, mult, ...)` tries to find a vector \vec{x} that satisfies the equation $A\vec{x} = \vec{b}$ by using Wiedemann's algorithm. The parameter `mult` must be a function such that the result of `mult(A, y)` equals $A\vec{y}$ for every n -dimensional column vector \vec{y} . The parameter `y` is of the same domain type as `A`. The argument `mult` does not need to handle other types of parameters, nor does it need to handle other matrices than `A`. `linalg::wiedemann` uses a probabilistic algorithm. For a deterministic variant enter `FALSE` for the optional parameter `prob`.

If the system $A\vec{x} = \vec{b}$ does not have a solution, then `linalg::wiedemann` returns `FAIL`.

If the system $A\vec{x} = \vec{b}$ has more than one solution, then a random one is returned.

Due to the probabilistic nature of Wiedemann's algorithm, the computation may fail with small probability. In this case `FAIL` is returned. If the deterministic variant is chosen, then the algorithm may be slower for a small number of matrices.

The vector `b` must be defined over the component ring of `A`.

The coefficient ring of `A` must be a field, i.e., a domain of category `Cat::Field`.

It is recommended to use `linalg::wiedemann` only if `mult` uses significantly less than $O(n^2)$ field operations.

Examples

Example 1

We define a matrix and a column vector over the finite field with 29 elements:

```
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)):
A := MatZ29([[1, 2, 3], [4, 7, 8], [9, 12, 17]]);
b := MatZ29([1, 2, 3])
```

$$\begin{pmatrix} 1 \bmod 29 & 2 \bmod 29 & 3 \bmod 29 \\ 4 \bmod 29 & 7 \bmod 29 & 8 \bmod 29 \\ 9 \bmod 29 & 12 \bmod 29 & 17 \bmod 29 \end{pmatrix}$$

$$\begin{pmatrix} 1 \bmod 29 \\ 2 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}$$

Since A does not have a special form that would allow a fast matrix-vector multiplication, we simply use `_mult`. Wiedemann's algorithm works in this case, although it is less efficient than Gaussian elimination:

```
linalg:wiedemann(A, b, _mult)
```

$$\left[\begin{pmatrix} 24 \bmod 29 \\ 21 \bmod 29 \\ 17 \bmod 29 \end{pmatrix}, \text{TRUE} \right]$$

Example 2

Now let us define another matrix that has a special form:

```
MatZ29 := Dom::Matrix(Dom::IntegerMod(29)):
A := MatZ29([[1, 0, 0], [0, 1, 2], [0, 0, 1]]);
b := MatZ29(3, 1, [1, 2, 3]):
```

$$\begin{pmatrix} 1 \bmod 29 & 0 \bmod 29 & 0 \bmod 29 \\ 0 \bmod 29 & 1 \bmod 29 & 2 \bmod 29 \\ 0 \bmod 29 & 0 \bmod 29 & 1 \bmod 29 \end{pmatrix}$$

For this particular matrix, it is easy to define an efficient multiplication method:

```
mult := proc(dummy, y)
begin
    y[2]:=y[2]+2*y[3];
    y
end:
linalg:wiedemann(A, b, mult)
```

$$\left[\begin{pmatrix} 1 \bmod 29 \\ 25 \bmod 29 \\ 3 \bmod 29 \end{pmatrix}, \text{TRUE} \right]$$

Parameters

A

An $n \times n$ matrix of a domain of category `Cat::Matrix`

b

An n -dimensional column vector, i.e., an $n \times 1$ matrix of a domain of category `Cat::Matrix`

mult

A matrix-vector multiplication method: function or functional expression; default: `_mult`

prob

TRUE or FALSE (default: TRUE)

Return Values

Either the list [x, TRUE] if a solution for the system $A \vec{x} = \vec{b}$ has been found, or the list [x, FALSE] if a non-zero solution for the corresponding homogeneous system $A \vec{x} = \vec{0}$ has been found, or the value FAIL (see below).

Algorithms

The expected running time for the probabilistic algorithm is $O(n^2 + nM)$, and the running time for the deterministic variant is $O(n^2M)$ in the worst case, but only $O(n^2 + nM)$ on average. Here, M is the number of field operations that the matrix-vector multiplication routine `mult` uses.

The basic idea of the algorithm is to solve a linear system $A \vec{x} = \vec{b}$ by finding the minimal polynomial $f(y)$ that solves $f(A) \vec{b} = \vec{0}$. If the constant coefficient $c = f(0)$ is non-zero and $g(y) := f(y) - c$, the equality

$g(A) \vec{b} = -c \vec{b}$ implies that $\vec{x} = -\frac{1}{c} \begin{pmatrix} g \\ y \end{pmatrix} (A)$ is the solution.

The polynomial f is found by looking for the minimal polynomial h

satisfying $\vec{u} h(A) \vec{b} = \vec{0}$ for some randomly chosen row vector \vec{u} . This may yield $h \neq f$ in unlucky cases, but in general the probability for this is small.

linopt::corners([constr, obj, <NonNegative>, <seti>],  
vars, <All>, <Logic>)  
linopt::corners([constr, obj, <NonNegative>, <All>],  
vars, <All>, <Logic>)  
linopt::corners([constr, obj, <setn>, <seti>],  
vars, <All>, <Logic>)  
linopt::corners([constr, obj, <setn>, <All>],  
vars, <All>, <Logic>)
```

Description `linopt::corners([constr, obj], vars)` returns all valid corners of the linear program.

`linopt::corners([constr, obj], vars, All)` returns all corners of the linear program.

`[constr, obj]` is a linear program of the same structure like in `linopt::maximize`. The second parameter `vars` specifies the order in which the components of the corners found are printed; if e.g. `{x=1, y=2}` is a corner and `[x,y]` was entered, `[1,2]` will be returned.

As options, for finding the corners, one may use `All` and/or `Logic`. `All` causes the output of non-feasible corners, too, `Logic` allows the algorithm to search for corners in planes like `x=0`, too, although `x ≥ 0` is not part of the input. This guarantees that for all non-empty feasible regions a corner will be found.

As the result of `linopt::corners` a triple consisting of the set of corners, the maximal objective function value found and the corner associated to it is returned. If there is no feasible corner found, only the empty set is returned.

Examples

Example 1

We compute all valid corners of a small linear program:

```
k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x,
```

```

      y - 2*x <= -2, y <= 6}, x + y):
linopt::corners(k, [x, y])

```

```

[[{ [4/3, 2/3], [5/3, 1/3], [4, 6], [5, 2], [7, 6] }, 13, [7, 6]]

```

Now we compute all corners, also the ones which are not valid. We see that we now get e.g. also the corner which is given by the cut of $-2x + 4y = 2$ and $-2x + y \leq -2$. Here we see that the invalid corner (13,6) has the maximal objective function value 19:

```

k := [{4 <= 2*x + 2*y, -2 <= 4*y - 2*x, -8 <= y - 2*x,
      y - 2*x <= -2, y <= 6}, x + y]:
linopt::corners(k, [x, y], All)

```

```

[[{-4, 6], [1, 0], [4/3, 2/3], [5/3, 1/3], [10/3, -4/3], [4, 6], [5, 2], [7, 6], [13, 6]}, 19, [13, 6]]

```

delete k:

Example 2

As one can see the linear program given by the constraints $x + y \geq -1$ and $x + y \leq 3$ and the linear objective function $x + 2y$ has no corners:

```

l := [{-1 <= x + y, x + y <= 3}, x + 2*y]:
linopt::corners(l, [x, y]), linopt::corners(l, [x, y], All)

```

```

∅, ∅

```

If one also assumes a cut with a coordinate plane as a corner, some corners exist. One can use `linopt::plot_data` to visualize this problem:

```

linopt::corners(l, [x, y], Logic)

```

linopt::corners

```
{[-1, 0], [0, 0], [0, -1], [0, 3], [3, 0]}, 6, [0, 3]
```

```
delete 1:
```

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminants

setn

A set which contains identifiers interpreted as indeterminants

vars

A list containing the variables of the linear program described by `constr` and `obj` and the existing options

Options

All

This option can appear at two different places in the call of `linopt::corners`. If it is part of the linear program it means that all variables are constrained to be integers. If it appears as the third or fourth argument of the call it means that all corners, not only the valid ones should be computed by `linopt::corners`.

NonNegative

All variables are constrained to be nonnegative

Logic

This allows the algorithm to search for corners in planes like $x=0$ too, although $x \geq 0$ is not part of the linear program.

Return Values

Set or a list with 3 elements.

MuPAD Functions

`linopt::maximize` | `linopt::minimize` | `linopt::plot_data`

linopt::maximize

Purpose Maximize a linear or mixed-integer program

Syntax

```
linopt::maximize([constr, obj], <DualPrices>)  
linopt::maximize([constr, obj, <NonNegative>, <seti>])  
linopt::maximize([constr, obj, <NonNegative>, <All>])  
linopt::maximize([constr, obj, <setn>, <seti>])  
linopt::maximize([constr, obj, <setn>, <All>])  
linopt::maximize([constr, obj, <NonNegative>], DualPrices)  
linopt::maximize([constr, obj, <set>], DualPrices)
```

Description `linopt::maximize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be maximized.

The expression `obj` is the linear objective function to be maximized subject to the linear constraints `constr`. The function `linopt::maximize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable Φ subject to the state, and finally the maximal objective function value, which can be either a number, `-infinity` or a linear function in Φ .

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::maximize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not have more than three elements). This option causes the output of the

dual-prices in addition to the solution-triplet. In this case the result of `linopt::maximize` is a sequence of a list containing the solution-triplet and a set containing the dual prices. See “Example 4” on page 15-8.

Examples

Example 1

We try to solve the linear program

$$2c_1 \leq 1$$

$$2c_2 \leq 1$$

with the linear objective function $c_1 + 2c_2$:

```
linopt::maximize([2*c1 <= 1, 2*c2 <= 1], c1 + 2*c2)
```

```
[OPTIMAL, {c1 = 1/2, c2 = 1/2}, 3/2]
```

Example 2

Now let's have a look at the linear program

$$3x + 4y - 3z \leq 23$$

$$5x - 4y - 3z \leq 10$$

$$7x + 4y + 11z \leq 30$$

with the linear objective function $-x + y + 2z$. If we make no restriction to the variables the result is unbounded:

```
c := [3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,  
      7*x + 4*y + 11*z <= 30], -x + y + 2*z]:  
linopt::maximize(c)
```

linopt::maximize

$$\left[\text{UNBOUNDED}, \left\{ x = -\text{PHI1}, y = 0, z = \frac{7 \text{PHI1}}{11} + \frac{30}{11} \right\}, \frac{25 \text{PHI1}}{11} + \frac{60}{11} \right]$$

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:

```
linopt::maximize(append(c, NonNegative));  
linopt::maximize(append(c, {x, y}))
```

$$\left[\text{OPTIMAL}, \left\{ x = 0, y = \frac{49}{8}, z = \frac{1}{2} \right\}, \frac{57}{8} \right]$$

$$\left[\text{OPTIMAL}, \left\{ x = 0, y = \frac{49}{8}, z = \frac{1}{2} \right\}, \frac{57}{8} \right]$$

```
delete c:
```

Example 3

The following linear program do not have a solution:

```
linopt::maximize([x <= -1, x >= 0], x)
```

$$[\text{EMPTY}, \emptyset, -\infty]$$

Example 4

The output of the dual prices can be enforced with the option DualPrices:

```
linopt::maximize([2*c1 <= 1, 2*c2 <= 1], c1 + 2*c2,  
DualPrices)
```

$$\left[\text{OPTIMAL}, \left\{ c1 = \frac{1}{2}, c2 = \frac{1}{2} \right\}, \frac{3}{2}, \left\{ \left[c1 \leq \frac{1}{2}, 1 \right], \left[c2 \leq \frac{1}{2}, 2 \right] \right\} \right]$$

Example 5

We have a look at the knapsack problem with $x_1, x_2, x_3, x_4 \in \{0, 1\}$:

```
c := {20*x1 + 15*x2 + 20*x3 + 5*x4 <= 25}:
c := c union {x1 <= 1, x2 <= 1, x3 <= 1, x4 <= 1}:
f := 10*x1 + 15*x2 + 16*x3 + x4:
linopt::maximize([c, f, NonNegative, All])
```

```
[OPTIMAL, {x1 = 0, x2 = 0, x3 = 1, x4 = 1}, 17]
```

```
delete c, f:
```

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

Options

All

All variables are constrained to be integers

NonNegative

All variables are constrained to be nonnegative

DualPrices

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-triple.

linopt::maximize

Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

MuPAD Functions

`linopt::minimize` | `linopt::plot_data` | `linopt::corners`

Purpose

Minimize a linear or mixed-integer program

Syntax

```
linopt::minimize([constr, obj], <DualPrices>)  
linopt::minimize([constr, obj, <NonNegative>, <seti>])  
linopt::minimize([constr, obj, <NonNegative>, <All>])  
linopt::minimize([constr, obj, <setn>, <seti>])  
linopt::minimize([constr, obj, <setn>, <All>])  
linopt::minimize([constr, obj, <NonNegative>], DualPrices)  
linopt::minimize([constr, obj, <set>], DualPrices)
```

Description

`linopt::minimize([constr, obj])` returns the solution of the linear or mixed-integer program given by the constraints `constr` and the linear objective function `obj` which should be minimized.

The expression `obj` is the linear objective function to be minimized subject to the linear constraints `constr`. The function `linopt::minimize` returns a triple consisting of the state of the output, `OPTIMAL`, `EMPTY` or `UNBOUNDED`, a set of equations which describes the optimal solution of the specified linear program, which is empty or depends on a free variable Φ subject to the state, and finally the minimal objective function value, which can be either a number, infinity or a linear function in Φ .

The states `OPTIMAL`, `EMPTY` or `UNBOUNDED` have the following meanings. `OPTIMAL` means an optimal solution for the linear program was found. If the state is `EMPTY` no optimal solution was found and if it is `UNBOUNDED` then the solution has no upper bound.

If the option `NonNegative` is used all variables are constrained to be nonnegative. If instead of `NonNegative` a set `setn` is given then only the variables from `setn` are constrained to be nonnegative.

If the option `All` is used all variables are constrained to be integers. If instead of `All` a set `seti` is given, then only the variables from `seti` are constrained to be integers.

As a second parameter for `linopt::minimize` the option `DualPrices` is provided for the linear case (the first parameter therefore must not have more than three elements). This option causes the output of the

linopt::minimize

dual-prices in addition to the solution-triplet. In this case the result of `linopt::minimize` is a sequence of a list containing the solution-triplet and a set containing the dual prices. See “Example 4” on page 15-13.

Examples

Example 1

We try to solve the linear program

$$\begin{aligned}c_1 + c_2 &\leq 3 \\c_2 &\leq 9\end{aligned}$$

with the linear objective function $-c_1 - c_2$:

```
linopt::minimize([c1 + c2 <= 3, c2 <= 9], -c1 - c2)
```

```
[OPTIMAL, {c1 = 0, c2 = 3}, -3]
```

Example 2

Now let's have a look at the linear program

$$\begin{aligned}3x + 4y - 3z &\leq 23 \\5x - 4y - 3z &\leq 10 \\7x + 4y + 11z &\leq 30\end{aligned}$$

with the linear objective function $-x + y + 2z$. If we make no restriction to the variables the result is unbounded:

```
c := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
      7*x + 4*y + 11*z <= 30}, -x + y + 2*z]:
linopt::minimize(c)
```

```
[UNBOUNDED, {y = -PHI1, x = -4 PHI1 - 13/2, z = -16 PHI1/3 - 85/6}, -23 PHI1/3 - 131/6]
```

But if all variables are constrained to be nonnegative, we get a result. That's also the case if only x and y are constrained to be nonnegative:

```
linopt::minimize(append(c, NonNegative));  
linopt::minimize(append(c, {x, y}))
```

```
[OPTIMAL, {x = 2, y = 0, z = 0}, -2]
```

```
[OPTIMAL, {x = 0, y =  $\frac{13}{8}$ , z =  $-\frac{11}{2}$ }, - $\frac{75}{8}$ ]
```

```
delete c:
```

Example 3

The following linear program does not have a solution:

```
linopt::minimize([x <= -1, x >= 0], x)
```

```
[EMPTY,  $\emptyset$ ,  $\infty$ ]
```

Example 4

The output of the dual prices can be enforced with the option DualPrices:

```
linopt::minimize([c1 + c2 <= 3, c2 <= 9], -c1 - c2,  
                 DualPrices)
```

```
[OPTIMAL, {c1 = 0, c2 = 3}, -3], {[c1 + c2 ≤ 3, 1], [c2 ≤ 9, 0]}
```

Parameters

constr

A set or list of linear constraints

obj

A linear expression

linopt::minimize

seti

S set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

DualPrices

This option is only available in the linear case. It causes the output of the dual-prices in addition to the solution-triplet.

Return Values

List or a sequence of a list and a set containing the solution of the linear or mixed-integer program.

MuPAD Functions

`linopt::maximize` | `linopt::plot_data` | `linopt::corners`

linopt::plot_data

Purpose Plot the feasible region of a linear program

Syntax

```
linopt::plot_data([constr, obj, <NonNegative>,
<seti>], vars)
linopt::plot_data([constr, obj, <NonNegative>,
<All>], vars)
linopt::plot_data([constr, obj, <setn>, <seti>], vars)
linopt::plot_data([constr, obj, <setn>, <All>], vars)
```

Description `linopt::plot_data([constr, obj], vars)` returns a graphical description of the feasible region of the linear program `[constr, obj]`, and the line vertical to the objective function vector through the corner with the maximal objective function value found.

`[constr, obj]` is a linear program with exactly two variables. The problem has the same structure like in `linopt::maximize`. The second parameter `vars` specifies which variable belongs to the horizontal and vertical axis.

Examples **Example 1**

We plot the feasible region of the given linear program. Here the valid corners of the linear program are easy to see:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
      -2*x + y <= -2, y <= 6}, x + y, NonNegative]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

In this example there is no difference if the Option NonNegative is given for the linear program or not:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
      -2*x + y <= -2, y <= 6}, x + y]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

linopt::plot_data

delete k, g:

Example 2

Now we give an example where one can see a difference if the variables are constrained to be nonnegative:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y]:  
g := linopt::plot_data(k, [x, y]):  
plot(g):
```

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
g := linopt::plot_data(k, [x, y]):
plot(g):
```

linopt::plot_data

delete k, g:

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

vars

A list containing the two variables of the linear program described by `constr` and `obj` and the existing options

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

Return Values

Expression describing a graphical object which can be used by `plot`.

MuPAD Functions

`linopt::maximize` | `linopt::minimize` | `linopt::corners`

linopt::Transparent

Purpose Return the ordinary simplex tableau of a linear program

Syntax

```
linopt::Transparent([constr, obj, <NonNegative>, <seti>])  
linopt::Transparent([constr, obj, <NonNegative>, <All>])  
linopt::Transparent([constr, obj, <setn>, <seti>])  
linopt::Transparent([constr, obj, <setn>, <All>])
```

Description `linopt::Transparent([constr, obj])` returns the ordinary simplex tableau of the given linear program given by the constraints `constr` and the linear objective function `obj`.

`[constr, obj]` is a Linear Optimization Problem of the same structure like in `linopt::maximize`. As the result the ordinary simplex tableau of the given problem is returned; this means that equations will be replaced by two unequations and unbounded variables will be replaced by two new variables.

Internally the tableau returned consists of more information than viewable on the screen. Therefore `linopt::Transparent::convert` is provided to perform the transduction into the structure of the screen-tableau. (This can be necessary if the returned tableau shall serve as an input-parameter for another function — e.g. a user defined procedure for the selection of pivot elements.) If an ordinary simplex with two phases is wished, the next step should be the call of `linopt::Transparent::phaseI_tableau`.

All functions of the `linopt` library using the tableau returned by `linopt::Transparent` try to minimize the problem! Therefore it can be necessary to multiply the objective function with `-1` first.

In the simplex tableau returned a special notation is used. "linopt" stands for the tableau them self, "obj" describes the linear objective function, "restr" stands for the vector of restrictions, `slk[1]`, `slk[2]`, ... are the slack variables and the names of the other variables stand for themselves. Variables which are given as row labels indicate that they are part of the base.

Examples

Example 1

First a small example, returning the ordinary simplex tableau of the given linear program. One can see that the slack variables are forming the basis:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:
linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

It follows a little bit larger example:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
       7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

The result of `linopt::Transparent` is of domain type `linopt::Transparent`. So it can be used as input for other `linopt::Transparent::*` function, e.g. for `linopt::Transparent::suggest`:

linopt::Transparent

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:  
t := linopt::Transparent(k):  
domtype(t), linopt::Transparent::suggest(t)
```

```
linopt::Transparent, OPTIMAL
```

```
delete k, t:
```

Parameters

constr

A set or list of linear constraints

obj

A linear expression

seti

A set which contains identifiers interpreted as indeterminates

setn

A set which contains identifiers interpreted as indeterminates

Options

All

All variables are constrained to be integer

NonNegative

All variables are constrained to be nonnegative

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparent::result | linopt::Transparent::simplex |  
linopt::Transparent::suggest | linopt::Transparent::userstep
```

linopt::Transparent::autostep

Purpose Perform the next simplex step

Syntax `linopt::Transparent::autostep(tableau)`

Description `linopt::Transparent::autostep(tableau)` performs the next step of the simplex algorithm. This is the same step that `linopt::Transparent::suggest` would suggest for the given simplex tableau `tableau`.

Normally `linopt::Transparent::autostep` returns the next simplex tableau. If the calculation of the simplex algorithm is finished `linopt::Transparent::autostep` returns a set containing a solution of the given linear program described by `tableau`.

Examples

Example 1

The ordinary simplex tableau of a given linear program is created:

```
k := [{x + y >= 2}, x, NonNegative]:  
t := linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

The next two steps of the simplex algorithm are executed for the given simplex tableau:

```
linopt::Transparent::autostep(t);  
linopt::Transparent::autostep(%)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 1 & -1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

delete k, t:

Example 2

The ordinary simplex tableau of a given linear program is created:

```
k := [{x + y >= -1, x + y <= 3}, x + 2*y, NonNegative]:  
t := linopt::Transparent(k)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

If the end of the simplex algorithm is reached,
linopt::Transparent::autostep returns a solution of the given
linear program:

```
linopt::Transparent::suggest(t),  
linopt::Transparent::autostep(t)
```

OPTIMAL, {x = 0, y = 0}

linopt::Transparent::autostep

delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent` or a set which contains the solution of the linear program.

MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::convert`
| `linopt::Transparent::dual_prices` |
`linopt::Transparent::phaseI_tableau` |
`linopt::Transparent::result` | `linopt::Transparent::simplex` |
`linopt::Transparent::suggest` | `linopt::Transparent::userstep`

Purpose Delete all slack variables of the first phase from the basis

Syntax `linopt::Transparent::clean_basis(tableau)`

Description `linopt::Transparent::clean_basis(tableau)` removes the additional slack variables of the phase one of the simplex algorithm from the optimal basic (described by `tableau`) calculated by `linopt::Transparent::phaseI_tableau` and `linopt::Transparent::simplex`.

At the end of the phase one of the 2-phase simplex algorithm, explicitly started by using `linopt::Transparent::phaseI_tableau`, it is necessary to eliminate all artificial variables from the optimal basis before phase two can be started by using `linopt::Transparent::phaseII_tableau`. `linopt::Transparent::clean_basis` performs some pivot steps until all phase one slack variables do not occur in the basis any longer.

Examples **Example 1**

In this example we first compute an optimal basis for the first phase of the simplex algorithm:

```
t := linopt::Transparent([{x <= 1,y <= 1,x + y >= 2},  
                          0,NonNegative]):  
t := linopt::Transparent::phaseI_tableau(t):  
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & & 0 & 2 & 2 & 0 & 1 & 1 & 1 & 0 & 0 \\ x & & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ y & & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_6 & & 0 & -1 & -1 & 1 & -1 & -1 & -1 & 0 & 0 \end{pmatrix}$$

linopt::Transparent::clean_basis

As we can see the artificial slack variable `slk[6]` is an element of the optimal basis. An error message is returned if we apply `linopt::Transparent::phaseII_tableau` or `linopt::Transparent::simplex` to this simplex tableau:

```
linopt::Transparent::phaseII_tableau(t);
```

```
Error: Clean the basis from phase I slack variables first. [linopt:
```

So we have to use `linopt::Transparent::clean_basis` before continuing with the appropriate function:

```
t := linopt::Transparent::clean_basis(t);  
linopt::Transparent::phaseII_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ x & 1 & 0 & -1 & 1 & 0 & -1 & -1 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_1 & 0 & 1 & 1 & -1 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 0 & 0 & 0 \\ x & 1 & 0 & -1 & -1 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_1 & 0 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$$

```
delete t;
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparent::convert

Purpose Transform the given tableau into a structure printable on screen

Syntax `linopt::Transparent::convert(tableau)`

Description `linopt::Transparent::convert` converts `tableau` into a two dimensional array which corresponds with the screen-tableau. One can now access the element in the i -th row and j -th column of the simplex tableau by accessing the corresponding element of the array.

Internally the given `tableau` of domain type `linopt::Transparent` contains a lot of more information than the simplex tableau which is printed by some functions of the `linopt` library, e.g. `linopt::Transparent::simplex`, and which is visible on the screen. Furthermore it is not possible to access the element in the i -th row and j -th column of `tableau` to get the corresponding element from the simplex tableau which is visible on the screen.

While the internal structure of `tableau` is not known the structure of the two dimensional array is well defined. So it can be easily used in own procedures. See "Example 2" on page 15-33.

Examples

Example 1

We convert a simplex tableau of domain type `linopt::Transparent` into a two dimensional array:

```
k := [{x + y >= 2}, x, NonNegative]:
t := linopt::Transparent(k):
a := linopt::Transparent::convert(t):
t, domtype(t);
a, domtype(a)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{linopt::Transparent}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}, \text{DOM_ARRAY}$$

delete a, k, t:

Example 2

We will write another simplex routine `mysimplex` for solving a linear program. For this we define the function `eigenpivot` for finding the pivot element of a given simplex tableau. `eigenpivot` assumes that the simplex tableau is given as a two dimensional array.

Here is the procedure `eigenpivot`, which is not coded in every detail, e.g., the error checking isn't implemented completely:

```
eigenpivot := proc(T: DOM_ARRAY)
  local i,j,m,n,k,l,mini;
  begin
    m := op(T,[0,2,2]):
    n := op(T,[0,3,2]):
    k := 0:
    l := 0:
    mini := unbesetzt:

    for j from 3 to n do
      if T[2,j] < 0 then
        l := j:
        break
      end_if:
    end_for:
    if l=0 then return(OPTIMAL) end_if:
    for i from 3 to m do
      if T[i,l] > 0 and (mini=unbesetzt or T[i,2]/T[i,l] < mini)
        k := i:
        mini := T[k,2]/T[k,l]
      end_if:
    end_for:
  end:
end:;
```

linopt::Transparent::convert

```
        end_if
    end_for:
    if k=0 then return(UNBOUNDED) end_if:
    return(T[k,1],T[1,1]):
end_proc:
```

This is the new simplex algorithm `mysimplex` which uses `eigenpivot` and some function from the `linopt` library:

```
mysimplex := proc(P)
    local T;
    begin
        T := linopt::Transparent(P):
        T := linopt::Transparent::phaseI_tableau(T):
        piv := eigenpivot(linopt::Transparent::convert(T)):
        while piv <> OPTIMAL and piv <> UNBOUNDED do
            T := linopt::Transparent::userstep(T,piv):
            piv := eigenpivot(linopt::Transparent::convert(T))
        end_while:

        if piv = UNBOUNDED then
            error(" Phase I unbounded !?")
        end_if:
        if T[2,2] <> 0
            then return(EMPTY)
        end_if:
        T := linopt::Transparent::clean_basis(T):

        T := linopt::Transparent::phaseII_tableau(T):
        piv := eigenpivot(linopt::Transparent::convert(T)):
        while piv <> OPTIMAL and piv <> UNBOUNDED do
            T := linopt::Transparent::userstep(T,piv):
            piv := eigenpivot(linopt::Transparent::convert(T))
        end_while:

        if piv = OPTIMAL
            then return(linopt::Transparent::result(T))
        end_if:
    end:
end:

```

```
        else return(UNBOUNDED)
      end_if
    end_proc:
```

We now apply `mysimplex` to a linear program:

```
k := [{2*x + 2*y >= 4, -2*x + 4*y >= -2, -2*x + y >= -8,
      -2*x + y <= -2, y <= 6}, -x - y]:
k := append(k, NonNegative):
mysimplex(k);
```

```
{x = 7, y = 6}
```

```
delete k, eigenpivot, mysimplex:
```

Parameters

tableau

A simplex tableau of domain type

Return Values

Two dimensional array, representing the given simplex tableau tableau.

MuPAD Functions

linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::phaseI_tableau |
linopt::Transparent::phaseII_tableau |
linopt::Transparent::suggest | linopt::Transparent::userstep

Purpose Get the dual solution belonging to the given tableau

Syntax `linopt::Transparent::dual_prices(tableau)`

Description `linopt::Transparent::dual_prices(tableau)` returns the dual solution of the linear optimization problem given by `tableau`.

This procedure returns the dual solution belonging to the given tableau in form of a set of lists containing two elements, the first one is a restriction and the second one is the value belonging to the slack variable connected to the restriction in the dual solution.

Examples **Example 1**

Here it is demonstrated that the dual solution of the final tableau is similar to the second element of the result of `linopt::minimize` using the option `DualPrices`:

First we compute the final tableau of the simplex algorithm:

```
k := [{x <= 2, y <= 2, x + 2*y >= 4}, - x + y, NonNegative]:  
t := linopt::Transparent(k):  
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 1 & \frac{3}{2} & 0 & \frac{1}{2} & 0 & 0 \\ x & 2 & 1 & 0 & 0 & 0 & 1 \\ \text{slk}_2 & 1 & \frac{1}{2} & 1 & \frac{1}{2} & 0 & 0 \\ y & 1 & -\frac{1}{2} & 0 & -\frac{1}{2} & 1 & 0 \end{pmatrix}$$

Now we compute the solutions:

```
linopt::Transparent::dual_prices(t);  
linopt::minimize(k, DualPrices)[2]
```

linopt::Transparent::dual_prices

$\left\{ \left[4 \leq x + 2y, \frac{1}{2} \right], [0 \leq x, 0], \left[x \leq 2, \frac{3}{2} \right], [0 \leq y, 0], [y \leq 2, 0] \right\}$

$\left\{ \left[4 \leq x + 2y, \frac{1}{2} \right], [0 \leq x, 0], \left[x \leq 2, \frac{3}{2} \right], [0 \leq y, 0], [y \leq 2, 0] \right\}$

delete k, t:

Example 2

We compute the dual solution of another linear program:

```
k := [{x <= 2, y <= 2, x + 2*y >= 4}, -x + y, NonNegative]:  
t := linopt::Transparent(k);  
linopt::Transparent::dual_prices(t)
```

"linopt"	"restr"	slk ₁	slk ₂	slk ₃	y	x
"obj"	0	0	0	0	1	-1
slk ₁	2	1	0	0	0	1
slk ₂	2	0	1	0	1	0
slk ₃	-4	0	0	1	-2	-1

$\{[4 \leq x + 2y, 0], [0 \leq x, -1], [x \leq 2, 0], [0 \leq y, 1], [y \leq 2, 0]\}$

delete k, t:

Parameters

tableau

A simplex tableau of domain type linopt::Transparent

Return Values

Set of lists, each containing 2 elements.

MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::result`

linopt::Transparent::phaseI_tableau

Purpose Start an ordinary phase one of a 2-phase simplex algorithm

Syntax `linopt::Transparent::phaseI_tableau(tableau)`

Description `linopt::Transparent::phaseI_tableau` explicitly starts an (ordinary) phase one of the simplex algorithm, i.e. rows associated with infeasible basic variables are multiplied with -1 and another identity matrix with new slack variables is added to the given tableau. As soon as an optimal tableau with relative costs 0 is found the calculation can be continued with `linopt::Transparent::clean_basis` and the second phase of the simplex algorithm (`linopt::Transparent::phaseII_tableau`).

Examples **Example 1**

The first simplex tableau is created and the first phase of the simplex algorithm is started:

```
t := linopt::Transparent([{x + y >= 2}, x, NonNegative]);  
t := linopt::Transparent::phaseI_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & -2 & 0 & 1 & -1 & -1 \\ \text{slk}_2 & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

We can see that a new slack variable, slk_2 , was added to the tableau. And if we now execute `linopt::Transparent::simplex` we can see that we have just finished the first phase of the simplex algorithm:

```
linopt::Transparent::suggest(t);  
t := linopt::Transparent::simplex(t);  
linopt::Transparent::suggest(t)
```

slk_2, y

"linopt::Transparent::phaseII_tableau"

We continue the simplex algorithm by executing `linopt::Transparent::clean_basis`, `linopt::Transparent::phaseII_tableau` and `linopt::Transparent::simplex`. Observe in this special case `linopt::Transparent::clean_basis` is not necessary:

```
t := linopt::Transparent::clean_basis(t);  
t := linopt::Transparent::phaseII_tableau(t);  
t := linopt::Transparent::simplex(t);  
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt" "restr" } slk_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete t;
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

linopt::Transparent::phaseII_tableau

MuPAD Functions

linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::convert |
linopt::Transparent::clean_basis |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseII_tableau |
linopt::Transparent::result | linopt::Transparent::simplex |
linopt::Transparent::suggest | linopt::Transparent::userstep

Purpose Start phase two of a 2-phase simplex algorithm

Syntax `linopt::Transparent::phaseII_tableau(tableau)`

Description `linopt::Transparent::phaseII_tableau(tableau)` starts the second phase of the simplex algorithm on the given simplex tableau `tableau`.

After the explicitly started first phase of the simplex algorithm (see `linopt::Transparent::phaseI_tableau`) terminated with an optimal tableau with associated costs 0 and no phase one slack variables in the basis (see `linopt::Transparent::clean_basis`) this procedure can be used to start phase II. The procedure eliminates all artificial variables of phase I and their associated columns and reenters the old objective function modified for the new basis.

Examples **Example 1**

The first simplex tableau is created and the first phase of the simplex algorithm is finished:

```
t := linopt::Transparent({{x + y >= 2}, x, NonNegative}):  
t := linopt::Transparent::simplex(  
    linopt::Transparent::phaseI_tableau(t))
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & 0 & 1 & 0 & 0 & 0 \\ y & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

One sees that the artificial slack variable `slk[2]` of the first phase is removed by `linopt::Transparent::phaseII_tableau`. In this example it is not necessary to use `linopt::Transparent::clean_basis` for cleaning the basis:

```
linopt::Transparent::phaseII_tableau(t)
```

linopt::Transparent::phasell_tableau

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

delete t:

Example 2

Again the first simplex tableau is created and the first phase of the simplex algorithm is finished:

```
t := linopt::Transparent([{x <= 1, y <= 1, x + y >= 2},  
                          0, NonNegative]):  
t := linopt::Transparent::phaseI_tableau(t):  
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_4 & \text{slk}_5 & \text{slk}_6 & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 2 & 2 & 0 & 1 & 1 & 1 & 0 & 0 \\ x & 1 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 1 \\ \text{slk}_6 & 0 & -1 & -1 & 1 & -1 & -1 & -1 & 0 & 0 \end{pmatrix}$$

In this example the artificial slack variable `slk[6]` is an element of the optimal basis. So we have to use `linopt::Transparent::clean_basis` before continuing with `linopt::Transparent::phaseII_tableau`, otherwise we will get an error message:

```
linopt::Transparent::phaseII_tableau(t)
```

```
Error: Clean the basis from phase I slack variables first. [linopt:
```

```
t := linopt::Transparent::clean_basis(t):  
linopt::Transparent::phaseII_tableau(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 0 & 0 & 0 \\ x & 1 & 0 & -1 & -1 & 0 & 1 \\ y & 1 & 0 & 1 & 0 & 1 & 0 \\ \text{slk}_1 & 0 & 1 & 1 & 1 & 0 & 0 \end{pmatrix}$$

```
delete t:
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent`.

| linopt::Transparent::convert |
linopt::Transparent::clean_basis |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseI_tableau |
linopt::Transparent::result | linopt::Transparent::simplex |
linopt::Transparent::suggest | linopt::Transparent::userstep

Purpose	Get the basic feasible solution belonging to the given simplex tableau
Syntax	<code>linopt::Transparent::result(tableau)</code>
Description	<code>linopt::Transparent::result(tableau)</code> returns the basic feasible solution belonging to the given simplex tableau <code>tableau</code> . Only the user defined variables are taken into account - the dual prices can be achieved by use of <code>linopt::Transparent::dual_prices</code> .

Examples

Example 1

We first compute an edge for an initial simplex tableau:

```
k := [{x <= 1, y <= 1, x + y >= 2}, 0, NonNegative]:  
t := linopt::Transparent(k):  
linopt::Transparent::result(t)
```

```
{x = 0, y = 0}
```

Now we compute the edge for the final tableau, which is identical to the optimal solution of the linear program given by `k`. We get the final simplex tableau by using `linopt::Transparent::simplex`:

```
t := linopt::Transparent(k):  
t := linopt::Transparent::simplex(t):  
linopt::Transparent::result(t)
```

```
{x = 1, y = 1}
```

```
linopt::minimize(k)
```

```
[OPTIMAL, {x = 1, y = 1}, 0]
```

```
delete k, t:
```

linopt::Transparent::result

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Set containing the values of the user defined variables for the feasible solution.

MuPAD Functions

`linopt::Transparent` | `linopt::Transparent::dual_prices`

Purpose

Finish the current phase of the 2-phase simplex algorithm

Syntax

```
linopt::Transparent::simplex(tableau)
```

Description

`linopt::Transparent::simplex` runs the current phase of the 2-phase simplex algorithm until the end, i.e. if phase I was explicitly started (see `linopt::Transparent::phaseI_tableau`) the first phase will lead the optimal tableau. Sometimes it can be necessary to eliminate some slack variables of phase one by using `linopt::Transparent::clean_basis`.

If there was no phase I started by the user, `(linopt::Transparent)::simplex` returns the last optimal tableau or the empty set if there was no feasible solution found.

Examples

Example 1

We apply `linopt::Transparent::simplex` to an ordinary simplex tableau of a linear program and we get the optimal tableau:

```
k := [{x + y >= 2}, x, NonNegative]:  
t := linopt::Transparent(k);  
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ \text{slk}_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ y & 2 & -1 & 1 & 1 \end{pmatrix}$$

Let us proof the obtained result:

linopt::Transparent::simplex

```
linopt::Transparent::suggest(t)
```

```
OPTIMAL
```

```
delete k, t:
```

Example 2

If the first phase of the simplex algorithm was started explicitly, `linopt::Transparent::simplex` returns only the optimal tableau of the first phase:

```
k := [{x + y >= 2}, y, NonNegative]:  
t := linopt::Transparent(k):  
t := linopt::Transparent::phaseI_tableau(t);  
t := linopt::Transparent::simplex(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & -2 & 0 & 1 & -1 & -1 \\ \text{slk}_2 & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_2 & \text{slk}_1 & y & x \\ \text{"obj"} & & 0 & 1 & 0 & 0 & 0 \\ y & & 2 & 1 & -1 & 1 & 1 \end{pmatrix}$$

The next step of the simplex algorithm is computed:

```
linopt::Transparent::suggest(t)
```

```
"linopt::Transparent::phaseII_tableau"
```

With `linopt::Transparent::autostep` we execute the first step of the second phase of the simplex algorithm. One can see that the simplex algorithm is not finished yet:

```
t := linopt::Transparent::autostep(t);  
linopt::Transparent::suggest(t);
```

`y, x`

If we then apply `linopt::Transparent::simplex` again we get the optimal solution. Here we don't had to use `linopt::Transparent::clean_basis`, before using `linopt::Transparent::autostep`, because there are no artificial variables in the basis computed by the first `linopt::Transparent::simplex` call above:

```
t := linopt::Transparent::simplex(t);  
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & y & x \\ \text{"obj"} & 0 & 0 & 1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete k, t;
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Simplex tableau of domain type `linopt::Transparent` or the empty set if there was no feasible solution found.

linopt::Transparent::simplex

linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::convert |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseI_tableau |
linopt::Transparent::result | linopt::Transparent::suggest |
linopt::Transparent::userstep

Purpose Suggest the next step in the simplex algorithm

Syntax `linopt::Transparent::suggest(tableau)`

Description `linopt::Transparent::suggest(tableau)` suggests the next step in the simplex algorithm for the given simplex tableau `tableau`.

Normally this suggestion will be a pivot element, i.e. a sequence of a basic and a non-basic variable. If a phase I of the 2-phase simplex algorithm was started explicitly (see `linopt::Transparent::phaseI_tableau`) and the current tableau belongs to a feasible solution the suggestion will be the string "`linopt::Transparent::phaseII_tableau`". At the end of the calculation the 'suggestion' is the identifier `OPTIMAL`.

The result of `linopt::Transparent::suggest` can be influenced if the global identifier `OPTIMAL` has a value. For this reason the identifier `OPTIMAL` is protected.

Examples **Example 1**

We have a look at a linear program where the ordinary simplex tableau of the given problem is not the last tableau during the computation of the simplex algorithm. Looking at the ordinary simplex tableau we see that the element of the `slk[2]`-labeled row and the `x`-labeled column is a pivot element:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
      7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative];
t := linopt::Transparent(k);
linopt::Transparent::suggest(t)
```

linopt::Transparent::suggest

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

slk_2, x

```
delete k, t:
```

Example 2

Here the ordinary simplex tableau still contains the solution of the linear program if the linear objective function is to minimize (see `linopt::Transparent` for more information):

```
k := [{x+y>=-1, x+y<=3}, x+2*y, NonNegative]:  
t := linopt::Transparent(k);  
linopt::Transparent::suggest(t)
```

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 2 & 1 \\ \text{slk}_1 & 1 & 1 & 0 & -1 & -1 \\ \text{slk}_2 & 3 & 0 & 1 & 1 & 1 \end{pmatrix}$$

OPTIMAL

```
delete k, t:
```

Example 3

Here we explicitly start the first phase of the simplex algorithm. If we want a solution of the original linear program we have to apply the second phase of the simplex algorithm:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,  
      7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:  
t := linopt::Transparent(k):  
t := linopt::Transparent::phaseI_tableau(t):  
t := linopt::Transparent::simplex(t):  
linopt::Transparent::suggest(t)
```

```
"linopt::Transparent::phaseII_tableau"
```

```
delete k, t:
```

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

Return Values

Sequence of 2 identifiers, the identifier `OPTIMAL` or the string `"linopt::Transparent::phaseII_tableau"`.

MuPAD Functions

linopt::Transparent | linopt::Transparent::autostep
| linopt::Transparent::convert |
linopt::Transparent::dual_prices |
linopt::Transparent::phaseI_tableau |
linopt::Transparent::result | linopt::Transparent::simplex |
linopt::Transparent::userstep

Purpose	Perform a user defined simplex step
Syntax	<code>linopt::Transparent::userstep(tableau, basvar, nonbasvar)</code>
Description	<code>linopt::Transparent::userstep(tableau, basvar, nonbasvar)</code> performs a user defined simplex step in the tableau with the pivot element defined by <code>basvar</code> and <code>nonbasvar</code> .
Examples	Example 1

We execute the simplex step given by the pivot element $(slk[1], x)$:

```
k := [{x + y >= 2}, x, NonNegative]:
t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, slk[1], x)
```

$$\begin{pmatrix} \text{"linopt" "restr" } slk_1 & y & x \\ \text{"obj"} & 0 & 0 & 0 & 1 \\ slk_1 & -2 & 1 & -1 & -1 \end{pmatrix}$$

$$\begin{pmatrix} \text{"linopt" "restr" } slk_1 & y & x \\ \text{"obj"} & -2 & 1 & -1 & 0 \\ x & 2 & -1 & 1 & 1 \end{pmatrix}$$

Example 2

If we specify a wrong pivot element, we will get an error message:

```
k := [{3*x + 4*y - 3*z <= 23, 5*x - 4*y - 3*z <= 10,
      7*x + 4*y + 11*z <= 30}, -x + y + 2*z, NonNegative]:
t:= linopt::Transparent(k);
linopt::Transparent::userstep(t, x, y)
```

linopt::Transparent::userstep

$$\begin{pmatrix} \text{"linopt"} & \text{"restr"} & \text{slk}_1 & \text{slk}_2 & \text{slk}_3 & y & x & z \\ \text{"obj"} & 0 & 0 & 0 & 0 & 1 & -1 & 2 \\ \text{slk}_1 & 23 & 1 & 0 & 0 & 4 & 3 & -3 \\ \text{slk}_2 & 10 & 0 & 1 & 0 & -4 & 5 & -3 \\ \text{slk}_3 & 30 & 0 & 0 & 1 & 4 & 7 & 11 \end{pmatrix}$$

Error: The pivot element is not specified or specified incorrectly.

delete k, t:

Parameters

tableau

A simplex tableau of domain type `linopt::Transparent`

basvar

A basic variable represented by an identifier that has to leave the basis

nonbasvar

A non-basic variable represented by an identifier that has to enter the basis

Return Values

Simplex tableau of domain type `linopt::Transparent`.

listlib – Manipulating Lists

listlib::insert
listlib::insertAt
listlib::merge
listlib::removeDuplicates
listlib::removeDupSorted
listlib::setDifference
listlib::singleMerge
listlib::sublist

listlib::insert

Purpose Insert an element into a list

Syntax `listlib::insert(list, element, <function>)`

Description `listlib::insert(list, element)` inserts `element` into `list`.

With the function `listlib::insert` any element can be inserted into any list.

With the third optional argument a function can be given that compare the elements of the list with the element to insert and therewith determines the position, the element is inserted. The given function is called with two elements and have to return `TRUE`, if the two elements are in the right order, otherwise `FALSE` (see next paragraph).

The given function is called step by step with an element of the list as first argument and the given element as second argument, until it returns `FALSE`. Then the given element is inserted into the list in *front* of the last proved element (see “Example 2” on page 16-3).

Note The list must be ordered with regard to the order function, otherwise the element could be inserted at the wrong place.

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

Examples

Example 1

Insert 3 into the given ordered list:

```
listlib::insert([1, 2, 4, 5, 6], 3)
```

```
[1, 2, 3, 4, 5, 6]
```

Insert 3 into the given descending ordered list. The insert function represents and preserves the order of the list:

```
listlib::insert([6, 5, 4, 2, 1], 3, _not@_less)
```

```
[6, 5, 4, 3, 2, 1]
```

Because identifiers cannot be ordered by `_less`, another function must be given, e.g., the function that represents the systems internal order:

```
listlib::insert([a, b, d, e, f], c, sysorder)
```

```
[a, b, c, d, e, f]
```

Example 2

Because no function is given as third argument, the function `_less` is used. `_less` is called: `_less(1, 3)`, `_less(2, 3)`, `_less(4, 3)` and then 3 is inserted in front of 4:

```
listlib::insert([1, 2, 4], 3)
```

```
[1, 2, 3, 4]
```

If the list is not ordered right, then the insert position could be wrong:

```
listlib::insert([4, 1, 2], 3)
```

```
[3, 4, 1, 2]
```

Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:

listlib::insert

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X)):
priority(x^2), priority(x + 2)
```

1, 3

The function `sortfunc` returns TRUE, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x^2)
```

TRUE, FALSE

Now the expression x^2 is inserted at the “right” place in the list:

```
listlib::insert([x^y, x^2, x*y, -y, x + y], x^2, sortfunc)
```

$[x^y, x^2, 2x, xy, -y, x+y]$

Parameters

list

MuPAD list

element

MuPAD expression to insert

function

Function that determines the insert position

Return Values

Given list enlarged with the inserted element

See Also

MuPAD Functions

`_concat` | `append` | `listlib::insertAt`

listlib::insertAt

Purpose Insert an element into a list at a given position

Syntax `listlib::insertAt(list, element, <pos>)`

Description `listlib::insertAt(list, element, pos)` inserts `element` into `list` at position `pos`.

With the function `listlib::insertAt` any element can be inserted into any list at a specified place.

The third argument (the “insert index”) determines the place to insert the element into the given list.

If the insert index is less than 1 the element is inserted in front of the list. If the insertion index is greater than `nops(list)` the element is appended to the list. To append an element to a list the kernel function `append` is faster.

If no third argument is given, the given element is inserted in front of the list.

If the argument `element` is a list too, the elements of this list will be inserted (or appended) instead of the whole list by preserving the order.

Examples

Example 1

Insertion 2 at the third place of the given list:

```
listlib::insertAt([1, 1, 1], 2, 3)
```

```
[1, 1, 2, 1]
```

Insertion of an element in front of a list. The third argument is optional in this case:

```
listlib::insertAt([1, 1, 3, 1], 2, 0), listlib::insertAt([1, 1, 3,
```

```
2, 1, 1, 3, 1], [2, 1, 1, 3, 1]
```

Appending of an element. This could be done faster with `append`:

```
listlib::insertAt([1, 2, 3], 4, 1000), append([1, 2, 3], 4)  
[1, 2, 3, 4], [1, 2, 3, 4]
```

Parameters

list

A list

element

Any MuPAD object

pos

Any integer

Return Values

Given list enlarged with the inserted element

See Also

MuPAD Functions

`listlib::insert` | `append` | `_concat`

listlib::merge

Purpose Merging two ordered lists

Syntax `listlib::merge(list1, list2, <function>)`

Description `listlib::merge(list1, list2)` merges both lists into one list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return TRUE, if the two elements are in the right order, otherwise FALSE (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns FALSE. Then the element of the second list is inserted into the first list in *front* of the last proved element (see “Example 2” on page 16-9).

Note The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

Examples

Example 1

Merging two ascending ordered lists:

```
listlib::merge([1, 3, 5, 7], [2, 4, 6, 8])
```

```
[1, 2, 3, 4, 5, 6, 7, 8]
```

Merging two descending ordered lists:

```
listlib::merge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)
[8, 7, 6, 5, 4, 3, 2, 1]
```

Example 2

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number, when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X))
priority(x^2), priority(x + 2)
1, 3
```

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x^2)
TRUE, FALSE
```

Now the both lists are merged with regard to the given priority:

```
listlib::merge([x^y, x*2, -y], [x^2, x*y, x + y], sortfunc)
[x^y, x^2, 2x, -y, x y, x + y]
delete priority, sortfunc:
```

Parameters `list1, list2`

listlib::merge

A MuPAD list

function

A function that determines the merging order

Return Values

Ordered list that contains the elements of both lists

See Also

MuPAD Functions

`listlib::singleMerge` | `listlib::insert` | `_concat` | `zip`

Purpose Removes duplicate entries

Syntax `listlib::removeDuplicates(list, <KeepOrder>)`

Description `listlib::removeDuplicates(list)` removes all duplicates of each entry of the list `list`. The new list is build up from right to left with the order of the *last* occurrence of each entry in `list`. Cf. “Example 1” on page 16-11.

A faster possibibliy to remove duplicate entries is to convert the list into a set and back into a list. You will loose the order of the list entries in this case. Cf. “Example 3” on page 16-11.

Examples **Example 1**

Per default `listlib::removeDuplicates` removes duplicate entries in reverse order:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:  
listlib::removeDuplicates(list)
```

```
[5, 3, 1, 7]
```

Example 2

With option `KeepOrder` entries are selected in the order of their occurrence:

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:  
listlib::removeDuplicates(list, KeepOrder)
```

```
[1, 3, 5, 7]
```

Example 3

If you don't need the order of list entries any more, you may convert the list into a set and back into a list, this is much faster:

listlib::removeDuplicates

```
list:= [1, 1, 1, 3, 1, 5, 5, 1, 3, 3, 1, 7]:  
[op({op(list)})]
```

```
[1, 3, 5, 7]
```

Parameters

list

A MuPAD list

Options

KeepOrder

`listlib::removeDuplicates(list, KeepOrder)` returns a list of the entries of `list` in the order of their *first* occurrence. The list is build up from left to right. See “Example 2” on page 16-11.

Return Values

List that contains each entry only once

See Also

MuPAD Domains

DOM_LIST

MuPAD Functions

`listlib::removeDupSorted`

Purpose Remove duplicates of any element from ordered lists

Syntax `listlib::removeDupSorted(list)`

Description `listlib::removeDupSorted(list)` removes all duplicates of any element of the ordered list `list`.

`listlib::removeDupSorted` does the same as `listlib::removeDuplicates`, but it assumes that the list is sorted and therefore it is faster. A notable gain will only occur, if there are only few duplicates in a long list.

Examples **Example 1**

`listlib::removeDupSorted` removes all duplicates from the given list:

```
listlib::removeDupSorted([1, 1, 1, 3, 5, 5, 5, 5, 5, 5, 7, 7, 7])  
  
[1, 3, 5, 7]
```

If the list is not ordered, `listlib::removeDupSorted` fails:

```
listlib::removeDupSorted([1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7])  
  
[1, 3, 5, 7, 1, 3, 5, 7, 1, 3, 5, 7]
```

Parameters **list**
An ordered MuPAD list

Return Values List that contains every element only once

listlib::removeDupSorted

See Also

MuPAD Functions

`listlib::removeDuplicates`

Purpose Remove elements from a list

Syntax `listlib::setDifference(list1, list2)`

Description `listlib::setDifference(list1, list2)` removes all elements from `list1`, that are given by `list2`.

Note The order of the list is not preserved.

Examples

Example 1

`listlib::setDifference` removes 2, 4, 6 and 8 from the given list:

```
listlib::setDifference([1, 2, 3, 4, 5, 6, 7, 8], [2, 4, 6, 8])
```

```
[1, 3, 5, 7]
```

Parameters **list1, list2**

A MuPAD list

Return Values First list without all elements of the second list

See Also

MuPAD Functions `minus`

listlib::singleMerge

Purpose Merging of two ordered lists without duplicates

Syntax `listlib::singleMerge(list1, list2, <function>)`

Description `listlib::singleMerge(list1, list2)` merges the both lists into one list. It is assumed that the lists are “disjunct”, no element appears in both lists. Otherwise such elements are inserted only once in the result list.

With the third optional argument a function can be given that compare the elements of the lists and therewith determines the order of the elements. The given function is called with two elements and have to return TRUE, if the two elements are in the right order, otherwise FALSE (see next paragraph).

The given function is called step by step with an element of the first list as first argument and an element of the second list as second argument, until it returns FALSE. Then the element of the second list is inserted into the first list in *front* of the last proved element (see “Example 3” on page 16-17).

Note The lists must be ordered with regard to the order function, otherwise the elements could be inserted at the wrong place.

If no third argument is given the function `_less` is used. If no order of the elements with regard to `_less` is defined, a function must be given, otherwise an error appears. The system function `sysorder` always can be used.

Examples

Example 1

Merging two ascending ordered lists:

```
listlib::singleMerge([1, 3, 5, 7], [2, 4, 6, 8])
```

```
[1, 2, 3, 4, 5, 6, 7, 8]
```

Merging two descending ordered lists:

```
listlib::singleMerge([7, 5, 3, 1], [8, 6, 4, 2], _not@_less)
```

```
[8, 7, 6, 5, 4, 3, 2, 1]
```

Example 2

Merging two ascending ordered lists with duplicates:

```
listlib::singleMerge([1, 2, 5, 7], [2, 5, 6, 8])
```

```
[1, 2, 5, 6, 7, 8]
```

But the following lists does not contain mutual equal elements:

```
listlib::singleMerge([1, 1, 3, 3], [2, 2, 4, 4])
```

```
[1, 1, 2, 2, 3, 3, 4, 4]
```

Example 3

The following example shows, how expressions can be ordered by a user defined priority. This order is given by the function named `priority`, which returns a smaller number when the expression has a type with higher priority:

```
priority := X -> contains(["_power", "_mult", "_plus"], type(X))  
priority(x^2), priority(x + 2)
```

```
1, 3
```

listlib::singleMerge

The function `sortfunc` returns `TRUE`, if the both given arguments are in the right order, i.e., the first argument has a higher (or equal) priority than the second argument:

```
sortfunc := (X, Y) -> bool(priority(Y) > priority(X)):
sortfunc(x^2, x + 2), sortfunc(x + 2, x*2)
```

`TRUE, FALSE`

Now the both lists are merged with regard to the given priority:

```
listlib::singleMerge([x^y, x*2, -y], [x^2, x*y, x + y], sortfunc)
```

`[x^y, x^2, 2 x, -y, x y, x + y]`

```
delete priority, sortfunc:
```

Parameters

list1, list2

A MuPAD list

function

A function that determines the merging order

Return Values

Ordered list that contains the elements of both lists

See Also

MuPAD Functions

`listlib::merge` | `listlib::insert` | `_concat` | `zip`

Purpose

Search sublists

Syntax

```
listlib::sublist(list1, list2, <index>, <Consecutive>)
```

Description

`listlib::sublist(list1, list2)` determines, whether the list `list1` contains another list `list2`.

With `listlib::sublist` the position of the first appearance of a list in another list can be determined.

The position that was found is returned as integer. If the given list does not contain the given `sublist`, the number 0 is returned.

If an index is given, the search starts at this position. There with multiple occurrence of a `sublist` can be determined.

With the option `Consecutive`, the list must contain the `sublist` in one piece without elements in between.

Examples

Example 1

The `sublist` is a part of the list, but not in one piece:

```
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6])
```

```
2
```

```
listlib::sublist([1, 2, 3, 4, 5, 6, 7, 8], [2, 3, 5, 6], Consecutive)
```

```
0
```

The list contains the `sublist`, coherent and incoherent:

```
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5])
```

```
1
```

listlib::sublist

```
listlib::sublist([1, 2, 3, 4, 5, 1, 3, 5], [1, 3, 5], Consecutive)
```

```
6
```

Example 2

Find the last occurrence of the sublist inside of the list:

```
POS:= 0:  
while listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)  
    POS:= listlib::sublist([1, 2, 3, 1, 3, 1, 2, 3], [1, 2, 3], POS + 1)  
end_while:  
POS
```

```
6
```

```
delete POS:
```

Parameters

list1, list2

MuPAD list

index

Integer that determines the first search position

Options

Consecutive

Determines that the sublist `list2` is containing coherent in `list1`

Return Values

Position of the first element of the containing sublist or zero

MuPAD Functions

`contains` | `op`

misc – Miscellanea

misc::breakmap
misc::genassop
misc::maprec
misc::pslq

misc::breakmap

Purpose Stops the mapping currently done by maprec

Syntax misc::breakmap()

Description misc::breakmap() stops the recursive application of a function to all subexpressions of an expression that misc::maprec is just working on. misc::breakmap is useful as a command inside the procedure mapped by misc::maprec in case we know that we are finished with our work and the remaining recursive mapping is not necessary.

Examples

Example 1

We want to know whether a given expression contains a particular type `t`. As soon as we have found the first occurrence of `t`, we can terminate our search.

```
myfound := FALSE:
misc::maprec(hold(((23+5.0)/3+4*I)*PI),
             {DOM_COMPLEX}=proc()
             begin
               myfound := misc::breakmap();
               args()
             end_proc):
myfound
```

TRUE

What did we do? We told misc::maprec just to go down the expression tree and look for subexpressions of type `DOM_COMPLEX`; and, whenever such subexpression should be found, to apply a certain procedure to it. That procedure stops the recursive mapping, remembers that we have found the type we had searched for, and returns exactly its argument such that the result returned by misc::maprec equals the input. In the example below, we test whether our given expression contains the type `DOM_POLY`.

```
myfound := FALSE:
misc::maprec(hold(((23+5.0)/3+4*I)*PI),
             {DOM_POLY}=proc()
             begin
                 myfound := misc::breakmap();
                 args()
             end_proc):
myfound
```

FALSE

Note that you do not need to use this method when searching for subexpressions of a given type; calling `hastype` is certainly more convenient.

Return Values

`misc::breakmap` always returns TRUE.

See Also

MuPAD Functions

`misc::maprec`

misc::genassop

Purpose Generates an n-ary associative operator from a binary one

Syntax `misc::genassop(binaryop, zeroelement)`

Description `misc::genassop(binaryop, zeroelement)` generates an n-ary associative operator from the binary operator `binaryop`, where `zeroelement` is a neutral element for `binaryop`.

`binaryop` must be a function taking two arguments (no matter of what kind) and returning a valid argument to itself. It must satisfy the associative law `binaryop(binaryop(a, b), c) = binaryop(a, binaryop(b, c))`.

`zeroelement` is an object such that `binaryop(a, zeroelement) = a` holds for every `a`.

`misc::genassop` returns a procedure which returns `zeroelement` if it is called without arguments and the argument if it is called with one argument.

Note `misc::genassop` doesn't check whether `binaryop` is really associative and whether `zeroelement` is really a neutral element for `binaryop`.

Examples

Example 1

We know that `_plus` is an n-ary operator anyway, but let us assume that `_plus` was only a binary operator. We can create an own n-ary addition as follows:

```
myplus := misc::genassop(_plus, 0)
```

```
proc genericAssop() ... end
```

Now we make `myplus` add some values.

```
myplus(3, 4, 8), myplus(-5), myplus()
```

```
15, -5, 0
```

As mentioned in the “Details” section, `myplus` returns the argument if it is called with exactly one argument, and it returns the zeroelement `0` if it is called without arguments.

Parameters

`binaryop`

A function

`zeroelement`

An object

Return Values

`misc::genassop` returns a procedure `f`. That procedure accepts an arbitrary number of arguments of the same kind `binaryop` does; it returns `zeroelement` if it is called without argument, and its only argument if it is called with one argument; its value on n arguments is inductively defined by $f(x_1, \dots, x_n) = f(\text{binaryop}(x_1, x_2), x_3, \dots, x_n)$.

MuPAD Functions

`operator`

misc::maprec

Purpose

Map a function to subexpressions of an expression

Syntax

```
misc::maprec(ex, selector = funci, , <PreMap | PostMap>, <NoOperators>, <Unsimplified>)
```

Description

`misc::maprec(ex, selector=funci)` maps the function `funci` to all subexpressions of the expression `ex` that satisfy a given criterion (defined by `selector`) and replaces each selected subexpression `s` by `funci(s)`.

Several different functions may be mapped to subexpressions satisfying different selection criteria.

`misc::maprec(ex, selector1 = funci1, , selectorn = funcin)` does two steps: it tests whether `ex` meets a selection criterion defined by some selector `selectork` (and, if yes, replaces `ex` by `funcik(ex)`); and it applies itself recursively to all operands of `ex`. The order of these steps is determined by the options `PreMap` and `PostMap`.

Selectors are applied from left to right; if the expression meets some selection criterion, no further selectors are tried.

`selector` can have two forms. It can be a set $\{t_1, \dots, t_n\}$. Here a subexpression `s` of `ex` is selected if `type(s)` is one of the types t_1, \dots, t_n . If it is not a set, a subexpression `s` of `ex` is selected if `p(s)` returns `TRUE`. As every MuPAD object may be applied as a function to `s`, `p` may be of any type in the latter case.

In order not to select a subexpression, the selector need not return `FALSE`; it suffices that it does not return `TRUE`.

If neither the option `PreMap` nor the option `PostMap` is given, then `PreMap` is used.

Use a `misc::breakmap` command inside `funci` in order to stop the recursive mapping. See the help page of `misc::breakmap` for an example.

Note Only subexpressions of domain type `DOM_ARRAY`, `DOM_EXPR`, `DOM_LIST`, `DOM_SET`, and `DOM_TABLE` are mapped recursively, as well as domain elements of a domain `T` for which a slot `T::enableMaprec` exists and equals `TRUE`; a slot `T::map` working properly must then exist, too. To subexpressions of other types, `selector` is applied, but `misc::maprec` is not mapped to their operands. (This is to avoid unwanted substitutions.) If you want to recurse on them, either add an `enableMaprec`-slot, or use a `selector` that selects such subexpressions, and make `funci` initiate another recursive mapping.

`misc::maprec` is overloadable. If the domain of a subexpression has a method "maprec", then this method is called with the subexpression and the other arguments of the call.

Note The subexpression is replaced by the result, but `misc::maprec` is not mapped to its operands; such recursive mapping must be done by the domain method if desired.

Note The operators of expressions (`op(expression, 0)`) are also mapped recursively like all the other operands. Use `NoOperators` to switch this off.

Examples

Example 1

In the following example every integer of the given expression `a+3+4` is substituted by the value 10. Since `10(n)` returns 10 for every integer `n`, it suffices to write 10 instead of `n -> 10` here.

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10)
```

```
a+20
```

In the example above, we used `hold` to suppress the evaluation of the expression because otherwise `a+3+4` is evaluated to `a+7` and we get the result:

```
misc::maprec(a+3+4, {DOM_INT} = 10)
```

```
a+10
```

The simplification of the resulting `10 + 10` to `20` can be avoided by using the option `Unsimplified`:

```
misc::maprec(hold(a+3+4), {DOM_INT} = 10, Unsimplified)
```

```
a+10+10
```

Example 2

Now we give an example where the `selector` is a function. We want to eliminate all the prime numbers from an expression.

```
misc::maprec(hold(_plus)(i $ i=1..20), isprime= null(), PostMap)
```

```
133
```

Here `isprime` returns `TRUE` for every prime number between 1 and 20. Every prime number between 1 and 20 is replaced by `null()` (since `null()(p)` gives `null()`) which means the above call computes the sum of all non-prime numbers between 1 and 20.

Example 3

Normally, `misc::maprec` recurses also into the operators of subexpressions. This may be unwanted in many cases:

```
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1))
```

```
plus(a1, b1)
```

We just wanted to replace the summands, but not the operator. Using the option `NoOperators` helps:

```
misc::maprec(a+b, {DOM_IDENT}= (x -> x.1), NoOperators)
```

```
a1 + b1
```

Parameters

ex

Any MuPAD object

selector

Any MuPAD object

funci

Any MuPAD object

Options

PreMap

For each subexpressions s of ex , the selector is applied to it *after* visiting all of its subexpressions; s may have changed at that time due to substitutions in the subexpressions.

PostMap

For each subexpressions s of ex , the selector is applied to it *before* visiting its subexpressions. If s is selected by selector, it is replaced by $funci(s)$, and `misc::maprec` is *not* recursively applied to the operands of $funci(s)$; otherwise, `misc::maprec` is recursively applied to the operands of s .

NoOperators

The selector is not applied to the operator of ex .

Unsimplified

misc::maprec

The resulting expressions are not further simplified.

Return Values

`misc::maprec` may return any MuPAD object.

Overloaded By

`ex`

Purpose	Heuristic detection of relations between real numbers
Syntax	<code>misc::pslq(numberlist, precision)</code>
Description	<p><code>misc::pslq(numberlist, precision)</code> returns a list of integers $[k_1, \dots, k_n]$ such that — denoting the elements of <code>numberlist</code> by a_1, \dots, a_n — the absolute value of $\sum_{i=1}^n a_i k_i$ is less than $\frac{1}{\text{precision}}$ times the Euclidean norm of <code>numberlist</code>, or FAIL if such integers could not be detected.</p> <p>This method can be used to get an idea about linear dependencies, before proving them.</p>
Environment Interactions	<code>misc::pslq</code> is <i>not</i> affected by the current value of DIGITS. Numerical computations are carried out with more significant digits such that the output meets the specification given above.
Examples	<p>Example 1</p> <p>Does π satisfy a polynomial equation of degree at most 2 ?</p> <pre>misc::pslq([1, PI, PI^2], 20)</pre> <pre>FAIL</pre> <p>Example 2</p> <p>Having forgotten the relation between sine and cosine, we can try the heuristic way.</p> <pre>misc::pslq([1, sin(0.32), sin(0.32)^2, cos(0.32), cos(0.32)^2],</pre> <pre>(1 0 -1 0 -1)</pre>

misc::pslq

Parameters

numberlist

List of real numbers or objects that can be converted to real numbers by the function `float`.

precision

Positive integer

Return Values

List of integers, or FAIL

Algorithms

This function has been written by Raymond Manzoni.

The algorithm has been taken from Bailey and Plouffe, *Recognizing numerical constants*. See also Helaman R.P. Ferguson and David Bailey, *A Polynomial Time, Numerically Stable Integer Relation Algorithm*, RNR Technical Report RNR-92-032.

Purpose Butcher parameters of Runge-Kutta schemes

Syntax `numeric::butcher(EULER1 | RKF43 | xRKF43 | RK4 | RKF34 | xRKF34 | RKF54a | xRKF54a | RKF54b | xRKF54b | DOPRI54 | xDOPRI54 | CK54 | xCK54 | RKF45a | xRKF45a | RKF45b | xRKF45b | DOPRI45 | xDOPRI45 | CK45 | xCK45 | DOPRI65 | xDOPRI65 | DOPRI56 | xDOPRI56 | BUTCHER6 | RKF87 | xRKF87 | RKF78 | xRKF78 | DOPRI87 | xDOPRI87 | DOPRI78 | xDOPRI78 | GAUSS(s) | GAUSS = s, <digits>)`

Description `numeric::butcher(method)` returns the Butcher parameters of the Runge-Kutta scheme named `method`.

An s -stage Runge-Kutta method for the numerical integration of a dynamical system $\frac{dy}{dt} = f(t, y)$ with step size h is a map

$$(t, y) \rightarrow (t+h, y+h b_1 k_1 + \dots + h b_s k_s)$$

The “intermediate stages” k_1, \dots, k_s are defined as the solutions of the algebraic equations

$$k_i = f(t+c_i h, y+h a_{i1} k_1 + \dots + h a_{is} k_s), 1 \leq i \leq s$$

If the $s \times s$ “Butcher matrix” a_{ij} is strictly lower triangular, the method is called “explicit”. In this case, the intermediate stages are computed recursively as:

$$k_1 = f(t, y)$$

$$k_2 = f(t+c_2 h, y+h a_{21} k_1)$$

$$\vdots$$

$$k_s = f(t+c_s h, y+h a_{s1} k_1 + \dots + h a_{s,s-1} k_{s-1})$$

numeric::butcher

Various numerical schemes arise from different choices of the Butcher parameters: the $s \times s$ -matrix a_{ij} , the weights $b = [b_1, \dots, b_s]$ and the abscissae $c = [c_1, c_2, \dots, c_s]$.

Embedded pairs of Runge-Kutta methods consist of two methods that share the matrix a_{ij} and the abscissae c_i , but use different weights b_i .

The returned list $[s, c, a, b_1, b_2, \text{order}_1, \text{order}_2]$ contains the Butcher data of the method: s is the number of stages, c is the list of abscissae, a is the Butcher matrix, b_1 and b_2 are lists of weights. The integers order_1 and order_2 are the orders of the scheme when using the weights b_1 or b_2 , respectively, in conjunction with the matrix a and the abscissae c .

The methods EULER1 (order 1), RK4 (order 4) and BUTCHER6 (order 6) are single methods with $b_1 = b_2$ and $\text{order}_1 = \text{order}_2$. All other methods are embedded pairs of Runge-Kutta-Fehlberg (RKFxx), Dormand-Prince (DOPRIxx) or Cash-Karp (CKxx) type. The names indicate the orders of the subprocesses, e.g., CK45 is the Cash-Karp pair of orders 4 and 5. CK54 is the same pair with reversed ordering of the subprocesses. The second subprocess is used to produce a time step of the Runge-Kutta method, the first subprocess is used for estimating the error of the time step.

The methods GAUSS(s) or, equivalently, GAUSS = s are the implicit Gauss methods with s stages of order $2s$.

The data of all explicit methods are returned as exact rational numbers. The data of the Gauss methods are returned as floating-point numbers.

The Butcher data are called by the routines `numeric::odesolve`, `numeric::odesolve2`, and `numeric::odesolveGeometric`.

Environment Interactions

When computing the data for GAUSS(s), the function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

The Butcher data of the classical 4 stage, 4th order Runge-Kutta scheme are:

```
numeric::butcher(RK4)
```

$$\left[4, \left(0 \quad \frac{1}{2} \quad \frac{1}{2} \quad 1 \right), \begin{pmatrix} 0 & 0 & 0 & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ 0 & \frac{1}{2} & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \left(\frac{1}{6} \quad \frac{1}{3} \quad \frac{1}{3} \quad \frac{1}{6} \right), \left(\frac{1}{6} \quad \frac{1}{3} \quad \frac{1}{3} \quad \frac{1}{6} \right), 4, 4 \right]$$

Note that the weights b_1 and b_2 coincide: this classical method does not provide an embedded pair.

The Butcher data of the (implicit) 3 stage Gauss method:

```
DIGITS := 5:
numeric::butcher(GAUSS(3));
delete DIGITS:
```

$$\left[3, \left(0.1127 \quad 0.5 \quad 0.8873 \right), \begin{pmatrix} 0.13889 & -0.035977 & 0.0097894 \\ 0.30026 & 0.22222 & -0.022485 \\ 0.26799 & 0.48042 & 0.13889 \end{pmatrix}, \left(0.27778 \quad 0.44444 \quad 0.27778 \right), \right. \\ \left. \left(0.27778 \quad 0.44444 \quad 0.27778 \right), 6, 6 \right]$$

Example 2

The Butcher data of the embedded Runge-Kutta-Fehlberg pair RKF34 of orders 3 and 4 are:

numeric::butcher

```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(RKF34):
```

The number of stages s of the 4th order subprocess is 5, the abscissae c and the matrix a are given by:

```
s, c, a
```

$$5, \left(0 \quad \frac{1}{4} \quad \frac{4}{9} \quad \frac{6}{7} \quad 1 \right), \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ \frac{1}{4} & 0 & 0 & 0 & 0 \\ \frac{4}{81} & \frac{32}{81} & 0 & 0 & 0 \\ \frac{57}{98} & -\frac{432}{343} & \frac{1053}{686} & 0 & 0 \\ \frac{1}{6} & 0 & \frac{27}{52} & \frac{49}{156} & 0 \end{pmatrix}$$

Using these parameters with the weights

```
b1, b2
```

$$\left(\frac{1}{6} \quad 0 \quad \frac{27}{52} \quad \frac{49}{156} \quad 0 \right), \left(\frac{43}{288} \quad 0 \quad \frac{243}{416} \quad \frac{343}{1872} \quad \frac{1}{12} \right)$$

yields a numerical scheme of order 3 or 4, respectively:

```
order1, order2
```

```
3, 4
```

```
delete s, c, a, b1, b2, order1, order2:
```

Example 3

We plot the stability regions of the two sub-methods of DOPRI78. The stability function of a Runge-Kutta scheme with Butcher parameters (c, a, b) is given by

$$p(z) = 1 + z \left(\left\langle b, \frac{e}{(1 - z a)} \right\rangle \right),$$

where e is the column vector $(1, 1, \dots, 1)^T$. For an explicit s -stage scheme (the matrix a is strictly lower triangular), this stability function reduces to the polynomial

$$p(z) = 1 + \left(\sum_{i=1}^s z^i \left(\left\langle b, a^{i-1} e \right\rangle \right) \right).$$

We compute the coefficients of the stability polynomials associated with the Butcher matrix a and the weights b_1 and b_2 of the sub-methods of DOPRI78:

```
[s, c, a, b1, b2, order1, order2] := numeric::butcher(DOPRI78):
e := matrix([1 $ s]):
a := float(matrix(a)):
b1 := linalg::transpose(float(matrix(b1))):
b2 := linalg::transpose(float(matrix(b2))):
for i from 1 to s do
    c1[i] := (b1*a^(i-1)*e)[1, 1];
    c2[i] := (b2*a^(i-1)*e)[1, 1];
end_for:
```

We define the stability polynomials:

```
z := x + I*y:
p1 := 1 + _plus(c1[i]*z^i $ i = 1..s):
p2 := 1 + _plus(c2[i]*z^i $ i = 1..s):
```

The boundary of the stability region $\{z \in \mathbb{C} \mid |p(z)| < 1\}$ is the curve defined by $|p(z)| = 1$. We plot these implicit curves associated with the stability polynomials $p_1(z)$ and $p_2(z)$ defined above:

numeric::butcher

```
plot(plot::Implicit2d(abs(p1) = 1, x = -6..1, y = 0..6,  
    Color = RGB::Red, Legend = "Order 7"),  
    plot::Implicit2d(abs(p2) = 1, x = -6..1, y = 0..6,  
    Color = RGB::Blue, Legend = "Order 8"),  
    Scaling = Constrained):
```

```
delete s, c, a, b1, b2, order1, order2, e, c1, c2, z, p1, p2:
```

Parameters **s**

The number of stages of the Gauss method: a positive integer

digits

The number of significant digits with which the Butcher data of the methods GAUSS(**s**) are computed. The default value for **digits** is the current value of the environment variable **DIGITS**. This argument is only relevant for the Gauss methods.

Return Values

A list `[s, c, a, b1, b2, order1, order2]` is returned.

Algorithms

The Butcher parameters provided in this original paper consist of rational *approximations* of solutions of the order equations of Runge-Kutta systems. The parameters provided by `numeric::butcher` are *exact* rational solutions of the order equations. The approximations given by Prince and Dormand coincide with the MuPAD exact values through 16 decimal digits.

MuPAD Functions

`numeric::odesolve` | `numeric::odesolve2` | `numeric::odesolveGeometric`

numeric::complexRound

Purpose Round a complex number towards the real or imaginary axis

Syntax `numeric::complexRound(z, <eps>)`

Description `numeric::complexRound(z)` discards small real or imaginary parts of complex floating-point numbers z .

If the real part of z satisfies $\Re(z) < \text{eps} |z|$, then it is replaced by zero and $\Im(z)i$ is returned.

If the imaginary part of z satisfies $\Im(z) < \text{eps} |z|$, then it is replaced by zero and $\Re(z)$ is returned.

With the default of `eps=10-DIGITS`, this rounding changes a complex floating-point number by less than the relative standard precision.

Only precisions `eps >= 10-DIGITS` are accepted.

Numerical expressions such as `eps = $\pi \sqrt{2} 10^{-10}$` etc. are accepted as `eps`.

This function removes small real or imaginary parts of complex floating-points numbers generated by numerical roundoff. It is used to simplify the floating-point output of `numeric::fsolve`, `numeric::polyroots`, `numeric::polysysroots` and `numeric::sum`.

Environment Interactions The function is sensitive to the environment variable `DIGITS`.

Examples **Example 1**

Exact numbers are not changed:

```
numeric::complexRound(2 + I/10^20)
```

$$2 + \frac{i}{100000000000000000000}$$

Also the following number has an exact imaginary part and is not rounded:

```
numeric::complexRound(2.0 + sqrt(2)*I/10^20)
```

$$2.0 + \frac{\sqrt{2}i}{100000000000000000000}$$

Rounding occurs for complex floats, if this does not change its value significantly:

```
numeric::complexRound(1.0 + 2.0*I/10^10),
```

```
numeric::complexRound(1.0 + 2.0*I/10^11)
```

$$1.0 + 0.0000000002i \quad 1.0$$

Note that rounding is based on relative precision, i.e., only the ratio of real and imaginary parts is relevant:

```
numeric::complexRound((1.0 + 2.0*I)/10^100)
```

$$1.0 \cdot 10^{-100} + 2.0 \cdot 10^{-100}i$$

```
numeric::complexRound((1.0 + 1.0/10^11*I)/10^100)
```

$$1.0 \cdot 10^{-100}$$

The relative precision for rounding may be reduced by the optional parameter `eps`:

```
numeric::complexRound(2.0/10^10 + I),
```

```
numeric::complexRound(2.0/10^10 + I, PI/10^5)
```

numeric::complexRound

0.0000000002 + 1.0 i, 1.0 i

Parameters

z

An arbitrary MuPAD object

eps

A real number no less than $\frac{1}{10^{\text{DIGITS}}}$

Return Values

If z is a complex floating-point number, then a real or complex floating-point number is returned. For all other types, z is returned unchanged.

Purpose

Interpolation by cubic splines

Syntax

```
numeric::cubicSpline([x0, y0], [x1, y1], ,
<BoundaryCondition>, <Symbolic>, <NoWarning>)
numeric::cubicSpline([x0, x1, ], [y0, y1, ],
<BoundaryCondition>, <Symbolic>, <NoWarning>)
numeric::cubicSpline([[x0, x1, ], [y0, y1, ]],
<BoundaryCondition>, <Symbolic>, <NoWarning>)
```

Description

`numeric::cubicSpline([x0, y0], [x1, y1],)` returns the cubic spline function interpolating a sequence of coordinate pairs $[x_i, y_i]$.

The call `S := numeric::cubicSpline([x0, y0], , [xn, yn])` yields the cubic spline function S interpolating the data $[x_0, y_0], \dots, [x_n, y_n]$, i.e., $S(x_i) = y_i$ for $i = 0, \dots, n$. The spline function is a piecewise polynomial

of degree ≤ 3 on the intervals $(-\infty, x_1], [x_1, x_2], \dots, [x_{n-1}, \infty)$. S and its first two derivatives S', S'' are continuous at the points x_1, \dots, x_n

$_{-1}$. Note that S extends the polynomial representation on $[x_0, x_1]$,

$[x_{n-1}, x_n]$ to $(-\infty, x_0]$ and $[x_{n-1}, \infty)$, respectively.

By default, NotAKnot boundary conditions are assumed, i.e., the third derivative S''' is continuous at the points x_1 and x_{n-1} . With this

boundary condition, S is a cubic polynomial on the intervals $(-\infty, x_2]$

and $[x_{n-2}, \infty)$.

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

Without the option `Symbolic`, the abscissae x_i must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline` reorders the abscissae internally, issuing a warning. The warning may be switched off by the option `NoWarning`.

The function S returned by `numeric::cubicSpline` may be called with one, two or three arguments:

numeric::cubicSpline

- The call `S(z)` returns an explicit expression or a number, if `z` is a real number. Otherwise, the symbolic call `S(z)` is returned.
- The call `S(z, [k])` with a nonnegative integer `k` returns the k -th derivative of S . Cf. “Example 4” on page 18-18. For $k > 3$, zero is returned for any z .
- The call `S(z, i)` is meant for symbolic arguments z . The argument i must be an integer. Internally, z is assumed to satisfy $x_i \leq z < x_{i+1}$, and `S(z, i)` returns the polynomial expression in z representing the spline function on this interval.
- The call `S(z, i, [k])` with an integer i and a nonnegative integer k returns the polynomial representation of the k -th derivative of the spline function on the interval $x_i \leq z < x_{i+1}$.

If `S` is generated with symbolic abscissae x_i (necessarily using the option `Symbolic`), then the call `S(z)` with numerical z leads to an error. The call `S(z, i)` must be used for symbolic abscissae!

Note Note that the interpolation of 2 points $(x_0, y_0), (x_1, y_1)$ must be specified by `numeric::cubicSpline([x0, y0] , [x1, y1])`, not by `numeric::cubicSpline([x0, x1] , [y0, y1])!`

Examples

Example 1

We demonstrate some calls with numerical input data:

```
data := [i, sin(i*PI/20)] $ i= 0..40:  
S1 := numeric::cubicSpline(data):  
S2 := numeric::cubicSpline(data, Natural):  
S3 := numeric::cubicSpline(data, Periodic):  
S4 := numeric::cubicSpline(data, Complete = [3, PI]):
```

At the abscissae, the corresponding input data are reproduced:

```
float(data[6][2]), S1(5), S2(5), S3(5), S4(5)
```

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812, 0.7071067812

Interpolation between the abscissae depends on the boundary condition:

S1(4.5), S2(4.5), S3(4.5), S4(4.5)

0.6494470263, 0.6494470123, 0.6494470123, 0.6517696766

These are the cubic polynomials in z defining the spline on the interval $x_0 = 0 \leq z < x_1 = 1$:

expand(S1(z, 0)); expand(S2(z, 0));
expand(S3(z, 0)); expand(S4(z, 0))

$-0.000632116114 z^3 - 0.00002961951081 z^2 + 0.1570962007 z$

$0.1570790998 z - 0.0006446347923 z^3$

$-0.0006446347923 z^3 + 1.270549421 \cdot 10^{-21} z^2 + 0.1570790998 z$

$2.080517906 z^3 - 4.924083441 z^2 + 3.0 z$

$-0.000632116114 z^3 - 0.00002961951081 z^2 + 0.1570962007 z$

$0.1570790998 z - 0.0006446347923 z^3$

$-0.0006446347923 z^3 + 1.270549421 \cdot 10^{-21} z^2 + 0.1570790998 z$

numeric::cubicSpline

$$2.080517906 z^3 - 4.924083441 z^2 + 3.0 z$$

delete data, S1, S2, S3, S4:

Example 2

We demonstrate some calls with symbolic data:

```
S := numeric::cubicSpline([i, y.i] $ i = 0..3):
```

```
S(1/2)
```

$$0.3125 y_0 + 0.9375 y_1 - 0.3125 y_2 + 0.0625 y_3$$

This is the cubic polynomial in z defining the spline on the interval $x_0 = 0 \leq z < x_1 = 1$:

```
S(z, 0)
```

$$y_0 - z (1.833333333 y_0 - 3.0 y_1 + 1.5 y_2 - 0.3333333333 y_3 + z (2.5 y_1 - 1.0 y_0 - 2.0 y_2 + 0.5 y_3 + z (0.1666666667 y_0 - 0.5 y_1 + 0.5 y_2 - 0.1666666667 y_3)))$$

With the option `Symbolic`, exact arithmetic is used:

```
S := numeric::cubicSpline([i, y.i] $ i = 0..3, Symbolic):
```

```
S(1/2)
```

$$\frac{5 y_0}{16} + \frac{15 y_1}{16} - \frac{5 y_2}{16} + \frac{y_3}{16}$$

Also symbolic boundary data are accepted:

```
S := numeric::cubicSpline([i, exp(i)] $ i = 0..10, Complete = [a, b
```

S(0.1)

0.08341154273 a + 0.00000005947817812 b + 1.020064753

S := numeric::cubicSpline([0, y0], [1, y1], [2, y2], Symbolic, C

collect(S(z, 0), z)

$$\left(\frac{3a}{4} + \frac{5y_0}{4} - 2y_1 + \frac{3y_2}{4} - \frac{5}{4}\right)z^3 + \left(3y_1 - \frac{9y_0}{4} - \frac{7a}{4} - \frac{3y_2}{4} + \frac{5}{4}\right)z^2 + az + y_0$$

$$\left(\frac{3a}{4} + \frac{5y_0}{4} - 2y_1 + \frac{3y_2}{4} - \frac{5}{4}\right)z^3 + \left(3y_1 - \frac{9y_0}{4} - \frac{7a}{4} - \frac{3y_2}{4} + \frac{5}{4}\right)z^2 + az + y_0$$

delete S:

Example 3

We demonstrate the use of symbolic abscissae. Here the option Symbolic is mandatory.

S := numeric::cubicSpline([x.i, y.i] \$ i = 0..2, Symbolic):

The spline function S can only be called with 2 arguments. This is the cubic polynomial in z defining the spline on the interval $x_0 \leq z < x_1$:

S(z, 0)

$$y_0 + (x_0 - z) \left((x_0 - z) \left(\frac{y_0 - y_1}{(x_0 - x_1)(x_0 - x_2)} - \frac{y_1 - y_2}{(x_0 - x_2)(x_1 - x_2)} \right) + \frac{(y_0 - y_1)(x_1 - 2x_0 + x_2)}{(x_0 - x_1)(x_0 - x_2)} + \frac{(x_0 - x_1)(y_1 - y_2)}{(x_0 - x_2)(x_1 - x_2)} \right)$$

numeric::cubicSpline

$$y_0 + (x_0 - z) \left((x_0 - z) \left(\frac{y_0 - y_1}{(x_0 - x_1)(x_0 - x_2)} - \frac{y_1 - y_2}{(x_0 - x_2)(x_1 - x_2)} \right) \right. \\ \left. + \frac{(y_0 - y_1)(x_1 - 2x_0 + x_2)}{(x_0 - x_1)(x_0 - x_2)} + \frac{(x_0 - x_1)(y_1 - y_2)}{(x_0 - x_2)(x_1 - x_2)} \right)$$

delete S:

Example 4

We plot a spline function together with its first three derivatives. The spline approximates the function $\sin(x)$:

```
n := 10:
x := array(0..n, [i/n*2*PI $ i = 0..n]):
S := numeric::cubicSpline([x[i], sin(x[i])] $ i = 0..n, Natural):
delete x:
plot(
  plot::Function2d(S(x), x = 0..2*PI, Color = RGB::Black),
  plot::Function2d(S(x, [1]), x = 0..2*PI, Color = RGB::Red),
  plot::Function2d(S(x, [2]), x = 0..2*PI, Color = RGB::Green,
    Mesh = 1000),
  plot::Function2d(S(x, [3]), x = 0..2*PI, Color = RGB::Blue,
    Mesh = 1000)
)
```

delete n, S:

Example 5

We demonstrate how to generate a phase plot of the differential equation $x''(t) + x(t)^3 = \sin(t)$, with initial conditions $x(0) = x'(0) = 0$. First, we use `numeric::odesolve` to compute a numerical mesh of solution points $[x_i, y_i] = [x(t_i), x'(t_i)]$ with $n + 1$ equidistant time nodes t_0, \dots, t_n in the interval $[0, 20]$:

```
DIGITS := 4: n := 100:
for i from 0 to n do t[i] := 20/n*i: end_for:
f := (t, x) -> [x[2], sin(t) - x[1]^3]:
x[0] := 0: y[0] := 0:
for i from 1 to n do
  [x[i], y[i]] :=
    numeric::odesolve(t[i-1]..t[i], f, [x[i-1], y[i-1]]):
```

numeric::cubicSpline

```
end_for:
```

The mesh of the $(x(t), x'(t))$ phase plot consists of the following points:

```
Plotpoints := [[x[i], y[i]] $ i = 0..n]:
```

We wish to connect these points by a spline curve. We define a spline interpoland $Sx(t)$ approximating the solution $x(t)$ by interpolating the data $[t_0, x_0], \dots, [t_n, x_n]$. A spline interpoland $Sy(t)$ approximating $x'(t)$ is obtained by interpolating the data $[t_0, y_0], \dots, [t_n, y_n]$:

```
Sx := numeric::cubicSpline([t[i], x[i]] $ i = 0..n):  
Sy := numeric::cubicSpline([t[i], y[i]] $ i = 0..n):
```

Finally, we plot the mesh points together with the interpolating spline curve:

```
plot(  
  plot::PointList2d(Plotpoints, PointColor = RGB::Black),  
  plot::Curve2d([Sx(z), Sy(z)], z = 0..20, Mesh = 5*(n - 1) + 1,  
    LineColor = RGB::Red)  
)
```

The functions `plot::Ode2d` and `plot::Ode3d` serve for displaying numerical solutions of ODEs. In fact, they are implemented as indicated by the previous commands. The following call produces the same plot:

```
plot(plot::Ode2d(
  [t[i] $ i = 0..n], f, [x[0], y[0]],
  [(t, x) -> [x[1], x[2]], Style = Points, Color = RGB::Black],
  [(t, x) -> [x[1], x[2]], Style = Splines, Color = RGB::Red])):
```

numeric::cubicSpline

delete DIGITS, n, i, t, f, x, y, Plotpoints, Sx, Sy:

Parameters

x_0, x_1, \dots

Numerical real values in ascending order

y_0, y_1, \dots

Arbitrary expressions

BoundaryCondition

The type of the boundary condition: either NotAKnot, Natural, Periodic, or Complete = [a, b] with arbitrary arithmetical expressions a, b.

Options

Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae x_i are accepted.

The ordering $x_0 < x_1 < \dots < x_n$ is assumed by `numeric::cubicSpline`. This ordering is not checked, even if the abscissae are numerical!

NoWarning

The x -values of the interpolation points must be in ascending order. If the input data violate this condition, the routine issues a warning and reorders the data automatically. With this option, the warning is switched off.

NotAKnot

With the default boundary condition `NotAKnot`, the third derivative S''' of the spline function is continuous at the points x_1 and x_{n-1} . With this boundary condition, S is a polynomial on the intervals $(-\infty, x_2]$ and $[x_{n-2}, \infty)$.

Natural

The boundary condition `Natural` produces a spline function S satisfying $S''(x_0) = S''(x_n) = 0$.

Periodic

The boundary condition `Periodic` produces a spline function S satisfying $S(x_0) = S(x_n)$, $S'(x_0) = S'(x_n)$, $S''(x_0) = S''(x_n)$. With this option, the input data y_0, y_n must coincide, otherwise an error is raised.

Complete

Option, specified as `Complete = [a, b]`

The boundary condition `Complete = [a, b]` produces a spline function S satisfying $S'(x_0) = a$, $S'(x_n) = b$. Symbolic data a, b are accepted.

numeric::cubicSpline

Return Values

Spline interpoland: a MuPAD procedure.

See Also

MuPAD Functions

`interpolate` | `numeric::cubicSpline2d`

Purpose

Interpolation by 2-dimensional bi-cubic splines

Syntax

`numeric::cubicSpline2d([x0, x1, ..., xn], [y0, y1, ..., ym], z, <[xBC, yBC]>, <Symbolic>)`

Description

`numeric::cubicSpline2d([x0, x1, ...], [y0, y1, ...], z)` returns the bi-cubic spline function interpolating data $z_{i,j}$ over a rectangular mesh (x_i, y_j) .

The call `S := numeric::cubicSpline2d([x0, ..., xn], [y0, ..., ym], z, Option)` yields the cubic spline function S interpolating the data $(x_i, y_j, z_{i,j})$, i.e. $S(x_i, y_j) = z_{i,j}$ for $i = 0, \dots, n, j = 0, \dots, m$. The spline function is a piecewise bi-cubic polynomial: on the 'patch'

$$P_{i,j} = \left\{ (x, y) \mid x_i \leq x < x_{i+1}, y_j \leq y < y_{j+1} \right\},$$

it has the representation

$$S(x, y) = \sum_{u=0}^3 \left(\sum_{v=0}^3 a_{i,j}^{(u,v)} (x-x_i)^u (y-y_j)^v \right)$$

with suitable coefficients $a_{i,j}^{(u,v)}$ depending on the patch. The spline S and its partial derivatives $S_x, S_y, S_{xx}, S_{xy}, S_{yy}, S_{xxy}, S_{xyy}, S_{xxxy}$ are continuous functions over the entire x, y plane. In the x -direction, S

extends the polynomial representation on the boundary patches $[x_0, x_1]$ and $[x_{n-1}, x_n]$ to $(-\infty, x_1]$ and $[x_{n-1}, \infty)$, respectively. The same holds with respect to the y -direction. $[y_{m-1}, y_m]$

By default, NotAKnot boundary conditions are assumed, i.e., the partial derivatives $S_{xxx}, S_{yyy}, \dots, S_{xxxxyy}$ are continuous at the points with x -coordinates x_1 and x_{n-1} or y -coordinates y_1 and y_{m-1} .

By default, all input data are converted to floating-point numbers. This conversion may be suppressed by the option `Symbolic`.

numeric::cubicSpline2d

Without the option `Symbolic`, the abscissae x_i, y_j must be numerical real values in ascending order. If these data are not ordered, then `numeric::cubicSpline2d` reorders the abscissae internally, issuing a warning.

The function `S` returned by `numeric::cubicSpline2d` may be called with two, three, four, or five arguments, respectively:

- The call `S(x, y)` returns an arithmetical expression if x and y are numerical expressions. A float is returned if either x or y is a float and all parameters involved can be converted to floats.

If either x or y contains symbolic objects, the symbolic call `S(x, y)` is returned.

- The call `S(x, y, [u, v])` with nonnegative integers u, v returns the

partial derivative $\frac{\partial^v}{\partial x^v} \frac{\partial^u}{\partial y^u} S$ of the spline. If either x or y contain symbolic objects, the symbolic call `S(x, y, [u, v])` is returned. The result is 0 if either $u > 3$ or $v > 3$. The calls `S(x, y, [0, 0])` and `S(x, y)` are equivalent.

- The call `S(x, y, i, j)` with nonnegative integers i, j returns the polynomial representation of the spline on the patch $p_{i,j}$. Here, x and y may be arbitrary numerical or symbolic arithmetical expressions. Internally, (x, y) are assumed to lie in the patch $p_{i,j}$.
- The call `S(x, y, i, j, [u, v])` with nonnegative integers i, j, u, v returns the polynomial representation of the partial derivatives of the spline function. In this call, x and y may be arbitrary numerical or symbolic arithmetical expressions which are assumed to lie in the patch $p_{i,j}$. The result is 0 if either $u > 3$ or $v > 3$. The calls `S(x, y, i, j, [0, 0])` and `S(x, y, i, j)` are equivalent.

If `S` is generated with symbolic abscissae x_i, y_j (necessarily using the option `Symbolic`), the call `S(x, y, [u, v])` is returned symbolically. The call `S(x, y, i, j, [u, v])` must be used for symbolic abscissae!

Examples

Example 1

We demonstrate some calls with numerical input data. The function $f(x, y) = \sin(2\pi(x + y))$ with $0 \leq x \leq 1$, $0 \leq y \leq 1$ is to be interpolated by $n + 1 = 11$ equidistant points in the x -direction and $m + 1 = 13$ equidistant points in the y -direction:

```
f := (x, y) -> sin((x + y)*2*PI):
n := 10: x := [i/n $ i = 0..n]:
m := 12: y := [j/m $ j = 0..m]:
z := array(0..n, 0..m, [[f(i/n, j/m) $ j = 0..m] $ i = 0..n]):
S1 := numeric::cubicSpline2d(x, y, z, [NotAKnot, NotAKnot]):
S2 := numeric::cubicSpline2d(x, y, z, [Natural, Natural]):
S3 := numeric::cubicSpline2d(x, y, z, [NotAKnot, Periodic]):
```

We consider Complete boundary conditions in the y -direction. They consist of the values $f_y(x_i, y_0) = f_y(x_i, 0) = 2\pi\cos(2\pi x_i)$ and $f_y(x_i, y_m) = f_y(x_i, 1) = 2\pi\cos(2\pi x_i)$:

```
ybc:= [[2*PI*cos(2*PI*i/n) $ i = 0..n],
        [2*PI*cos(2*PI*i/n) $ i = 0..n]]:
S4 := numeric::cubicSpline2d(x, y, z, [Periodic, Complete = ybc])
```

At the mesh points (x_i, y_j) , the input data $z_{i,j}$ are reproduced:

```
x := 4/n: y := 8/m:
float(f(x, y), S1(x, y), S2(x, y), S3(x, y), S4(x, y))
```

```
0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431, 0.4067366431
```

Interpolation between the mesh points depends on the boundary condition:

```
x := 0.92: y:= 0.55: S1(x, y), S2(x, y), S3(x, y), S4(x, y)
```

```
0.1879484554, 0.1897776244, 0.1879457306, 0.1873726747
```

numeric::cubicSpline2d

The approximation of the function value $f(0.92, 0.55)$ is good for the NotAKnot, Periodic, and Complete boundary conditions. The Natural boundary conditions are less appropriate because the second partial derivatives of the function f do not vanish at the boundaries. Consequently, the approximation error of S2 is larger than the other approximation errors:

```
z := float(f(x, y)):
S1(x, y) - z, S2(x, y) - z, S3(x, y) - z, S4(x, y) - z

0.0005671407743, 0.002396309797, 0.0005644160155, -0.00000863986878
```

This is the bi-cubic polynomial in X, Y defining the spline S1 on the patch $x_0 = 0 \leq X < x_1 = \frac{1}{n}, y_3 = \frac{3}{m} \leq Y \leq y_4 = \frac{4}{m}$:

```
expand(S1(X, Y, 0, 3))

-804.8629918 X3 Y3 + 6.210308852 X3 Y2 + 323.2124519 X3 Y - 39.06086335 X3
-373.407714 X2 Y3 + 770.1743348 X2 Y2 - 297.137889 X2 Y + 7.665899226 X2
+260.7571691 X Y3 - 199.7700052 X Y2 + 10.51686235 X Y + 6.008422078 X
+10.65805697 Y3 - 28.15535765 Y2 + 12.07773495 Y - 0.426256024
```

```
delete f, n, m, ybc, x, y, z, S1, S2, S3, S4:
```

Example 2

We demonstrate some calls with symbolic data. With the option Symbolic, exact arithmetic is used:

```
S := numeric::cubicSpline2d(
    [i $ i = 0..3],
    [j $ j = 0..4],
    array(0..3, 0..4, [[z.i.j $ j = 0..4] $ i = 0..3]),
```

Symbolic
):

S(1/2, 3/2)

$$\begin{aligned} & \frac{5 z_{01}}{32} - \frac{15 z_{00}}{1024} + \frac{105 z_{02}}{512} - \frac{5 z_{03}}{128} + \frac{5 z_{04}}{1024} - \frac{45 z_{10}}{1024} + \frac{15 z_{11}}{32} + \frac{315 z_{12}}{512} - \frac{15 z_{13}}{128} + \frac{15 z_{14}}{1024} \\ & + \frac{15 z_{20}}{1024} - \frac{5 z_{21}}{32} - \frac{105 z_{22}}{512} + \frac{5 z_{23}}{128} - \frac{5 z_{24}}{1024} - \frac{3 z_{30}}{1024} + \frac{z_{31}}{32} + \frac{21 z_{32}}{512} - \frac{z_{33}}{128} + \frac{z_{34}}{1024} \end{aligned}$$

This is the bi-cubic polynomial in X, Y defining the spline with $x_0 = 0 \leq X \leq x_1 = 1, y_1 = 1 \leq Y \leq y_2 = 2$:

expand(S(X, Y, 0, 1))

$$z_{00} + X^2 z_{00} - \frac{X^3 z_{00}}{6} - \frac{5 X^2 z_{10}}{2} + \dots - \frac{X Y z_{34}}{36}$$

numeric::cubicSpline2d

$$\begin{aligned} & z00 - \frac{11 X z00}{6} + 3 X z10 - \frac{3 X z20}{2} + \frac{X z30}{3} - \frac{23 Y z00}{12} + \frac{10 Y z01}{3} - 2 Y z02 + \frac{2 Y z03}{3} \\ & + X^2 z00 - \frac{X^3 z00}{6} - \frac{5 X^2 z10}{2} + \frac{X^3 z10}{2} + 2 X^2 z20 - \frac{X^3 z20}{2} - \frac{X^2 z30}{2} + \frac{X^3 z30}{6} + \frac{9 X^2 Y z00}{8} \\ & - 3 Y^2 z01 - \frac{5 Y^3 z00}{24} + \frac{11 Y^2 z02}{4} + \frac{2 Y^3 z01}{3} - Y^2 z03 - \frac{3 Y^3 z02}{4} + \frac{Y^2 z04}{8} + \frac{Y^3 z03}{3} \\ & + \frac{9 X^2 Y^2 z00}{8} - 3 X^2 Y^2 z01 - \frac{5 X^2 Y^3 z00}{24} - \frac{3 X^3 Y^2 z00}{16} + \frac{11 X^2 Y^2 z02}{4} + \frac{2 X^2 Y^3 z01}{3} \\ & + \frac{X^3 Y^2 z01}{2} + \frac{5 X^3 Y^3 z00}{144} - X^2 Y^2 z03 - \frac{3 X^2 Y^3 z02}{4} - \frac{11 X^3 Y^2 z02}{24} - \frac{X^3 Y^3 z01}{9} \\ & + \frac{X^2 Y^3 z03}{3} + \frac{X^3 Y^2 z03}{6} + \frac{X^3 Y^3 z02}{8} - \frac{X^2 Y^3 z04}{24} - \frac{X^3 Y^2 z04}{48} - \frac{X^3 Y^3 z03}{18} + \frac{X^3 Y^2 z01}{3} \\ & - \frac{45 X^2 Y^2 z10}{16} + \frac{15 X^2 Y^2 z11}{2} + \frac{25 X^2 Y^3 z10}{48} + \frac{9 X^3 Y^2 z10}{16} - \frac{55 X^2 Y^2 z12}{8} - \frac{5 X^3 Y^2 z11}{2} \\ & - \frac{3 X^3 Y^2 z11}{2} - \frac{5 X^3 Y^3 z10}{48} + \frac{5 X^2 Y^2 z13}{2} + \frac{15 X^2 Y^3 z12}{8} + \frac{11 X^3 Y^2 z12}{8} + \frac{X^3 Y^2 z11}{3} \\ & - \frac{5 X^2 Y^2 z14}{16} - \frac{5 X^2 Y^3 z13}{6} - \frac{X^3 Y^2 z13}{2} - \frac{3 X^3 Y^3 z12}{8} + \frac{5 X^2 Y^3 z14}{48} + \frac{X^3 Y^2 z14}{16} \\ & + \frac{X^3 Y^3 z13}{6} - \frac{X^3 Y^3 z14}{48} + \frac{9 X^2 Y^2 z20}{4} - 6 X^2 Y^2 z21 - \frac{5 X^2 Y^3 z20}{12} - \frac{9 X^3 Y^2 z20}{16} \\ & + \frac{11 X^2 Y^2 z22}{2} + \frac{4 X^2 Y^3 z21}{3} + \frac{3 X^3 Y^2 z21}{2} + \frac{5 X^3 Y^3 z20}{48} - 2 X^2 Y^2 z23 - \frac{3 X^2 Y^2 z22}{2} \\ & - \frac{11 X^3 Y^2 z22}{8} - \frac{X^3 Y^3 z21}{3} + \frac{X^2 Y^2 z24}{4} + \frac{2 X^2 Y^3 z23}{3} + \frac{X^3 Y^2 z23}{2} + \frac{3 X^3 Y^3 z22}{8} \\ & - \frac{X^2 Y^3 z24}{12} - \frac{X^3 Y^2 z24}{16} - \frac{X^3 Y^3 z23}{6} + \frac{X^3 Y^3 z24}{48} - \frac{9 X^2 Y^2 z30}{16} + \frac{3 X^2 Y^2 z31}{2} + \end{aligned}$$

delete S:

Example 3

We consider a spline interpolation of the function $f(x, y) = \frac{1}{e^{x^2+y^2}}$ with $-1 \leq x \leq 1$, $-1 \leq y \leq 1$:

```
n := 10: xmesh := [-1 + 2*i/n $ i = 0..n]:
m := 12: ymesh := [-1 + 2*j/m $ j = 0..m]:
f := (x, y) -> exp(-x^2 - y^2):
z := array(0..n, 0..m,
  [[f(-1 + 2*i/n, -1 + 2*j/m) $ j=0..m] $ i = 0..n]):
S := numeric::cubicSpline2d(xmesh, ymesh, z):
```

We plot the spline function $S(x, y)$:

```
plotfunc3d(S(x, y), x = -1 .. 1, y = -1 .. 1):
```

numeric::cubicSpline2d

We plot the partial derivative $S_{xxxxyy}(x, y)$. It is constant on each patch with jumps at the boundaries of the patches. The renderer uses $[5n + 1, 5m + 1]$ mesh points: in each direction, 4 extra points between adjacent mesh points of the spline are used for the graphical representation:

```
plotfunc3d(S(x, y, [3, 3])/10, x = -1 .. 1, y = -1 .. 1,  
Mesh = [5*n + 1, 5*m + 1])
```

```
delete n, xmesh, m, ymesh, f, z, S:
```

Example 4

We demonstrate the spline interpretation of a surface. We consider a sphere parametrized by spherical coordinates u, v with $0 \leq u \leq 2\pi$, $0 \leq v \leq \pi$:

$$x = \cos(u) \sin(v), \quad y = \sin(u) \sin(v), \quad z = \cos(v)$$

We interpolate the functions x , y , z over a rectangular mesh in the u - v -plane. Since x , y and (trivially) z are 2π -periodic in u , we choose Periodic boundary conditions for u . For v , we choose Complete boundary conditions with boundary values of the first partial v -derivative fitting the parametrization:

```
x:= (u, v) -> cos(u)*sin(v): x_v := diff(x(u, v), v):
y:= (u, v) -> sin(u)*sin(v): y_v := diff(y(u, v), v):
z:= (u, v) -> cos(v): z_v := diff(z(u, v), v):
n := 4: umesh := [i*2*PI/n $ i = 0..n]:
m := 4: vmesh := [j*PI/m $ j = 0..m]:

vBC := Complete = [
    [subs(x_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
    [subs(x_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
X := numeric::cubicSpline2d(umesh, vmesh,
    array(0..n, 0..m, [[x(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
    [Periodic, vBC]):

vBC := Complete = [
    [subs(y_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
    [subs(y_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
Y := numeric::cubicSpline2d(umesh, vmesh,
    array(0..n, 0..m, [[y(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
    [Periodic, vBC]):

vBC := Complete = [
    [subs(z_v, u = umesh[i], v = vmesh[1]) $ i = 1 .. n+1],
    [subs(z_v, u = umesh[i], v = vmesh[n + 1]) $ i = 1 .. n+1]]:
Z := numeric::cubicSpline2d(umesh, vmesh,
    array(0..n, 0..m, [[z(i*2*PI/n, j*PI/m) $ j=0..m] $ i=0..n]),
    [Periodic, vBC]):
```

With only $(n + 1) \times (m + 1) = 5 \times 5$ mesh points, the spline surface yields a respectable approximation of a sphere. The interpolation nodes are added to the plot as blue points:

numeric::cubicSpline2d

```
plot(  
  plot::Surface([X(u, v), Y(u, v), Z(u, v)],  
    u = 0..2*PI, v = 0..PI,  
    Mesh = [5*n + 1, 5*m + 1],  
    Color = RGB::Red),  
  plot::Point3d(x(umesh[i], vmesh[j]),  
    y(umesh[i], vmesh[j]),  
    z(umesh[i], vmesh[j]),  
    PointSize = 2*unit::mm,  
    Color = RGB::Blue  
  ) $ i = 1..n+1 $ j = 1..m+1  
):
```

```
delete x, x_v, y, y_v, z, z_v, n, m,  
  umesh, vmesh, vBC, X, Y, Z:
```

Parameters x_0, x_1, \dots, x_n

The x -coordinates of the nodes: distinct numerical real values in ascending order

Y_0, Y_1, \dots, Y_m

The y -coordinates of the nodes: distinct numerical real values in ascending order

z

The function values: an array of the form `array(0..n, 0..m, [...])` with numerical or symbolic arithmetical expressions.

xBC, yBC

The type of the boundary condition: the boundary condition in the x - or y -direction may be one of the flags `NotAKnot`, `Natural`, `Periodic` or `Complete = [...]`.

`Complete` boundary conditions consist of prescribed values for the derivatives S_x or S_y , respectively, along the mesh boundaries in the x - or y -direction, respectively. In the x -direction, these value may be passed in the form `Complete = [[a0, , am], [b0, , bm]]` with arbitrary numerical or symbolic arithmetical expressions $a_0, , b_m$.

In the y -direction, these value may be passed in the form `Complete = [[a0, , an], [b0, , bn]]` with arbitrary numerical or symbolic arithmetical expressions $a_0, , b_n$.

Options

Symbolic

With this option, no conversion of the input data to floating point numbers occurs.

Symbolic abscissae x_i, y_j are accepted.

The ordering $x_0 < x_1 < \dots < x_n, y_0 < y_1 < \dots < y_m$ is assumed. This ordering is not checked even if the node coordinates are numerical!

NotAKnot

With the default boundary condition `xBC = yBC = NotAKnot`, all partial derivatives of the spline function are continuous at the nodes with x -coordinates x_1 and x_{n-1} or y -coordinates y_1 and y_{m-1} , respectively. With this boundary condition, S is a polynomial on the union of the patches $p_{0,j}, p_{1,j}$ and $p_{n-2,j}, p_{n-1,j}$ or $p_{i,0}, p_{i,1}$ and $p_{i,m-2}, p_{i,m-1}$, respectively.

This boundary condition is recommended if no information on the behaviour of the data near the mesh boundaries is available.

Natural

The boundary condition `Natural` produces a spline function S with vanishing second partial derivatives at the boundary of the mesh.

This boundary condition is recommended if it is known that the data correspond to a surface with vanishing curvature near the mesh boundaries.

Periodic

The boundary condition `Periodic` produces a spline function S satisfying

$$S(x_0, y) = S(x_n, y), S'(x_0, y) = S'(x_n, y), S''(x_0, y) = S''(x_n, y)$$

Or

$$S(x, y_0) = S(x, y_m), S'(x, y_0) = S'(x, y_m), S''(x, y_0) = S''(x, y_m),$$

Respectively. With this option, the input data $z_{0,j}, z_{n,j}$, respectively $z_{i,0}, z_{i,m}$, must coincide. Otherwise, an error is raised.

This boundary condition is recommended if the interpolation is to represent a periodic function.

Complete

Option, specified as `Complete = [...]`

The xBC boundary condition `Complete = [[a0, ..., am], [b0, ..., bm]]` produces a spline function S satisfying $S_x(x_0, y_j) = a_j$, $S_x(x_n, y_j) = b_j$, $j = 0, \dots, m$.

The yBC boundary condition `Complete = [[a0, ..., an], [b0, ..., bn]]` produces a spline function S satisfying $S_y(x_i, y_0) = a_i$, $S_y(x_i, y_m) = b_i$, $i = 0, \dots, n$.

Symbolic data a_k , b_k are accepted.

This boundary condition is recommended if the data $z_{i,j}$ correspond to a function with known values of the first partial derivatives at the mesh boundaries.

Return Values

Spline function: a MuPAD procedure.

MuPAD Functions

`interpolate` | `numeric::cubicSpline`

numeric::det

Purpose Determinant of a matrix

Syntax `numeric::det(A, <mode>, <MinorExpansion>, <NoWarning>)`

Description `numeric::det(A)` returns the determinant of the matrix A .
Without the option `Symbolic`, all entries of A must be numerical. Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::det` automatically switches to `Symbolic` issuing a warning.
The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Note Matrices A of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `det` must be used, when the determinant is to be computed over the component domain. See “Example 2” on page 18-39. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Environment Interactions Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples **Example 1**
Numerical matrices can be processed with or without the option `Symbolic`:

```
A := array(1..3, 1..3, [[1, 1, I], [1, exp(1), I], [1, 2, 2]]):  
numeric::det(A), numeric::det(A, Symbolic)
```

```
3.436563657 - 1.718281828 i e (2 - i) - 2 + i
```

The option `Symbolic` must be used when the matrix has non-numerical entries:

```
A := array(1..2, 1..2, [[1/(x + 1), 1], [1/(x + 2), PI]]):
numeric::det(A, Symbolic)
```

$$\frac{2\pi - x + \pi x - 1}{(x+1)(x+2)}$$

If the option `MinorExpansion` is used, symbolic entries are accepted, even if the option `Symbolic` is not specified:

```
detN := numeric::det(A, MinorExpansion);
detS := numeric::det(A, Symbolic, MinorExpansion)
```

$$\frac{0.0000000008 (2676990817.0 x + 6603981634.0)}{(x + 1.0) (x + 2.0)}$$

$$\frac{2\pi - x + \pi x - 1}{(x+1)(x+2)}$$

Simplify these results using `Simplify`:

```
Simplify(detN), Simplify(detS)
```

$$\frac{3.141592654}{x+1.0} - \frac{1.0}{x+2.0}, \frac{\pi}{x+1} - \frac{1}{x+2}$$

`delete A:`

Example 2

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])
```

numeric::det

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::det` computes the determinant of the following matrix:

```
expr(A), numeric::det(A)
```

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, 30.0$$

`det` must be used, if the determinant is to be computed over the component domain `Dom::IntegerMod(7)`:

```
det(A)
```

$$2 \bmod 7$$

```
delete A:
```

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the determinant is subject to severe cancellation effects. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical roundoff:

```
A := linalg::hilbert(15):  
float(numeric::det(A, Symbolic)),  
numeric::det(A, HardwareFloats),  
numeric::det(A, SoftwareFloats)
```

$$1.058542743 \cdot 10^{-124}, -3.822215463 \cdot 10^{-121}, 3.277553006 \cdot 10^{-123}$$

delete A:

Parameters

A

A square matrix of domain type `DOM_ARRAY`, or `DOM_HFARRAY`, or of category `Cat::Matrix`

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that HardwareFloats can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

Note For ill conditioned matrices the results returned with HardwareFloats and SoftwareFloats may differ significantly! See “Example 3” on page 18-40.

Symbolic

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted. It overrides the option `HardwareFloats`.

Note This option should not be used for floating-point matrices! The `Symbolic` algorithm does not implement safeguards against numerical instabilities in floating-point operations.

MinorExpansion

With this option, recursive minor expansion along the columns is used. This option may be useful for small matrices with symbolic entries.

This option implies `SoftwareFloats`.

With this option, symbolic entries are accepted even if the option `Symbolic` is not used.

NoWarning

Suppresses warnings

Return Values

By default, the determinant is returned as a floating-point number. With the option `Symbolic`, an expression is returned.

Algorithms

Without the option `Symbolic`, *QR*-factorization of *A* via Householder transformations is used.

With `Symbolic`, *LU*-factorization of *A* is used.

`det`

numeric::det

Related Examples

- “Compute Determinant Numerically”

Purpose Numerical eigenvalues of a matrix

Syntax `numeric::eigenvalues(A, options)`

Description `numeric::eigenvalues(A)` returns numerical eigenvalues of the matrix A.

All entries of A must be numerical. Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Note Matrices A of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(..)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::eigenvalues` must be used, when the eigenvalues are to be computed over the component domain. Cf. “Example 2” on page 18-47.

The eigenvalues are sorted by `numeric::sort`.

Note Eigenvalues are approximated with an *absolute* precision of $\frac{r}{\text{DIGITS}}$, where r is the spectral radius of A (i.e., r is the maximum of the absolute values of the eigenvalues). Consequently, large eigenvalues should be computed correctly to DIGITS decimal places. The numerical approximations of the small eigenvalues are less accurate.

Environment Interactions The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples **Example 1**

We compute the eigenvalues of the 3×3 Hilbert matrix:

numeric::eigenvalues

```
numeric::eigenvalues(linalg::hilbert(3))
```

```
[1.408318927, 0.1223270659, 0.002687340356]
```

The following matrix is ill-conditioned. It has very large as well as very small eigenvalues:

```
A := array(1..3, 1..3,
           [[ 1      ,      PI  ,  exp(1) ],
            [ 2      ,  10^100 ,  1      ],
            [10^(-100), 10^(-100), 10^(-100)]
           ]):
```

Precision goal and working precision are set by DIGITS. With the standard setting of *DIGITS* = 10, the following result is computed with HardwareFloats:

```
numeric::eigenvalues(A)
```

```
[1.0 10100, 5.0 10-101, 1.0 i]
```

```
[1.0 10100, 5.0 10-101, 1.0 i]
```

Note that small eigenvalues may be influenced by roundoff. We increase the working precision by increasing DIGITS. The smallest of the eigenvalues is computed more accurately:

```
DIGITS := 200:
eigenvals := numeric::eigenvalues(A):
DIGITS := 5:
eigenvals;
```

$$\left[1.0 \cdot 10^{100} + 6.2832 \cdot 10^{-200} i, 1.0 \cdot 10^{-100} + 2.7183 \cdot 10^{-100} i, -6.2832 \cdot 10^{-100} + 1.0 i \right]$$

delete A, eigenvals, DIGITS:

Example 2

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))(
  [[6, -1, 4], [0, 3, 3], [0, 0, 3]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 & 4 \bmod 7 \\ 0 \bmod 7 & 3 \bmod 7 & 3 \bmod 7 \\ 0 \bmod 7 & 0 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

Note that `numeric::eigenvalues` computes the eigenvalues of the following matrix:

```
expr(A), numeric::eigenvalues(A)
```

$$\begin{pmatrix} 6 & 6 & 4 \\ 0 & 3 & 3 \\ 0 & 0 & 3 \end{pmatrix}, [6.0, 3.0, 3.0]$$

If the eigenvalues are to be computed over the component domain `Dom::IntegerMod(7)`, `linalg::eigenvalues` should be used:

```
linalg::eigenvalues(A, Multiple)
```

$$[[3 \bmod 7, 2], [6 \bmod 7, 1]]$$

```
delete A:
```

numeric::eigenvalues

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of small eigenvalues is subject to severe roundoff effects. In the following results, both with `HardwareFloats` as well as with `SoftwareFloats`, the small eigenvalues are marred by numerical roundoff:

```
A := linalg::hilbert(15):
numeric::eigenvalues(A, HardwareFloats),
numeric::eigenvalues(A, SoftwareFloats)
```

$$\left[1.845927746, \dots, 8.619013323 \cdot 10^{-17}, 2.268836709 \cdot 10^{-17} \right],$$
$$\left[1.845927746, \dots, 2.095930088 \cdot 10^{-18}, 6.646989777 \cdot 10^{-21} \right]$$

```
delete A:
```

Parameters

A

A numerical matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

numeric::eigenvalues

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-48.

NoWarning

Suppresses warnings

Return Values

Ordered list of numerical eigenvalues

- “Compute Eigenvalues and Eigenvectors Numerically”

Purpose

Numerical eigenvalues and eigenvectors of a matrix

Syntax

```
numeric::eigenvectors(A, options)
```

Description

`numeric::eigenvectors(A)` returns numerical eigenvalues and eigenvectors of the matrix A .

All entries of the matrix must be numerical. Numerical expressions such as e^{π} , $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

The eigenvalues are sorted by `numeric::sort`.

The matrix X provides the eigenvectors: the i -th column of X is a numerical eigenvector corresponding to the eigenvalue d_i . Each column is either zero or normalized to the Euclidean length 1.0.

For matrices with multiple eigenvalues and an insufficient number of eigenvectors, some of the eigenvectors may coincide or may be zero, i.e., X is not necessarily invertible.

The list of residues $res = [res_1, res_2, \dots]$ provides some control over the quality of the numerical spectral data. The residues are given by

$$res_i = \|A x_i - d_i x_i\|_2,$$

where x_i is the normalized eigenvector (the i -th column of X) associated with the numerical eigenvalue d_i . For Hermitian matrices, res_i provides an upper bound for the absolute error of d_i .

With the option `NoResidues`, the computation of the residues is suppressed, the returned value is `NIL`.

If no return type is specified via the option `ReturnType = t`, the domain type of the eigenvector matrix X depends on the type of the input matrix A :

- The eigenvectors of an array are returned as an array.
- The eigenvectors of an `hfarray` are returned as an `hfarray`.

numeric::eigenvectors

- The eigenvectors of a dense matrix of type `Dom::DenseMatrix()` are returned as a dense matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices of category `Cat::Matrix`, the eigenvectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Note Matrices `A` of a matrix domain such as `Dom::Matrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that `linalg::eigenvectors` must be used, when the eigenvalues/vectors are to be computed over the component domain. Cf. “Example 3” on page 18-55.

Note Eigenvalues are approximated with an *absolute* precision of $\frac{r}{\text{DIGITS}}$, where r is the spectral radius of `A` (i.e., r is the maximal singular value of `A`). Consequently, large eigenvalues should be computed correctly to `DIGITS` decimal places. The numerical approximations of the small eigenvalues are less accurate.

Note For a numerical algorithm, it is not possible to distinguish between badly separated distinct eigenvalues and multiple eigenvalues. For this reason, `numeric::eigenvectors` and `linalg::eigenvectors` use different return formats: the latter can provide information on the multiplicity of eigenvalues due to its internal exact arithmetic.

Use `numeric::eigenvalues` if only eigenvalues are to be computed.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We compute the spectral data of the 2×2 Hilbert matrix:

```
A := linalg::hilbert(2)
```

$$\begin{pmatrix} 1 & \frac{1}{2} \\ \frac{1}{2} & \frac{1}{3} \end{pmatrix}$$

```
[d, X, res] := numeric::eigenvectors(A):
```

The eigenvalues:

```
d
```

```
[1.267591879, 0.06574145409]
```

The eigenvectors:

```
X
```

$$\begin{pmatrix} 0.8816745988 & -0.4718579255 \\ 0.4718579255 & 0.8816745988 \end{pmatrix}$$

Hilbert matrices are Hermitian, i.e., computing the spectral data is a numerically stable process. This is confirmed by the small residues:

```
res
```

numeric::eigenvectors

```
[2.355138688 10-16, 1.388645872 10-16]
```

The routine `linalg::hilbert` provides the input as a matrix of type `Dom::Matrix()`. Consequently, the eigenvectors also consist of such a matrix. For further processing, we convert the list of eigenvalues to a diagonal matrix:

```
d := matrix(2, 2, d, Diagonal):
```

We reconstruct the matrix from its spectral data:

```
X*d*X(-1)
```

```
( 1.0    0.5  
  0.5  0.3333333333 )
```

We extract an eigenvector from the matrix `X` and doublecheck its numerical quality:

```
eigenvector1 := X::dom::col(X, 1);  
norm(A*eigenvector1 - d[1, 1]*eigenvector1)
```

```
( 0.8816745988  
  0.4718579255 )
```

```
1.769417945 10-16
```

```
delete A, d, X, res, eigenvector1:
```

Example 2

We demonstrate a numerically ill-conditioned case. The following matrix has only one eigenvector and cannot be diagonalized. Numerically, the zero vector is returned as the second column of the eigenvector matrix:

```
A := array(1..2, 1..2, [[5, -1], [4, 1]]):
DIGITS := 6:
numeric::eigenvectors(A)
```

```
[3.0, 3.0], ( 0.447214 0
              0.894427 0 ), [1.66533 10^-16, 0.0]]
```

```
delete A, DIGITS:
```

Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [0, 3]])
```

```
( 6 mod 7 6 mod 7
  0 mod 7 3 mod 7 )
```

Note that `numeric::eigenvectors` computes the spectral data of the following matrix:

```
expr(A)
```

```
( 6 6
  0 3 )
```

```
numeric::eigenvectors(A, NoResidues)
```

```
[6.0, 3.0], ( 1.0 0.894427191
              0 -0.4472135955 ), NIL]
```

The routine `linalg::eigenvectors` should be used if the spectral data are to be computed over the component domain `Dom::IntegerMod(7)`:

```
linalg::eigenvectors(A)
```

numeric::eigenvectors

$$\left[\left[3 \bmod 7, 1, \left[\begin{pmatrix} 5 \bmod 7 \\ 1 \bmod 7 \end{pmatrix} \right] \right], \left[6 \bmod 7, 1, \left[\begin{pmatrix} 1 \bmod 7 \\ 0 \bmod 7 \end{pmatrix} \right] \right] \right]$$

delete A:

Example 4

We demonstrate the use of hardware floats. The following matrix is degenerate: it has rank 1. For the double eigenvalue 0, different base vectors of the corresponding eigenspace are returned with HardwareFloats and SoftwareFloats, respectively:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [3*10^12, 6*10^12, 9*10^12]])
[d1, X1, res1] := numeric::eigenvectors(A, HardwareFloats):
d1, X1
```

$$\left[9.0 \cdot 10^{12}, 0.0, -4.543838814 \cdot 10^{-16} \right],$$

$$\begin{pmatrix} 3.333333333 \cdot 10^{-13} & 0.9486832981 & 0.9621023987 \\ 6.666666667 \cdot 10^{-13} & -2.108185107 \cdot 10^{-13} & -0.1012739367 \\ 1.0 & -0.316227766 & -0.2531848418 \end{pmatrix}$$

```
[d2, X2, res2] := numeric::eigenvectors(A, SoftwareFloats):
d2, X2
```

$$\left[9.0 \cdot 10^{12}, 5.421010862 \cdot 10^{-20}, 0.0 \right], \begin{pmatrix} 0 & 0.9592641938 & 0.9486832981 \\ 0 & -0.06851887098 & 0 \\ 1.0 & -0.2740754839 & -0.316227766 \end{pmatrix}$$

```
delete A, d1, X1, res1, d2, X2, res2:
```

Parameters

A

A numerical matrix of domain type `DOM_ARRAY`, or `DOM_HFARRAY`, or of category `Cat::Matrix`.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix **A** is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`, or if one of the options **Soft**, **SoftwareFloats** or **Symbolic** is specified, MuPAD

numeric::eigenvectors

computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 4” on page 18-56.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues `res`. The return values for these data are NIL.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the eigenvectors as a matrix of domain type `t`. The following return types `t` are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

NoWarning

Suppresses warnings

Return Values

List `[d, X, res]`. The list `d = [d1, d2, ...]` contains the numerical eigenvalue. The i -th column of the matrix `X` is the eigenvector associated with the eigenvalue `di`. The list of residues `res = [res1, res2, ...]` provides error estimates for the numerical eigenvalues.

Algorithms

The routine implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

numeric::expMatrix

Purpose Exponential of a matrix

Syntax
numeric::expMatrix(A, <mode>, <method>, options)
numeric::expMatrix(A, x, <mode>, <method>, options)
numeric::expMatrix(A, X, <mode>, <method>, options)

Description numeric::expMatrix(A) returns the exponential e^A of a square matrix A .

numeric::expMatrix(A, x) with a vector x returns the vector $e^A x$.

numeric::expMatrix(A, X) with a matrix X returns the matrix $e^A X$.

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix A :

- For an array A , the result is returned as an array.
- For an hfarray A , the result is returned as an hfarray.
- For a dense matrix A of type `Dom::DenseMatrix(Ring)`, the result is again a matrix of type `Dom::DenseMatrix()` over the ring of expressions.
- For all other matrices A of category `Cat::Matrix`, the result is returned as a matrix of type `Dom::Matrix()` over the ring of expressions. This includes input matrices A of type `Dom::Matrix(Ring)`, `Dom::SquareMatrix(Ring)`, `Dom::MatrixGroup(Ring)` etc.

The components of A must not contain symbolic objects which cannot be converted to numerical values via `float`. Numerical symbolic expressions such as π , $\sqrt{2}$, e^{-1} etc. are accepted. They are converted to floats.

The specification of a method such as `TaylorExpansion` etc. implies `SoftwareFloats`, i.e., the result is computed via the software arithmetic of the MuPAD kernel.

The methods `Diagonalization` and `Interpolation` do not work for all matrices (see below).

With `SoftwareFloats`, special algorithms are implemented for traceless 2×2 matrices and skew symmetric 3×3 matrices. Specification of a particular method does not have any effect for such matrices.

If $e^A x$ or $e^A X$ is required, one should not compute e^A first and then multiply the resulting matrix with the vector/matrix x/X . In general, the call `numeric::expMatrix(A, x)` or `numeric::expMatrix(A, X)`, respectively, is faster.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider a lower triangular matrix given by an array:

```
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):
expA := numeric::expMatrix(A)
```

```
( 2.718281828    0
  9.536085572 23.14069263 )
```

We consider a vector given by a list `x1` and by an equivalent 1-dimensional array `x2`, respectively:

```
x1 := [1, 1]:
x2 := array(1..2, [1, 1]):
```

Further, an equivalent input vector `X` of type `Dom::Matrix()` is used:

```
X := matrix(x1):
```

The following three calls all yield a vector represented by an 2×1 array corresponding to the type of the input matrix `A`:

numeric::expMatrix

```
numeric::expMatrix(A, x1),  
numeric::expMatrix(A, x2, Krylov),  
numeric::expMatrix(A, X, Diagonalization)
```

```
( 2.718281828 ) ( 2.718281828 ) ( 2.718281828 )  
 ( 32.6767782 ) ( 32.6767782 ) ( 32.6767782 )
```

For further processing, the array `expA` is converted to an element of the matrix domain `Dom::Matrix()`:

```
expA := matrix(expA):
```

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:

```
expA*X
```

```
( 2.718281828 )  
 ( 32.6767782 )
```

```
delete A, expA, x1, x2, X:
```

Example 2

We demonstrate the different precision goals of the methods. Note that software arithmetic is used when a method is specified:

```
A := array(1..3, 1..3, [[ 1000,    1,    0 ],  
                        [    0,    1,    1 ],  
                        [1/10^100, 0, -1000]]):
```

The default method `TaylorExpansion` computes *each component* of e^A correctly:

```
numeric::expMatrix(A, SoftwareFloats)
```

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 9.860215786 \cdot 10^{427} \\ 9.860215786 \cdot 10^{327} & 9.870085871 \cdot 10^{324} & 4.935042936 \cdot 10^{321} \\ 9.85035557 \cdot 10^{330} & 9.860215786 \cdot 10^{327} & 4.930107893 \cdot 10^{324} \end{pmatrix}$$

The method `Diagonalization` produces a result, which is accurate in

the sense that $\|\text{error}\|_{\infty} \leq \|e^A\|_{\infty} \frac{1}{10^{\text{DIGITS}}}$ holds. Indeed, the largest components of e^A are correct. However, `Diagonalization` does not even get the right order of magnitude of the smaller components:

```
numeric::expMatrix(A, Diagonalization)
```

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 0 \\ 0 & 2.718281828 & 0 \\ 0 & 0 & 5.075958898 \cdot 10^{-435} \end{pmatrix}$$

Note that e^A is very sensitive to small changes in A . After elimination of the small lower triangular element, both methods yield the same result with correct digits for all entries:

```
B := array(1..3, 1..3, [[ 1000, 1, 0 ],
                        [ 0, 1, 1 ],
                        [ 0, 0, -1000]]):
numeric::expMatrix(B, SoftwareFloats)
```

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 9.860215786 \cdot 10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958897 \cdot 10^{-435} \end{pmatrix}$$

```
numeric::expMatrix(B, Diagonalization)
```

numeric::expMatrix

$$\begin{pmatrix} 1.970071114 \cdot 10^{434} & 1.972043157 \cdot 10^{431} & 9.860215786 \cdot 10^{427} \\ 0 & 2.718281828 & 0.002715566262 \\ 0 & 0 & 5.075958898 \cdot 10^{-435} \end{pmatrix}$$

delete A, B:

Example 3

Hilbert matrices $H_{ij} = \frac{1}{i+j-1}$ have real positive eigenvalues. For large dimension, most of these eigenvalues are small and may be regarded as a single cluster. Consequently, the option `Krylov` is useful:

```
numeric::expMatrix(linalg::hilbert(100), [1 $ 100], Krylov)
[25.47080919, 18.59337041, ..., 2.863083064, 2.848538965]
```

Parameters

A

A square $n \times n$ matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

x

A vector represented by a list $[x_1, \dots, x_n]$ or a 1-dimensional array `array(1..n, [x_1, \dots, x_n])`, or a 1-dimensional `hfarray` `hfarray(1..n, [x_1, \dots, x_n])`

X

An $n \times m$ matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix(Ring)` or `Dom::DenseMatrix(Ring)` with a suitable coefficient ring `Ring`

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, or `SoftwareFloats`

method

One of the flags `Diagonalization`, `Interpolation`, `Krylov`, or `TaylorExpansion`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Diagonalization, Interpolation, Krylov, TaylorExpansion

The specification of a method implies `SoftwareFloats`, i.e., the result is always computed via the software arithmetic of the MuPAD kernel.

The method `TaylorExpansion` is the default algorithm. It produces fast results for matrices with small norms.

The default method `TaylorExpansion` computes *each individual component* of e^A , $e^A x$, $e^A X$ to a relative precision of about $10^{-(\text{DIGITS})}$, unless numerical roundoff prevents reaching this precision goal. Roughly speaking: all digits of all components of the result are reliable up to roundoff effects.

Note The methods `Diagonalization`, `Interpolation`, and `Krylov` compute the result to a relative precision w.r.t. the norm:

$\|error\|_{\infty} \leq \frac{\|result\|_{\infty}}{10^{DIGITS}}$. Consequently, if the result has components of different orders of magnitude, then the smaller components have larger relative errors than the large components. Not all digits of the small components are reliable! Cf. “Example 2” on page 18-62.

Note The method `Diagonalization` only works for diagonalizable matrices. For matrices without a basis of eigenvectors, `numeric::expMatrix` may either produce an error or the returned result is dominated by roundoff effects. For symmetric/Hermitian or skew/skew-Hermitian matrices, this method produces reliable results.

Note The method `Interpolation` may become numerically unstable for certain matrices. The algorithm tries to detect such instabilities and stops with an error message.

The method `Krylov` is only available for computing $e^{-A}x$ with a vector x . Also vectors represented by $n \times 1$ matrices are accepted.

This method is fast when x is spanned by few eigenvectors of A . Further, if A has only few clusters of similar eigenvalues, then this method can be much faster than the other methods. Cf. “Example 3” on page 18-64.

NoWarning

Suppresses warnings

ReturnType

numeric::expMatrix

Option, specified as `ReturnType = d`

Return the result matrix or vector as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

All results are float matrices/vectors. For an $n \times n$ matrix A :

- `numeric::expMatrix(A, method)` returns e^A as an $n \times n$ matrix,
- `numeric::expMatrix(A, x, method)` returns $e^A x$ as an $n \times 1$ matrix,
- `numeric::expMatrix(A, X, method)` returns $e^A X$ as an $n \times m$ matrix.

The domain type of the result depends on the domain type of the input matrix A unless a return type is requested explicitly via `ReturnType = d`.

Algorithms

The method `TaylorExpansion` sums the usual Taylor series

$$e^A = 1 + A + \frac{A^2}{2} + \dots$$

in a suitable numerically stable way.

The method `Diagonalization` computes $e^A = T \operatorname{diag}(e^{\lambda_1}, e^{\lambda_2}, \dots) T^{-1}$ by a diagonalization $A = T \operatorname{diag}(\lambda_1, \lambda_2, \dots) T^{-1}$.

The method `Interpolation` computes a polynomial P interpolating the function \exp at the eigenvalues of A . Evaluation of the matrix polynomial yields $e^A = P(A)$.

The method `Krylov` reduces A to a Hessenberg matrix H and computes an approximation of $e^A x$ from e^H . Depending on A and x , the dimension of H may be smaller than the dimension of A .

`numeric::expMatrix` uses polynomial arithmetic to multiply matrices and vectors. Thus, sparse matrices are handled efficiently based on the MuPAD internal sparse representation of polynomials.

`exp`

numeric::factorCholesky

Purpose Cholesky factorization of a matrix

Syntax `numeric::factorCholesky(A, options)`

Description `numeric::factorCholesky(A)` returns the factor L of the Cholesky factorization $A = LL^H$ of a positive definite Hermitian matrix A .

`numeric::factorCholesky(A, Symmetric)` returns the factor L of a Cholesky type factorization $A = LL^T$ of a symmetric matrix A .

The Cholesky factorization of a square Hermitian matrix is $A = LL^H$, where L is a regular complex lower triangular matrix and L^H is the Hermitian transpose of L (i.e., the complex conjugate of the transpose of L). Such a factorization only exists if A is positive definite.

By default, a numerical factorization is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π , $\sqrt{2}$, e^{-1} etc. are accepted.

If no return type is specified via the option `ReturnType = d`, the domain type of the Cholesky factor L depends on the type of the input matrix A :

- The factor of an array is returned as an array.
- The factor of an hffarray is returned as an hffarray.
- The factor of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the factor L is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices A of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The Cholesky factor returned by `numeric::factorCholesky` is normalized such that its diagonal elements are real and positive.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider the matrix

```
A := array(1..2, 1..2, [[1, I] , [-I, PI]]):
```

We compute a numerical factorization

```
numeric::factorCholesky(A)
```

$$\begin{pmatrix} 1.0 & 0 \\ -1.0i & 1.46341814 \end{pmatrix}$$

and a symbolic factorization:

```
L := numeric::factorCholesky(A, Symbolic)
```

$$\begin{pmatrix} 1 & 0 \\ -i & \sqrt{\pi-1} \end{pmatrix}$$

For further processing, the Cholesky factor (of domain type `DOM_ARRAY`) is converted to an element of the matrix domain `Dom::Matrix()`:

```
L := matrix(L):
```

Now, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further computations:

```
L*linalg::transpose(conjugate(L))
```

numeric::factorCholesky

$$\begin{pmatrix} 1 & i \\ -i & \pi \end{pmatrix}$$

```
delete A, L:
```

Example 2

The following matrix is not positive definite:

```
A := matrix([[ -2, sqrt(2)], [sqrt(2), 1]]):  
numeric::factorCholesky(A)
```

```
Error: The matrix is not positive definite within working precision
```

However, a symmetric factorization with a complex Cholesky factor does exist:

```
numeric::factorCholesky(A, Symmetric)
```

$$\begin{pmatrix} 1.414213562i & 0 \\ -1.0i & 1.414213562 \end{pmatrix}$$

```
delete A:
```

Example 3

The option NoCheck should be used when the matrix contains symbolic objects:

```
assume(x > 0): assume(z > 0):  
A := array(1..2, 1..2, [[x, conjugate(y)], [y, z]]):  
numeric::factorCholesky(A, Symbolic, NoCheck)
```

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

Note that with NoCheck, it is assumed that the matrix is Hermitian and positive definite! All upper triangular entries are ignored. The following result implicitly assumes $u = \text{conjugate}(y)$:

```
A := array(1..2, 1..2, [[x, u], [y, z]]):
numeric::factorCholesky(A, Symbolic, NoCheck)
```

$$\begin{pmatrix} \sqrt{x} & 0 \\ \frac{y}{\sqrt{x}} & \sqrt{z - \frac{|y|^2}{x}} \end{pmatrix}$$

```
delete A:
```

Example 4

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to factor with low values of DIGITS. The following results, both with HardwareFloats as well as with SoftwareFloats, are marred by numerical roundoff. Consequently, the factorization with and without hardware floats, respectively, differ significantly:

```
A := linalg::hilbert(13):
L1 := numeric::factorCholesky(A, HardwareFloats):
L2 := numeric::factorCholesky(A, SoftwareFloats):
L1[13, 13] <> L2[13, 13]
```

```
0.0000001052365221 ≠ 0.00000007585706698
```

numeric::factorCholesky

All Hilbert matrices are positive definite. However, in the following call, numerical roundoff makes the hardware floating-point tool think that the matrix is not definite:

```
numeric::factorCholesky(linalg::hilbert(14), HardwareFloats):
```

```
Error: The matrix is not positive definite within working precision
```

A factorization is computed successfully with SoftwareFloats:

```
L := numeric::factorCholesky(linalg::hilbert(14), SoftwareFloats):  
norm(linalg::hilbert(14) - L*linalg::transpose(L))
```

```
8.67361738 10-19
```

```
delete A, L1, L2, L:
```

Parameters

A

A square matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by

default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no HardwareFloats or SoftwareFloats are requested explicitly, the following strategy is used: If the current value of DIGITS is smaller than 16 or if the matrix A is a hardware float array of domain type DOM_HFARRAY, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY, or if one of the options Soft, SoftwareFloats or Symbolic is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of DIGITS is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither HardwareFloats nor SoftwareFloats is specified, the user is not informed whether hardware floats or software floats are used.

If HardwareFloats are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

numeric::factorCholesky

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 4” on page 18-73.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects. Note that the option `NoCheck` must be used for the Hermitian factorization when non-numerical symbolic objects are present.

Symmetric

Makes `numeric::factorCholesky` compute a symmetric factorization $A = LL^T$ rather than a Hermitian factorization $A = LL^H$.

The symmetric Cholesky factorization of a square symmetric matrix is $A = LL^T$, where L is a regular complex lower triangular matrix and L^T is the transpose of L . The matrix A does not have to be positive definite. Consequently, with the option `Symmetric` no internal check is performed whether A is positive definite. Note that the symmetric factorization with regular L does not exist for all matrices.

For real symmetric positive definite matrices A the Cholesky factor L is real and the Hermitian factorization $A = LL^H$ coincides with the symmetric factorization $A = LL^T$.

NoCheck

Prevents `numeric::factorCholesky` from checking that the matrix is Hermitian and positive definite

Without the option `Symmetric`, `numeric::factorCholesky` checks that the matrix A is Hermitian and positive definite. The option `NoCheck` may be used to suppress these checks. It must be used when the matrix contains symbolic objects. Elements in the upper triangular part of the matrix will never be touched by the algorithm!

Note With this option, `numeric::factorCholesky` returns a result for matrices that are not Hermitian or not positive definite (i.e., no Cholesky factorization exists)! When using this option, it is the user's responsibility to make sure that the input matrix is appropriate.

This option has no effect when the option `Symmetric` is used.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorCholesky` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

numeric::factorCholesky

Return Values

Depending on the type of the input matrix A , the lower triangular Cholesky factor L is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`. Its components are real or complex floats, unless the option `Symbolic` is used. Without the option `NoCheck`, an error is raised if the matrix is not Hermitian or not positive definite.

Related Examples

- “Compute Factorizations Numerically”

Purpose LU factorization of a matrix

Syntax numeric::factorLU(A, options)

Description numeric::factorLU(A) returns a LU factorization of the matrix A .

The LU factorization of a real or complex $m \times n$ matrix A is $PA = LU$. The $m \times m$ matrix L is lower triangular, normalized to 1 along the diagonal. The $m \times n$ matrix U is upper triangular, i.e., $U_{ij} = 0$ for $j < i$. The list $p = [p_1, \dots, p_m]$ returned by numeric::factorLU is a permutation of the numbers $1, \dots, m$ corresponding to row exchanges of A . It represents the following $m \times m$ permutation matrix P (we assume that the matrix indices range from 1 to m):

$$P_{ij} = \delta_{p_i j} = \begin{cases} 1 & \text{if } j = p_i \\ 0 & \text{if } j \neq p_i \end{cases}$$

Left multiplication of matrices and vectors with P is realized easily using the permutation list p : $Y_{i,j} := X_{p_i,j}$ defines the row permutation $Y = PX$ of a matrix X , $y_i := x_{p_i}$ defines the row permutation $y = Px$ of a vector x .

By default, a numerical factorization with partial pivoting is computed. If the option `Symbolic` is not used, all components of the matrix are converted to floating-point numbers. In this case, the matrix must not contain symbolic objects that cannot be converted to floats. Numerical symbolic expressions such as π , $\sqrt{2}$, e^{-1} etc. are accepted.

The factorization depends on the pivoting strategy. The results obtained with/without the option `Symbolic` may differ. See “Example 2” on page 18-81. For numerical factorizations, the results obtained with `HardwareFloats` and `SoftwareFloats`, respectively, may differ. See “Example 3” on page 18-82.

If no return type is specified via the option `ReturnType = d`, the domain type of the factors L and U depends on the type of the input matrix A :

numeric::factorLU

- The factors of an array are returned as arrays.
- The factors of an hfarray are returned as hfarrays.
- The factors of a dense matrix of type `Dom::DenseMatrix()` are again dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the factors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Environment Interactions

Without the optional argument `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We factor a matrix specified by an array:

```
A := array(1..3, 1..3, [[1, 2, 3], [2, 4, 6], [4, 8, 9]]):  
[L, U, p] := numeric::factorLU(A)
```

$$\left[\left(\begin{array}{ccc} 1.0 & 0 & 0 \\ 0.5 & 1.0 & 0 \\ 0.25 & 0 & 1.0 \end{array} \right), \left(\begin{array}{ccc} 4.0 & 8.0 & 9.0 \\ 0 & 0 & 1.5 \\ 0 & 0 & 0.75 \end{array} \right), [3, 2, 1] \right]$$

The factors (of domain type `DOM_ARRAY`) are converted to elements of the matrix domain `Dom::Matrix()`. After the conversion, the overloaded arithmetical operators `+`, `*`, `^` etc. can be used for further processing:

```
L := matrix(L): U := matrix(U):  
L*U
```

$$\begin{pmatrix} 4.0 & 8.0 & 9.0 \\ 2.0 & 4.0 & 6.0 \\ 1.0 & 2.0 & 3.0 \end{pmatrix}$$

The product LU coincides with A after exchanging the rows according to the permutation stored in the list p :

```
PA := array(1..3, 1..3, [[A[p[i], j] $ j=1..3] $ i=1..3])
```

$$\begin{pmatrix} 4 & 8 & 9 \\ 2 & 4 & 6 \\ 1 & 2 & 3 \end{pmatrix}$$

```
delete A, L, U, p, PA:
```

Example 2

We consider a non-square matrix of dimension 3×2 :

```
A := matrix([[3*I, 10], [I, 1], [I, 1]]):
[L1, U1, p1] := numeric::factorLU(A)
```

$$\left[\begin{pmatrix} 1.0 & 0 & 0 \\ 3.0 & 1.0 & 0 \\ 1.0 & 0 & 1.0 \end{pmatrix}, \begin{pmatrix} 1.0i & 1.0 \\ 0 & 7.0 \\ 0 & 0 \end{pmatrix}, [2, 1, 3] \right]$$

Note that the symbolic factorization is different, because a different pivoting strategy is used:

```
[L2, U2, p2] := numeric::factorLU(A, Symbolic)
```

numeric::factorLU

$$\left[\begin{pmatrix} 1 & 0 & 0 \\ \frac{1}{3} & 1 & 0 \\ \frac{1}{3} & 1 & 1 \end{pmatrix}, \begin{pmatrix} 3i & 10 \\ 0 & -\frac{7}{3} \\ 0 & 0 \end{pmatrix}, [1, 2, 3] \right]$$

Here, the matrix factors are of type `Dom::Matrix()`, because the input matrix A was of this type. We can use the overloaded arithmetic directly. We convert the permutation lists $p1$, $p2$ to matrices and verify the relation $PA = LU$ for the factorization:

```
P1 := matrix(3, 3):
P2 := matrix(3, 3):
for i from 1 to 3 do
  P1[i, p1[i]] := 1;
  P2[i, p2[i]] := 1;
end_for:
P1*A - L1*U1, P2*A - L2*U2
```

$$\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}$$

```
delete A, L1, U1, p1, L2, U2, p2:
```

Example 3

We demonstrate the use of hardware floats. The internal rounding of `HardwareFloats` and `SoftwareFloats` differs. Consequently, the following results do not coincide:

```
n := 14:
A := linalg::hilbert(n):
[L1, U1, p1] := numeric::factorLU(A, HardwareFloats):
[L2, U2, p2] := numeric::factorLU(A, SoftwareFloats):
p1, p2
```

```
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 14, 13], [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14]
```

However, both factorizations satisfy $PA = LU$ numerically:

```
P1A := matrix([[A[p1[i], j] $ j = 1..n] $ i = 1..n]):
P2A := matrix([[A[p2[i], j] $ j = 1..n] $ i = 1..n]):
norm(P1A - L1*U1), norm(P2A - L2*U2)
```

```
8.131516294 10-17, 5.421010862 10-19
```

```
delete n, A, L1, U1, p1, L2, U2, p2, P1A, P2A:
```

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are done using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the SoftwareFloats used by the MuPAD kernel, the computation with HardwareFloats may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point

numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-82.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects.

With this option, no row exchanges are performed in the internal Gaussian elimination unless necessary.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorLU` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the factors as matrices of domain type d . The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

List $[L, U, p]$ is returned. The domain type of the $m \times m$ matrix L and the $m \times n$ matrix U depends on the type of the input matrix A ; p is a list with m elements consisting of a permutation of the integers $1, \dots, m$. It represents row exchanges in pivoting steps. The components of L and U are real or complex floats, unless the option `Symbolic` is used.

numeric::factorQR

Examples

Example 1

We consider a quadratic matrix:

```
A := array(1..2, 1..2, [[1, 0] , [1, PI]]):
```

First, we compute a numerical factorization:

```
[Q1, R1] := numeric::factorQR(A)
```

$$\left[\begin{pmatrix} 0.7071067812 & -0.7071067812 \\ 0.7071067812 & 0.7071067812 \end{pmatrix}, \begin{pmatrix} 1.414213562 & 2.221441469 \\ 0 & 2.221441469 \end{pmatrix} \right]$$

Next, the symbolic factorization is computed:

```
[Q2, R2] := numeric::factorQR(A, Symbolic)
```

$$\left[\begin{pmatrix} \frac{\sqrt{2}}{2} & -\frac{\sqrt{2}}{2} \\ \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} \end{pmatrix}, \begin{pmatrix} \sqrt{2} & \frac{\pi\sqrt{2}}{2} \\ 0 & \frac{\pi\sqrt{2}}{2} \end{pmatrix} \right]$$

For further processing, the factors (of domain type DOM_ARRAY) are converted to elements of the matrix domain Dom::Matrix():

```
Q1 := matrix(Q1): R1 := matrix(R1):  
Q2 := matrix(Q2): R2 := matrix(R2):
```

Now, the overloaded arithmetical operators +, *, ^ etc. can be used for further computations:

```
Q1*R1, Q2*R2
```

$$\begin{pmatrix} 1.0 & -4.926614672 \cdot 10^{-16} \\ 1.0 & 3.141592654 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 1 & \pi \end{pmatrix}$$

We finally verify the orthogonality of the factors Q1 and Q2:

```
Q1 * linalg::transpose(Q1), Q2 * linalg::transpose(Q2)
```

$$\left(\begin{array}{cc} 1.0 & -1.569924746 \cdot 10^{-16} \\ -1.569924746 \cdot 10^{-16} & 1.0 \end{array} \right), \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

```
delete A, Q1, R1, Q2, R2:
```

Example 2

We consider a non-square matrix of rank 1:

```
A := array(1..3, 1..2, [[0, 0], [I, 1], [I, 1]]):
numeric::factorQR(A, Symbolic)
```

$$\left[\left(\begin{array}{cc} 0 & 1 \\ \frac{\sqrt{2}i}{2} & 0 \\ \frac{\sqrt{2}i}{2} & 0 \end{array} \right), \begin{pmatrix} \sqrt{2} & -\sqrt{2}i \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right]$$

In this case, the QR factorization is not unique. Note that the numerical factorization yields different factors:

```
numeric::factorQR(A)
```

$$\left[\left(\begin{array}{cc} 0 & 0.7071067812i \\ 0.7071067812i & 0.5 \\ 0.7071067812i & -0.5 \end{array} \right), \begin{pmatrix} 1.414213562 & -1.414213562i \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right]$$

```
delete A:
```

numeric::factorQR

Example 3

We demonstrate the difference between hardware floats and software floats. For rank deficient matrices, the QR factorization is not unique. Depending on the options, different results are returned for the following matrix of rank 1:

```
A := matrix([[1, 1], [10^4, 10^4], [10^8, 10^8]]):  
[Q1, R1] := float(numeric::factorQR(A, Symbolic))
```

$$\left[\begin{pmatrix} 0.00000000999999995 & 1.0 & 0 \\ 0.000099999999995 & -9.9999999 \cdot 10^{-13} & 0.999999995 \\ 0.999999995 & -0.00000000999999999 & -0.00009999999995 \end{pmatrix}, \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right]$$

```
[Q2, R2] := numeric::factorQR(A, SoftwareFloats)
```

$$\left[\begin{pmatrix} 0.00000000999999995 & -0.000099999999995 & -0.999999995 \\ 0.000099999999995 & 0.99999999 & -0.0000999999998 \\ 0.999999995 & -0.0000999999998 & 0.00000001999999975 \end{pmatrix}, \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0 \\ 0 & 0 \end{pmatrix} \right]$$

```
[Q3, R3] := numeric::factorQR(A, HardwareFloats)
```

$$\left[\begin{pmatrix} 0.000000009999999939 & 0.9999999998 & -0.00002207031223 \\ 0.0000999999995 & -0.00002207031311 & -0.9999999948 \\ 0.999999995 & -0.000000007792968604 & 0.0000999999997 \end{pmatrix}, \begin{pmatrix} 100000000.5 & 100000000.5 \\ 0 & 0.0000000149011613 \\ 0 & 0 \end{pmatrix} \right]$$

However, all factorizations satisfy $A = QR$ numerically:

```
norm(A - Q1*R1), norm(A - Q2*R2), norm(A - Q3*R3)
```

```
3.469446952 10-18, 7.327374818 10-11, 0.00000001583248377
```

```
delete A, Q1, R1, Q2, R2, Q3, R3:
```

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are done using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill conditioned matrices the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-90.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

The usual arithmetic for MuPAD expressions is used. With this option, the matrix A may contain symbolic objects.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::factorQR` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; the routine still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the Cholesky factor as a matrix of domain type d . The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

List $[Q, R]$ with matrices Q and R is returned. The domain type of the orthogonal/unitary $m \times m$ matrix Q and the upper triangular $m \times n$ matrix R depends on the type of the input matrix A . The components of Q and R are real or complex floats, unless the option `Symbolic` is used.

numeric::factorQR

Algorithms

Householder transformations are used to compute the numerical factorization. With the option `Symbolic`, Gram-Schmidt orthonormalization of the columns of A is used.

For an invertible square matrix A , the QR factorization is unique up to scaling factors of modulus 1. The normalization of R to real positive diagonal elements determines the factorization uniquely. Consequently, the results obtained with/without the option `Symbolic` coincide for invertible square matrices.

For singular or non-square matrices, the factorization is not unique and the results obtained with/without the option `Symbolic` may differ. Cf. “Example 2” on page 18-89.

Purpose Fast Fourier Transform

Syntax
 numeric::fft(L, <mode>, <ReturnType = t>, <Clean>)
 numeric::fft(M, <mode>, <ReturnType = t>, <Clean>)
 numeric::fft(A, <mode>, <ReturnType = t>, <Clean>)

Description numeric::fft(data) returns the discrete Fourier transform of the data.

The 1-dimensional discrete Fourier transform $F = fft(L)$ of N data elements L_j stored in the list $L = [L_1, \dots, L_N]$ is the list $F = [F_1, \dots, F_N]$ given by

$$F_k = \sum_{j=1}^N L_j e^{-\frac{i 2 \pi (j-1) (k-1)}{N}}, k = 1, \dots, N$$

fft transforms the data by a Fast Fourier Transform (FFT) algorithm.

The d -dimensional discrete Fourier transform $F = fft(A)$ of $N = n_1 \times \dots \times n_d$ data elements (A_{j_1, \dots, j_d}) stored in the array A is the array $F = (F_{k_1, \dots, k_d})$ given by

$$F_{k_1, \dots, k_d} = \sum_{j_1=1}^{n_1} \dots \sum_{j_d=1}^{n_d} A_{j_1, \dots, j_d} e^{-i 2 \pi \left(\frac{(j_1-1) (k_1-1)}{n_1} + \dots + \frac{(j_d-1) (k_d-1)}{n_d} \right)}$$

with $k_1 = 1, \dots, n_1, \dots, k_d = 1, \dots, n_d$.

Data provided by lists or 1-dimensional arrays or hfarrays are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays are transformed according to the multi-dimensional transform matching the format of the input array.

numeric::fft

If the data size factorizes ($N = pq$, say), the discrete Fourier transform can be computed by p different Fourier transforms of subsets of the data, each subset having the data size q . The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `fft` routine employs the FFT algorithm. It is most efficient, when the data size N is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs $O(N \log_2(N))$ elementary operations.

Note More generally, FFT is efficient, if the data size is the product of many small factors!

Following Bluestein, the Fourier transform is written as a convolution if the data size N is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs $O(N \log_2(N))$ elementary operations even if N is a prime.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]:  
F := numeric::fft(L)
```

```
[5.555806216 + 3.0 i 1.0 - 1.272620909 i - 3.555806216 + 3.0 i 1.0 - 4.727379091 i]
```

```
numeric::invfft(F)
```

```
[1.0, 1.414213562 + 2.512840965 10-17 i, 3.0 i, 3.141592654 - 2.512840965 10-17 i]
```

```
numeric::invfft(F, Clean)
```

```
[1.0, 1.414213562, 3.0 i, 3.141592654]
```

Exact arithmetic is used with the option Symbolic:

```
F := numeric::fft(L, Symbolic)
```

```
[ $\pi + \sqrt{2} + 1 + 3i$ ,  $\pi i - \sqrt{2}i + 1 - 3i$ ,  $1 - \sqrt{2} - \pi + 3i$ ,  $1 + \sqrt{2}i - \pi i - 3i$ ]
```

```
numeric::invfft(F, Symbolic)
```

```
[1,  $\sqrt{2}$ , 3 i,  $\pi$ ]
```

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

```
L := [x, 2, 3, x]:
numeric::fft(L)
```

```
[2x + 5.0, x (1.0 + 1.0 i) - 3.0 - 2.0 i, 1.0, x (1.0 - 1.0 i) - 3.0 + 2.0 i]
```

```
numeric::fft(L, Symbolic)
```

```
[2x + 5, x (1 + i) - 3 - 2i, 1, x (1 - i) - 3 + 2i]
```

```
delete L, F:
```

Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

```
A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]):  
numeric::fft(A, Symbolic)
```

$$\begin{pmatrix} a+b+c+d+10 & a-bi-c+di-2+2i & a-b+c-d-2 & a+bi-c-di-2-2i \\ 10-b-c-d-a & c+bi-a-di-2+2i & b-a-c+d-2 & c-bi-a+di-2-2i \end{pmatrix}$$

```
numeric::invfft(%, Symbolic)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

```
A := array(1..2, 1..4, 1..2,  
          [[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2)  
           $ j3 = 1..2 ] $ j2 = 1..4 ] $ j1 = 1..2]):  
numeric::fft(A)
```

```
array(1..2, 1..4, 1..2,  
      (1, 1, 1) = -1.0  
  
      (1, 1, 2) = -1.0  
  
      (1, 2, 1) = - 1.414213562 - 1.0 I  
  
      (1, 2, 2) = - 1.414213562 - 1.0 I  
  
      (1, 3, 1) = 1.0
```

```
(1, 3, 2) = 1.0
(1, 4, 1) = - 1.414213562 + 1.0 I
(1, 4, 2) = - 1.414213562 + 1.0 I
(2, 1, 1) = -1.0
(2, 1, 2) = -1.0
(2, 2, 1) = - 1.414213562 - 1.0 I
(2, 2, 2) = - 1.414213562 - 1.0 I
(2, 3, 1) = 1.0
(2, 3, 2) = 1.0
(2, 4, 1) = - 1.414213562 + 1.0 I
(2, 4, 2) = - 1.414213562 + 1.0 I
)
```

delete A:

Example 3

Data of arbitrary length can be transformed:

```
L := [1, 2 + I, PI/3]:
numeric::fft(L)
```

```
[4.047197551 + 1.0 i, 0.3424266282 - 1.325151125 i, -1.389624179 + 0.3251511255 i]
```

delete L:

Parameters

L

A list or a 1-dimensional array(1 .. N, [Symbol::hellip]) or a 1-dimensional hfarray(1 .. N, [Symbol::hellip]) of arithmetical expressions.

M

A matrix of category `Cat::Matrix` of arithmetical expressions.

A

A d -dimensional array(1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip]) or a d -dimensional hfarray(1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip]) of arithmetical expressions.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point

numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both

floating-point numbers as well as symbolic objects. See. “Example 1” on page 18-96.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Symbolic

Without this option, the floating-point converter `float` is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

ReturnType

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: `DOM_LIST`, or `DOM_ARRAY`, or `DOM_HFARRAY`, or `matrix`, or `densematrix`.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result is of the same type and format as the input data.

If the return type `DOM_LIST` is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an $n_1 \times n_2$ matrix is entered, the return value is a list with $n_1 n_2$ values representing the entries of a $n_1 \times n_2$ matrix. The first n_2 entries of the list represent the first row of the result, the next n_2 entries represent the second row, etc.

With `ReturnType = matrix` or `ReturnType = densematrix`, only the results of 1 and 2 dimensional Fourier transformations can be represented.

Clean

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than $10^{-(\text{DIGITS})}$ times the maximal absolute value of all operands of the result are set to 0.0. Further, the routine `numeric::complexRound` is applied to all entries of the result.

Note The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

This option is ignored when used in conjunction with the option `Symbolic`.

Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter L/A/M. The type of the return value can be changed with the option `ReturnType`.

See Also**MuPAD Functions**

`numeric::invfft`

Concepts

- “Discrete Fourier Transforms”

numeric::invfft

Purpose Inverse Fast Fourier Transform

Syntax
numeric::invfft(L, <mode>, <ReturnType = t>, <Clean>)
numeric::invfft(M, <mode>, <ReturnType = t>, <Clean>)
numeric::invfft(A, <mode>, <ReturnType = t>, <Clean>)

Description numeric::invfft(data) returns the inverse discrete Fourier transform.

The inverse discrete Fourier transform $L = \text{invfft}(F)$ of N data elements F_k stored in the list $F = [F_1, \dots, F_N]$ is the list $L = [L_1, \dots, L_N]$ given by

$$L_j = \frac{1}{N} \sum_{k=1}^N F_k e^{\frac{i 2 \pi (j-1) (k-1)}{N}}, j = 1, \dots, N$$

invfft transforms the data by a Fast Fourier Transform (FFT) algorithm.

The d -dimensional inverse discrete Fourier transform $A = \text{invfft}(F)$ is given by

$$A_{j_1, \dots, j_d} = \frac{1}{N} \sum_{k_1=1}^{n_1} \dots \sum_{k_d=1}^{n_d} F_{k_1, \dots, k_d} e^{i 2 \pi \left(\frac{(j_1-1) (k_1-1)}{n_1} + \dots + \frac{(j_d-1) (k_d-1)}{n_d} \right)}$$

with $j_1 = 1, \dots, n_1, \dots, j_d = 1, \dots, n_d$.

Data provided by lists or 1-dimensional arrays or hfarrays are transformed according to the 1-dimensional transform. Data provided by matrices are transformed according to the 2-dimensional transform. Data provided by multidimensional arrays or hfarrays are transformed according to the multidimensional transform matching the format of the input array.

If the data size factorizes ($N = pq$, say), the inverse discrete Fourier transform can be computed by p different inverse Fourier transforms of subsets of the data, each subset having the data size q . The corresponding 'divide and conquer' algorithm is known as FFT ('Fast Fourier Transform'). The `invfft` routine employs the FFT algorithm. It is most efficient, when the data size N is an integer power of 2 ('radix 2 FFT'). In this case, the algorithm needs $O(N \log_2(N))$ elementary operations.

Note More generally, FFT is efficient, if the data size is the product of many small factors!

Following Bluestein, the inverse Fourier transform is written as a convolution if the data size N is a prime. The data are zero-padded to a data length that is an integer power of 2. The convolution is then computed via radix 2 FFTs. Thus, the algorithm needs $O(N \log_2(N))$ elementary operations even if N is a prime.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We give a demonstration of 1-dimensional transformations using lists. By default, numerical expressions are converted to floats:

```
L := [1, 2^(1/2), 3*I, PI]:
F := numeric::fft(L)
```

```
[5.555806216 + 3.0 i 1.0 - 1.272620909 i - 3.555806216 + 3.0 i 1.0 - 4.727379091 i]
```

```
numeric::invfft(F)
```

numeric::invfft

```
[1.0, 1.414213562 + 2.512840965 10-17 i, 3.0 i, 3.141592654 - 2.512840965 10-17 i]
```

```
numeric::invfft(F, Clean)
```

```
[1.0, 1.414213562, 3.0 i, 3.141592654]
```

Exact arithmetic is used with the option Symbolic:

```
F := numeric::fft(L, Symbolic)
```

```
[ $\pi + \sqrt{2} + 1 + 3i$ ,  $\pi i - \sqrt{2}i + 1 - 3i$ ,  $1 - \sqrt{2} - \pi + 3i$ ,  $1 + \sqrt{2}i - \pi i - 3i$ ]
```

```
numeric::invfft(F, Symbolic)
```

```
[1,  $\sqrt{2}$ , 3 i,  $\pi$ ]
```

Symbolic expressions are accepted. Internally, however, the default method `HardwareFloats` (with `DIGITS < 16`) fails because of the symbolic parameter `x`. The following results are computed with the software arithmetic provided by the MuPAD kernel:

```
L := [x, 2, 3, x]:  
numeric::fft(L)
```

```
[2x + 5.0, x (1.0 + 1.0 i) - 3.0 - 2.0 i, 1.0, x (1.0 - 1.0 i) - 3.0 + 2.0 i]
```

```
numeric::fft(L, Symbolic)
```

```
[2x + 5, x (1 + i) - 3 - 2i, 1, x (1 - i) - 3 + 2i]
```

```
delete L, F:
```

Example 2

We give a demonstration of multi-dimensional transformations. First, a 2-dimensional transformation is computed by using an array with 2 indices:

```
A := array(1..2, 1..4, [[1, 2, 3, 4], [a, b, c, d]]):
numeric::fft(A, Symbolic)
```

$$\begin{pmatrix} a+b+c+d+10 & a-bi-c+di-2+2i & a-b+c-d-2 & a+bi-c-di-2-2i \\ 10-b-c-d-a & c+bi-a-di-2+2i & b-a-c+d-2 & c-bi-a+di-2-2i \end{pmatrix}$$

```
numeric::invfft(%, Symbolic)
```

$$\begin{pmatrix} 1 & 2 & 3 & 4 \\ a & b & c & d \end{pmatrix}$$

The next example is 3-dimensional as indicated by the format of the array:

```
A := array(1..2, 1..4, 1..2,
           [[sin(j1*PI/2)*cos(j2*3*PI/4)*sin(j3*PI/2)
            $ j3 = 1..2 ] $ j2 = 1..4 ] $ j1 = 1..2)):
numeric::fft(A)
```

```
array(1..2, 1..4, 1..2,
      (1, 1, 1) = -1.0

      (1, 1, 2) = -1.0

      (1, 2, 1) = - 1.414213562 - 1.0 I

      (1, 2, 2) = - 1.414213562 - 1.0 I

      (1, 3, 1) = 1.0
```

numeric::invfft

```
(1, 3, 2) = 1.0
(1, 4, 1) = - 1.414213562 + 1.0 I
(1, 4, 2) = - 1.414213562 + 1.0 I
(2, 1, 1) = -1.0
(2, 1, 2) = -1.0
(2, 2, 1) = - 1.414213562 - 1.0 I
(2, 2, 2) = - 1.414213562 - 1.0 I
(2, 3, 1) = 1.0
(2, 3, 2) = 1.0
(2, 4, 1) = - 1.414213562 + 1.0 I
(2, 4, 2) = - 1.414213562 + 1.0 I
)
```

delete A:

Example 3

Data of arbitrary length can be transformed:

```
L := [1, 2 + I, PI/3]:
numeric::fft(L)
```

```
[4.047197551 + 1.0 i, 0.3424266282 - 1.325151125 i, -1.389624179 + 0.3251511255 i]
```

delete L:

Parameters

L

A list or a 1-dimensional array(1 .. N, [Symbol::hellip]) or a 1-dimensional hfarray(1 .. N, [Symbol::hellip]) of arithmetical expressions.

M

A matrix of category `Cat::Matrix` of arithmetical expressions.

A

A d -dimensional array(1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip]) or a d -dimensional hfarray(1..n_1,Symbol::hellip,1..n_d, [Symbol::hellip]) of arithmetical expressions.

mode

One of the flags `Hard`, `HardwareFloats`, `Soft`, `SoftwareFloats`, or `Symbolic`

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point

numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

With `Soft` and `SoftwareFloats`, symbolic objects are accepted even if they cannot be converted to floating-point numbers. The result consists of arithmetical expressions involving both

floating-point numbers as well as symbolic objects. See. “Example 1” on page 18-105.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Symbolic

Without this option, the floating-point converter `float` is applied to all input data. Use this option if no such conversion is desired. Exact arithmetic is used to compute the Fourier transformation.

This option prevents conversion of the input data to floats.

ReturnType

Option, specified as `ReturnType = t`

Return the result in a container of domain type `t`. The following return types `t` are available: `DOM_LIST`, or `DOM_ARRAY`, or `DOM_HFARRAY`, or `matrix`, or `densematrix`.

This option determines the domain type `t` of the result.

If no return type is specified by this option, the result is of the same type and format as the input data.

If the return type `DOM_LIST` is specified, the result is always a plain list of floating-point numbers. If the input data are given by a matrix or a multi-dimensional array, the returned list represents the operands of the multi-dimensional Fourier data. E.g., if an $n_1 \times n_2$ matrix is entered, the return value is a list with $n_1 n_2$ values representing the entries of a $n_1 \times n_2$ matrix. The first n_2 entries of the list represent the first row of the result, the next n_2 entries represent the second row, etc.

With `ReturnType = matrix` or `ReturnType = densematrix`, only the results of 1 and 2 dimensional Fourier transformations can be represented.

Clean

numeric::invfft

Reduce roundoff garbage in the result. All entries of the result with absolute values smaller than $10^{(-DIGITS)}$ times the maximal absolute value of all operands of the result are set to 0.0. Further, the routine `numeric::complexRound` is applied to all entries of the result.

Note The postprocessing of the result is done on the software float level. When using hardware floats, this option may increase the runtime significantly!

This option is ignored when used in conjunction with the option `Symbolic`.

Return Values

List/array/hfarray/matrix of the same length and format as the first input parameter `L/A/M`. The type of the return value can be changed with the option `ReturnType`.

MuPAD Functions

`numeric::fft`

Concepts

- “Discrete Fourier Transforms”

Purpose

Functional calculus for numerical square matrices

Syntax

`numeric::fMatrix(f, A, p1, p2, , options)`

Description

`numeric::fMatrix(f, A)` computes the matrix $f(A)$ with a function f and a square matrix A .

If no return type is specified via the option `ReturnType = d`, the domain type of the result depends on the type of the input matrix A :

- For an array A , the result is returned as an array.
- For an hfarray A , the result is returned as an array.
- For a dense matrix A of type `Dom::DenseMatrix()` the result is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices A of category `Cat::Matrix`, the result is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices A of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The components of A must not contain symbolic objects which cannot be converted to numerical values via `float`. Numerical symbolic expressions such as π , $\sqrt{2}$, e^{-1} etc. are accepted. They are converted to floats.

Note The matrix A must be diagonalizable; `numeric::fMatrix` aborts with an error message if it detects numerically that A is not diagonalizable. For most non-diagonalizable matrices, however, the numerical algorithm fails to detect this fact and the returned matrix is dominated by round-off effects. It is the user's responsibility to make sure that the diagonalization is feasible and well conditioned.

numeric::fMatrix

Symmetric/Hermitian and skew/skew Hermitian matrices can always be diagonalized in a numerically stable way; `numeric::fMatrix` produces reliable numerical results for such matrices.

The procedure `f` must accept complex floating-point numbers as first argument. It may return arbitrary MuPAD expressions, provided these can be multiplied with floating-point numbers.

The parameters p_1 , p_2 , ... may be numerical or symbolic objects. They must be accepted by `f` as 2nd argument, 3rd argument etc.

In contrast to the components of A , numerical symbolic objects such as π , $\sqrt{2}$ etc. passed as parameters p_1 , p_2 , ... are not converted to floats.

Inversion or exponentiation of a matrix may be realized with the functions $a \rightarrow \frac{1}{a}$ and `exp`, respectively. However, it is recommended to use the specialized algorithms `numeric::inverse` and `numeric::expMatrix` instead. Also matrix evaluation of low degree polynomials should be done with standard matrix arithmetic rather than with `numeric::fMatrix`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute the matrix power A^{100} :

```
A := array(1..2, 1..2, [[2, PI], [exp(-10), 0]]):  
numeric::fMatrix(x -> x^100, A)
```

$$\begin{pmatrix} 1.272133133 \cdot 10^{-30} & 1.998190806 \cdot 10^{30} \\ 2.887634784 \cdot 10^{-25} & 4.535724387 \cdot 10^{25} \end{pmatrix}$$

Alternatively, you may use the function `_power` which takes the exponent as a second parameter:

```
numeric::fMatrix(_power, A, 100)
```

$$\begin{pmatrix} 1.272133133 \cdot 10^{30} & 1.998190806 \cdot 10^{30} \\ 2.887634784 \cdot 10^{25} & 4.535724387 \cdot 10^{25} \end{pmatrix}$$

```
delete A:
```

Example 2

We compute the square root of a matrix:

```
A := matrix([[0, 1], [-1, 1]]):
B := numeric::fMatrix(sqrt, A)
```

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 + 1.110223025 \cdot 10^{-16} i \\ -0.5773502692 + 5.551115123 \cdot 10^{-17} i & 1.154700538 - 1.110223025 \cdot 10^{-16} i \end{pmatrix}$$

The small imaginary parts are caused by numerical round-off. We eliminate them by extracting the real parts of the components:

```
B := map(B, Re)
```

$$\begin{pmatrix} 0.5773502692 & 0.5773502692 \\ -0.5773502692 & 1.154700538 \end{pmatrix}$$

We verify that B^2 is A . Since A was passed as a matrix of type `Dom::Matrix()`, the matrix B is also of this type. We may compute the square by the overloaded standard arithmetic using the operator `^`:

```
B^2
```

numeric::fMatrix

$$\begin{pmatrix} -1.283695372 \cdot 10^{-16} & 1.0 \\ -1.0 & 1.0 \end{pmatrix}$$

delete A, B:

Example 3

We compute $e^{t\pi A}$ with a symbolic parameter t :

```
A := array(1..2, 1..2, [[0, 1], [-1, 0]]):  
numeric::fMatrix(exp@_mult, A, t*PI)
```

$$\begin{pmatrix} \sigma_1 & -0.5 e^{1.0\pi r i} i + 0.5 e^{-1.0\pi r i} i \\ 0.5 e^{1.0\pi r i} i - 0.5 e^{-1.0\pi r i} i & \sigma_1 \end{pmatrix}$$

where

$$\sigma_1 = 0.5 e^{1.0\pi r i} + 0.5 e^{-1.0\pi r i}$$

delete A:

Example 4

We demonstrate the difference between HardwareFloats and SoftwareFloats. The diagonalization of the following matrix is ill-conditioned. The result is dominated by round-off effects:

```
A := array(1..3, 1..3, [[10, 1, 1],  
                        [0, 1, 1],  
                        [1, 0, 10^(-14)]]):  
numeric::fMatrix(ln, A, SoftwareFloats)
```

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -4.117444729 & 4.03009691 & 41.43799398 \\ 4.380991419 & -4.117444729 & -41.5253418 \end{pmatrix}$$

```
numeric::fMatrix(ln, A, HardwareFloats)
```

$$\begin{pmatrix} 2.284572396 & 0.2635466905 & 0.2635466905 \\ -3.532353481 & 3.445005663 & 35.5870815 \\ 3.795900172 & -3.532353481 & -35.67442932 \end{pmatrix}$$

In the following case, the round-off effects of `SoftwareFloats` makes the algorithm think that the matrix cannot be diagonalized. Consequently, `FAIL` is returned. With `HardwareFloats`, however, a result is computed:

```
A := array(1..3, 1..3, [[ 1      , 1 , 1 ],
                        [ 0      , 1 , 1 ],
                        [ 10^(-30), 0 , 10^(-30)]]):
numeric::fMatrix(ln, A, SoftwareFloats)
```

`FAIL`

```
numeric::fMatrix(ln, A, HardwareFloats)
```

$$\begin{pmatrix} -5.469808086 \cdot 10^{-17} & 1.000000477 & 0.9999345993 \\ 9.98400946 \cdot 10^{-31} & -5.632422161 \cdot 10^{-17} & 69.07755279 \\ 0 & 0 & -69.07755279 \end{pmatrix}$$

```
delete A:
```

numeric::fMatrix

Parameters **f**

A procedure representing a scalar function $f: \mathbb{C} \rightarrow \mathbb{C}$ or $f: \mathbb{C} \times P \times \dots \times P \rightarrow \mathbb{C}$, where P is a set of parameters

A

A square matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

P₁, P₂, ...

Arbitrary MuPAD objects accepted by f as additional input parameters

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix **A** is a hardware float array of

domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 4” on page 18-116.

NoWarning

Suppresses warnings

ReturnType

numeric::fMatrix

Option, specified as `ReturnType = d`

Return the result as a matrix of domain type `d`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the matrix $f(A)$ is returned as a matrix of type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()` or `Dom::DenseMatrix()`. If the algorithm thinks that `A` is not diagonalizable, then `FAIL` is returned.

Algorithms

A numerical diagonalization $A = X \text{diag}(\lambda_1, \lambda_2, \dots) X^{-1}$ is computed. The columns of `X` are the (right) eigenvectors of `A`, the diagonal entries $\lambda_1, \lambda_2, \dots$ are the corresponding eigenvalues. The function f is mapped to the eigenvalues, the matrix result is computed by

$$f(A, p_1, p_2, \dots) = X \text{diag}(f(\lambda_1, p_1, p_2, \dots), f(\lambda_2, p_1, p_2, \dots), \dots) X^{-1}$$

The eigenvector matrix `X` may be obtained via `numeric::eigenvectors(A)[2]`.

The condition number $\|X\|_\infty \left\| \frac{1}{X} \right\|_\infty$ of the eigenvector matrix is a measure indicating how well conditioned the diagonalization of the matrix `A` is. If this number is larger than 10^{DIGITS} , then not a single digit of the diagonalization data is trustworthy.

The call `numeric::fMatrix(exp, A)` corresponds to `numeric::expMatrix(A, Diagonalization)`.

MuPAD Functions

`numeric::expMatrix` | `numeric::inverse`

Purpose Search for a numerical root of a system of equations

Syntax

```

numeric::fsolve(eq, x, options)
numeric::fsolve(eq, x = a, options)
numeric::fsolve(eq, x = a .. b, options)
numeric::fsolve(eqs, [x1, x2, ], options)
numeric::fsolve(eqs, {x1, x2, }, options)
numeric::fsolve(eqs, [x1 = a1, x2 = a2, ], options)
numeric::fsolve(eqs, {x1 = a1, x2 = a2, }, options)
numeric::fsolve(eqs, [x1 = a1 .. b1, x2 = a2 ..
b2, ], options)
numeric::fsolve(eqs, {x1 = a1 .. b1, x2 = a2 ..
b2, }, options)

```

Description `numeric::fsolve(eqs, ...)` returns a numerical approximation of a solution of the system of equations `eqs`.

This is the MuPAD numerical solver for non-linear systems of equations.

Note By default, this routine returns only *one* numerical solution!

The equations must not contain symbolic objects other than the unknowns that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. are accepted. The same holds true for starting values and search ranges. Search ranges may contain $\pm\infty$. Cf. “Example 2” on page 18-126.

`numeric::fsolve` implements a purely numerical Newton type root search with a working precision set by the environment variable `DIGITS`. Well separated simple roots should be exact within this precision. However, multiple roots or badly separated roots may be computed with a restricted precision. Cf. “Example 3” on page 18-126.

Note For systems of equations, the expressions defining the equations must have a symbolic derivative!

Overdetermined systems (i.e., more equations than indeterminates) are not accepted. However, there may be more indeterminates than equations. Cf. “Example 4” on page 18-126.

Specifying indeterminates $[x_1, x_2, \dots]$ without starting values or search ranges is equivalent to the search ranges $[x_1 = -\text{infinity} .. \text{infinity}, x_2 = -\text{infinity} .. \text{infinity}, \dots]$. Note, however, that the user should assist `numeric::fsolve` by providing specific search ranges whenever possible! If a complex starting point or a search range involving a complex number is specified for at least one of the unknowns, the search is extended to the entire complex plane for all variables for which no explicit search interval is given.

For real equations and real starting points or search ranges, the internal Newton iteration will usually produce real values, i.e., `numeric::fsolve` searches for real roots only (unless square roots, logarithms etc. happen to produce complex values from real input). Use complex starting points or search ranges to search for complex roots of real equations. Cf. “Example 5” on page 18-127.

Starting values and search ranges can be mixed. Cf. “Example 6” on page 18-127.

Search ranges should only be provided if a solution is known to exist inside the search range. Otherwise, the search may take some time before `numeric::fsolve` gives up.

Specification of a search range primarily means that starting points from this range are used for the internal Newton search. For sufficiently small search ranges enclosing a solution the search will usually pick out this solution. However, it may also happen that the Newton iteration drifts towards other solutions.

With the default search strategy `RestrictedSearch`, only solutions from the search range are accepted, even if solutions outside the search

range are found internally. More specifically, if a search range such as $x = a \dots b$ is specified for the variable x , then solutions satisfying $\min(a, b) \leq x \leq \max(a, b)$ and $\min(a, b) \leq x \leq \max(a, b)$ are searched for. Thus, the values a, b specify the bottom left and top right corner of a rectangular search area in the complex plane when the `RestrictedSearch` strategy is used.

With the search strategy `UnrestrictedSearch`, any solution inside or outside the search range is accepted and returned. Cf. “Example 7” on page 18-128.

If starting values for all indeterminates are provided, then a *single* Newton iteration with these initial data is launched. It either leads to a solution or `numeric::fsolve` gives up and returns `FAIL`. The same holds true if search ranges $x = a \dots a$ or $[x_1 = a_1 \dots a_1, x_2 = a_2 \dots a_2, \dots]$ of zero length are specified.

Note The risk of failure is high when providing bad starting values! Starting values are appropriate only if a sufficiently good approximation of the solution is known! On the other hand, providing good starting values is the fastest way to a solution. Cf. “Example 8” on page 18-128.

If at least one of the indeterminates has a non-trivial search range, then `numeric::fsolve` uses *several* Newton iterations with different starting values from the search range. Cf. “Example 9” on page 18-129. Search ranges in conjunction with the option `UnrestrictedSearch` provide a higher chance of detecting roots than (bad) starting values!

Note User defined assumptions such as `assume(x > 0)` are not taken into account in the numerical search! Provide search ranges instead! Cf. “Example 2” on page 18-126.

numeric::fsolve

Note Convergence may be slow for multiple roots! Furthermore, `numeric::fsolve` may fail to detect such roots!

Use `linsolve` or `numeric::linsolve` for systems of *linear* equations.

Use `numeric::realroots`, if *all real roots* of a single non-polynomial real equation in a finite range are desired.

Use `polylib::realroots`, if *all real roots* of a real univariate polynomial are desired.

Use `numeric::polyroots`, if *all real and complex roots* of a univariate polynomial are desired.

Use `numeric::solve`, if *all roots* of a multivariate polynomial system are desired.

The routine `numeric::solve` provides a common interface to all these numerical solvers.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute roots of the sine function:

```
numeric::fsolve(sin(x) = 0, x)
```

```
[x = 0.0]
```

With the option `Random`, several calls may result in different roots:

```
numeric::fsolve(sin(x), x, Random)
```

```
[x = -226.1946711]
```

```
numeric::fsolve(sin(x), x, Random)
```

```
[x = 97.38937226]
```

Particular solutions can be chosen by an appropriate starting point close to the wanted solution, or by a search interval:

```
numeric::fsolve(sin(x), x = 3),  
numeric::fsolve(sin(x), x = -4 .. -3)
```

```
[x = 3.141592653], [x = -3.141592654]
```

The solutions found by `numeric::fsolve` can be used in `subs` and `assign` to substitute or assign the indeterminates:

```
eqs := [x^2 = sin(y), y^2 = cos(x)]:  
solution := numeric::fsolve(eqs, [x, y])
```

```
[x = -0.8517004887, y = 0.8116062151]
```

```
eval(subs(eqs, solution))
```

```
[0.7253937224 = 0.7253937224, 0.6587046485 = 0.6587046485]
```

```
assign(solution): x, y
```

```
-0.8517004887, 0.8116062151
```

```
delete eqs, solution, x, y:
```

Example 2

We demonstrate the use of search ranges. The following system has solutions with positive and negative x . The solution with $x \geq 0$ is obtained with the search interval $x = 0 \dots \text{infinity}$:

```
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = 0 .. infinity, y])  
  
[x = 0.753089165, y = -0.753089165]
```

We search for a solution with $x \leq 0$:

```
numeric::fsolve([x^2 = exp(x*y), x^2 = y^2], [x = -infinity .. 0, y])  
  
[x = -0.753089165, y = 0.753089165]
```

Example 3

Multiple roots can only be computed with a restricted precision:

```
numeric::fsolve(expand((x - 1/3)^5), x = 0.3)  
  
[x = 0.3333672906]
```

Example 4

The following system of equations is degenerate and has a 1-parameter family of solutions. Each call to `numeric::fsolve` picks out one random solution:

```
numeric::fsolve([x^2 - y^2, x^2 - y^2], [x, y], Random) $ i = 1 ..  
  
[x = 34.70258251, y = 34.70258251], [x = -29.16650501, y = 29.16650501],  
[x = 5.933941324, y = -5.933941324]
```

The equation may also be specified as an underdetermined system:

```
numeric::fsolve([x^2 - y^2], [x, y])
```

```
[x = 0.0, y = 0.0]
```

Example 5

The following equation has no real solution. Consequently, the numerical search with real starting values fails:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x)
```

```
FAIL
```

With a complex starting value, a solution is found:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = I)
```

```
[x = 0.2972513613 + 1.128383965 i]
```

Also complex search ranges may be specified. In the following, the internal starting point is a random value on the line from $2 + I$ to $3 + 2*I$. Solutions are accepted if they lie in the complex rectangle with the bottom left corner $2 + I$ and the top right corner $3 + 2*I$:

```
numeric::fsolve(sin(x) + cos(x)^2 = 3, x = 2 + I .. 3 + 2*I)
```

```
[x = 2.844341292 + 1.128383965 i]
```

Example 6

Starting values and search intervals can be mixed:

```
numeric::fsolve([x^2 + y^2 = 1, y^2 + z^2 = 1, x^2 + z^2 = 1],
                [x = 1, y = 0 .. 10, z])
```

numeric::fsolve

```
[x = 0.7071067812, y = 0.7071067812, z = 0.7071067812]
```

Example 7

With `UnrestrictedSearch`, search intervals are only used for choosing starting values for the internal Newton search. The numerical iteration may drift towards a solution outside the search range:

```
eqs := [x*sin(10*x) = y^3, y^2 = exp(-2*x/3)]:  
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], UnrestrictedSearch)
```

```
[x = 1.232766201, y = -0.6630386021]
```

With the default strategy `RestrictedSearch`, only solutions inside the search range are accepted:

```
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0])
```

```
[x = 0.9816416007, y = -0.7209295436]
```

In the last search, also the previous solution outside the search range was found. With the option `MultiSolutions`, `numeric::fsolve` returns a sequence of all solutions that were found in the internal search:

```
numeric::fsolve(eqs, [x = 0 .. 1, y = -1 .. 0], MultiSolutions)
```

```
[x = 0.9816416007, y = -0.7209295436], [x = 1.232766201, y = -0.6630386021]
```

```
delete eqs:
```

Example 8

Usually, most of the time is spent internally searching for some (crude) approximations of the root. If high precision roots are required, it is recommended to compute first approximations with moderate values of `DIGITS` and use them as starting values for a refined search:

```
eq := exp(-x) = x:
DIGITS := 10:
firstApprox := numeric::fsolve(eq, x)
```

```
[x = 0.5671432904]
```

This output is suitable as input defining a starting value for x :

```
DIGITS := 1000: numeric::fsolve(eq, firstApprox)
```

```
[x = 0.5671432904097838729999686622103555497538...]
```

```
[x = 0.5671432904097838729999686622103555497538157871865125081351

```

```
delete eq, firstApprox, DIGITS:
```

Example 9

Specifying starting values for the indeterminates launches a *single* Newton iteration. This may fail, if the starting values are not sufficiently close to the solution:

numeric::fsolve

```
eq := [x*y = x + y - 4, x/y = x - y + 4]:  
numeric::fsolve(eq, [x = 1, y = 1])
```

FAIL

If a search range is specified for at least one of the unknowns, then *several* Newton iterations with random starting values in the search range are used, until a solution is found or until `numeric::fsolve` gives up:

```
numeric::fsolve(eq, [x = 1, y = 0 .. 10])
```

```
[x = 4.02644145 10-14, y = 4.0]
```

```
delete eq:
```

Parameters

eq

An arithmetical expression or an equation in one indeterminate x . An expression `eq` is interpreted as the equation `eq = 0`.

eqs

A list, set, array, or matrix (`Cat::Matrix`) of expressions or equations in several indeterminates x_1, x_2, \dots . Expressions are interpreted as homogeneous equations.

x, x₁, x₂, ...

Identifiers or indexed identifiers to be solved for.

a, a₁, a₂, ...

Real or complex numerical starting values for the internal search. Typically, crude approximations of solution.

a .. b, a₁ .. b₁, a₂ .. b₂, ...

Ranges of numerical values defining search intervals for the numerical root.

Options

RestrictedSearch

Makes `numeric::fsolve` return only numerical roots in the user-defined search range $x = a \dots b$ and $[x_1 = a_1 \dots b_1, x_2 = a_2 \dots b_2, \text{Symbol::hellip}]$, respectively. This is the default search strategy, if a search range is specified for at least one of the unknowns.

Once a root with components (r_1, r_2, \dots) is found, it is checked whether $\min(\mathcal{R}(a_i), \mathcal{R}(b_i)) \leq \mathcal{R}(r_i) \leq \max(\mathcal{R}(a_i), \mathcal{R}(b_i))$ and $\min(\mathcal{I}(a_i), \mathcal{I}(b_i)) \leq \mathcal{I}(r_i) \leq \max(\mathcal{I}(a_i), \mathcal{I}(b_i))$ is satisfied. If the root is not inside the search range, the search is continued. Note that solutions outside the search range may be found internally. These may be accessed with the option `MultiSolutions`. See “Example 7” on page 18-128.

UnrestrictedSearch

Allows `numeric::fsolve` to find and return solutions outside the specified search range. With this option, the search range is only used to choose random starting points for the internal numerical search.

This option switches off the search strategy `RestrictedSearch`. With `UnrestrictedSearch`, `numeric::fsolve` stops its internal search whenever a root is found, even if the root is not inside the specified search range. Starting points for the internal Newton search are taken from the search range.

MultiSolutions

Makes `numeric::fsolve` return all solutions found in the internal search

This option only has an effect when used with the default search strategy `RestrictedSearch`. A sequence of all roots found in the internal search is returned. Cf. “Example 7” on page 18-128.

numeric::fsolve

Random

With this option, several calls to `numeric::fsolve` with the same input parameters may produce different roots.

With this option, random starting values are chosen for the internal search. Consequently, calling `numeric::fsolve` several times with the same parameters may lead to different solutions. This may be useful when several roots of one and the same equation or set of equations are desired.

Return Values

Single numerical root is returned as a list of equations `[x = value]` or `[x1 = value1, x2 = value2, ...]`, respectively. `FAIL` is returned if no solution is found. With the option `MultiSolutions`, sequences of solutions may be returned.

Algorithms

Internally the set of equations $f(x) = 0$ is solved by a modified Newton iteration $x \rightarrow x - t f'(x)^{-1} f(x)$ with some adaptively chosen step size t . For degenerate or ill-conditioned Jacobians f' a minimization strategy for $\langle f, f \rangle$ is implemented. For scalar real equations, `numeric::realroot` is used, if a real finite search range is specified.

Concepts

- “Solve Equations Numerically”

Purpose Gauss' arithmetic geometric mean

Syntax numeric::gaussAGM(a, b)

Description numeric::gaussAGM(a, b) computes the arithmetic geometric mean of the numbers a and b .

The iteration

$$a_{n+1} = \frac{a_n + b_n}{2}, b_{n+1} = (a_n + b_n) \sqrt{\frac{a_n b_n}{(a_n + b_n)^2}}$$

with the starting values $a_0 = a, b_0 = b$ converges quadratically to some

value $\lim_{n \rightarrow \infty} a_n = \lim_{n \rightarrow \infty} b_n$. This limit is called Gauss' arithmetic geometric mean of the starting values a, b .

If both arguments a and b can be converted to real or complex floating-point numbers, then a floating point value is computed and returned. Otherwise, the symbolic call numeric::gaussAGM(a, b) is returned.

If $a = 0$ or $b = 0$ or $a + b = 0$, then 0.0 is returned, even if a or b are symbolic objects.

The following relation to elliptic integrals holds for all complex values a and b :

$$\text{numeric::gaussAGM}(a, b) = \frac{\pi}{4} \frac{a+b}{K\left(\sqrt{\left(\frac{a-b}{a+b}\right)^2}\right)}$$

Environment Interactions

The function is sensitive to the environment variable DIGITS.

numeric::gaussAGM

Examples

Example 1

A floating-point number is returned if the arguments can be converted to floating-point numbers:

```
numeric::gaussAGM(0, 5)
```

```
0.0
```

```
numeric::gaussAGM(sqrt(2), PI)
```

```
2.192033978
```

```
numeric::gaussAGM(-10, PI)
```

```
-2.377943461 - 2.966350545 i
```

```
numeric::gaussAGM(1 + I, 1 + 2*I)
```

```
1.020054126 + 1.471349363 i
```

A symbolic call is returned if one of the arguments cannot be converted to a float:

```
numeric::gaussAGM(1, b)
```

```
numeric::gaussAGM(1, b)
```

For the special cases $a = 0$, $b = 0$ and $a + b = 0$, the result 0.0 is returned even for symbolic arguments:

```
numeric::gaussAGM(a, 0)
```

0.0

`numeric::gaussAGM(a, -a)`

0.0

Parameters

a, b

arithmetical expressions

Return Values

Floating point number or a symbolic call `numeric::gaussAGM(a, b)`.

MuPAD Functions

`elliptick`

numeric::gldata

Purpose Weights and abscissae of Gauss-Legendre quadrature

Syntax `numeric::gldata(n, digits)`

Description `numeric::gldata(n, digits)` returns the weights and the abscissae of the Gauss-Legendre quadrature rule with n nodes with a precision of `digits` decimal digits.

The Gauss-Legendre quadrature rule $\sum_{i=1}^n b_i f(c_i)$ produces the exact integral $\int_0^1 f(x) dx$ for all polynomial integrands $f(x)$ through degree $2n - 1$. The weights b_i and abscissae c_i are related to the roots of the n -th Legendre polynomial.

The weights and abscissae are computed by a straightforward numerical algorithm with a working precision set by the argument `digits`. The resulting floating-point numbers are correct to `digits` leading decimal places.

Typically, the argument `digits` is chosen as the current value of the environment variable `DIGITS`.

The data for $n = 20, 40, 80, 160$ with `digits` ≤ 200 are stored internally. They are returned immediately without any computational costs.

Due to the internal remember mechanism, only the first call to `numeric::gldata` leads to computational costs. For any further call with the same arguments, the data are returned immediately.

For odd n , the abscissa $c_{\frac{n+1}{2}} = \frac{1}{2}$ and the corresponding weight $b_{\frac{n+1}{2}}$ are rational numbers.

Environment Interactions `numeric::gldata` is *not* sensitive to changes of the environment variable `DIGITS`, because the numerical working precision is specified by the second argument `digits`.

The function uses option `remember`.

Examples

Example 1

The following call computes the Gauss-Legendre data with a precision given by the current value of the environment variable DIGITS (the default value is DIGITS = 10):

```
[b, c] := numeric::gldata(4, DIGITS)

[[0.1739274226, 0.3260725774, 0.3260725774, 0.1739274226],
 [0.0694318442, 0.3300094782, 0.6699905218, 0.9305681558]]
```

The Gauss-Legendre data with 4 nodes provide exact numerical quadrature results for polynomials through degree 7:

```
f := x -> x^7:
int(f(x), x= 0..1) = _plus(b[i]*f(c[i]) $ i=1..4)
```

$$\frac{1}{8} = 0.125$$

```
delete b, c, f:
```

Example 2

For odd n , exact rational data for $\frac{c}{2}$ and $\frac{b}{2}$ are returned. The other data are computed as floating-point approximations:

```
DIGITS := 4: numeric::gldata(5, DIGITS)

[[[0.1185, 0.2393,  $\frac{64}{225}$ , 0.2393, 0.1185], [0.04691, 0.2308,  $\frac{1}{2}$ , 0.7692, 0.9531]]]
```

```
delete DIGITS:
```

numeric::gldata

Parameters

n

The number of nodes: a positive integer

digits

The number of decimal digits: a positive integer

Return Values

List [b, c] is returned. The lists $b = [b_1, \dots, b_n]$ and $c = [c_1, \dots, c_n]$ are numerical approximations of the weights and abscissae with digits significant digits.

Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::gldata` to provide the data for Gaussian quadrature.

MuPAD Functions

`numeric::gtdata` | `numeric::ncdata` | `numeric::int` | `numeric::quadrature`

Purpose

Weights and abscissae of Gauss-Tschebyscheff quadrature

Syntax

numeric::gtdata(n)

Description

numeric::gtdata(n) returns the weights and the abscissae of the Gauss-Tschebyscheff quadrature rule with n nodes.

The Gauss-Tschebyscheff quadrature rule $\sum_{i=1}^n b_i f(c_i)$ produces the

exact integral $\int_0^1 f(x) dx$ for all integrands of the form $f(x) = \frac{p(x)}{\sqrt{x(1-x)}}$ with polynomials $p(x)$ through degree $2n - 1$.

The exact weights $b = [b_1, \dots, b_n]$ and abscissae $c = [c_1, \dots, c_n]$ are given by

$$b_i = \frac{\pi}{2n} \sin\left(\frac{(2i-1)\pi}{2n}\right), c_i = \frac{1 + \cos\left(\frac{(2i-1)\pi}{2n}\right)}{2}$$

Environment Interactions

numeric::gtdata is not sensitive to the environment variable DIGITS.

The function uses option remember.

Examples

Example 1

The following call produces exact data for the quadrature rule with two nodes:

`numeric::gtdata(2)`

$$\left[\left[\frac{\pi \sqrt{2}}{8}, \frac{\pi \sqrt{2}}{8} \right], \left[\frac{\sqrt{2}}{4} + \frac{1}{2}, \frac{1}{2} - \frac{\sqrt{2}}{4} \right] \right]$$

Parameters

n

The number of nodes: a positive integer

numeric::gtdata

Return Values

List $[b, c]$ is returned. The lists $b = [b_1, \dots, b_n]$ and $c = [c_1, \dots, c_n]$ are the exact weights and abscissae of the Gauss-Tschebyscheff quadrature rule, respectively.

Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::gtdata` to provide the data for Gauss-Tschebyscheff quadrature.

MuPAD Functions

`numeric::gldata` | `numeric::ncdata` | `numeric::int` | `numeric::quadrature`

Purpose Search for indeterminates

Syntax `numeric::indets(object)`

Description `numeric::indets(object)` returns a set of the indeterminates contained in the object.

This is an auxiliary routine used by `numeric::polyroots`, `numeric::quadrature`, `numeric::realroots`, `numeric::solve` etc. to find indeterminates.

It recursively searches the operands of `object` for indeterminates. In particular, the search is applied to the elements of lists, sets, arrays, tables, etc.

Following objects are regarded as indeterminates: identifiers, indexed identifiers and the indeterminates of `DOM_POLY` objects. Also coefficients of such polynomials are searched for indeterminates.

The following objects are *not* regarded as indeterminates: the numerical constants `PI`, `EULER`, and `CATALAN` (cf. `Type::ConstantIdentis`) and zero operands of expressions and subexpressions (i.e., the function names in unevaluated function calls such as `f(2)`, `sin(PI/13)` etc.). Also integration variables in unevaluated calls of `int`, `numeric::int` and `numeric::quadrature` and summation indices in unevaluated calls of `sum` and `numeric::sum` are not considered.

Examples **Example 1**

Identifiers and indexed identifiers are regarded as indeterminates:

```
numeric::indets([{a + b*PI}, sin(c + sqrt(2) + EULER),
                table(1 = d - cos(e), 2 = f + 0.1*I),
                array(1..2, [g, h]), F(i[2], i[2]),
                D([1], G)(j[1]), k[3 + L[4]])])
```

$$\{a, b, c, d, e, f, g, h, i_2, j_1, k_{L_4+3}\}$$

numeric::indets

Both indeterminates as well as symbolic coefficients are considered in polynomials of domain type DOM_POLY:

```
numeric::indets(poly(a[1]*x^2 + a[2]*x + a, [x, y]))
```

$$\{a, x, y, a_1, a_2\}$$

Example 2

The zero operands of unevaluated function calls such as $f(\)$ or $\sin(\)$ are not regarded as indeterminates:

```
numeric::indets(f(a + sin(b) + PI + EULER))
```

$$\{a, b\}$$

Integration variables and summation indices are not regarded as indeterminates:

```
numeric::indets({int(f(x), x = a..b),  
                sum(f(i), i = c..infinity)})
```

$$\{a, b, c\}$$

Parameters

object

An arbitrary MuPAD object

Return Values

Set of indeterminates is returned, if the argument is an object of some basic data type of the kernel. The empty set is returned, if the object is from some library domain.

Functions**

`indets` | `freeIndets`

numeric::int

Purpose Numerical integration (the Float attribute of Int)

Syntax
`numeric::int(f(x), x = a .. b, options)`
`float(holdint(f(x), x = a .. b, options))`
`float(freezeint(f(x), x = a .. b, options))`

Description `numeric::int(f(x), x = a..b)` computes a numerical approximation of $\int_a^b f(x) dx$.

The calls `numeric::int(...)`, `float (freeze(int)(...))`, and `float (hold(int)(...))` are equivalent.

The calls `numeric::int(...)` and `numeric::quadrature(...)` are almost equivalent: `numeric::int` calls `numeric::quadrature`. A numerical result produced by `numeric::quadrature` is returned as is. Otherwise, `hold(numeric::int)(...)` is returned.

See the help page of `numeric::quadrature` for details.

Environment Interactions The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples **Example 1**

We demonstrate some equivalent calls for numerical integration:

```
numeric::int(exp(x^2), x = -1..1),  
float(hold(int)(exp(x^2), x = -1..1)),  
float(freeze(int)(exp(x^2), x = -1..1)),  
numeric::quadrature(exp(x^2), x = -1..1)
```

```
2.925303492, 2.925303492, 2.925303492, 2.925303492
```

```
numeric::int(max(1/10, cos(PI*x)), x = -2..0.0123),  
float(hold(int)(max(1/10, cos(PI*x)), x = -2..0.0123)),  
float(freeze(int)(max(1/10, cos(PI*x)), x = -2..0.0123)),  
numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)
```

0.752102471, 0.752102471, 0.752102471, 0.752102471

```
numeric::int(exp(-x^2), x = -2..infinity),
float(hold(int)(exp(-x^2), x = -2..infinity)),
float(freeze(int)(exp(-x^2), x = -2..infinity)),
numeric::quadrature(exp(-x^2), x = -2..infinity)
```

1.768308316, 1.768308316, 1.768308316, 1.768308316

```
numeric::int(sin(x)/x, x = -1..10, GaussLegendre = 5),
float(hold(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)),
float(freeze(int)(sin(x)/x, x = -1..10, GaussLegendre = 5)),
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5)
```

2.604430665, 2.604430665, 2.604430665, 2.604430665

The calls `numeric::int(...)`, `float(hold(int)(...))`, and `numeric::quadrature(...)` are equivalent in multiple numerical integrations, too:

```
numeric::int(numeric::int(x*y, x = 0..y), y = 0..1),
numeric::int(numeric::quadrature(x*y, x = 0..y), y = 0..1),
float(freeze(int)(numeric::int(x*y, x = 0..y), y = 0..1)),
float(hold(int)(numeric::quadrature(x*y, x = 0..y), y = 0..1)),
numeric::quadrature(numeric::int(x*y, x = 0..y), y = 0..1),
numeric::quadrature(numeric::quadrature(x*y, x = 0..y), y = 0..1)
```

0.125, 0.125, 0.125, 0.125, 0.125, 0.125

Example 2

The following integral do not exist. Consequently, numerical integration runs into problems:

```
numeric::quadrature(1/x, x = 0..infinity)
```

numeric::int

Warning: Precision goal is not achieved after 10000 function calls.

172.711431

Note that `numeric::int` handles errors produced by `numeric::quadrature` and returns a symbolic call to `numeric::int`:

```
numeric::int(1/x, x = 0..infinity)
```

```
numeric::int( $\frac{1}{x}$ , x = 0..∞)
```

Parameters

f(x)

An arithmetical expression in x

x

An identifier or an indexed identifier

a, b

arithmetical expressions

Options

All options of `numeric::quadrature` can be used.

Return Values

Floating point number or a symbolic call `numeric::int(f(x), x = a..b)` if the integral cannot be evaluated numerically.

MuPAD Functions

`int` | `numeric::quadrature`

Concepts

- “Integration”

Purpose Inverse of a matrix

Syntax `numeric::inverse(A, options)`

Description `numeric::inverse(A)` returns the inverse of the matrix `A`.

If no return type is specified via the option `ReturnType = t`, the domain type of the inverse depends on the type of the input matrix `A`:

- The inverse of an array is returned as an array.
- The inverse of an hfarray is returned as an hfarray.
- The inverse of a dense matrix of type `Dom::DenseMatrix()` is a dense matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the inverse is returned as a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices `A` of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

The option `Symbolic` should be used if the matrix contains symbolic objects that cannot be converted to floating point numbers.

Without the option `Symbolic`, all entries of `A` must be numerical. Floating point arithmetic is used, the working precision is set by the environment variable `DIGITS`. Exact numerical expressions such as $\pi + \sqrt{2}$, `sin(3)` etc. are accepted and converted to floats. If symbolic entries are found in the matrix, `numeric::inverse` automatically switches to `Symbolic`, issuing a warning. This warning may be suppressed via the option `NoWarning`.

Note Invertibility of the matrix can only be safely detected with exact arithmetic, i.e., using the option `Symbolic`. See “Example 2” on page 18-149.

numeric::inverse

Note Matrices A of a matrix domain such as `Dom::Matrix(..)` or `Dom::SquareMatrix(..)` are internally converted to arrays over expressions via `expr(A)`. Note that `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that $1/A$ must be used, when the inverse is to be computed over the component domain. See “Example 3” on page 18-152.

We recommend to use `numeric::linsolve` or `numeric::matlinsolve` if a sparse system of linear equations is to be solved. In particular, these routines are more efficient than `numeric::inverse` for large sparse systems.

`numeric::linsolve` uses sparse input and output via symbolic equations and features internal sparse arithmetic.

Alternatively, sparse matrices of domain type `Dom::Matrix()` may be used with `numeric::matlinsolve`.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical matrices can be processed with or without the option `Symbolic`. In the following, the inverses are returned as arrays because the input matrix is an array:

```
A := array(1..2, 1..2, [[1, 2], [3, PI]]):
```

```
numeric::inverse(A), numeric::inverse(A, Symbolic)
```

$$\begin{pmatrix} -1.099071012 & 0.6996903372 \\ 1.049535506 & -0.3498451686 \end{pmatrix}, \begin{pmatrix} \frac{\pi}{\pi-6} & -\frac{2}{\pi-6} \\ -\frac{3}{\pi-6} & \frac{1}{\pi-6} \end{pmatrix}$$

Matrices of category `Cat::Matrix` are accepted. The inverse is returned as a corresponding matrix:

```
A := Dom::Matrix()([[2, PI], [0, 1]]):
numeric::inverse(A); domtype(%)
```

$$\begin{pmatrix} 0.5 & -1.570796327 \\ 0 & 1.0 \end{pmatrix}$$

```
Dom::Matrix()
```

```
delete A:
```

Example 2

The following matrix is not invertible:

```
A := linalg::hilbert(6):
A[6,6] := 5773/63504:
A
```

numeric::inverse

$$\begin{pmatrix} 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} \\ \frac{1}{2} & \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} \\ \frac{1}{3} & \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} \\ \frac{1}{4} & \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} \\ \frac{1}{5} & \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} \\ \frac{1}{6} & \frac{1}{7} & \frac{1}{8} & \frac{1}{9} & \frac{1}{10} & \frac{5773}{63504} \end{pmatrix}$$

With exact arithmetic, `numeric::inverse` detects this fact:

```
numeric::det(A, Symbolic), numeric::inverse(A, Symbolic)
```

```
0, FAIL
```

Due to internal round-off, the matrix is regarded as invertible if float arithmetic is used:

```
numeric::det(A, HardwareFloats), numeric::inverse(A, HardwareFloats)
```

$$\begin{aligned} & -3.239912837 \cdot 10^{-28}, \left[\left[-1.339975706 \cdot 10^{11}, 4.019927119 \cdot 10^{12}, \sigma_3, 7.503863956 \cdot 10^{13}, \sigma_5, \right. \right. \\ & \left. \left. 3.37673878 \cdot 10^{13} \right], \right. \\ & \left[4.019927119 \cdot 10^{12}, -1.205978136 \cdot 10^{14}, 8.441846951 \cdot 10^{14}, \sigma_4, 2.532554085 \cdot 10^{15}, \sigma_6 \right], \\ & \left[\sigma_3, 8.441846951 \cdot 10^{14}, -5.909292865 \cdot 10^{15}, 1.575811431 \cdot 10^{16}, \sigma_2, 7.091151439 \cdot 10^{15} \right], \\ & \left[7.503863956 \cdot 10^{13}, \sigma_4, 1.575811431 \cdot 10^{16}, -4.202163815 \cdot 10^{16}, 4.727434292 \cdot 10^{16}, \sigma_1 \right], \\ & \left[\sigma_5, 2.532554085 \cdot 10^{15}, \sigma_2, 4.727434292 \cdot 10^{16}, -5.318363579 \cdot 10^{16}, 2.127345432 \cdot 10^{16} \right], \\ & \left. \left[3.37673878 \cdot 10^{13}, \sigma_6, 7.091151439 \cdot 10^{15}, \sigma_1, 2.127345432 \cdot 10^{16}, -8.509381726 \cdot 10^{15} \right] \right] \end{aligned}$$

where

$$\sigma_1 = -1.890973717 \cdot 10^{16}$$

$$\sigma_2 = -1.77278786 \cdot 10^{16}$$

$$\sigma_3 = -2.813948983 \cdot 10^{13}$$

$$\sigma_4 = -2.251159187 \cdot 10^{15}$$

$$\sigma_5 = -8.441846951 \cdot 10^{13}$$

$$\sigma_6 = -1.013021634 \cdot 10^{15}$$

numeric::inverse

With SoftwareFloats, the internal rounding is slightly different and the kernel of the matrix is detected:

```
numeric::det(A, SoftwareFloats), numeric::inverse(A, SoftwareFloats)
-3.731550906 10-30, FAIL
```

```
delete A;
```

Example 3

The following matrix has domain components:

```
A := Dom::Matrix(Dom::IntegerMod(7))([[6, -1], [1, 6]])
```

$$\begin{pmatrix} 6 \bmod 7 & 6 \bmod 7 \\ 1 \bmod 7 & 6 \bmod 7 \end{pmatrix}$$

Note that `numeric::inverse` computes the inverse of the following matrix:

```
expr(A), numeric::inverse(A)
```

$$\begin{pmatrix} 6 & 6 \\ 1 & 6 \end{pmatrix}, \begin{pmatrix} 0.2 & -0.2 \\ -0.03333333333 & 0.2 \end{pmatrix}$$

The overloaded arithmetic should be used if the inverse is to be computed over the component domain `Dom::IntegerMod(7)`:

```
1/A
```

$$\begin{pmatrix} 3 \bmod 7 & 4 \bmod 7 \\ 3 \bmod 7 & 3 \bmod 7 \end{pmatrix}$$

```
delete A:
```

Example 4

The option `Symbolic` should not be used for float matrices because no internal pivoting is used to stabilize the numerical algorithm:

```
A := matrix([[1.0/10^20, 1.0], [1.0, 1.0]]):
bad = numeric::inverse(A, Symbolic),
good = numeric::inverse(A)
```

$$\text{bad} = \begin{pmatrix} 0 & 1.0 \\ 1.0 & -1.0 \cdot 10^{-20} \end{pmatrix}, \text{good} = \begin{pmatrix} -1.0 & 1.0 \\ 1.0 & -1.0 \cdot 10^{-20} \end{pmatrix}$$

```
delete A:
```

Example 5

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned and difficult to invert with low values of `DIGITS`. The following results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical round-off. Consequently, the inverses with and without hardware floats, respectively, differ significantly:

```
A := linalg::hilbert(10):
DIGITS := 10:
B1 := numeric::inverse(A, HardwareFloats):
B2 := numeric::inverse(A, SoftwareFloats):
B1[8, 8] <> B2[8, 8]
```

$$3.267405722 \cdot 10^{12} \neq 3.26785917 \cdot 10^{12}$$

```
norm(B1 - B2)
```

```
1681640193.0
```

delete A, B1, B2:

Parameters **A**

A square matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

Options **Hard, HardwareFloats, Soft, SoftwareFloats**

With **Hard** (or **HardwareFloats**), computations are done using fast hardware float arithmetic from within a MuPAD session. **Hard** and **HardwareFloats** are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With **Soft** (or **SoftwareFloats**) computations are done using software float arithmetic provided by the MuPAD kernel. **Soft** and **SoftwareFloats** are equivalent. **SoftwareFloats** is used by default if the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`.

Compared to the **SoftwareFloats** used by the MuPAD kernel, the computation with **HardwareFloats** may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no **HardwareFloats** or **SoftwareFloats** are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix **A** is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix **A** is not of domain type `DOM_HFARRAY`, or if one of the

options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 2” on page 18-149 and “Example 5” on page 18-153.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

numeric::inverse

This option prevents conversion of the input data to floats. With this option, symbolic entries are accepted.

Note This option should not be used for floating-point matrices! No internal pivoting is used, unless necessary. Consequently, numerical instabilities may occur in floating-point operations. See “Example 4” on page 18-153.

NoWarning

Without the option `Symbolic`, `numeric::inverse` automatically switches to the `Symbolic` mode with a warning if symbolic coefficients are found. With the option `NoWarning`, this warning is suppressed. Note, however, that `numeric::inverse` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = t`

Return the inverse as a matrix of domain type `t`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Return Values

Depending on the type of the input matrix `A`, the inverse is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`. `FAIL` is returned if the inverse cannot be computed.

Algorithms

Gaussian elimination with partial pivoting is used. Partial pivoting is switched off by the option `Symbolic`.

`linsolve` | `linalg::matlinsolve` | `numeric::linsolve` |
`numeric::matlinsolve` | `solve`

numeric::leastSquares

Purpose Least squares solution of linear equations

Syntax `numeric::leastSquares(A, B, <mode>, <method>, options)`

Description `numeric::leastSquares(A, B)` computes a matrix X that solves the linear matrix equation $AX = B$ in the least squares sense: the columns X_j of X minimize $\|AX_j - B_j\|_2$ where the B_j are the columns of B .

For a given vector B , a vector X minimizes $\|AX - B\|_2$ if and only if X is a solution of the “normal equations” $A^HAX = A^HB$, where A^H is the Hermitian transpose of the $m \times n$ matrix A . The solution is unique if $\text{rank}(A) = n$.

`numeric::leastSquares` allows to solve several least squares problems simultaneously by combining several ‘right hand sides’ B_j columnwise to a matrix B .

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix A :

- The special solution X as well as the kernel of an array A are returned as arrays.
- The special solution and the kernel of an hfarray of domain type `DOM_HFARRAY` are returned as hfarrays.
- For a dense matrix A of type `Dom::DenseMatrix()`, both the special solution X as well as the kernel are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, both the special solution X as well as the kernel are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices A of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, the input data are converted to floating-point numbers. The matrix A must not contain non-convertible parameters, unless `Symbolic` is used. If such objects are found,

`numeric::leastSquares` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

Symbolic parameters in B are accepted without warning. However, `HardwareFloats` cannot be used if there are any symbolic parameters in A or B .

If $A^H A$ has a non-trivial kernel, the least squares solution X is not unique. The return value X is a *special* solution of the equation $A^H A X = A^H B$. With the SVD method, X is the special solution with columns of minimal Euclidean length.

Note The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel. Further, the results computed with QRD and SVD may differ.

The kernel is computed only in the symbolic mode (option `Symbolic`). All floating-point methods return the value `NIL` for the kernel.

With `Symbolic`, the $n \times d$ matrix `KernelBasis` is the most general solution of $A^H A X = 0$. Its columns span the d -dimensional kernel of $A^H A$.

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension d of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension d of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

numeric::leastSquares

Note Without the option `Symbolic`, the implemented algorithms take care of numerical stabilization.

With `Symbolic`, exact data are assumed. The least squares solutions is computed via `numeric::matlinsolve(AH A, AH B , Symbolic)`. The symbolic strategy tries do maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for systems involving floating-point entries! In particluar, due to round-off, it may happen that no solution of $A^H A X = A^H B$ is found. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. “Example 4” on page 18-164.

All entries of `A` and `B` must be arithmetical expressions.

Note Apart from matrices of type `Dom::Matrix(...)`, `Cat::Matrix` objects `A` from matrix domains such as `Dom::DenseMatrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

The same holds true for matrices `B` passed as `Cat::Matrix` objects.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We consider a matrix `A` of rank 1:

```
A := array(1..3, 1..2, [[1, 2], [1, 2], [1, 2]]):  
B := [3, 4, 5]:
```

The normal equations have a 1-parameter set of of solutions:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, Symbolic)
```

$$\left[\begin{pmatrix} 4 \\ 0 \end{pmatrix}, \begin{pmatrix} -2 \\ 1 \end{pmatrix}, [\sqrt{2}] \right]$$

The numerical method QRD produces a special solution:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, QRD)
```

$$\left[\begin{pmatrix} 4.0 \\ 0 \end{pmatrix}, \text{NIL}, [1.414213562] \right]$$

The numerical method SVD produces a solution X of minimal norm:

```
[X, KernelBasis, Res] := numeric::leastSquares(A, B, SVD)
```

$$\left[\begin{pmatrix} 0.8 \\ 1.6 \end{pmatrix}, \text{NIL}, [1.414213562] \right]$$

```
delete A, B, X, KernelBasis, Res:
```

Example 2

We consider an ill-conditioned least squares problem. By construction, the following overdetermined system has an exact solution $X = [1, 2, \dots, n]$:

```
m := 10: n := 8:  
A := array(1..m, 1..n, [[1/(i + j + 100) $ j=1..n] $ i=1..m]):  
B := array(1..m, [_plus(A[i,j]*j $ j=1..n) $ i=1..m]):  
numeric::leastSquares(A, B, Symbolic)
```

numeric::leastSquares

$$\left[\begin{pmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \\ 6 \\ 7 \\ 8 \end{pmatrix}, 0, [0] \right]$$

The coefficient matrix A is rather ill-conditioned:

```
singvals := numeric::singularvalues(A):  
conditionOfA := max(op(singvals))/min(op(singvals))
```

6.31539107 10¹⁶

Consequently, round-off has a drastic effect in a numerical approximation. The methods yield results of different quality:

```
numeric::leastSquares(A, B, QRD)
```

$$\left[\begin{pmatrix} 205.7634088 \\ -506.7540812 \\ 336.9881724 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix}, \text{NIL}, [0.000000007174860922] \right]$$

```
numeric::leastSquares(A, B, SVD)
```

$$\left[\begin{pmatrix} 44440.34961 \\ -36432.38255 \\ -44826.69677 \\ -14839.48585 \\ 23895.8882 \\ 45730.9635 \\ 28571.67227 \\ -46506.25357 \end{pmatrix}, \text{NIL}, [0.0000007416898216] \right]$$

delete m, n, A, B, singvals, conditionOfA:

Example 3

This example involves a symbolic parameter c in the matrix A . The option `Symbolic` must be used:

```
A:= matrix([[c, 2], [1/3, 2/3], [1/7, 2/7]]):
B:= [1, 2, 3]:
numeric::leastSquares(A, B, Symbolic)
```

$$\left[\begin{pmatrix} -\frac{425}{58(c-1)} \\ \frac{483c-58}{116(c-1)} \end{pmatrix}, 0, \left[\sqrt{\left| \frac{425c}{58(c-1)} - \frac{483c-58}{58(c-1)} + 1 \right|^2 + \left| \frac{425}{174(c-1)} - \frac{483c-58}{174(c-1)} + 2 \right|^2} + \left| \frac{425}{406(c-1)} - \frac{483c-58}{406(c-1)} + 3 \right|^2 \right] \right]$$

`normal(%)`

numeric::leastSquares

$$\left[\left(\begin{array}{c} -\frac{425}{58(c-1)} \\ \frac{483c-58}{116(c-1)} \end{array} \right), 0, \left[\frac{15\sqrt{58}}{58} \right] \right]$$

delete A, B:

Example 4

Floating point entries may cause problems in conjunction with the option `Symbolic`, because the computation is not stabilized numerically in the symbolic node. The following matrix A has rank 2:

```
A := matrix([[1, 30], [10.0^(-15), 31*10.0^(-15)]]):
```

However, due to round-off, the 'normal matrix' $A^H A$ has rank 1. No solution is found with `Symbolic`:

```
A::dom::transpose(A) * A
```

$$\begin{pmatrix} 1.0 & 30.0 \\ 30.0 & 900.0 \end{pmatrix}$$

```
numeric::leastSquares(A, [31, 32*10^5], Symbolic)
```

```
[FAIL, NIL, NIL]
```

No such problem arises in the numerical schemes. Note, however, that the numerical methods yield different results in this extremely ill-conditioned problem:

```
numeric::leastSquares(A, [31, 32*10^5], QRD)
```

$$\left[\begin{pmatrix} -9.6 \cdot 10^{22} \\ 3.2 \cdot 10^{21} \end{pmatrix}, \text{NIL}, [31.0] \right]$$

```
numeric::leastSquares(A, [31, 32*10^5], SVD)
```

$$\left[\begin{pmatrix} 0.03440621532 \\ 1.03218646 \end{pmatrix}, \text{NIL}, [3200000.0] \right]$$

```
delete A:
```

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY or of category Cat::Matrix

B

An $m \times p$ matrix of domain type DOM_ARRAY or of category Cat::Matrix. Column vectors B may also be represented by a 1-dimensional array(1..m, [B₁, B₂, ...]) or by a list [B₁, B₂, ...].

mode

One of the flags Hard, HardwareFloats, Soft, SoftwareFloats, or Symbolic

method

One of the flags QRD, SVD

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

numeric::leastSquares

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used, if the matrix A contains symbolic parameters that cannot be converted to floating-point numbers.

The normal equations $A^HAX = A^HB$ are passed to `numeric::matlinsolve` with the option `Symbolic`.

If the least squares problem does not have a unique solution, a special solution X is returned together with the kernel of A^HA . Cf. “Example 1” on page 18-160.

Note This option should not be used for systems with floating-point coefficients! Numerical instabilities may occur in floating-point operations. Further, if the rank of A is not maximal, then `numeric::leastSquares` may fail to find a solution due to numerical round-off. In such a case, `[FAIL, NIL, NIL]` is returned. Cf. “Example 4” on page 18-164.

QRD

Use a QR decomposition. All entries of A must be convertible to floating-point values.

This is the default method.

numeric::leastSquares

The matrix A must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its Symbolic mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating-point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in B are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as e^{π} , $\sqrt{2}$ etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, only a special solution is returned. The kernel is not computed: it is returned as `NIL`.

The method `QRD` provides a numerically stable way of solving the normal equations $A^H A X = A^H B$ by a QR decomposition. In extremely ill-conditioned situations, it may be worthwhile to consider the slower, yet more stable method `SVD`.

The conditioning is given by the ratio of the largest singular value of A divided by the smallest singular value of A . If this value is large, the problem is ill-conditioned.

Cf. "Example 2" on page 18-161.

SVD

Use a singular value decomposition. All entries of A must be convertible to floating-point values.

The matrix A must not contain symbolic parameters that cannot be converted to floating point numbers. If such objects are found, then `numeric::leastSquares` automatically switches to its symbolic mode, issuing a warning. The computation proceeds with exact arithmetic, using the input data without floating point conversions.

The warning may be suppressed by the option `NoWarning`.

Symbolic parameters in B are accepted without warning. They are processed by the floating-point algorithm.

Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted and converted to floats.

If the least squares problem does not have a unique solution, the columns X_j of the solution X have a minimal Euclidean length

$$\|X_j\|_2.$$

The kernel is not computed: it is returned as `NIL`.

A singular value decomposition $A = UDV^H$ is used to solve the normal equations in the form $D^2V^HX = DU^HB$. For small or zero singular values d_i in $D = \text{diag}(d_1, d_2, \dots)$, the corresponding components of V^Hx are set to zero.

Usually, the numerical method `SVD` is slower than the default method `QRD`. However, in ill-conditioned situations, it is numerically more stable.

The conditioning is given by the ratio of the largest singular value of A divided by the smallest singular value of A . If this value is large, the problem is ill-conditioned.

NoWarning

Suppresses warnings

If symbolic coefficients are found in A , `numeric::leastSquares` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed.

ReturnType

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type d . The following return types d are available: `DOM_ARRAY`, or `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

numeric::leastSquares

Return Values

A list [X, KernelBasis, Residues] is returned.

The (special) least squares solution X is an $n \times p$ matrix.

With Symbolic, KernelBasis is an $n \times d$ matrix (d is the dimension of the kernel of $A^H A$). Its columns span the kernel of $A^H A$. If the kernel is trivial, KernelBasis is the integer 0.

Without Symbolic, the kernel is not computed. The value NIL is returned for the KernelBasis.

The list of arithmetical expressions Residues consists of the minimized least squares deviations $\|A X_j - B_j\|_2$ corresponding to the columns of X and B.

Purpose

Solve a system of linear equations

Syntax

`numeric::linsolve(eqs, <vars>, options)`

Description

`numeric::linsolve(eqs, vars)` solves a system of linear equations eqs for the unknowns vars.

`numeric::linsolve` is a fast numerical linear solver. It is also a recommended solver for linear systems with exact or symbolic coefficients (using `Symbolic`).

Expressions are interpreted as homogeneous equations. E.g., the input `[x = y - 1, x - y]` is interpreted as the system of equations `[x = y - 1, x - y = 0]`.

Note Without the option `Symbolic`, the input data are converted to floating-point numbers. The coefficient matrix A of the system $Ax = b$ represented by eqs must not contain non-convertible parameters, unless the option `Symbolic` is used! If such objects are found, then `numeric::linsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`. Symbolic parameters in the “right hand side” b are accepted without warning.

The numerical working precision is set by the environment variable `DIGITS`.

The solutions are returned as a list of solved equations of the form

$$[x_1 = \text{value}_1, x_2 = \text{value}_2, \dots],$$

where x_1, x_2, \dots are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown x_1 , say, does not turn up in the form `[x1 = ..., ...]` in the solution, then there is no constraint on this unknown; it is an arbitrary parameter.

Generally, all unknowns that do not turn up on the left hand side of the solved equations are arbitrary parameters spanning the solution space. Cf. “Example 9” on page 18-183.

In particular, if the empty list is returned as the solution, there are no constraints whatsoever on the unknowns, i.e., the system is trivial.

The ordering of the solved equations corresponds to the ordering of the unknowns vars. It is recommended that the user specifies vars by a *list* of unknowns. This guarantees that the solved equations are returned in the expected order. If vars are specified by a set, or if no vars are specified at all, then an internal ordering is used.

If no unknowns are specified by vars, numeric::linsolve solves for all symbolic objects in eqs. The unknowns are determined internally by indets(eqs, PolyExpr).

numeric::linsolve returns the general solution of the system eqs. It is valid for arbitrary complex values of the symbolic parameters which may be present in eqs. If no such solution exists, FAIL is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with the option ShowAssumptions. See “Example 2” on page 18-174, “Example 3” on page 18-175, “Example 4” on page 18-176, and “Example 11” on page 18-185.

The solved equations representing the solution are suitable as input for assign and subs. See “Example 8” on page 18-183.

numeric::linsolve is suitable for solving large sparse systems. See “Example 6” on page 18-177.

If eqs represents a system with a banded coefficient matrix, then this is detected and used by numeric::linsolve. Note that in this case, it is important to specify both the equations as well as the unknowns by lists to guarantee the desired form of the coefficient matrix. When using sets, the data may be reordered internally leading to a loss of band structure and, consequently, of efficiency. See “Example 6” on page 18-177.

Note `numeric::linsolve` is tuned for speed. For this reason, it does not check systematically that the equations `eqs` are indeed linear in the unknowns! For non-linear equations, strange things may happen; `numeric::linsolve` might even return wrong results! See “Example 5” on page 18-176.

Note `numeric::linsolve` does not react to any properties of the unknowns or of symbolic parameters that are set via `assume`.

Note Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, floating-point arithmetic is used and the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed and the pivoting strategy tries to maximize speed, not taking care of numerical stabilization! See “Example 7” on page 18-182.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Equations and variables may be entered as sets or lists:

```
numeric::linsolve({x = y - 1, x + y = z}, {x, y});  
numeric::linsolve([x = y - 1, x + y = z], {x, y});  
numeric::linsolve({x = y - 1, x + y = z}, [x, y]);  
numeric::linsolve([x = y - 1, x + y = z], [x, y])
```

```
[x = 0.5 z - 0.5, y = 0.5 z + 0.5]
```

numeric::linsolve

$$[x = 0.5 z - 0.5, y = 0.5 z + 0.5]$$

$$[x = 0.5 z - 0.5, y = 0.5 z + 0.5]$$

$$[x = 0.5 z - 0.5, y = 0.5 z + 0.5]$$

With the option `Symbolic`, exact arithmetic is used. The following system has a 1-parameter set of solution; the unknown x_3 is arbitrary:

```
numeric::linsolve([x[1] + x[2] = 2, x[1] - x[2] = 2*x[3]],  
                  [x[1], x[2], x[3]], Symbolic)
```

$$[x_1 = x_3 + 1, x_2 = 1 - x_3]$$

The unknowns may be expressions:

```
numeric::linsolve([f(0) - sin(x + 1) = 2, f(0) = 1 - sin(x + 1)],  
                  [f(0), sin(x + 1)])
```

$$[f(0) = 1.5, \sin(x + 1) = -0.5]$$

The following system does not have a solution:

```
numeric::linsolve([x + y = 1, x + y = 2], [x, y])
```

FAIL

Example 2

We demonstrate some examples with symbolic coefficients. Note that the option `Symbolic` has to be used:

```
eqs := [x + a*y = b, x + A*y = b]:  
numeric::linsolve(eqs, [x, y], Symbolic)
```

```
[x = b, y = 0]
```

Note that for $a = A$, this is not the general solution. Using the option `ShowAssumptions`, it turns out that the above result is the general solution subject to the assumption $a \neq A$:

```
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

```
[[x = b, y = 0], [], [A - a ≠ 0]]
```

```
delete eqs:
```

Example 3

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter a :

```
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic)
```

```
FAIL
```

With `ShowAssumptions`, `numeric::linsolve` investigates under which conditions (on the parameter a) there is a solution:

```
numeric::linsolve([x + y = 1, x + y = a], [x, y], Symbolic,
                  ShowAssumptions)
```

```
[[x = 1 - y], [a - 1 = 0], []]
```

We conclude that there is a 1-parameter set of solutions for $a = 1$. The constraint in a is a linear equation, since the parameter a enters the equations linearly. If a is regarded as an unknown rather than as a parameter, the constraint becomes part of the solution:

numeric::linsolve

```
numeric::linsolve([x + y = 1, x + y = a], [x, y, a], Symbolic,  
                  ShowAssumptions)
```

```
[[x = 1 - y, a = 1], [], []]
```

Example 4

With exact arithmetic, π is regarded as a symbolic parameter. The following system has a solution subject to the constraint $\pi = 1$:

```
numeric::linsolve([x = x - y + 1, y = PI], [x, y],  
                  Symbolic, ShowAssumptions)
```

```
[[y =  $\pi$ ], [1 -  $\pi$  = 0], []]
```

With floating-point arithmetic, π is converted to 3.1415... The system has no solution:

```
numeric::linsolve([x = x - y + 1, y = PI], [x, y],  
                  ShowAssumptions)
```

```
[FAIL, [], []]
```

Example 5

Since `numeric::linsolve` does not do a systematic internal check for non-linearities, the user should make sure that the equations to be solved are indeed linear in the unknowns. Otherwise, strange things may happen. Garbage is produced for the following non-linear systems:

```
a := sin(x):  
numeric::linsolve([y = 1 - a, x = y], [x, y], Symbolic)
```

```
[x = 1 - sin(x173), y = 1 - sin(x173)]
```

```
numeric::linsolve([a*x + y = 1, x = y], [x, y], Symbolic)
```

$$\left[x = \frac{1}{\sin(x18^3) + 1}, y = \frac{1}{\sin(x18^3) + 1} \right]$$

Polynomial non-linearities are usually detected. Regarding x , y , c as unknowns, the following quadratic system yields an error:

```
numeric::linsolve([x*c + y = 1, x = y], Symbolic)
```

```
Error: This system does not seem to be linear. [numeric::linsolve]
```

```
Error:
```

```
This system does not seem to be linear. [numeric::linsolve]
```

This system is linear in x , y if c is regarded as a parameter:

```
numeric::linsolve([x*c + y = 1, x = y], [x, y], Symbolic)
```

$$\left[x = \frac{1}{c+1}, y = \frac{1}{c+1} \right]$$

```
delete a:
```

Example 6

We solve a large sparse system. The coefficient matrix has only 3 diagonal bands. Note that both the equations as well as the variables are passed as lists. This guarantees that the band structure is not lost internally:

```
n := 500: x[0] := 0: x[n + 1] := 0:
eqs := [x[i-1] - 2*x[i] + x[i+1] = 1 $ i = 1..n]:
vars := [x[i] $ i = 1..n]:
numeric::linsolve(eqs, vars)
```

numeric::linsolve

$$[x_1 = -250.0, x_2 = -499.0, x_3 = -747.0, x_4 = -994.0, \dots, x_{498} = -747.0, x_{499} = -499.0, \\ x_{500} = -250.0]$$

[$x_1 = -250.0$, $x_2 = -499.0$, $x_3 = -747.0$, $x_4 = -994.0$, $x_5 = -1240.0$, $x_6 = -1485.0$, $x_7 = -1729.0$, $x_8 = -1972.0$, $x_9 = -2214.0$, $x_{10} = -2455.0$, $x_{11} = -2695.0$, $x_{12} = -2935.0$, $x_{13} = -3172.0$, $x_{14} = -3409.0$, $x_{15} = -3645.0$, $x_{16} = -3880.0$, $x_{17} = -4114.0$, $x_{18} = -4347.0$, $x_{19} = -4579.0$, $x_{20} = -4810.0$, $x_{21} = -5040.0$, $x_{22} = -5269.0$, $x_{23} = -5497.0$, $x_{24} = -5724.0$, $x_{25} = -5950.0$, $x_{26} = -6175.0$, $x_{27} = -6399.0$, $x_{28} = -6622.0$, $x_{29} = -6844.0$, $x_{30} = -7065.0$, $x_{31} = -7285.0$, $x_{32} = -7504.0$, $x_{33} = -7722.0$, $x_{34} = -7939.0$, $x_{35} = -8155.0$, $x_{36} = -8370.0$, $x_{37} = -8584.0$, $x_{38} = -8797.0$, $x_{39} = -9009.0$, $x_{40} = -9220.0$, $x_{41} = -9430.0$, $x_{42} = -9639.0$, $x_{43} = -9847.0$, $x_{44} = -10054.0$, $x_{45} = -10260.0$, $x_{46} = -10465.0$, $x_{47} = -10669.0$, $x_{48} = -10872.0$, $x_{49} = -11074.0$, $x_{50} = -11275.0$, $x_{51} = -11475.0$, $x_{52} = -11674.0$, $x_{53} = -11872.0$, $x_{54} = -12069.0$, $x_{55} = -12265.0$, $x_{56} = -12460.0$, $x_{57} = -12654.0$, $x_{58} = -12847.0$, $x_{59} = -13039.0$, $x_{60} = -13230.0$, $x_{61} = -13420.0$, $x_{62} = -13609.0$, $x_{63} = -13797.0$, $x_{64} = -13984.0$, $x_{65} = -14170.0$, $x_{66} = -14355.0$, $x_{67} = -14539.0$, $x_{68} = -14722.0$, $x_{69} = -14904.0$, $x_{70} = -15085.0$, $x_{71} = -15265.0$, $x_{72} = -15444.0$, $x_{73} = -15622.0$, $x_{74} = -15799.0$, $x_{75} = -15975.0$, $x_{76} = -16150.0$, $x_{77} = -16324.0$, $x_{78} = -16497.0$, $x_{79} = -16669.0$, $x_{80} = -16840.0$, $x_{81} = -17010.0$, $x_{82} = -17179.0$, $x_{83} = -17347.0$, $x_{84} = -17514.0$, $x_{85} = -17680.0$, $x_{86} = -17845.0$, $x_{87} = -18009.0$, $x_{88} = -18172.0$, $x_{89} = -18334.0$, $x_{90} = -18495.0$, $x_{91} = -18655.0$, $x_{92} = -18814.0$, $x_{93} = -18972.0$, $x_{94} = -19129.0$, $x_{95} = -19285.0$, $x_{96} = -19440.0$, $x_{97} = -19594.0$, $x_{98} = -19747.0$, $x_{99} = -19899.0$, $x_{100} = -20050.0$, $x_{101} = -20200.0$, $x_{102} = -20349.0$, $x_{103} = -20497.0$, $x_{104} = -20644.0$, $x_{105} = -20790.0$, $x_{106} = -20935.0$, $x_{107} = -21079.0$, $x_{108} = -21222.0$, $x_{109} = -21364.0$, $x_{110} = -21505.0$, $x_{111} = -21645.0$, $x_{112} = -21784.0$, $x_{113} = -21922.0$, $x_{114} = -22059.0$, $x_{115} = -22195.0$, $x_{116} = -22330.0$, $x_{117} = -22464.0$, $x_{118} = -22597.0$, $x_{119} = -22729.0$, $x_{120} = -22860.0$, $x_{121} = -22990.0$, $x_{122} = -23119.0$, $x_{123} = -23247.0$, $x_{124} = -23374.0$, $x_{125} = -23500.0$, $x_{126} = -23625.0$, $x_{127} = -23749.0$, $x_{128} = -23872.0$, $x_{129} = -23994.0$, $x_{130} = -24115.0$, $x_{131} = -24235.0$, $x_{132} = -24354.0$, $x_{133} = -24472.0$, $x_{134} = -24589.0$, $x_{135} = -24705.0$, $x_{136} = -24820.0$, $x_{137} = -24934.0$, $x_{138} = -25047.0$, $x_{139} = -25159.0$, $x_{140} = -25270.0$, $x_{141} = -25380.0$, $x_{142} = -25489.0$, $x_{143} = -25597.0$, $x_{144} = -25704.0$, $x_{145} = -25810.0$, $x_{146} = -25915.0$, $x_{147} = -26019.0$, $x_{148} = -26122.0$, $x_{149} = -26224.0$, $x_{150} = -26325.0$, $x_{151} = -26425.0$, $x_{152} = -26524.0$, $x_{153} = -26622.0$, $x_{154} = -26719.0$, $x_{155} = -26815.0$, $x_{156} = -26910.0$, $x_{157} = -27004.0$, $x_{158} = -27097.0$, $x_{159} = -27189.0$, $x_{160} = -27280.0$, $x_{161} = -27370.0$, $x_{162} = -27459.0$, $x_{163} = -27547.0$, $x_{164} = -27634.0$, $x_{165} = -27720.0$, $x_{166} = -27805.0$, $x_{167} = -27889.0$, $x_{168} = -27972.0$, $x_{169} = -28054.0$, $x_{170} = -28135.0$, $x_{171} = -28215.0$, $x_{172} = -28294.0$, $x_{173} = -28372.0$, $x_{174} = -28449.0$, $x_{175} = -28525.0$, $x_{176} = -28600.0$, $x_{177} = -28674.0$, $x_{178} = -28747.0$, $x_{179} = -28819.0$, $x_{180} = -28890.0$, $x_{181} = -28960.0$, $x_{182} = -29029.0$, $x_{183} = -29097.0$, $x_{184} = -29164.0$, $x_{185} = -29230.0$, $x_{186} = -29295.0$, $x_{187} = -29359.0$, $x_{188} = -29422.0$, $x_{189} = -29484.0$, $x_{190} = -29545.0$, $x_{191} = -29605.0$, $x_{192} = -29664.0$, $x_{193} = -29722.0$, $x_{194} = -29779.0$, $x_{195} = -29835.0$, $x_{196} = -29890.0$, $x_{197} = -29944.0$, $x_{198} = -29997.0$, $x_{199} = -30049.0$, $x_{200} = -30100.0$, $x_{201} = -30150.0$, $x_{202} = -30200.0$, $x_{203} = -30247.0$, $x_{204} = -30294.0$, $x_{205} = -30340.0$, $x_{206} = -30385.0$, $x_{207} = -30429.0$]

numeric::linsolve

The band structure is lost if the equations or the unknowns are specified by sets. The following call takes more time than the previous call:

```
numeric::linsolve({op(eqs)}, {x[i] $ i = 1..n})
```

```
[x1 = -250.0, x2 = -499.0, x3 = -747.0, x4 = -994.0, ..., x498 = -747.0, x499 = -499.0,  
x500 = -250.0]
```

```
delete n, x, eqs, vars:
```

Example 7

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.

```
eqs := [x + 10^20*y = 10^20, x + y = 0]:
```

The float approximation of the exact solution is:

```
map(numeric::linsolve(eqs, [x, y], Symbolic), map, float)
```

```
[x = -1.0, y = 1.0]
```

We now convert the exact coefficients to floating-point numbers:

```
feqs := map(eqs, map, float)
```

```
[x + 1.0 1020 y = 1.0 1020, x + y = 0.0]
```

The default pivoting strategy stabilizes floating-point operations. Consequently, one gets a correct result:

```
numeric::linsolve(feqs, [x, y])
```

```
[x = -1.0, y = 1.0]
```

With `Symbolic`, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following incorrect result is caused by internal round-off effects (“cancellation”):

```
numeric::linsolve(feqs, [x, y], Symbolic)
```

```
[x = 0.0, y = 1.0]
```

```
delete eqs, feqs:
```

Example 8

We demonstrate that the simplified equations representing the solution can be used for further processing with subs:

```
eqs := [x + y = 1, x + y = a]:
[Solution, Constraints, Pivots] :=
  numeric::linsolve(eqs, [x, y], ShowAssumptions)
```

```
[[x = 1.0 - 1.0 y], [1.0 a - 1.0 = 0], []]
```

```
subs(eqs, Solution)
```

```
[1.0 = 1, 1.0 = a]
```

The solution can be assigned to the unknowns via assign:

```
assign(Solution):
x, y, eqs
```

```
1.0 - 1.0 y, y, [1.0 = 1, 1.0 = a]
```

```
delete eqs, Solution, Constraints, Pivots, x:
```

Example 9

If the solution of the linear system is not unique, then some of the unknowns are used as “free parameters” spanning the solution space. In the following example, the unknowns z , w are such parameters. They do not turn up on the left hand side of the solved equations:

```
eqs := [x + y = z, x + 2*y = 0, 2*x - z = -3*y, y + z = 0]:
```

numeric::linsolve

```
vars := [x, y, z, w]:  
Solution := numeric::linsolve(eqs, vars, Symbolic)
```

```
[x = 2 z, y = -z]
```

You may define a function such as the following `NewSolutionList` to rename your free parameters to “myName1”, “myName2” etc. and fill up your list of solved equations accordingly:

```
NewSolutionList :=  
proc(Solution : DOM_LIST, vars : DOM_LIST, myName : DOM_STRING)  
local i, solvedVars, newEquation;  
begin  
    solvedVars := map(Solution, op, 1);  
    for i from 1 to nops(vars) do  
        if not has(solvedVars, vars[i]) then  
            newEquation := vars[i] = genident(myName);  
            Solution := listlib::insertAt(  
                subs(Solution, newEquation), newEquation, i)  
        end_if  
    end_for:  
    Solution  
end_proc:
```

```
NewSolutionList(Solution, vars, "FreeParameter")
```

```
[x = 2 FreeParameter1, y = -FreeParameter1, z = FreeParameter1, w = FreeParameter2]
```

```
delete eqs, vars, Solution, NewSolutionList:
```

Example 10

We demonstrate the difference between hardware and software arithmetic. The following problem is very ill-conditioned. The results, both with `HardwareFloats` as well as with `SoftwareFloats`, are marred by numerical round-off:

```
n:= 10:
eqs:= [(_plus(x[j]/(i + j -1) $ j = 1..n) = 1) $ i = 1..n]:
vars:= [x[i] $ i = 1..n]:
numeric::linsolve(eqs, vars, SoftwareFloats);
numeric::linsolve(eqs, vars, HardwareFloats)
```

```
[x1 = -9.999986342, x2 = 989.9988244, x3 = -23759.97502, x4 = 240239.7733,
x5 = -1261258.92, x6 = 3783777.035, x7 = -6726715.139, x8 = 7001275.306,
x9 = -3938217.537, x10 = 923779.4586]
```

```
[x1 = -9.997364824, x2 = 989.7718609, x3 = -23755.13378, x4 = 240195.7143,
x5 = -1261048.597, x6 = 3783198.501, x7 = -6725765.49, x8 = 7000357.238,
x9 = -3937735.418, x10 = 923673.4085]
```

This is the exact solution:

```
numeric::linsolve(eqs, vars, Symbolic);
```

```
[x1 = -10, x2 = 990, x3 = -23760, x4 = 240240, x5 = -1261260, x6 = 3783780, x7 = -6726720,
x8 = 7001280, x9 = -3938220, x10 = 923780]
```

```
delete eqs, vars:
```

Example 11

We demonstrate how a complete solution of the following linear system in x, y with symbolic parameters a, b, c, d may be found:

```
eqs := [x + y = d, a*x + b*y = 1, x + c*y = 1]:
```

numeric::linsolve

```
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$\left[\left[x = -\frac{bd-1}{a-b}, y = \frac{ad-1}{a-b} \right], [a-b+c+bd-acd-1=0], [b-a \neq 0] \right]$$

This is the general solution, assuming $a \neq b$. We now set $b = a$ to investigate further solution branches:

```
eqs := subs(eqs, b = a):  
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$\left[\left[x = \frac{cd-1}{c-1}, y = -\frac{d-1}{c-1} \right], [1-ad=0], [c-1 \neq 0] \right]$$

This is the general solution for $a = b$, assuming $c \neq 1$. We finally set $c = 1$ to obtain the last solution branch:

```
eqs := subs(eqs, c = 1):  
numeric::linsolve(eqs, [x, y], Symbolic, ShowAssumptions)
```

$$[[x = d - y], [1 - ad = 0, 1 - d = 0], []]$$

From the constraints on the symbolic parameters a and d , we conclude that there is a special 1-parameter solution $x = 1 - y$ for $a = b = c = d = 1$.

```
delete eqs:
```

Parameters

eqs

A list, set, array, or matrix (Cat::Matrix) of linear equations or arithmetical expressions

vars

A list or set of unknowns to solve for. Unknowns may be identifiers or indexed identifiers or arithmetical expressions.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.

- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned systems, the result is subject to round-off errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 10” on page 18-184.

Symbolic

Prevents conversion of input data to floating-point numbers. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the coefficients of the equations contain symbolic parameters that cannot be converted to floating-point numbers.

Note This option should not be used for equations with floating-point coefficients! Numerical instabilities may occur in floating-point operations. See “Example 7” on page 18-182.

ShowAssumptions

Returns information on internal assumptions on symbolic parameters in eqs.

This option is only useful if the equations contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

Note The format of the return value is changed to [Solution, Constraints, Pivots].

`Solution` is a set of simplified equations representing the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in eqs, which are necessary and sufficient to make the system solvable.

Such constraints arise if Gaussian elimination of the original equations leads to equations of the form $0 = c$, where c is some expression involving symbolic parameters in the “right hand side” of the system. All such equations are collected in `Constraints`. `numeric::linsolve` assumes that these equations are satisfied and returns a solution.

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in the coefficient matrix A of the linear system $Ax = b$ represented by eqs. Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are the numerators of the pivot elements that contain symbolic parameters. If only numerical pivot elements were used, the return value of `Pivots` is the empty list.

Note The option `ShowAssumptions` changes the return strategy for “unsolvable” systems. Without the option `Symbolic`, `FAIL` is returned whenever Gaussian elimination produces an equation $0 = c$ with non-zero c . With `ShowAssumptions`, such equations are returned via `Constraints`, provided c involves symbolic parameters.

If c is a purely numerical value, then `[FAIL, [], []]` is returned.

See “Example 2” on page 18-174, “Example 3” on page 18-175, “Example 4” on page 18-176, and “Example 11” on page 18-185.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::linsolve` automatically switches to the `Symbolic` mode with a warning. With this option, this warning is suppressed; `numeric::linsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

Return Values

Without the option `ShowAssumptions`, a list of simplified equations is returned. It represents the general solution of the system `eqs`. `FAIL` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[Solution, Constraints, Pivots]` is returned. `Solution` is a list of simplified equations representing the general solution of `eqs`. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in `eqs`. Internally, these were assumed to hold true when solving the system.

`[FAIL, [], []]` is returned if the system is not solvable.

numeric::matlinsolve

Purpose Solve a linear matrix equation

Syntax `numeric::matlinsolve(A, B, options)`

Description `numeric::matlinsolve(A, B)` returns the matrix solution X of the matrix equation $AX = B$ together with the kernel of the matrix A .

`numeric::matlinsolve` is a fast numerical linear solver for both sparse and dense systems. It is also a recommended solver for linear systems with exact or symbolic coefficients (use option `Symbolic`).

If no return type is specified via the option `ReturnType = d`, the domain type of the return data depends on the type of the input matrix A :

- The special solution X as well as the kernel of an array A are returned as arrays.
- The special solution X as well as the kernel of an hfarray A are returned as hfarrays.
- For a dense matrix A of type `Dom::DenseMatrix()`, both the special solution X as well as the kernel of A are returned as matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, both the special solution X as well as the kernel of A are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices A of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.

Without `Symbolic`, exact numerical input data such as `PI + sqrt(2)`, `sin(3)` etc. are converted to floating-point numbers. Floating point arithmetic is used. Its precision is given the environment variable `DIGITS`. If symbolic data are found that cannot be converted to floating-point numbers, `numeric::matlinsolve` automatically switches to its symbolic mode, issuing a warning. This warning may be suppressed via `NoWarning`.

With `Symbolic`, symbolic parameters in the coefficient matrix A as well as in the right hand side B are accepted and processed without a warning.

With `SoftwareFloats`, the right hand side B may contain symbolic parameters that cannot be converted to floating-point numbers. All entries of the coefficient matrix A , however, must be convertible to floating-point numbers.

With `HardwareFloats`, neither A nor B must contain symbolic parameters that cannot be converted to floating-point numbers.

X is a *special* solution of the equation $AX = B$. If A has a non-trivial kernel, the solution X is not unique.

Note The result computed with `HardwareFloats` may differ from the solution computed with `SoftwareFloats` or `Symbolic`! In particular, this is the case for systems with a non-trivial kernel.

Cf. “Example 9” on page 18-202.

The $n \times d$ matrix `KernelBasis` is the most general solution of $AX = 0$. Its columns span the d -dimensional kernel of A .

Thus, the kernel of A may be computed via `numeric::matlinsolve(A, [0, ..., 0])[2]`.

If the kernel is 0-dimensional, the return value of `KernelBasis` is the integer 0. If `KernelBasis` is returned as an array, the dimension d of the kernel is `d = op(KernelBasis, [0, 3, 2])`. If `KernelBasis` is returned as a matrix of type `Dom::Matrix()` or `Dom::DenseMatrix()`, the dimension d of the kernel is `d = KernelBasis::dom::matdim(KernelBasis)[2]`.

Note Due to round-off errors, some or all basis vectors in the kernel of A may be missed in the numerical modes.

numeric::matlinsolve

The special solution X in conjunction with `KernelBasis` provides the general solution of $AX = B$. Solutions generated without the option `ShowAssumptions` are valid for arbitrary complex values of the symbolic parameters which may be present in A and B . If no such solution exists, then `[FAIL,NIL]` is returned. Solutions that are valid only for special values of the symbolic parameters may be obtained with `ShowAssumptions`. See “Example 3” on page 18-197, “Example 4” on page 18-198, and “Example 7” on page 18-200.

`numeric::matlinsolve` internally uses a sparse representation of the matrices. It is suitable for solving large sparse systems. See “Example 5” on page 18-198.

Note `numeric::matlinsolve` does not react to any assumptions on symbolic parameters in A, B that are set via `assume`.

Note Gaussian elimination with partial pivoting is used. Without the option `Symbolic`, the pivoting strategy takes care of numerical stabilization. With `Symbolic`, exact data are assumed. The symbolic pivoting strategy tries to maximize speed and does not take care of numerical stabilization! Do not use `Symbolic` for linear systems involving floating-point entries! See “Example 6” on page 18-199.

Note Apart from matrices of type `Dom::Matrix(...)`, `Cat::Matrix` objects `A` from matrix domains such as `Dom::DenseMatrix(...)` or `Dom::SquareMatrix(...)` are internally converted to arrays over expressions via `expr(A)`. Note that the option `Symbolic` should be used if the entries cannot be converted to numerical expressions.

Note that `linalg::matlinsolve` must be used, when the solution is to be computed over the component domain. See . “Example 8” on page 18-201.

Environment Interactions

Without the option `Symbolic`, the function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We use equivalent input formats (B_1 , B_2) to represent a vector with components $[a, \pi]$. First, this vector is defined as a 2-dimensional array:

```
A := array(1..2, 1..3, [[1, 2, 3],[1, 1, 2]]):
B1 := array(1..2, 1..1, [[a], [PI]]):
numeric::matlinsolve(A, B1)
```

$$\left[\begin{pmatrix} 6.283185307 - 1.0 a \\ 1.0 a - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix} \right]$$

Next, we use a 1-dimensional array and compute an exact solution:

```
B2 := array(1..2, [a, PI]):
numeric::matlinsolve(A, B2, Symbolic)
```

numeric::matlinsolve

$$\left[\begin{pmatrix} 2\pi - \alpha \\ \alpha - \pi \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ -1 \\ 1 \end{pmatrix} \right]$$

Now, a list is used to specify the vector. No internal assumptions were used by `numeric::matlinsolve` to obtain the solution:

```
B3 := [a, PI]:  
numeric::matlinsolve(A, B3, ShowAssumptions)
```

$$\left[\begin{pmatrix} 6.283185307 - 1.0 \alpha \\ 1.0 \alpha - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix}, [], [] \right]$$

Finally, we use `Dom::Matrix` objects to specify the system. Note that the results are returned as corresponding matrix objects:

```
A := matrix([[1, 2, 3],[1, 1, 2]]):  
B4 := matrix([a, PI]):  
numeric::matlinsolve(A, B4)
```

$$\left[\begin{pmatrix} 6.283185307 - 1.0 \alpha \\ 1.0 \alpha - 3.141592654 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \\ -1.0 \\ 1.0 \end{pmatrix} \right]$$

```
delete A, B1, B2, B3, B4:
```

Example 2

We invert a matrix by solving $AX = 1$:

```
A := hfarray(1..3, 1..3, [[1, 1, 0], [0, 1, 1], [0, 0, 1]]):  
B := matrix::identity(3, 3):
```

```
InverseOfA := numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} 1.0 & -1.0 & 1.0 \\ 0.0 & 1.0 & -1.0 \\ 0.0 & 0.0 & 1.0 \end{pmatrix}$$

```
delete A, B, InverseOfA:
```

Example 3

We solve an equation with a symbolic parameter x :

```
A := matrix([[2, 2, 3], [1, 1, 2], [3, 3, 5]]):
B := matrix([sin(x)^2, cos(x)^2, 0]):
[X, Kernel, Constraints, Pivots] :=
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\begin{pmatrix} 5 \sin(x)^2 \\ 0 \\ -3 \sin(x)^2 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \\ 0 \end{pmatrix}, [\cos(x)^2 + \sin(x)^2 = 0], [] \right]$$

This solution holds subject to the constraint $\sin(x)^2 + \cos(x)^2 = 0$ on the parameter x . `numeric::matlinsolve` does not investigate the `Constraints` and does not realize that they cannot be satisfied. We check the consistency of the “result” by inserting the solution into the original system. Since the input matrix A was of type `Dom::Matrix()`, the results `X` and `Kernel` were returned as corresponding matrices. The overloaded operators `*` and `-` for matrix multiplication and subtraction can be used:

```
A*X - B, A*Kernel
```

numeric::matlinsolve

$$\begin{pmatrix} 0 \\ -\cos(x)^2 - \sin(x)^2 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

```
delete A, B, X, Kernel, Constraints, Pivots:
```

Example 4

We give a further demonstration of the option `ShowAssumptions`. The following system does not have a solution for all values of the parameter `a`:

```
A := array(1..2, 1..2, [[1, 1], [1, 1]]):  
B := array(1..2, 1..1, [[1], [a]]):  
numeric::matlinsolve(A, B, Symbolic)
```

```
[FAIL, NIL]
```

With `ShowAssumptions`, `numeric::matlinsolve` investigates under which conditions (on the parameter `a`) there is a solution:

```
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

```
[ $\begin{pmatrix} 1 \\ 0 \end{pmatrix}, \begin{pmatrix} -1 \\ 1 \end{pmatrix}, [a-1=0], []$ ]
```

We conclude that there is a 1-dimensional solution space for $a = 1$.

```
delete A, B:
```

Example 5

We solve a sparse system with 3 diagonal bands:

```
n := 100:  
A := matrix(n, n, [1, -2, 1], Banded):
```

```
B := array(1..n, [1 $ n]):
numeric::matlinsolve(A, B)
```

$$\left[\begin{pmatrix} -50.0 \\ -99.0 \\ -147.0 \\ \dots \\ -147.0 \\ -99.0 \\ -50.0 \end{pmatrix}, 0 \right]$$

```
delete n, A, B:
```

Example 6

The option `Symbolic` should not be used for equations with floating-point coefficients, because the symbolic pivoting strategy favors efficiency instead of numerical stability.

```
A := array(1..2, 1..2, [[1, 10^20], [1, 1]]):
B := array(1..2, 1..1, [[10^20], [0]]):
```

The float approximation of the exact solution is:

```
map(numeric::matlinsolve(A, B, Symbolic)[1], float)
```

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

We now convert the exact input data to floating-point approximations:

```
A := map(A, float): B := map(B, float):
```

The default pivoting strategy of the floating-point algorithm stabilizes floating-point operations. Consequently, one gets a correct result:

numeric::matlinsolve

```
numeric::matlinsolve(A, B)[1]
```

$$\begin{pmatrix} -1.0 \\ 1.0 \end{pmatrix}$$

With the option `Symbolic`, however, the pivoting strategy optimizes speed, assuming exact arithmetic. Numerical instabilities may occur if floating-point coefficients are involved. The following result is caused by internal round-off effects (“cancellation”):

```
numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} 0 \\ 1.0 \end{pmatrix}$$

We need to increase `DIGITS` to obtain a better result:

```
DIGITS := 20:  
numeric::matlinsolve(A, B, Symbolic)[1]
```

$$\begin{pmatrix} -1.0000000149011611938 \\ 1.0 \end{pmatrix}$$

```
delete A, B, DIGITS:
```

Example 7

We demonstrate how a complete solution of the following linear system with symbolic parameters may be found:

```
A := array(1..3, 1..2, [[1, 1], [a, b], [1, c]]):  
B := array(1..3, 1..1, [[1], [1], [1]]):  
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\left(\begin{array}{c} -\frac{b-1}{a-b} \\ \frac{a-1}{a-b} \end{array} \right), 0, [-(a-1)(c-1) = 0], [b-a \neq 0] \right]$$

This is the general solution assuming $a \neq b$. We now set $b = a$ to investigate further solution branches:

```
A := subs(A, b = a):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\left(\begin{array}{c} 1 \\ 0 \end{array} \right), 0, [1-a=0], [c-1 \neq 0] \right]$$

This is the general solution for $a = b$, assuming $c \neq 1$. We finally set $c = 1$ to obtain the last solution branch:

```
A := subs(A, c = 1):
numeric::matlinsolve(A, B, Symbolic, ShowAssumptions)
```

$$\left[\left(\begin{array}{c} 1 \\ 0 \end{array} \right), \left(\begin{array}{c} -1 \\ 1 \end{array} \right), [1-a=0], [] \right]$$

From the constraint on a , we conclude that there is a 1-dimensional solution space for the special values $a = b = c = 1$ of the symbolic parameters.

```
delete A, B:
```

Example 8

Matrices from a domain such as `Dom::Matrix(...)` are converted to arrays with numbers or expressions. Hence, `numeric::matlinsolve` finds no solution for the following system:

```
M := Dom::Matrix(Dom::IntegerMod(7)):
```

numeric::matlinsolve

```
A := M([[1, 4], [6, 3], [3, 2]]):  
B := M([[9], [5], [0]]):  
numeric::matlinsolve(A, B)
```

[FAIL, NIL]

Use `linalg::matlinsolve` to solve the system over the coefficient field of the matrices. A solution does exist over the field `Dom::IntegerMod(7)`:

```
linalg::matlinsolve(A, B)
```

$$\begin{pmatrix} 1 \bmod 7 \\ 2 \bmod 7 \end{pmatrix}$$

```
delete M, A, B:
```

Example 9

We demonstrate the difference between `Symbolic`, `HardwareFloats`, and `SoftwareFloats`. The following matrix A has a 1-dimensional kernel. Due to round-off, a further spurious kernel vector appears with `SoftwareFloats`. No kernel vector is detected with `HardwareFloats`:

```
A := matrix([[2*10^14 + 2, 2*10^(-9), 2*10^(-4)],  
             [3*10^15 + 3, 3*10^(-8), 3*10^(-3)],  
             [4*10^16 + 4, 4*10^(-7), 4*10^(-2)]  
            ]):  
b := matrix([2*10^(-9), 3*10^(-8), 4*10^(-7)]):  
float(numeric::matlinsolve(A, b, Symbolic));  
numeric::matlinsolve(A, b, SoftwareFloats);  
numeric::matlinsolve(A, b, HardwareFloats)
```

$$\left[\begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ -100000.0 \\ 1.0 \end{pmatrix} \right]$$

$$\left[\left(\begin{pmatrix} 1.0 \cdot 10^{-23} \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} -1.0 \cdot 10^{-23} & -1.0 \cdot 10^{-18} \\ 1.0 & 0 \\ 0 & 1.0 \end{pmatrix} \right) \right]$$

$$\left[\left(\begin{pmatrix} 0 \\ 1.0 \\ 0 \end{pmatrix}, 0 \right) \right]$$

delete A, b:

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

B

An $m \times p$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix. Column vectors B may also be represented by a 1-dimensional array(1..m, [B₁, B₂, ...]), a 1-dimensional hfarray(1..m, [B₁, B₂, ...]), or by a list [B₁, B₂, ...].

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are done using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 9” on page 18-202.

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used. This option overrides `HardwareFloats` and `SoftwareFloats`.

This option *must* be used if the matrix A contains symbolic parameters that cannot be converted to floating-point numbers.

Note This option should not be used for matrices with floating-point entries! Numerical instabilities may occur in floating-point operations. Cf. “Example 6” on page 18-199.

ShowAssumptions

Returns information on internal assumptions on symbolic parameters in A and B . With this option, either exact arithmetic or `SoftwareFloats` are used.

This option is only useful if the matrices contain symbolic parameters. Consequently, it should only be used in conjunction with the option `Symbolic`.

Note This option changes the format of the return value to $[X, \text{KernelBasis}, \text{Constraints}, \text{Pivots}]$.

`X` and `KernelBasis` represent the general solution subject to `Constraints` and `Pivots`.

`Constraints` is a list of equations for symbolic parameters in B which are necessary and sufficient for $AX = B$ to be solvable.

Such constraints arise if Gaussian elimination leads to equations of the form $0 = c$, where c is some expression involving symbolic parameters contained in B . All such equations are collected in `Constraints`; `numeric::matlinsolve` assumes that these equations are satisfied and returns a special solution X .

If no such constraints arise, the return value of `Constraints` is the empty list.

`Pivots` is a list of inequalities involving symbolic parameters in A . Internally, division by pivot elements occurs in the Gaussian elimination. The expressions collected in `Pivots` are the numerators of those pivot elements that involve symbolic parameters contained in A . If only numerical pivot elements are used, then the return value of `Pivots` is the empty list.

Note `Constraints` usually is a list of *non-linear* equations for the symbolic parameters. It is not investigated by `numeric::matlinsolve`, i.e., solutions may be returned, even if the `Constraints` cannot be satisfied. See “Example 3” on page 18-197.

Note This option changes the return strategy for “unsolvable” systems. Without the option `ShowAssumptions`, the result `[FAIL, NIL]` is returned, whenever Gaussian elimination produces an equation $0 = c$ with non-zero c . With `ShowAssumptions`, such equations are returned via `Constraints`, provided c involves symbolic parameters. If c is a purely numerical value, then `[FAIL, NIL, [], []]` is returned.

See “Example 3” on page 18-197, “Example 4” on page 18-198, and “Example 7” on page 18-200.

NoWarning

Suppresses warnings

If symbolic coefficients are found, `numeric::matlinsolve` automatically switches to the Symbolic mode with a warning. With this option, this warning is suppressed; `numeric::matlinsolve` still uses the symbolic mode for symbolic coefficients, i.e., exact arithmetic without floating-point conversions is used.

ReturnType

Option, specified as `ReturnType = d`

Return the (special) solution and the kernel as matrices of domain type d . The following return types d are available: `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Sparse

Use a sparse internal representation for matrices.

This option only has an effect when used in conjunction with `HardwareFloats`. With the `Sparse` option, the linear solver uses a sparse representation of the matrices to save memory and increase efficiency. However, if the coefficient matrix is not sparse, this option will cost some additional memory and runtime.

Return Values

Without the option `ShowAssumptions`, a list `[X, KernelBasis]` is returned. The (special) solution X is an $n \times p$ matrix. `KernelBasis` is an $n \times d$ matrix (d is the dimension of the kernel of A). Its columns span the kernel of A . If the kernel is trivial, `KernelBasis` is the integer 0.

`[FAIL, NIL]` is returned if the system is not solvable.

With `ShowAssumptions`, a list `[X, KernelBasis, Constraints, Pivots]` is returned. The lists `Constraints` and `Pivots` contain equations and inequalities involving symbolic parameters in A and B .

numeric::matlinsolve

Internally these were assumed to hold true when solving the system.
[FAIL, NIL, [], []] is returned if the system is not solvable.

`numeric::linsolve` | `solve`

Purpose Weights and abscissae of Newton-Cotes quadrature

Syntax numeric::ncdata(n)

Description numeric::ncdata(n) returns the weights and the abscissae of the Newton-Cotes quadrature rule with n equidistant nodes.

The Newton-Cotes quadrature rule $\sum_{i=1}^n b_i f(c_i)$ produces the exact integral $\int_0^1 f(x) dx$ for all polynomials f through degree $n - 1$. If n is odd, then the quadrature rule is exact through degree n .

The equidistant abscissae $c = [c_1, \dots, c_n]$ are given by $c_i = \frac{i-1}{n-1}$.

Environment Interactions numeric::ncdata is not sensitive to the environment variable DIGITS. The function uses option remember.

Examples **Example 1**

The following call produces exact data for the quadrature rule with four nodes:

```
numeric::ncdata(4)
```

```
[[[1/8, 3/8, 3/8, 1/8], [0, 1/3, 2/3, 1]]]
```

Parameters **n**
The number of nodes: a positive integer

Return Values List [b,c] is returned. The lists $b = [b_1, \dots, b_n]$ and $c = [c_1, \dots, c_n]$ are the rational weights and abscissae of the Newton-Cotes quadrature rule, respectively.

numeric::ncdata

Algorithms

The numerical integrator `numeric::quadrature` calls `numeric::ncdata` to provide the data for Newton-Cotes quadrature.

Purpose

Numerical solution of an ordinary differential equation

Syntax

```
numeric::odesolve(f, t_0 .. t, Y_0, <method>, <RelativeError =
rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize
= h_max>, <Alldata = n>, <Symbolic>)
numeric::odesolve(t_0 .. t, f, Y_0, <method>, <RelativeError =
rtol>, <AbsoluteError = atol>, <Stepsize = h>, <MaxStepsize
= h_max>, <Alldata = n>, <Symbolic>)
```

Description

`numeric::odesolve(f, t_0..t, Y_0)` returns a numerical approximation of the solution $Y(t)$ of the first order differential equation (dynamical system) $\frac{dY}{dt} = f(t, Y)$, $Y(t_0) = Y_0$ with $t, t_0 \in \mathbb{R}$ and $Y(t), Y_0 \in \mathbb{C}^n$.

`numeric::odesolve` is a general purpose solver able to deal with initial value problems of various kinds of ordinary differential equations.

Equations $y^{(p)} = f(t, y, y', \dots, y^{(p-1)})$ of order p can be solved by `numeric::odesolve` after reformulation to dynamical system form. This can always be achieved by writing the equation as a first order system

$$\frac{d}{dt} \begin{pmatrix} Y_1 \\ \dots \\ Y_{p-1} \\ Y_p \end{pmatrix} = \begin{pmatrix} Y_2 \\ \dots \\ Y_p \\ f(t, Y_1, \dots, Y_p) \end{pmatrix}$$

for the vector $Y = [Y_1, \dots, Y_p] = [y, y', \dots, y^{(p-1)}]$. See “Example 4” on page 18-217.

The following single-step Runge-Kutta-type methods are implemented:

- EULER1 (order 1)
- RKF43 (order 3)
- xRKF43 (order 3)

numeric::odesolve

- RKF34 (order 4)
- xRKF34 (order 4)
- RK4 (order 4)
- RKF54a (order 4)
- RKF54b (order 4)
- DOPRI54 (order 4)
- xDOPRI54 (order 4)
- CK54 (order 4)
- xRKF54a (order 4)
- xRKF54b (order 4)
- xCK54 (order 4)
- RKF45a (order 5)
- RKF45b (order 5)
- DOPRI45 (order 5)
- CK45 (order 5)
- xRKF45a (order 5)
- xRKF45b (order 5)
- xDOPRI45 (order 5)
- xCK45 (order 5)
- DOPRI65 (order 5)
- xDOPRI65 (order 5)
- DOPRI56 (order 6)
- xDOPRI56 (order 6)
- BUTCHER6 (order 6)
- RKF87 (order 7)

- xRKF87 (order 7)
- DOPRI87 (order 7)
- xDOPRI87 (order 7)
- RKF78 (order 8)
- xRKF78 (order 8)
- DOPRI78 (order 8)
- xDOPRI78 (order 8)
- GAUSS(s) (order 2s)
- GAUSS = s

For the Gauss methods, GAUSS(s) is equivalent to GAUSS = s. The positive integer s indicates the number of stages. The order of the s stage Gauss method is 2s.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters f , t_0 , Y_0 from a set of differential expressions representing the ODE. See “Example 1” on page 18-215.

The input data t_0 , t and Y_0 must not contain symbolic objects which cannot be converted to floating point values via `float`. Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted.

The vector field f defining the dynamical system $Y' = f(t, Y)$ must be represented by a procedure with two input parameters: the scalar time t and the vector Y . `numeric::odesolve` internally calls this function with real floating-point values t and a list Y of floating-point values. It has to return the vector $f(t, Y)$ either as a list or as a 1-dimensional array. The output of f may contain numerical expressions such as π , e^2 etc. However, all values must be convertible to real or complex floating point numbers by `float`.

Autonomous systems, where $f(t, Y)$ does not depend on t , must also be represented by a procedure with 2 arguments `t` and `Y`.

numeric::odesolve

Scalar functions Y also must be represented by a list or an array with one element. For instance, the input data for the scalar initial value problem $y' = t \sin(y)$, $y(0) = 1$ may be of the form

```
f := proc(t,Y)                               /* Y is a 1-dimensional vector */
local y;                                       /* represented by a list with */
begin                                          /* one element: Y = [y]. */
    y := Y[1];
    [t*sin(y)]                                 /* the output is a list with 1
                                                element */
end_proc:
Y0 := [1]:                                     /* the initial value */
```

The numerical precision is controlled by the global variable DIGITS: an adaptive control of the step size keeps local relative discretization errors below $rtol=10^{-DIGITS}$, unless a different tolerance is specified via the option `RelativeError = rtol`. For small values of the solution vector Y , the absolute discretization error can be bounded by the threshold `atol` specified via the option `AbsoluteError = atol`.

If `AbsoluteError` is not specified, only relative discretization errors are controlled and kept below `rtol`.

The error control may be switched off by specifying a fixed `Stepsize = h`.

Note Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

With `Y := t -> numeric::odesolve(f, t_0..t, Y_0)`, the numerical solution can be represented by a MuPAD function: the call `Y(t)` will start the numerical integration from t_0 to t . A more

sophisticated form of this function may be generated via `Y := numeric::odesolve2(f, t0, Y0)`.

This equips `Y` with a remember mechanism that uses previously computed values to speed up the computation. See “Example 2” on page 18-216.

For systems of the special form $Y' = f(t, Y) Y$ with a matrix valued function $f(t, Y)$, there is a special solver `numeric::odesolveGeometric` which preserves geometric features of the system more faithfully than `numeric::odesolve`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We compute the numerical solution $y(10)$ of the initial value problem

$y' = t \sin(y)$, $y(0) = 2$:

```
f := proc(t, Y) begin [t*sin(Y[1])] end_proc;
numeric::odesolve(f, 0..10, [2])
```

```
[3.141592654]
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] :=
[numeric::ode2vectorfield({y'(t) = t*sin(y(t))}, y(0) = 2), [y(
```

```
[proc f(t, Y) ... end, 0, [2]]
```

```
numeric::odesolve(f, t0..10, Y0)
```

```
[3.141592654]
```

numeric::odesolve

```
delete f, t0, Y0:
```

Example 2

We consider $y' = y$, $y(0) = 1$. The numerical solution may be represented by the function

```
Y := t -> numeric::odesolve((t,Y) -> Y, 0..t, [1]):
```

Calling $Y(t)$ starts the numerical integration:

```
Y(-5), Y(0), Y(1), Y(PI)
```

```
[0.006737946999], [1.0], [2.718281828], [23.14069263]
```

```
delete Y:
```

Example 3

We compute the numerical solution $Y(\pi) = [x(\pi), y(\pi)]$ of the system

$$x' = x + y, y' = x - y, x(0) = 1, y(0) = \sqrt{-1}$$

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]: Y0 := [1, I]:  
numeric::odesolve(f, 0..PI, Y0)
```

```
[72.57057163 + 30.05484302 i, 30.05484302 + 12.46088558 i]
```

The solution of a linear dynamical system $Y' = A Y$ with a constant matrix A is $Y(t) = e^{tA} Y_0$. The solution of the system above can also be computed by:

```
t := PI: tA := array(1..2, 1..2, [[t, t], [t, -t]]):  
numeric::expMatrix(tA, Y0)
```

```
( 72.57057163 + 30.05484303 i
 30.05484303 + 12.46088558 i)
```

```
delete f, Y0, t, tA:
```

Example 4

We compute the numerical solution $y(1)$ of the differential equation $y'' = y^2$ with initial conditions $y(0) = 0$, $y'(0) = 1$. The second order equation is converted to a first order system for the vector $Y = [y, y'] = [y, z]$:

$$y' = z, z' = y^2, y(0) = 0, z(0) = 1$$

```
f := proc(t, Y) begin [Y[2], Y[1]^2] end_proc:
Y0 := [0, 1]:
numeric::odesolve(f, 0..1, Y0)
```

```
[1.087473533, 1.362851121]
```

```
delete f, Y0:
```

Example 5

We demonstrate how numerical data can be obtained on a user defined time mesh $t[i]$. The initial value problem is $y' = \sin(t) - y$, $y(0) = 1$, the sample points are $t_0 = 0.0$, $t_1 = 0.1$, ..., $t_{100} = 10.0$. First, we define the differential equation and the initial condition:

```
f := (t, Y) -> [sin(t) - Y[1]]:
Y[0] := [1]:
```

We define the time mesh:

```
for i from 0 to 100 do t[i] := i/10 end_for:
```

numeric::odesolve

The equation is integrated iteratively from $t[i-1]$ to $t[i]$ with a working precision of 4 significant decimal places:

```
DIGITS := 4:  
for i from 1 to 100 do  
  Y[i] := numeric::odesolve(f, t[i-1]..t[i], Y[i-1])  
end_for:
```

The following mesh data are produced:

```
[t[i], Y[i]] $ i = 0..100
```

```
[0, [1]], [1/10, [0.9097]], [1/5, [0.8374]], [3/10, [0.7813]], [2/5, [0.7397]], ..., [99/10, [0.2159]],  
[10, [0.1476]]
```

$[0, [1]], [\frac{1}{10}, [0.9097]], [\frac{1}{5}, [0.8374]], [\frac{3}{10}, [0.7813]], [\frac{2}{5}, [0.7397]], [\frac{1}{2}, [0.7107]],$

numeric::odesolve

```
plotpoints := [[t[i], op(Y[i])] $ i = 0..100]:  
plot(plot::PointList2d(plotpoints, PointColor = RGB::Black)):
```

The same plot can be obtained directly via `plot::Ode2d`:

```
plot(plot::Ode2d(  
  [t[i] $ i = 0..100], f, Y[0],  
  [(t, Y) -> [t, Y[1]], Style = Points, Color = RGB::Black]))
```

```
delete f, t, DIGITS, Y, plotpoints:
```

Example 6

We compute the numerical solution $y(1)$ of $y' = -y, y(0) = 1$ by the classical 4-th order Runge-Kutta method RK4. By internal local extrapolation, its effective order is 5:

```
f := (t, Y) -> -Y:
DIGITS := 13:
numeric::odesolve(f, 0..1, [1], RK4)
```

```
[2.718281828459]
```

Next, we use local extrapolation xRK78 of the 8-th order submethod of the Runge-Kutta-Fehlberg pair RK78. This scheme has effective order 9:

numeric::odesolve

```
numeric::odesolve(f, 0..1, [1], xRK78)
```

```
[2.718281828459]
```

Both methods yield the same result because of the internal adaptive error control. However, due to its higher order, the method xRK78 is faster.

```
delete f, DIGITS:
```

Example 7

We consider the stiff ODE $y' = 10^4 (\cos(t) - y)$, $y(0) = 1$. The default method DOPRI78 is explicit and not very efficient in solving very stiff problems:

```
f := (t, Y) -> [10^4*(cos(t) - Y[1])]:  
t0 := time():  
numeric::odesolve(f, 0..1, [1]), (time() - t0)*msec
```

```
[0.5403864476], 16065.004 msec
```

We use the implicit A-stable method GAUSS(6). For this stiff problem, it is more efficient than the default method DOPRI78:

```
t0 := time():  
numeric::odesolve(f, 0..1, [1], GAUSS(6)), (time() - t0)*msec
```

```
[0.5403864476], 796.05 msec
```

```
delete t0:
```

Example 8

We consider the initial value problem $y' = -10^{20} y (1 - \cos(y))$, $y(0) = 1$. We note that the numerical evaluation of the right hand side of the equation suffers from cancellation effects, when $|y|$ is small.

```
f := (t, Y) -> [-10^20*Y[1]*(1 - cos(Y[1]))]:
Y0 := [1]:
```

We first attempt to compute $y(1)$ with a working precision of 6 digits using the default setting `RelativeError = 10^-DIGITS=10^-6`:

```
DIGITS := 6: numeric::odesolve(f, 0..1, Y0)
```

```
[0.000000000329271]
```

Due to numerical round-off in the internal steps, no digit of this result is correct. Next, we use a working precision of 20 significant decimal places to eliminate roundoff effects:

```
DIGITS := 20:
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^(-6))
```

```
[0.00000000010000000007495004558]
```

Since relative local discretization errors are of the magnitude 10^{-6} , not all displayed digits are trustworthy. We finally use a working precision of 20 digits and constrain the local relative discretization errors by the tolerance 10^{-10} :

```
numeric::odesolve(f, 0..1, Y0, RelativeError = 10^(-10))
```

```
[0.0000000001000000000003105061]
```

```
delete f, Y0, DIGITS:
```

Example 9

We compute the numerical solution $y(1)$ of $y' = y$, $y(0) = 1$ with various methods and various constant step sizes. We compare the result with the exact solution $y(1) = e = 2.718281828\dots$

```
f := (t, Y) -> Y:  
Y0 := [1]:
```

We first use the Euler method of order 1 with two different step sizes:

```
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.1):  
Y, globalerror = float(exp(1)) - Y[1]  
  
[2.59374246], globalerror = 0.1245393684
```

Decreasing the step size by a factor of 10 should reduce the global error by a factor of 10. Indeed:

```
Y := numeric::odesolve(f, 0..1, Y0, EULER1, Stepsize = 0.01):  
Y, globalerror = float(exp(1)) - Y[1]  
  
[2.704813829], globalerror = 0.01346799904
```

Next, we use the classical Runge-Kutta method of order 4 with two different step sizes:

```
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.1):  
Y, globalerror = float(exp(1)) - Y[1]  
  
[2.718279744], globalerror = 0.00000208432388
```

Decreasing the step size by a factor of 10 in a 4-th order scheme should reduce the global error by a factor of 10^4 . Indeed:

```
Y := numeric::odesolve(f, 0..1, Y0, RK4, Stepsize = 0.01):
Y, globalerror = float(exp(1)) - Y[1]
```

```
[2.718281828], globalerror = 0.0000000002246438591
```

```
delete f, Y0, Y:
```

Example 10

We integrate $y' = y^2$, $y(0) = 1$ over the interval t $[0, 0.99]$ with a

working precision of 4 digits. The exact solution is $y(t) = \frac{1}{1-t}$. Note the singularity at $t = 1$.

```
DIGITS := 4:
f := (t, Y) -> [Y[1]^2]:
Y0 := [1]:
```

The option `Alldata`, equivalent to `Alldata = 1`, yields all mesh data generated during the internal adaptive process:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata)
```

```
[[0.0, [1.0]], [0.4933, [1.974]], [0.74, [3.846]], [0.8633, [7.314]], [0.9249, [13.32]],
 [0.9558, [22.61]], [0.9712, [34.71]], [0.9866, [74.68]], [0.99, [99.97]]]
```

With `Alldata = 2`, only each second point is returned:

```
numeric::odesolve(f, 0..0.99, Y0, Alldata = 2)
```

```
[[0.0, [1.0]], [0.74, [3.846]], [0.9249, [13.32]], [0.9712, [34.71]], [0.99, [99.97]]]
```

One can control the time mesh using the option `Stepsize = h`:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize=0.1, Alldata = 1)
```

numeric::odesolve

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]],  
 [0.7, [3.333]], [0.8, [5.0]], [0.9, [10.0]], [0.99, [94.3]]]
```

However, with the option `Stepsize = h`, no automatic error control is provided by `numeric::odesolve`. Note the poor approximation $y(t) = 94.3$ for $t = 0.99$ (the exact value is $y(0.99) = 100.0$). The next computation with smaller step size yields better results:

```
numeric::odesolve(f, 0..0.99, Y0, Stepsize = 0.01, Alldata = 10)
```

```
[[0.0, [1.0]], [0.1, [1.111]], [0.2, [1.25]], [0.3, [1.429]], [0.4, [1.667]], [0.5, [2.0]], [0.6, [2.5]],  
 [0.7, [3.333]], [0.8, [5.0]], [0.9, [10.0]], [0.99, [100.0]]]
```

“Example 5” on page 18-217 demonstrates how accurate numerical data on a user defined time mesh can be generated using the automatic error control of `numeric::odesolve`.

```
delete DIGITS, f, Y0:
```

Example 11

The second order equation $y'' + \sin(y) = 0$ is written as the dynamical system $y' = z$, $z' = -\sin(y)$ for the vector $Y = [y, z]$. A single symbolic step

$$[y(t_0), z(t_0)] \rightarrow [y(t_0 + h), z(t_0 + h)]$$

of the Euler method is computed:

```
f := proc(t, Y) begin [Y[2], -sin(Y[1])] end_proc:  
numeric::odesolve(f, t0..t0+h, [y0, z0], EULER1, Symbolic)
```

```
[y0 + h z0, z0 - h sin(y0)]
```

```
delete f:
```

Parameters

f

A procedure representing the vector field

t₀

A numerical real value for the initial time

t

A numerical real value (the “time”)

Y₀

A list or 1-dimensional array of numerical values representing the initial condition

method

One of the Runge-Kutta schemes listed below.

Options

BUTCHER6, CK45, CK54, DOPRI45, DOPRI54, DOPRI56, DOPRI65, DOPRI78, DOPRI87, EULER1, RK4, RKF34, RKF43, RKF45a, RKF45b, RKF54a, RKF54b, RKF78, RKF87, xCK45, xCK54, xDOPRI45, xDOPRI54, xDOPRI56, xDOPRI65, xDOPRI78, xDOPRI87, xRKF34, xRKF43, xRKF45a, xRKF45b, xRKF54a, xRKF54b, xRKF78, xRKF87

Name of the Runge-Kutta scheme. See “Example 6” on page 18-221. For details on these schemes, see the Algorithms section.

GAUSS

Name of the Runge-Kutta scheme specified as GAUSS(s) or GAUSS = s.

The methods GAUSS(s) or, equivalently, GAUSS = s are the implicit Gauss methods with s stages of order 2s.

These methods are implicit A-stable schemes. The time steps are rather costly to compute. The Gauss methods are useful for integrating stiff ODEs. For non-stiff ODEs, there is usually no need to change the default method DOPRI78. This method is an embedded Runge-Kutta pair of orders 7 and 8.

Further, the Gauss methods are symplectic methods. When used with constant step size (`Stepsize = h`), numerical integration of Hamiltonian systems benefits from this property.

See “Example 7” on page 18-222.

RelativeError, AbsoluteError

Option specified as `RelativeError = rtol` forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance must be a positive

numerical real value not smaller than $\frac{1}{10^{\text{DIGITS}}}$. The default tolerance is `RelativeError = 10(-DIGITS)`.

Option specified as `AbsoluteError = atol` forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a nonnegative numerical real value. The default tolerance is `AbsoluteError = 10(-10*DIGITS)`.

The internal control mechanism estimates the local discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below the specified tolerances `rtol` or `atol`, respectively. The code uses the criterion

$$\|\text{discretization error}\|_{\infty} = \max(\|Y\|_{\infty} \text{rtol}, \text{atol})$$

For accepting a solution vector Y . Roughly speaking, the relative error is controlled when the solution Y is sufficiently large. For very small solution values Y , absolute discretization errors are kept below the threshold `atol`.

Specify `AbsoluteError = 0` if only control of the relative discretization errors is desired.

The error control may be switched off by specifying a fixed `Stepsize = h`.

The default setting of $\text{rtol} = \frac{1}{10^{\text{DIGITS}}}$, $\text{atol} = \frac{1}{10^{\text{DIGITS}}}$ ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use these options to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case these options may be used to bound the local discretization errors and use a higher working precision given by DIGITS.

Only positive real numerical values $\text{rtol} \geq \frac{1}{10^{\text{DIGITS}}}$ are accepted.

Note The global error of the result returned by `numeric::odesolve` is usually larger than the local errors bounded by `rtol`, `atol`, respectively. Although the result is displayed with DIGITS decimal places one should not expect that all of them are correct. The relative precision of the final result is `rtol` at best!

See “Example 8” on page 18-223.

Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h` which must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified (or the default method `DOPRI78`) with constant step size `h`.

A final step with smaller step size is used to match the end t of the integration interval $t_0 . . t$ if $\frac{t-t_0}{h}$ is not an integer.

Note With this option, there is no automatic error control! Depending on the problem and on the order of the method the result may be a poor numerical approximation of the exact solution.

There is usually no need to invoke this option. However, occasionally the built-in adaptive error control mechanism may fail when integrating close to a singularity. In such a case this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Cf. “Example 9” on page 18-224.

MaxStepsize

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than h_{\max} ; h_{\max} must be a positive numerical value.

By default, `numeric::odesolve` uses an adaptive step size control mechanism in the numerical iteration. The option `MaxStepsize = h_{\max}` restricts the adaptive step size to values no larger than h_{\max} .

If a larger stepsize h is requested explicitly by `Stepsize = h` , the option `MaxStepsize = h_{\max}` reduces h to h_{\max} .

Alldata

Option, specified as `Alldata = n`

Makes `numeric::odesolve` return a list of numerical mesh points generated by the internal Runge-Kutta iteration. The integer n controls the size of the output list.

With this option, `numeric::odesolve` returns a list of numerical mesh points $[[t_0, Y_0], [t_1, Y_1], \dots, [t, Y(t)]]$ generated by the internal Runge-Kutta iteration.

The integer `n` controls the size of the output list. For $n = 1$, all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For $n > 1$, only each n -th mesh point is stored in the list. The list always contains the initial point $[t_0, Y_0]$ and the final point $[t, Y(t)]$. For $n \leq 0$, only the data $[[t_0, Y_0], [t, Y(t)]]$ are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Cf. “Example 10” on page 18-225.

Symbolic

Makes `numeric::odesolve` return a vector of symbolic expressions representing a single symbolic step of the Runge-Kutta iteration.

The call `numeric::odesolve(f, t_0..t, Y_0, < method >, Symbolic)` returns a vector (list or array) of expressions representing a single step of the numerical scheme with step size $t - t_0$. In this mode symbolic values for t_0 , t and the components of Y_0 are accepted.

This option may be useful if the specified numerical method applied to a given differential equation is to be investigated symbolically.

Cf. “Example 11” on page 18-226.

Return Values

The solution vector $Y(t)$ is returned as a list or as a 1-dimensional array of floating-point values. The type of the result vector coincides with the type of the input vector Y_0 .

With the option `Alldata`, a list of mesh data is returned.

Algorithms

All methods presently implemented are adaptive versions of Runge-Kutta type single step schemes.

The methods RKF43, RKF34, RKF54a, RKF54b, RKF45a, RKF45b, RKF87, RKF78, DOPRI54, DOPRI45, DOPRI65, DOPRI56, DOPRI87, DOPRI78, CK54, CK45 are embedded pairs of Runge-Kutta-Fehlberg, Dormand-Prince and Cash-Karp type, respectively. Estimates of the local discretization error are obtained in the usual way by comparing the results of the two submethods of the pair. The names indicate the orders of the subprocesses. For instance, RKF34 and RKF43 denote the same embedded Runge-Kutta-Fehlberg pair with orders 3 and 4. In RKF34 the result of the fourth order submethod is accepted, whereas RKF43 advances using the result of the third order submethod. In both cases the discretization error of the lower order subprocess is estimated and controlled.

For the single methods EULER1 (the first order Euler scheme), RK4 (the classical fourth order Runge-Kutta scheme) and BUTCHER6 (a Runge-Kutta scheme of order 6), the relative local error is controlled by comparing steps with different step sizes. The effective order of these methods is increased by one through local extrapolation.

Local extrapolation is also available for the submethods of the embedded pairs. For instance, the method xRKF78 uses extrapolation of the 8-th order subprocess of RKF78, yielding a method of effective order 9. The 7-th order subprocess is ignored. The cheap error estimate based on the embedded pair is not used implying some loss of efficiency when comparing RKF78 (order 8) and xRKF78 (effective order 9).

The call `numeric::butcher(method)` returns the Butcher data of the methods used in `numeric::odesolve`. Here `method` is one of EULER1, RKF43, RK4, RKF34, RKF54a, RKF54b, DOPRI54, CK54, RKF45a, RKF45b, DOPRI45, CK45, DOPRI65, DOPRI56, BUTCHER6, RKF87, DOPRI87, RKF78, DOPRI78.

Note Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

Note The run time of the numerical integration with a method of order

p grows like $O\left(10^{\frac{\text{DIGITS}}{p+1}}\right)$, when DIGITS is increased. Computations with high precision goals are very expensive! High order methods such as the default method DOPRI78 should be used.

Presently, only single step methods of Runge-Kutta type are implemented. Stiff problems cannot be handled efficiently with explicit methods such as the default method DOPRI78. For stiff problems, one may use one of the implicit A-stable methods GAUSS(s). See “Example 7” on page 18-222.

For problems of the special type $Y' = f(t, Y) Y$ with a matrix valued function $f(t, Y)$, there is a specialized (“geometric”) integration routine `numeric::odesolveGeometric`. Generally, `numeric::odesolve` is faster than the geometric integrator. However, `odesolveGeometric` preserves certain invariants of the system more faithfully.

Concepts

- “Solve Equations Numerically”

numeric::odesolve2

Purpose

Numerical solution of an ordinary differential equation

Syntax

```
numeric::odesolve2(f, t0, Y0, <method>, <RememberLast>,
<RelativeError = rtol>, <AbsoluteError = atol>,
<Stepsize = h>, <MaxStepsize = hmax>)
```

Description

`numeric::odesolve2(f, t0, Y0,)` returns a function representing the numerical solution $Y(t)$ of the first order differential equation

(dynamical system) $\frac{dY}{dt} = f(t, Y)$, $Y(t_0) = Y_0$ with $t, t_0 \in \mathbb{R}$ and $Y(t), Y_0 \in \mathbb{C}^n$.

The utility function `numeric::ode2vectorfield` may be used to produce the input parameters `f`, `t0`, `Y0` from a set of differential expressions representing the ODE. Cf. “Example 1” on page 18-235.

The function generated by `Y := numeric::odesolve2(f, t0, Y0)` is essentially

```
Y := t -> numeric::odesolve(t_0..t, f, Y_0).
```

Numerical integration is launched, when `Y` is called with a real numerical argument. The call `Y(t)` returns the solution vector in a format corresponding to the type of the initial condition Y_0 with which `Y` was defined: `Y(t)` either yields a list or a 1-dimensional array.

If `t` is not a real numerical value, then `Y(t)` returns a symbolic function call.

See the help page of `numeric::odesolve` for details on the parameters and the options.

The options `Alldata = n` and `Symbolic` accepted by `numeric::odesolve` have no effect: `numeric::odesolve2` ignores these options.

Note Without `RememberLast`, the function `Y` remembers all values it has computed. When calling `Y(T)`, it searches its remember table for the time $t_0 < T < t$ closest to t , and integrates from T to t using the previously computed `Y(T)` as initial value. Here, t_0 is the time for which the initial value of the ODE is given. This reduces the costs of a call considerably, if `Y` must be evaluated many times, for example, when plotting the ODE solution. The best approach is to call `Y` only with a monotonically increasing (or decreasing) sequence of values t starting from t_0 . Further, the function must be re-initialized whenever `DIGITS` is increased. See “Example 3” on page 18-238.

Environment Interactions

The function returned by `numeric::odesolve2` is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Without `RememberLast`, the function returned by `numeric::odesolve2` uses option `remember`.

Examples

Example 1

The numerical solution of the initial value problem $y' = t \sin(y)$, $y(0) = 2$ is represented by the following function `Y = [y]`:

```
f := (t, Y) -> [t*sin(Y[1])]:
```

Alternatively, the utility function `numeric::ode2vectorfield` can be used to generate the input parameters in a more intuitive way:

```
[f, t0, Y0] :=  
  [numeric::ode2vectorfield({y'(t) = t*sin(y(t)), y(0) = 2}, [y(
```

```
  [proc f(t, Y) ... end, 0, [2]]
```

```
Y := numeric::odesolve2(f, t0, Y0)
```

numeric::odesolve2

```
proc Y(t) ... end
```

The procedure `Y` starts the numerical integration when called with a numerical argument:

```
Y(-2), Y(0), Y(0.1), Y(PI + sqrt(2))
```

```
[2.968232567], [2.0], [2.004541745], [3.141552691]
```

Calling `Y` with a symbolic argument yields a symbolic call:

```
Y(t), Y(t + 5), Y(t^2 - 4)
```

```
Y(t), Y(t+5), Y(t2 - 4)
```

```
eval(subs(%, t = PI))
```

```
[3.132357009], [3.141592654], [3.141592611]
```

The numerical solution can be plotted. Note that `Y(t)` returns a list, so we plot the list element `Y(t)[1]`:

```
plotfunc2d(Y(t)[1], t = -5..5):
```

delete f, t0, Y0, Y:

Example 2

We consider the differential equation $y'' = y^2$ with initial conditions $y(0) = 0$, $y'(0) = 1$. The second order equation is converted to a first order system for $Y = [Y_1, Y_2] = [y, y']$:

$$Y_1' = Y_2, Y_2' = Y_1^2, Y_1(0) = 0, Y_2(0) = 1$$

```
f := (t, Y) -> [Y[2], Y[1]^2]:
t0 := 0: Y0 := [0, 1]:
Y := numeric::odesolve2(f, t0, Y0):
Y(1), Y(PI)
```

numeric::odesolve2

```
[1.087473533, 1.362851121], [1274.867469, 37166.52262]
```

```
delete f, t0, Y0, Y:
```

Example 3

We consider the system

$$x' = x + y, y' = x - y, x(0) = 1, y(0) = \sqrt{-1}.$$

```
f := (t, Y) -> [Y[1] + Y[2], Y[1] - Y[2]]:  
Y := numeric::odesolve2(f, 0, [1, I]):  
DIGITS := 5:  
Y(1)
```

```
[3.5465 + 1.3683 i, 1.3683 + 0.80988 i]
```

Increasing DIGITS does not lead to a more accurate result because of the remember mechanism:

```
DIGITS := 15: Y(1)
```

```
[3.54648112716477 + 1.36829878277279 i, 1.36829878277279 + 0.809883561619181 i]
```

This is the previous value computed with 5 digits, printed with 15 digits. Indeed, only 5 digits are correct. For getting a result that is accurate to full precision, one has to erase the remember table via `Y:=subsop(Y,5=NIL)`. Alternatively, one may create a new numerical solution with a fresh (empty) remember table:

```
Y := numeric::odesolve2(f, 0, [1, I]):  
Y(1)
```

```
[3.54648242861716 + 1.36829887200859 i, 1.36829887200859 + 0.80988468459998 i]
```

```
delete f, Y, DIGITS:
```

Example 4

We demonstrate the effect of the option `RememberLast`. We consider the ODE

$$y'(t) = -y + \sin(t), y(0) = 1.$$

```
f := (t, Y) -> [-Y[1] + sin(t)]:
Y := numeric::odesolve2(f, 0, [1]):
Z := numeric::odesolve2(f, 0, [1], RememberLast):
```

After many calls of `Y`, its remember table has grown large. In each call, searching the remember table for input parameters close to the present time value becomes expensive. Created with `RememberLast`, the procedure `Z` does not remember all its previously computed values apart from the last one. Consequently, it becomes faster than `Y`:

```
time(for i from 1 to 1000 do Y(i/100) end)*msec,
time(for i from 1 to 1000 do Z(i/100) end)*msec
```

```
11592.724 msec, 4352.272 msec
```

Apart from the efficiency, the values returned by `Y` and `Z` coincide:

```
Y(10.5), Z(10.5)
```

```
[-0.2020381113], [-0.2020381113]
```

```
delete f, Y, Z, i:
```

Parameters

f

A procedure representing the vector field of the dynamical system

t₀

numeric::odesolve2

A numerical real value for the initial time

Y_0

A list or 1-dimensional array of numerical values representing the initial value

method

One of the Runge-Kutta schemes listed below.

Options

BUTCHER6, CK45, CK54, DOPRI45, DOPRI54, DOPRI56, DOPRI65, DOPRI78, DOPRI87, EULER1, GAUSS, RK4, RKF34, RKF43, RKF45a, RKF45b, RKF54a, RKF54b, RKF78, RKF87, xCK45, xCK54, xDOPRI45, xDOPRI54, xDOPRI56, xDOPRI65, xDOPRI78, xDOPRI87, xRKF34, xRKF43, xRKF45a, xRKF45b, xRKF54a, xRKF54b, xRKF78, xRKF87

Option, specified as `GAUSS = s`

Name of the Runge-Kutta scheme. For details, see the documentation of `numeric::odesolve`.

RememberLast

Modifies the internal remember mechanism: the procedure returned by `numeric::odesolve2` does not remember the results of all previous calls, but only the result of the last call.

Without this option, the procedure returned by `numeric::odesolve2` employs option `remember` to remember the results of all preceding calls. If the function is called very often (hundreds or thousands of times), the `remember` table grows large and searching this table for entries close to the current time value may become costly. With `RememberLast`, the procedure returned by `numeric::odesolve2` does not use option `remember` to remember *all* previous results but implements a very simple and inexpensive mechanism to remember only the result of the very last call.

This option is highly recommended when the numerical procedure returned by `numeric::odesolve2` is to be called often (hundreds

of thousands of times) with monotonically increasing or decreasing time values. Cf. “Example 4” on page 18-239.

RelativeError

Option, specified as `RelativeError = rtol`

Forces internal numerical Runge-Kutta steps to use step sizes with relative local discretization errors below `rtol`. This tolerance

must be a positive numerical real value not smaller than $\frac{1}{10^{\text{DIGITS}}}$. The default tolerance is `RelativeError = 10-(DIGITS)`. See the help page of `numeric::odesolve` for further details.

AbsoluteError

Option, specified as `AbsoluteError = atol`

Forces internal numerical Runge-Kutta steps to use step sizes with absolute local discretization errors below `atol`. This tolerance must be a non-negative numerical real value. The default tolerance is `AbsoluteError = 10(-10*DIGITS)`. See the help page of `numeric::odesolve` for further details.

Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size `h`. `h` must be a positive real value. See the help page of `numeric::odesolve` for further details.

MaxStepsize

Option, specified as `MaxStepsize = hmax`

Restricts adaptive step sizes to values not larger than h_{\max} ; h_{\max} must be a positive numerical value. See the help page of `numeric::odesolve` for further details.

Return Values

Procedure.

Concepts

- “Solve Equations Numerically”

Purpose

Numerical solution of an ordinary differential equation on a homogeneous manifold

Syntax

```
numeric::odesolveGeometric(f, t_0 .. t, Y_0, <LieGroupAction =
LAMBDA>, <method>, <RelativeError = tol>, <Stepsize
= h>, <Alldata = n>)
numeric::odesolveGeometric(t_0 .. t, f, Y_0, <LieGroupAction =
LAMBDA>, <method>, <RelativeError = tol>, <Stepsize
= h>, <Alldata = n>)
```

Description

`numeric::odesolveGeometric(f, t_0..t, Y_0)` approximates the solution of $\frac{dY(t)}{dt} = f(t, Y(t)) Y(t)$, where $f(t, Y(t))$ returns $n \times n$ matrices and $Y \in \mathbb{C}^{n \times m}$.

`numeric::odesolveGeometric` is a “geometrical integrator” for ordinary differential equations on homogeneous manifolds embedded in the space of $n \times m$ matrices.

The call `numeric::odesolveGeometric(f, t_0..t, Y_0)` returns a numerical approximation of the solution $Y(t)$ of the first order differential equation (dynamical system)

$$\frac{dY(t)}{dt} = f(t, Y(t)) Y(t), Y(t_0) = Y_0$$

with $t, t_0 \in \mathbb{R}$. Here, $Y(t)$ is a curve of $n \times m$ matrices (or vectors in \mathbb{R}^n or \mathbb{C}^n). The function f must produce $n \times n$ matrices as return values.

The following geometrical feature is preserved by the numerical solution: If the matrices produced by f lie in some Lie subalgebra g of the $n \times n$ matrices, then, within the numerical working precision, the approximation produced by `numeric::odesolveGeometric` stays on the homogeneous manifold $\{m Y_0 \mid m \in G\}$, where G is the matrix Lie group of g .

numeric::odesolveGeometric

As an introductory example, consider the ODE $\frac{dY}{dt} = f(t, Y) Y$, where Y is a vector in \mathbb{R}^n and f produces skew symmetric matrices. The solution lies on the orbit of the orthogonal group $SO(n)$ generated by the skew symmetric matrices through the initial point $Y_0 \in \mathbb{R}^n$. Here, $SO(n)$ acts on \mathbb{R}^n by standard matrix multiplication. The homogeneous manifold given by the orbit of $SO(n)$ through Y_0 is the sphere

$$\{G Y_0 \mid G \in SO(n)\} = \{Y \in \mathbb{R}^n \mid \langle Y, Y \rangle = \langle Y_0, Y_0 \rangle\}$$

Using standard numerical schemes, the numerical solution drifts away from this manifold in the course of the integration. The geometrical “Lie group” integrator `numeric::odesolveGeometric`, however, produces a numerical solution that stays on this manifold, preserving the invariants of the group action. In this case, the invariant $\langle Y, Y \rangle$ is preserved numerically. See “Example 1” on page 18-247.

With $Y(t) = G(t)Y_0$, the matrix ODE

$$\frac{dG(t)}{dt} = f(t, G(t) Y_0) G(t), \quad G(t_0) = 1_{n,n}$$

is solved on the space $\mathbb{C}^{n \times n}$ of the complex $n \times n$ matrices ($1_{n,n}$ is the identity matrix). Following Munthe-Kaas [1], the ansatz $G(t) = e^{u(t)}$ reduces a time step for the ode above to the solution of the matrix ODE

$$\frac{du}{dt} = \text{dexpinv}(u, f) = f - \frac{[u, f]}{2} + \frac{[u, [u, f]]}{12} + \dots, \quad u(t_0) = 0$$

where $f = f(t, e^{u(t)} Y_0)$ and $[u, f] = uf - fu$ is the commutator on the Lie algebra of $n \times n$ matrices. In each step, the ODE for u is solved numerically in a classical way by the Runge-Kutta scheme specified by the parameter `method`. Finally,

`numeric::odesolveGeometric` performs the time step $t_0 \rightarrow t_0 + h$ by computing $Y(t_0 + h) = G(t_0 + h) Y_0 = e^{u(h)} Y_0$.

If the matrices produced by $f(t, Y)$ lie in a Lie subalgebra g of the $n \times n$ matrices, then the numerical solution u also lies in g . The matrix $G = e^u$ is an element of the corresponding Lie group, and $Y = GY_0$ lies on the orbit of the Lie group through the initial value Y_0 . Thus, the geometrical invariants of the homogeneous manifold are preserved in the course of the numerical integration.

The input data t_0 and t must not contain symbolic objects which cannot be converted to floating point values via `float`. Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted.

The initial condition Y_0 defines the space in which the homogeneous manifold containing the solution is embedded.

If Y_0 is a list with n entries or a 1-dimensional array `array(1..n)`, then the solution $Y(t)$ consists of vectors from a submanifold of \mathbb{R}^n or \mathbb{C}^n , respectively.

If Y_0 is specified as a 2-dimensional array `array(1..n, 1..m)` or as a matrix of the corresponding dimension generated by the function `matrix`, then the solution $Y(t)$ consists of matrices from a submanifold of the space $\mathbb{C}^{n \times m}$ of $n \times m$ matrices.

Internally, 2-dimensional $n \times m$ arrays are used to represent the points on the manifold where $m = 1$ for vectors in \mathbb{R}^n or \mathbb{C}^n . It is recommended to specify Y_0 in the form `array(1..n, 1..m)` in order to avoid the overhead of internal conversions.

The “vector field” f defining the dynamical system $\frac{dY}{dt} = f(t, Y) Y$ must be represented by a procedure with two input parameters: the scalar time t and the matrix or vector Y . Internally, f is called with real floating-point values t and matrices/vectors Y of the same domain type as the initial condition Y_0 .

numeric::odesolveGeometric

The procedure `f` has to return an $n \times n$ matrix either as an array `(1..n, 1..n)` or as a corresponding matrix object of category `Cat::Matrix` (generated by the function `matrix`).

It is recommended that the procedure returns an array of the type `array(1..n, 1..n)`. This avoids the overhead of internal conversions.

The return value of `f` may contain numerical expressions such as π , $\sqrt{2}$ etc. However, all values must be convertible to real or complex floating point numbers by `float`.

Autonomous systems, where $f(t, Y)$ does not depend on t , must be represented by a procedure with two arguments `t` and `Y`, too.

The optional arguments `method`, `RelativeError = tol`, and

`Stepsize = h` determine how the ODE $\frac{du}{dt} = \text{dexpinv}(u, f)$ is solved. They correspond to the methods of the classical ODE solver `numeric::odesolve`.

The numerical precision is controlled by the global variable `DIGITS`: an adaptive control of the step size keeps local relative discretization

errors below $\text{tol} = \frac{1}{\text{DIGITS}}$, unless a different tolerance is specified via the option `RelativeError = tol`. The error control may be switched off by specifying a fixed `Stepsize = h`.

Note Only local errors are controlled by the adaptive mechanism. No control of the global error is provided!

With `Y := t -> numeric::odesolveGeometric(f, t_0..t, Y_0)`, the numerical solution can be represented by a MuPAD function: the call `Y(t)` will start the numerical integration from t_0 to t .

Classical integration preserves the geometrical invariants up to the relative precision of the solution whereas the geometrical integrator preserves the invariants independent of `tol` up to the working precision

set by DIGITS: departure from the homogeneous manifold is a pure roundoff effect.

numeric::odesolveGeometric is useful when a tolerance *tol* much larger than $\frac{1}{\text{DIGITS}}$ is specified by RelativeError = *tol*. For small tolerances, you may consider to use the classical solver numeric::odesolve instead.

Since classical integration is significantly faster, larger values of DIGITS and smaller tolerances for the discretization error may be used in numeric::odesolve. Depending on the concrete problem, this may lead to better results than produced by numeric::odesolveGeometric.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We consider the initial value problem

$$\frac{dY}{dt} = \begin{pmatrix} (J_2 - J_3) Y_2 Y_3 \\ (J_3 - J_1) Y_3 Y_1 \\ (J_1 - J_2) Y_1 Y_2 \end{pmatrix}, Y(0) = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$$

for $Y = [Y_1, Y_2, Y_3] \in \mathbb{R}^3$ with fixed parameters $J_1 = \frac{1}{2}$, $J_2 = 1$, $J_3 = 2$. Writing this ODE as

$$\frac{dY}{dt} = \begin{pmatrix} 0 & -J_3 Y_3 & J_2 Y_2 \\ J_3 Y_3 & 0 & -J_1 Y_1 \\ -J_2 Y_2 & J_1 Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_1(t, Y) Y$$

numeric::odesolveGeometric

it is clear that the solution is restricted to the orbit of the orthogonal group $SO(3)$ through the initial point (f_1 produces skew symmetric matrices). The invariant of this action is

$H_1(Y) = \langle Y, Y \rangle = Y_1^2 + Y_2^2 + Y_3^2$, i.e., the solution is restricted to a sphere. Writing the ODE as

$$\frac{dY}{dt} = \begin{pmatrix} 0 & J_2 Y_3 & -J_3 Y_2 \\ -J_1 Y_3 & 0 & J_3 Y_1 \\ J_1 Y_2 & -J_2 Y_1 & 0 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix} = f_2(t, Y) Y$$

$$= \begin{pmatrix} 0 & Y_3 & -Y_2 \\ -Y_3 & 0 & Y_1 \\ Y_2 & -Y_1 & 0 \end{pmatrix} \begin{pmatrix} J_1 & 0 & 0 \\ 0 & J_2 & 0 \\ 0 & 0 & J_3 \end{pmatrix} \begin{pmatrix} Y_1 \\ Y_2 \\ Y_3 \end{pmatrix}$$

it is clear that the solution is also restricted to the orbit of the “J-orthogonal” group $SO(J, 3)$ through the initial point. This group consists of matrices G satisfying $G^T J G = J$, where $J = \text{diag}(J_1, J_2, J_3)$. The invariant of this group action is

$H_2(Y) = \langle Y, J Y \rangle = J_1 Y_1^2 + J_2 Y_2^2 + J_3 Y_3^2$, i.e., the solution is restricted to an ellipsoid.

We consider the first representation and compute a numerical solution that is restricted to a sphere:

```
f1 := proc(t, Y) begin
    array(1..3, 1..3, [ [ 0      , -J3*Y[3],  J2*Y[2]],
                       [ J3*Y[3],  0      , -J1*Y[1]],
                       [-J2*Y[2],  J1*Y[1],  0      ]])
end_proc:
J1 := 1/2: J2 := 1: J3 := 2:
tol := 10^(-2):
```

```
Gsolve:= (f, t0_t, Y0) ->
  numeric::odesolveGeometric(f, t0_t, Y0, RelativeError = tol):

Y(0) := [1.0, 1.0, 1.0];
Y(1) := Gsolve(f1, 0..1, Y(0));
Y(2) := Gsolve(f1, 1..2, Y(1));
Y(3) := Gsolve(f1, 2..3, Y(2));
Y(4) := Gsolve(f1, 3..4, Y(3));
Y(5) := Gsolve(f1, 4..5, Y(4))
```

```
[1.0, 1.0, 1.0]
```

```
[-0.1234874253, 1.573899124, 0.7124551935]
```

```
[-1.188837997, 0.6164504304, 1.098477621]
```

```
[-0.7811791671, -1.258922776, 0.8971468953]
```

```
[0.3530511101, -1.520952843, 0.7497048516]
```

```
[1.281782142, -0.1892246302, 1.149447075]
```

The invariant H_1 is preserved numerically up to the working precision set by DIGITS:

```
H1 := Y -> Y[1]^2 + Y[2]^2 + Y[3]^2:
H1(Y(i)) - H1(Y(0)) $ i = 1..5
```

```
3.045480534 10-14, -2.691596945 10-14, 4.011374566 10-14, 3.491859579 10-13,
```

```
2.851746617 10-13
```

numeric::odesolveGeometric

The invariant H_2 is only preserved within the relative precision of the solution set by the option `RelativeError = tol`:

```
H2 := Y -> J1*Y[1]^2 + J2*Y[2]^2 + J3*Y[3]^2:  
H2(Y(i)) - H2(Y(0)) $ i = 1..5
```

```
-0.00003216929769, -0.00001480619998, -0.0002478937317, -0.0002651787298,  
-0.0002541517488
```

Now, we solve the ODE using the second representation:

```
f2 := proc(t, Y) begin  
    array(1..3, 1..3, [ [ 0, J2*Y[3], -J3*Y[2]],  
                        [-J1*Y[3], 0, J3*Y[1]],  
                        [ J1*Y[2], -J2*Y[1], 0 ]])  
end_proc:
```

```
Y(0) := [1.0, 1.0, 1.0];  
Y(1) := Gsolve(f2, 0..1, Y(0));  
Y(2) := Gsolve(f2, 1..2, Y(1));  
Y(3) := Gsolve(f2, 2..3, Y(2));  
Y(4) := Gsolve(f2, 3..4, Y(3));  
Y(5) := Gsolve(f2, 4..5, Y(4))
```

```
[1.0, 1.0, 1.0]
```

```
[-0.1234661822, 1.573904531, 0.7124614294]
```

```
[-1.188842584, 0.6165012417, 1.098465492]
```

```
[-0.7810696492, -1.258800682, 0.8973254548]
```

```
[0.3534089311, -1.520647212, 0.7500610376]
```

[1.28178089, -0.1880404787, 1.149599855]

Now, the invariant H_2 is preserved to working precision, whilst H_1 is only preserved to the tolerance specified by `RelativeError = tol`:

$H_2(Y(i)) - H_2(Y(0)) \text{ \$ } i = 1..5$

2.70894418 10⁻¹⁴, 5.287437155 10⁻¹⁵, 2.071884331 10⁻¹³, 1.704608676 10⁻¹³,
2.268046861 10⁻¹³

$H_1(Y(i)) - H_1(Y(0)) \text{ \$ } i = 1..5$

0.0000206606336, 0.00004690748333, -0.0001580733145, -0.0001426238818,
-0.0000987012679

`delete J1, J2, J3, Gsolve, f1, f2, Y, H1, H2:`

Example 2

We consider the “Toda lattice equations”

$$\frac{da_i}{dt} = a_i (b_i - b_{i+1}), i \in \{1, \dots, n-1\}$$

$$\frac{db_i}{dt} = 2 (a_{i-1}^2 - a_i^2), i \in \{1, \dots, n\}$$

with $a_0 = a_n = 0$. Introducing the tridiagonal $n \times n$ matrices

numeric::odesolveGeometric

$$Y = \begin{pmatrix} b_1 & a_1 & & \\ a_1 & \dots & & \\ & \dots & \dots & a_{n-1} \\ & & a_{n-1} & b_n \end{pmatrix}, f(Y) = \begin{pmatrix} 0 & -a_1 & & \\ a_1 & \dots & & \\ & \dots & \dots & -a_{n-1} \\ & & a_{n-1} & 0 \end{pmatrix},$$

these equations can be encoded by the matrix ODE

$\frac{dY}{dt} = f(Y)Y - Yf(Y)$. The solution $Y(t)$ is known to be “isospectral”, i.e., the eigenvalues of $Y(t)$ do not depend on the time parameter t . As mentioned in the description of the option `LieGroupAction`, the solution of this type of matrix ODE is given by the group action $Y(t) = G(t)Y(0)G(t)^{-1} = G(t)Y(0)G(t)^T$, where $G(t)$ are orthogonal matrices (note that $f(Y)$ is skew symmetric). The eigenvalues of the matrices $Y(t)$ are invariants of the group action.

The exact dynamics also preserves the tridiagonal form of the matrices. The numerical dynamics, however, fills in further elements. The following vector field f ignores alle elements outside the central bands:

```
f := proc(t, Y)
local i, r;
begin
  r := array(1..n, 1..n, [[0 $ n] $ n]);
  for i from 1 to n - 1 do
    r[i + 1, i] := Y[i, i + 1];
    r[i, i + 1] := -Y[i, i + 1];
  end_for;
  return(r)
end_proc;
```

In the following, the initial value $Y(0)$ is specified by a matrix generated by the function `matrix`. Consequently, both arguments G and Y are passed to the Lie group action `LAMBDA` as corresponding matrices. They can be multiplied by the multiplication operator `*`:

```
LAMBDA:= proc(G, Y)
begin
  G*Y*(G::dom::transpose(G))
end_proc:
```

We define the initial value:

```
n := 3:
Y(0) := matrix(n, n, [1, 1, 1], Banded)
```

$$\begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

Now, the dynamics is integrated from $t = 0$ to $t = 1$:

```
tol := 10^(-4):
Y(1) := numeric::odesolveGeometric(f, 0..1, Y(0),
  LieGroupAction = LAMBDA, RelativeError = tol)
```

$$\begin{pmatrix} -0.256354686 & 0.4591148565 & -1.716329601 \cdot 10^{-14} \\ 0.4591148565 & 1.0 & 0.4591148565 \\ -1.716329601 \cdot 10^{-14} & 0.4591148565 & 2.256354686 \end{pmatrix}$$

The invariants of the dynamics are the eigenvalues of the matrices $Y(t)$. They are preserved numerically:

```
numeric::eigenvalues(Y(0)) = numeric::eigenvalues(Y(1))
[2.414213562, 1.0, -0.4142135624] = [2.414213562, 1.0, -0.4142135624]
```

numeric::odesolveGeometric

For comparison, we also solve the Toda lattice equations by classical numerics using `numeric::odesolve`. The system is encoded by a vector

$Y = [b_1, \dots, b_n, a_1, \dots, a_{n-1}]$ in \mathbb{R}^{2n-1} :

```
f := proc(t, Y)
local a, b, i;
begin
  b := [Y[i] $ i = 1..n];
  a := [Y[n + i] $ i = 1..n-1];
  [-2*a[1]^2, // = d/dt b[1]
   2*(a[i-1]^2 - a[i]^2) $ i = 2..n-1, // = d/dt b[i]
   2*a[n-1]^2, // = d/dt b[n]
   a[i]*(b[i] - b[i+1]) $ i = 1..n-1 // = d/dt a[i]
  ]
end_proc:
```

```
solution := numeric::odesolve(f, 0..1, [1 $ 2*n - 1],
                              RelativeError = tol);
```

```
[-0.2563650696, 1.0, 2.25636507, 0.459099923, 0.459099923]
```

The invariants are only preserved up to the precision of the solution determined by the tolerance set via `RelativeError = tol`:

```
Y(1) := array(1..n, 1..n, [[0 $ n] $ n]):
for i from 1 to n do
  Y(1)[i, i] := solution[i];
end_for:
for i from 1 to n-1 do
  Y(1)[i, i + 1] := solution[n + i];
  Y(1)[i + 1, i] := solution[n + i];
end_for:

Y(1)
```

$$\begin{pmatrix} -0.2563650696 & 0.459099923 & 0 \\ 0.459099923 & 1.0 & 0.459099923 \\ 0 & 0.459099923 & 2.25636507 \end{pmatrix}$$

`numeric::eigenvalues(Y(1))`

`[2.414213091, 1.0, -0.4142130909]`

Comparing these data with the previously computed eigenvalues of the initial condition $Y(0)$, one sees that the invariants are not preserved numerically to the working precision determined by DIGITS.

`delete f, LAMBDA, n, Y, tol, solution, i:`

Parameters

f

A procedure accepting two parameters (t , Y)

t_0

A numerical real value for the initial time

t

A numerical real value (the “time”)

Y_0

The initial condition: a list, a 1-dimensional array(1..n), a 2-dimensional array(1..n, 1..m), or an $n \times m$ matrix of category `Cat::Matrix` with numerical entries

Options

LieGroupAction

Option, specified as `LieGroupAction = LAMBDA`

The procedure `LAMBDA = proc(G, Y) ... end_proc` defines the action of the group element G (an $n \times n$ matrix) on the point Y on the homogeneous manifold (an $n \times m$ matrix or an n dimensional

numeric::odesolveGeometric

vector). This procedure must return a corresponding point (a matrix or a vector).

The default action is the usual matrix multiplication

$$(G, Y) \rightarrow G Y.$$

With this option, the default group action LAMBDA: $(G, Y) \rightarrow G Y$ of the $n \times n$ matrices G acting on the $n \times m$ matrices or n dimensional vectors Y by left multiplication may be replaced by other group actions.

As a group action, the procedure LAMBDA must satisfy $LAMBDA(1_n, Y) = Y$ and

$$LAMBDA(G_2, LAMBDA(G_1, Y)) = LAMBDA(G_2 G_1, Y)$$

numeric::odesolveGeometric computes the solution of the matrix ODE

$$\frac{dG(t)}{dt} = f(t, LAMBDA(G(t), Y_0)) G(t), G(t_0) = 1_{n,n}$$

On the space $\mathbb{C}^{n \times n}$ of the $n \times n$ matrices and returns $Y(t) = LAMBDA(G(t), Y_0)$.

For the standard group action $LAMBDA(G, Y) = GY$, this is the solution of the ODE $\frac{dY}{dt} = f(t, Y) Y$.

For homogeneous manifolds embedded in the $n \times n$ matrices, the group action $LAMBDA(G, Y) = GYG^{-1}$ may be considered. For this action, the curve $Y(t) = LAMBDA(G(t), Y_0)$ returned by numeric::odesolveGeometric is the solution of the ODE

$$\frac{dY}{dt} = f(t, Y) Y - Y f(t, Y). \text{ Cf. "Example 2" on page 18-251.}$$

LAMBDA(G, Y) is called with $n \times m$ matrices or n dimensional vectors Y of the same domain type as the initial condition Y_0 . If Y_0 is a matrix generated by the function matrix, then also the $n \times n$

matrix G is passed to LAMBDA as such a matrix object. In all other cases, G is passed as a 2-dimensional array (1..n, 1..n).

The procedure LAMBDA should return a 2-dimensional array (1..n, 1..m) or a corresponding matrix of category `Cat::Matrix`.

If the initial condition Y_0 is specified by a list or a 1-dimensional array (1..n), LAMBDA may also return a corresponding list or array.

Internally, the return value of LAMBDA is converted to a 2-dimensional array (1..n, 1..m) where $m = 1$ if a list or a 1-dimensional array is returned.

It is recommended that LAMBDA returns a 2-dimensional array (1..n, 1..m) in order to avoid the overhead of internal conversions.

RelativeError

Option, specified as `RelativeError = tol`

Forces internal numerical Runge-Kutta steps to use step sizes with local discretization errors below `tol`. This tolerance must

be a numerical real value $\geq \frac{1}{10^{\text{DIGITS}}}$. The default tolerance is

$$\frac{1}{10^{\text{DIGITS}}}$$

The internal control mechanism estimates the local relative discretization error of a Runge-Kutta step and adjusts the step size adaptively to keep this error below `tol`.

The default setting of `tol = $\frac{1}{10^{\text{DIGITS}}}$` ensures that the local discretization errors are of the same order of magnitude as numerical roundoff.

Usually there is no need to use this option to change this setting. However, occasionally the numerical evaluation of the Runge-Kutta steps may be ill-conditioned or step sizes are so small that the time parameter cannot be incremented by the step size within working precision. In such a case, this option may be

numeric::odesolveGeometric

used to bound the local discretization error by *tol* and use a higher working precision given by DIGITS.

Only real numerical values $\text{tol} \geq \frac{1}{10^{\text{DIGITS}}}$ are accepted.

Note Usually, the global error of the numeric approximation returned by `numeric::odesolveGeometric` is larger than the local errors bounded by *tol*. Although the result is displayed with DIGITS decimal places, one should not expect that all of them are correct. The relative precision of the final result is *tol* at best!

Stepsize

Option, specified as `Stepsize = h`

Switches off the internal error control and uses a Runge-Kutta iteration with constant step size *h*. *h* must be a numerical real value.

By default, `numeric::odesolveGeometric` uses an adaptive step size control mechanism in the numerical iteration. The option `Stepsize = h` switches off this adaptive mechanism and uses the Runge-Kutta method specified by `method` (or the default method DOPRI78) with constant step size *h*.

A final step with smaller step size is used to match the end *t* of

the integration interval $t_0 \dots t$, if $\frac{t-t_0}{h}$ is not an integer.

Note With this option, there is no automatic error control! Depending on the problem and on the order of the method, the result may be a poor numerical approximation of the exact solution.

There is usually no need to invoke this option. However, occasionally the builtin adaptive error control mechanism may fail when integrating close to a singularity. In such a case, this option may be used to customize a control mechanism for the global error by using different step sizes and investigating the convergence of the corresponding results.

Alldata

Option, specified as `Alldata = n`

With this option, `numeric::odesolveGeometric` returns a list of numerical mesh points $[[t_0, Y_0], [t_1, Y_1], \dots, [t, Y(t)]]$ generated by the internal Runge-Kutta iteration.

The integer n controls the size of the output list. For $n = 1$, all internal mesh points are returned. This case may also be invoked by entering the simplified option `Alldata`, which is equivalent to `Alldata = 1`. For $n > 1$, only each n -th mesh point is stored in the list. The list always contains the initial point $[t_0, Y_0]$ and the final point $[t, Y(t)]$. For $n \leq 0$, only the data $[[t_0, Y_0], [t, Y(t)]]$ are returned.

The output list may be useful to inspect the internal numerical process. Also further graphical processing of the mesh data may be useful.

Return Values

The solution $Y(t)$ is returned as a list or as an array of floating-point values. The type of the result matrix/vector coincides with the type of the input matrix/vector Y_0 .

With the option `Alldata`, a list of mesh data is returned.

Purpose Convert an ode system to vectorfield notation

Syntax `numeric::ode2vectorfield(IVP, fields)`

Description `numeric::ode2vectorfield` converts a system of ordinary differential equations of arbitrary order to a vector field representation suitable for the numerical ODE solver `numeric::odesolve2`.

`numeric::ode2vectorfield` and `numeric::odeToVectorField` are equivalent.

`numeric::ode2vectorfield` is a utility function to generate input parameters for the numerical ODE solver `numeric::odesolve2`. This solver requires a procedure representing the vectorfield $f(t, Y)$ of a first order system of differential equations (dynamic system) $\frac{dY}{dt} = f(t, Y)$ and initial data $Y_0 = Y(t_0)$. Given an initial value problem IVP consisting of (possibly higher order) differential expressions together with initial conditions, `numeric::ode2vectorfield` converts the higher order equations to an equivalent system of first order ODEs and returns the input parameters for `numeric::odesolve2`.

Higher-order differential equations can always be represented as an equivalent dynamic system $\frac{dY}{dt} = f(t, Y)$ with some vector Y . E.g., the n -th order equation

$$y^{(n)} = g(t, y, y', \dots, y^{(n-1)})$$

may be written as the first order system

$$\frac{dY}{dt} = [y', \dots, y^{(n-1)}, g(t, y, \dots, y^{(n-1)})]$$

for the vector $Y = [y, y', \dots, y^{(n-1)}]$.

numeric::ode2vectorfield

The input list `fields` corresponds to the vector Y . It must be a *complete* specification of all functions and their derivatives through but *not including the highest derivatives* of the unknown functions. E.g., for the second order differential equation $y''(t) = y(t)$, the appropriate list of unknown fields is $[y(t), y'(t)]$. The differential equations $y''(t) = z(t)$, $z'(t) = y(t)$ are of second order in y and of first order in z . Hence, the appropriate list of unknown fields is $[y(t), y'(t), z(t)]$.

The ordering of the fields in `list` determines the ordering of the components of the list that the numerical solver produces as the solution vector. Cf. “Example 2” on page 18-264.

The differential equations must be linear in the highest derivatives of the unknown functions involved. E.g., the ODE $y'(t)^2 = y(t)$ is not admitted. However, equations such as $y_2(t) y_1'(t) = y_1(t)$, $y_1(t) y_2'(t) = y_2(t)$ are

accepted and converted to $y_1'(t) = \frac{y_1(t)}{y_2(t)}$, $y_2'(t) = \frac{y_2(t)}{y_1(t)}$.

A *complete* specification of initial conditions must be contained in IVP: for each component in `list`, an initial value must be provided. The initial conditions may be specified by linear equations which will be solved for the initial values of the unknown fields automatically. E.g., for `fields = [y(t), y'(t), z(t)]`, initial conditions may be specified explicitly by $y(t_0) = 1$, $y'(t_0) = 2$, $z(t_0) = 3$, say, or via linear equations such as $y(t_0) + z(t_0) = y'(t_0)$, $y(t_0) = z(t_0)$, $z(t_0) = 2 y(t_0)$. Cf. “Example 3” on page 18-265.

The differential equations, the initial ‘time’ t_0 , and the initial conditions may involve symbolic parameters. However, such parameters must evaluate to numerical objects, when the sequence returned by `numeric::ode2vectorfield` is passed to the numerical solver.

The vectorfield procedure `f` and the initial values Y_0 returned by `numeric::ode2vectorfield` can also be used by the functions `numeric::odesolve`, `plot::Ode2d`, `plot::Ode3d`. Cf. “Example 3” on page 18-265.

Examples

Example 1

We consider the initial value problem

$$y'(t) = t \sin(y(t)), y(0) = 1.$$

The solver `numeric::odesolve2` requires the procedure

$f:(t, Y) \rightarrow t \sin(Y_1)$ for the 1-dimensional vector $Y = [y(t)]$ specified by `fields`. The utility `numeric::ode2vectorfield` accepts a more convenient representation via arithmetical expressions:

```
IVP := {y'(t) = t*sin(y(t)), y(t0) = y0}:
fields := [y(t)]:
IVP := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, t0, [y0]
```

This sequence may be passed to the numerical solver which returns a procedure representing the numerical solution:

```
t0 := 0: y0 := 1:
Y := numeric::odesolve2(IVP)
```

```
proc Y(t) ... end
```

Calling the numerical solution `Y` invokes the numerical integration from the initial 'time' $t_0 = 0$ to the 'time' specified in the call to `Y`:

```
Y(0), Y(1), Y(2), Y(3)
```

```
[1.0], [1.466404006], [2.655911348], [3.100928494]
```

```
delete IVP, fields, Y:
```

numeric::ode2vectorfield

Example 2

We consider the second order initial value problem

$$y''(t) = t \sin(y(t)), y(0) = 1, y'(0) = 0$$

The corresponding vectorfield representation involves the vector

$Y = [y(t), y'(t)]$ specified by fields:

```
IVP := {y''(t) = t*sin(y(t)), y(0) = 1, y'(0) = 0}:  
fields := [y(t), y'(t)]:  
numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, 0, [1, 0]
```

This sequence is accepted by `numeric::odesolve2`. The numerical solution `Y` returns lists representing the components of the vector specified by `fields`:

```
Y := numeric::odesolve2(%):  
Y(5)
```

```
[1.916536393, -0.8765542819]
```

With a reordering of the unknown fields, the numerical solver returns the solution vector with rearranged components:

```
fields := [y'(t), y(t)]:  
Y := numeric::odesolve2(numeric::ode2vectorfield(IVP, fields)):  
Y(5)
```

```
[-0.8765542819, 1.916536393]
```

```
delete IVP, fields, Y:
```

Example 3

The following IVP involves the unknown fields $u(t)$, $v(t)$, $w(t)$. Since it is of second order in u , of first order in v and of third order in w , the list of unknowns $[y(t), y'(t), v(t), w(t), w'(t), w''(t)]$ is appropriate:

```
IVP := {u''(t) - u(t)*v'(t) = exp(-t)*v'(t), v'(t) = w''(t),
        u'(t)*w'''(t) = t + u''(t),
        u(PI) = 3, u'(PI) = 1,
        v(PI) = 0,
        w(PI) = w'(PI), w'(PI) = 2 - w(PI), w''(PI) = 3*w(PI)}:
fields := [u(t), u'(t), v(t), w(t), w'(t), w''(t)]:
ivp := numeric::ode2vectorfield(IVP, fields)
```

```
proc(t, Y) ... end, pi, [3, 1, 0, 1, 1, 3]
```

```
Y := numeric::odesolve2(ivp):
Y(5)
```

```
[195.9501263, 604.3872242, 13.15053015, 13.29454726, 14.15053015, 10.04763196]
```

We plot the components v , w , and w'' of the solution vector:

```
plotfunc2d(Y(t)[3], Y(t)[4], Y(t)[6], t = PI .. 5,
           Colors = [RGB::Red, RGB::Green, RGB::Blue]):
```

numeric::ode2vectorfield

Alternatively, we use the vectorfield procedure `ivp[1]` and the initial conditions `ivp[3]` as input parameters for `plot::Ode2d`:

```
plot(plot::Ode2d([PI + i*(5 - PI)/30 $ i = 0..30],  
               ivp[1], ivp[3],  
               [(t, Y) -> [t, Y[3]], Color = RGB::Red],  
               [(t, Y) -> [t, Y[4]], Color = RGB::Green],  
               [(t, Y) -> [t, Y[6]], Color = RGB::Blue])):
```

delete IVP, fields, ivp, Y:

Parameters

IVP

The initial value problem: a list or a set of equations involving univariate function calls $y_1(t)$, $y_2(t)$ etc. and derivatives $y_1'(t)$, $y_1''(t)$, ..., $y_2'(t)$, $y_2''(t)$ etc. The differential equations must be quasi-linear: the highest derivative of each of the dependent functions $y_1(t)$, $y_2(t)$ etc. must enter the equations linearly. IVP must also contain corresponding initial conditions specified by linear equations in the expressions $y_1(t_0)$, $y_1'(t_0)$, ..., $y_2(t_0)$, $y_2'(t_0)$ etc. Alternatively, arithmetical expressions may be specified which are interpreted as equations with vanishing right hand side.

fields

numeric::ode2vectorfield

The vector of the dynamical system equivalent to IVP: a list of symbolic function calls such as $[y_1(t), y_1'(t), \text{dots}, y_2(t), y_2'(t), \text{dots}]$ representing the unknown fields to be solved for.

Return Values

Sequence f, t_0, Y_0 . These data represent the dynamical system $\frac{dY}{dt} = f(t, Y)$ with the initial condition $Y(t_0) = Y_0$ equivalent to IVP. The vectorfield $f:(t, Y) \rightarrow f(t, Y)$ is a procedure, t_0 is a numerical expression representing the initial 'time', and Y_0 is a list of numerical expressions representing the components of the initial vector Y_0 .

| polylib::realroots | solve

Purpose

Numerical roots of a univariate polynomial

Syntax

```
numeric::polyroots(eqs, <FixedPrecision>, <SquareFree>,  
<Factor>, <NoWarning>)
```

Description

`numeric::polyroots(eqs)` returns numerical approximations of all real and complex roots of the univariate polynomials `eqs`.

The coefficients may be real or complex numbers. Also symbolic coefficients are accepted if they can be converted to floats.

The trivial polynomial $eqs = 0$ results in an error message. The empty list is returned for constant polynomials $eqs \neq 0$.

Multiple roots are listed according to their multiplicities, i.e., the length of the root list coincides with the degree of `eqs`.

The root list is sorted by `numeric::sort`.

Up to roundoff effects, the numerical roots should be accurate to DIGITS significant digits, unless the option `FixedPrecision` is used.

All floating-point entries in `eqs` are internally approximated by rational numbers: `numeric::polyroots(eqs)` computes the roots of `numeric::rationalize(eqs, Minimize)`.

For polynomial expressions in factored form, the numerical search is applied to each factor separately.

It is recommended to use `numeric::realroots` or `polylib::realroots` if `eqs` is a real polynomial and only real roots are of interest.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

Both polynomial expressions as well as `DOM_POLY` objects may be used to specify the polynomial:

```
numeric::polyroots(x^3 - 3*x - sqrt(2))
```

numeric::polyroots

```
[1.931851653, -0.5176380902, -1.414213562]
```

```
numeric::polyroots(PI*z^4 + I*z + 0.1)
```

```
[0.5936837297 - 0.3729248918 i, 0.6455316068 i,  
0.1003181767 i, -0.5936837297 - 0.3729248918 i]
```

```
numeric::polyroots(poly(x^5 - x^2, [x]))
```

```
[1.0, 0.0, 0.0, -0.5 + 0.8660254038 i, -0.5 - 0.8660254038 i]
```

Example 2

The following polynomial has exact coefficients:

```
p := poly((x - 1)*(x - PI)^3, [x]):  
numeric::polyroots(p)
```

```
[3.141592654, 3.141592654, 3.141592654, 1.0]
```

Note that roundoff errors in the coefficients of eqs have a dramatic effect on multiple roots:

```
p := poly((x - 1.0)*(x - float(PI))^3, [x]):  
numeric::polyroots(p)
```

```
[3.144422386, 3.140177788 - 0.00244957836 i, 3.140177788 + 0.00244957836 i, 0.9999999995]
```

These are the roots of the following rationalized polynomial:

```
numeric::rationalize(p, Minimize)
```

```
poly( $x^4 - \frac{461286 x^3}{44249} + \frac{176627 x^2}{4525} - \frac{2515405 x}{41498} + \frac{1837649}{59267}$ , [x])
```

```
delete p:
```

Example 3

The multiple root $\frac{i}{3}$ of the following polynomial can only be computed with restricted precision by fixed precision arithmetic:

```
p := poly((x^2 - 6*x + 8)*(x - I/3)^5, [x]):
numeric::polyroots(p, FixedPrecision)
```

```
[4.0, 2.0, 0.006617926628 + 0.330782186 i, 0.004459639998 + 0.3388505458 i,
 -0.0003838250804 + 0.3262671926 i, -0.003866386513 + 0.3392634968 i,
 -0.006827355033 + 0.3315032456 i]
```

Without the option FixedPrecision, the working precision is increased internally to compute better approximations:

```
numeric::polyroots(p)
```

```
[4.0, 2.0, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i, 0.3333333333 i]
```

```
delete p:
```

Example 4

The following polynomial has badly separated roots. numeric::polyroots does not manage to separate them properly:

```
p := poly(_mult((x - 1 - i/10^9) $ i=0..5), [x]):
numeric::polyroots(p)
```

```
[1.000000003, 1.000000003, 1.000000003, 1.000000003, 1.000000003, 0.9999999987]
```

One can preprocess the polynomial by a symbolic factorization:

numeric::polyroots

```
numeric::polyroots(p, Factor)
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

Alternatively, one can increase the working precision to separate the roots:

```
DIGITS := 20:  
numeric::polyroots(p)
```

```
[1.000000005, 1.000000004, 1.000000003, 1.000000002, 1.000000001, 1.0]
```

```
delete p, DIGITS:
```

Parameters

eqs

A univariate polynomial expression or a univariate polynomial of domain type `DOM_POLY`. The function also accepts a list, set, array, or matrix (`Cat::Matrix`) of polynomial expressions.

Options

FixedPrecision

This option provides the fastest way to obtain approximations of the roots by a numerical search with a fixed internal precision of $2DIGITS$ decimal places.

Note that badly isolated roots or multiple roots will usually not be approximated to `DIGITS` decimals when using this option. The problem of finding such roots is numerically ill-conditioned, i.e., such roots cannot be found to full precision with fixed precision arithmetic. Typically, a q -fold root will be approximated only to

about $\frac{2 DIGITS}{q}$ decimal places. Cf. “Example 3” on page 18-281.

Without this option, `numeric::polyroots` internally increases the working precision until all roots are found to `DIGITS` decimal places.

SquareFree

With this option, a symbolic square free factorization is computed via `polylib::sqrfree(eqs)`. The numerical root finding algorithm is then applied to each square free factor.

This option is recommended, when `p` is known to have multiple roots. Such roots force `numeric::polyroots` to increase the working precision internally increasing the costs of the numerical search. A square free factorization reduces the multiplicity of each root to one, speeding up the final numerical search.

For polynomials with real rational coefficients, a square free factorization is always used, i.e., this option does not have any effect for such polynomials. For all other types of coefficients, a square free factorization may be costly and must be requested by this option.

Multiple roots of `eqs` can be successfully dealt with by this option. However, for badly separated distinct roots the square free factorization will not improve the performance of the numerical search.

Factor

With this option, a symbolic factorizations of `eqs` via `factor` are computed. The numerical root finding algorithm is then applied to each factor.

This option is useful, when `eqs` can be successfully factorized (e.g., when each expression from `eqs` has multiple roots). The numerical search on the factors is much more efficient than the search on the original polynomial. On the other hand, symbolic factorization of `eqs` may be costly.

NoWarning

Suppresses warnings

Return Values

List of numerical roots.

numeric::polyroots

Algorithms

The numerical root finding algorithm implemented by `numeric::polyroots` is Laguerre's method: W.H. Press, B.P. Flannery, S.A. Teukolsky and W.T. Vetterling: *Numerical Recipes in C*, Cambridge University Press, 1988.

MuPAD Functions

`RootOf` | `numeric::fsolve` | `numeric::polysysroots` |
`numeric::realroot` | `numeric::realroots` | `polylib::realroots`
| `solve`

Purpose

Numerical roots of a system of polynomial equations

Syntax

```
numeric::polysysroots(eqs, <NoWarning>)  
numeric::polysysroots(eqs, vars, <NoWarning>)
```

Description

`numeric::polysysroots(eqs, ...)` returns numerical approximations of all real and complex roots of the polynomial system of equations `eqs`.

The coefficients of the polynomials may contain symbolic parameters.

If no unknowns are specified by `vars`, then `numeric::indets(eqs)` is used in place of `vars`.

In most cases, the solution is returned as a set of lists of solved equations of the form

$$[x_1 = \text{value}_1, x_2 = \text{value}_2, \dots],$$

where x_1, x_2, \dots are the unknowns. These simplified equations should be regarded as constraints on the unknowns. E.g., if an unknown x_1 , say, does not turn up in the form $x_1 = \dots$ in the solution, then there is no constraint on this unknown and it is an arbitrary parameter. This holds true in general for all unknowns that do not turn up on the left hand side of the solved equations. Cf. “Example 2” on page 18-287.

If no explicit solutions can be computed, expressions of the form

$$\begin{pmatrix} x_1 \\ x_2 \\ \dots \end{pmatrix} \in S \text{ may be returned, where } S \text{ is the solution set.}$$

The ordering of the unknowns in `vars` determines the ordering of the solved equations. If a `setvars` is used, then an internal ordering is used.

numeric::polysysroots

Note If the solution set of eqs is not finite, then `numeric::polysysroots` may return solutions with some of the unknowns remaining as free parameters. In this case the representation of the solution depends on the ordering of the unknowns! Cf. “Example 3” on page 18-287. Further, if higher degree polynomials are involved, then `numeric::polysysroots` may fail to compute roots. Cf. “Example 5” on page 18-288. The same may happen, when eqs contains symbolic parameters.

You may try `numeric::fsolve` to compute a single numerical root, if `numeric::polysysroots` cannot compute all roots of the system. Note, however, that `numeric::fsolve` does not accept symbolic parameters in the equations.

We recommend to use `numeric::polyroots` to compute all roots of a single univariate polynomial with numerical coefficients.

`numeric::polysysroots` is a hybrid routine: it calls the symbolic solver `solve(eqs, vars, BackSubstitution = FALSE)` and processes its symbolic result numerically. Cf. “Example 4” on page 18-288.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Equations, expressions as well as `DOM_POLY` objects may be used to specify the polynomials:

```
numeric::polysysroots(x^2 = PI^2, x)
```

```
{[x = 3.141592654], [x = -3.141592654]}
```

```
numeric::polysysroots({x^2 + y^2 - 1, x^2 - y^2 = 1/2}, [x, y])
```

```
{[x = 0.8660254038, y = 0.5], [x = 0.8660254038, y = -0.5], [x = -0.8660254038, y = -0.5],
 [x = -0.8660254038, y = 0.5]}
```

```
numeric::polysysroots({poly(x^2 + y + 1), y^2 + x = 1}, [x, y])
```

```
{[x = -0.4533976515, y = -1.20556943], [x = 0.2266988258 + 1.467711509 i,
 y = 1.102784715 - 0.6654569512 i], [x = 0, y = -1.0],
 [x = 0.2266988258 - 1.467711509 i, y = 1.102784715 + 0.6654569512 i]}
```

Symbolic parameters are accepted:

```
numeric::polysysroots(x^2 + y + exp(z), [x, y])
```

```
{[x = sqrt(-1.0 y - 1.0 e^z)], [x = -1.0 sqrt(-1.0 y - 1.0 e^z)]}
```

Example 2

The returned solutions may contain some of the unknowns remaining as free parameters:

```
numeric::polysysroots({x^2 + y^2 = z}, [x, y, z])
```

```
{[x = sqrt(z - 1.0 y^2)], [x = -1.0 sqrt(z - 1.0 y^2)]}
```

Example 3

The ordering of the unknowns determines the representation of the solution, if the solution set is not finite. First, the following equation is solved for x leaving y as a free parameter:

```
numeric::polysysroots({x^3 = y^2}, [x, y])
```

```
{[x = (y^2)^(1/3)], [x = (y^2)^(1/3) (-0.5 + 0.8660254038 i)], [x = (y^2)^(1/3) (-0.5 - 0.8660254038 i)]}
```

numeric::polysysroots

Reordering the unknowns leads to a representation with x as a free parameter:

```
numeric::polysysroots({x^3 = y^2}, [y, x])
```

```
{[y = sqrt(x^3), [y = -1.0 sqrt(x^3)]}
```

Example 4

The symbolic solver produces a RootOf solution of the following system:

```
eqs := {y^2 - y = x, x^3 = y^3 + x}:  
solve(eqs, BackSubstitution = FALSE)
```

$$\begin{pmatrix} x \\ y \end{pmatrix} \in \left\{ \begin{pmatrix} 0 \\ 0 \end{pmatrix} \right\} \cup \left\{ \begin{pmatrix} y^2 - y \\ z_1 \end{pmatrix} \mid z_1 \in \text{RootOf}(z^5 - 3z^4 + 3z^3 - 2z^2 - z + 1, z) \right\}$$

Internally, `numeric::polysysroots` calls `solve` and processes this result numerically:

```
numeric::polysysroots(eqs, [x, y])
```

```
{[x = 2.237302267, y = 2.077118343], [x = -1.445049623 - 0.1279930535 i,  
y = 0.441542078 + 1.094745154 i], [x = 0.8911259621, y = -0.5682349751],  
[x = -0.2383289841, y = 0.6080324763], [x = -1.445049623 + 0.1279930535 i,  
y = 0.441542078 - 1.094745154 i], [x = 0, y = 0]}
```

```
delete eqs:
```

Example 5

The following equation is solved for the first of the specified unknowns:

```
eqs := y^5 - PI*y = x:  
solve(eqs, [x, y])
```

$$\{[x = z^5 - \pi z, y = z]\}$$

numeric::polysysroots processes this output numerically:

```
numeric::polysysroots(eqs, [x, y])
```

$$\{[x = y^5 - 3.141592654 y]\}$$

The equation is solved for y when the unknowns are reordered. However, no simple representation of the solution exists, so a RootOf object is returned:

```
solve(eqs, [y, x])
```

$$\begin{pmatrix} y \\ x \end{pmatrix} \in \bigcup_{z_2 \in \mathbb{C}} \left\{ \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \mid z_1 \in \text{RootOf}(z^5 - \pi z - z_2, z) \right\}$$

The roots represented by the RootOf expression cannot be computed numerically, because the symbolic parameter x is involved:

```
numeric::polysysroots(eqs, [y, x])
```

$$\begin{pmatrix} y \\ x \end{pmatrix} \in \bigcup_{z_2 \in \mathbb{C}} \left\{ \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \mid z_1 \in \text{RootOf}(z^5 - \pi z - z_2, z) \right\}$$

```
delete eqs:
```

Parameters

eqs

A polynomial equation or a list, set, array, or matrix (Cat::Matrix) of such equations. Also expressions and polynomials of domain type DOM_POLY are accepted wherever an equation is expected. They are interpreted as homogeneous equations.

numeric::polysysroots

vars

An unknown or a list or set of unknowns. Unknowns may be identifiers or indexed identifiers.

Options

NoWarning

By default, the roots are double-checked, automatically. Warnings are issued if a solution seems to be marred by some numerical instability. With this option, this check is suppressed and no warnings will be issued.

Return Values

a set of lists of equations or an expression of the form $\begin{pmatrix} x_1 \\ x_2 \\ \dots \end{pmatrix} \in S$, where x_1, x_2, \dots are the unknowns and S is the solution set.

The set $\{\}$ containing an empty list is returned, if no solutions can be computed.

MuPAD Functions

`linsolve` | `numeric::fsolve` | `numeric::linsolve` | `numeric::polyroots` | `numeric::realroot` | `numeric::realroots` | `polylib::realroots` | `solve`

Purpose Numerical approximation of products

Syntax

```
numeric::product(f, i = a .. b)
numeric::product(f, i in RootOf(p, <x>))
numeric::product(f, i = RootOf(p, <x>))
numeric::product(f, i in {x1, x2, })
numeric::product(f, i = {x1, x2, })
```

Description `numeric::product(f, i = a..b)` computes a numerical approximation of $\prod_{i=a}^b f(i)$.
`numeric::product(f, i = RootOf(p,x))` computes a numerical approximation of the product of f over the roots of the polynomial p .
`numeric::product(f, i in { x1, x2, })` computes a numerical

approximation of $\prod_{i \in \{x_1, x_2, \dots\}} f(i)$.

The call `numeric::product(...)` is equivalent to calling the `float` attribute of `product` via `float (hold(product)(...))`, `float (freeze(product)(...))` or `product::float(...)`.

If there are other symbolic parameters in f , apart from the variable i , a symbolic call to `numeric::product` is returned. Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted and converted to floating-point numbers.

Note For finite products, `numeric::product` just returns `_mult (float(f) $ i=a..b)`. Cf. “Example 3” on page 18-293.

The call `numeric::product(f, i = { x1, x2, })` computes numerical approximations of $x[1]$, $x[2]$ etc., substitutes these values into $f(i)$ and multiplies the results.

The calls `numeric::product(f, i in { x1, x2, })` and `numeric::product(f, i = { x1, x2, })` are equivalent.

numeric::product

The call `numeric::product (f, i in RootOf(p, x))` computes numerical approximations of all roots of p , substitutes these values into $f(i)$ and multiplies the results. Cf. “Example 2” on page 18-293.

The calls `numeric::product(f, i in RootOf(p, x))` and `numeric::product(f, i = RootOf(p, x))` are equivalent.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision and influences the maximum number of steps used in the computation.

Examples

Example 1

We demonstrate some equivalent calls for numerical products:

```
numeric::product(1+1/k^2, k = 1..infinity),  
float(hold(product)(1+1/k^2, k = 1..infinity)),  
float(freeze(product)(1+1/k^2, k = 1..infinity)),  
product::float(1+1/k^2, k = 1..infinity);
```

```
3.67607791, 3.67607791, 3.67607791, 3.67607791
```

`product` fails to find a closed form for the following product:

```
product(1 - 1/4^k, k = 1..infinity);
```

$$\prod_{k=1}^{\infty} \frac{2^{2k} - 1}{2^{2k}}$$

`float` implicitly uses `numeric::product` to compute a numerical approximation:

```
float(%);
```

```
0.6885375371
```

The exact value of the following infinite product is $e^{(1-\sqrt{2})} \zeta\left(\frac{1}{2}\right)$:

```
numeric::product(exp((-1)^(k+1)*k^(-1/2)), k = 1..infinity)
= float(exp((1-sqrt(2))*zeta(1/2)))

1.831066609 = 1.831066609
```

Example 2

We calculate an approximation of the product over the roots of a polynomial:

```
numeric::product(sin(r), r = RootOf(x^2 - PI^2/4, x))

-1.0
```

If the polynomial expression contains additional indeterminates, a symbolic call to `numeric::product` is returned:

```
numeric::product(r+PI, r = RootOf(x^8 + c*x - PI^2/4, x))

numeric::product(r + 3.141592654, r = RootOf(x^8 + c x - 2.4674011, x))
```

Example 3

`numeric::product` can also be used to compute finite products:

```
numeric::product(1-1/k^2, k = 2..10^n) $ n in { 2, 3, 4 }

0.505, 0.5005, 0.50005
```

However, since `numeric::product` uses `_mult` internally anyway, it is more efficient to call `_mult` directly:

```
_mult(float(1-1/k^2) $ k = 2..10^n) $ n in { 2, 3, 4 }
```

numeric::product

0.505, 0.5005, 0.50005

Example 4

The following product is returned symbolically because it contains the additional indeterminate k :

```
numeric::product(1-1/n^k, n = 2..infinity)
```

```
numeric::product( $1.0 - \frac{1.0}{n^{1.0 k}}$ , n = 2..∞)
```

Parameters

f

An arithmetical expression depending on i

i

The product index: an identifier or indexed identifier

a, b

integers or $\pm\infty$ satisfying $a \leq b$

P

A univariate polynomial expression in x

x

Indeterminate

x₁, x₂, ...

numerical expressions

Return Values

floating-point number or a symbolic expression of type `numeric::product`.

Algorithms

Infinite products are calculated by summing the series $\sum_{i=a}^{\infty} \ln(f)$ via `numeric::sum`.

`numeric::product` uses `numeric::polyroots` to calculate numerical approximations to the roots of a polynomials.

MuPAD Functions

`_mult` | `product` | `numeric::sum` | `numeric::polyroots`

numeric::quadrature

Purpose Numerical integration (Quadrature)

Syntax `numeric::quadrature(f(x), x = a .. b, <GaussLegendre = n | GaussTschebyscheff = n | NewtonCotes = n>, <Adaptive = v>, <MaxCalls = m>)`

Description `numeric::quadrature(f(x), x = a..b)` computes a numerical approximation of $\int_a^b f(x) dx$.

`numeric::quadrature` returns itself symbolically if the integrand $f(x)$ contains symbolic objects apart from the integration variable x that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. are accepted.

The integrand $f(x)$ should be integrable in the Riemann sense. In particular, $f(x)$ should be bounded on the integration interval $x = a..b$. Certain types of mild singularities are handled, but numerical convergence is not guaranteed and will be slow in most cases. Also discontinuities and singularities of (higher) derivatives of $f(x)$ slow down numerical convergence. For integrands with irregular points, it is recommended to split the integration into several parts, using subintervals on which the integrand is smooth. Cf. “Example 4” on page 18-301.

Integrands given by user-defined procedures can be handled. See “Example 4” on page 18-301 and “Example 5” on page 18-302.

`numeric::quadrature` returns itself symbolically if the boundaries a, b contain symbolic objects that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. as well as `infinity` and `-infinity` are accepted.

Note For infinite ranges, the user should make sure that the integral

exists! If $f(x)$ does not decay as fast as $O\left(\frac{1}{|x|^2}\right)$ at infinity, then convergence may be slow.

Boundaries $a > b$ are accepted, using $\int_a^b f(x) dx = -\int_b^a f(x) dx$.

For complex values of a, b , the integration is to be understood as a contour integral along a straight line from a to b . Complex boundaries must not involve infinity.

Multi-dimensional integration such as

```
numeric::quadrature ( numeric::quadrature(f(x,y), y =
A(x)..B(x)), x = a..b)
```

is possible. See “Example 3” on page 18-300 and “Example 5” on page 18-302.

Internally, an adaptive mechanism based on a fixed quadrature rule specified by `method = n` is used. It tries to keep the relative quadrature

error of the result below $\frac{1}{\text{DIGITS}}$. The last digit(s) of the result may be incorrect due to roundoff effects.

The routine `numeric::quadrature` is purely numerical: no symbolic check for singularities etc. is carried out.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

We demonstrate the standard calls for adaptive numerical integration:

```
numeric::quadrature(exp(x^2), x = -1..1)
```

```
2.925303492
```

```
numeric::quadrature(max(1/10, cos(PI*x)), x = -2..0.0123)
```

```
0.752102471
```

numeric::quadrature

```
numeric::quadrature(exp(-x^2), x = -2..infinity)
```

```
1.768308316
```

The precision goal is set by DIGITS:

```
DIGITS := 50:
```

```
numeric::quadrature(besselJ(0, x), x = 0..PI)
```

```
1.3475263146739901712314731279612149642205400522774
```

Note that due to the internal adaptive mechanism, the choice of different methods should not have any significant effect on the quadrature result:

```
DIGITS := 10:
```

```
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 5),  
numeric::quadrature(sin(x)/x, x = -1..10, GaussLegendre = 160),  
numeric::quadrature(sin(x)/x, x = -1..10, NewtonCotes = 8)
```

```
2.604430665, 2.604430665, 2.604430665
```

Example 2

The user should make sure that the integrand is well defined and sufficiently regular. The following fails, because Newton-Cotes quadrature tries to evaluate the integrand at the boundaries:

```
numeric::quadrature(sin(x)/x, x = 0..1, NewtonCotes = 8)
```

```
Error: Division by zero. [_power]  
Evaluating: Quadsum
```

One may cure this problem by assigning a value to $f(0)$. The integrand is passed to the integrator as `hold(f)` to prevent premature evaluation

of $f(x)$ to $\sin(x)/x$. Internally, `numeric::quadrature` replaces x by numerical values and then evaluates the integrand. Note that one has to define `f(0.0) := 1` rather than `f(0) := 1`:

```
f := x -> sin(x)/x:  
f(0.0) := 1:  
numeric::quadrature(hold(f)(x), x = 0..1, NewtonCotes = 8)
```

```
0.9460830704
```

The default method (Gauss-Legendre quadrature) does not evaluate the integrand at the end points:

```
numeric::quadrature(sin(x)/x, x = 0..1)
```

```
0.9460830704
```

Nevertheless, problems may still arise for improper integrals:

```
numeric::quadrature(ln((1 + x^4)^2 - 1), x = 0 .. 1)
```

```
Warning: Precision goal is not achieved after 10000 function cal
```

```
-3.213735532
```

In this example, the integrand is evaluated close to 0. The expression $(1 + x^4)^2 - 1$ suffers from severe numerical cancellation and is dominated by round-off. A numerically stable representation is $(1 + x^4)^2 - 1 = x^4(x^4 + 2)$:

```
numeric::quadrature(ln(x^4*(x^4 + 2)), x = 0..1)
```

```
-3.218234378
```

numeric::quadrature

Note that convergence is rather slow, because the integrand is not bounded.

```
delete f:
```

Example 3

We demonstrate multi-dimensional quadrature:

```
Q := numeric::quadrature:  
Q(Q(exp(x*y), x = 0..y), y = 0..1)
```

```
0.6589510757
```

Also more complex types of nested calls are possible. We use numerically defined functions

```
b := y -> Q(exp(-t^2-t*y), t = y..infinity):
```

and

```
f := y -> cos(y^2) + Q(exp(x*y), x = 0..b(y)):
```

for the following quadrature:

```
Q(f(y), y = 0..1)
```

```
1.261578952
```

Multi dimensional quadrature is computationally expensive. Note that a call to `numeric::quadrature` evaluates the integrand at least $3n$ times, where n is the number of nodes of the internal quadrature rule (by default, $n = 20$ for $DIGITS \leq 10$). The following triple quadrature would call the `exp` function no less than $(320)^3 = 216000$ times!

```
Q(Q(Q(exp(x*y*z), x = 0..y+z), y = 0..z), z = 0..1)
```

For low precision goals, low order quadrature rules suffice. In the following, we reduce the computational costs by using Gauss-Legendre quadrature with 5 nodes. We use the shorthand notation GL to specify the GaussLegendre method:

```
DIGITS := 4:
Q(Q(Q(exp(x*y*z), x=0..y+z, GL=5), y=0..z, GL=5), z=0..1, GL=5)
```

```
0.665
```

```
delete Q, b, f, DIGITS:
```

Example 4

We demonstrate how integrands given by user-defined procedures should be handled. The following integrand

```
f := proc(x) begin
    if x<1 then sin(x^2) else cos(x^5) end_if
end_proc:
```

cannot be called with a symbolic argument:

```
f(x)
```

```
Error: Cannot evaluate to Boolean. [_less]
Evaluating: f
```

Consequently, one must use hold to prevent premature evaluation of $f(x)$:

```
numeric::quadrature(hold(f)(x), x = -1..PI/2)
```

```
0.5354101317
```

numeric::quadrature

Note that the above integrand is discontinuous at $x = 1$, causing slow convergence of the numerical quadrature. It is much more efficient to split the integral into two subquadratures with smooth integrands:

```
numeric::quadrature(sin(x^2), x = -1..1) +  
numeric::quadrature(cos(x^5), x = 1..PI/2)
```

0.5354101318

See “Example 5” on page 18-302 for multi-dimensional quadrature of user-defined procedures.

```
delete f:
```

Example 5

The following integrand

```
f := proc(x, y) begin  
    if x<y then x-y else (x-y) + (x-y)^5 end_if  
end_proc:
```

can only be called with numerical arguments and must be delayed twice for 2-dimensional quadrature:

```
Q := numeric::quadrature:
```

```
Q(Q(hold(hold(f)))(x, y), x = 0..1), y = 0..1)
```

0.02380952381

Note that delaying the integrand via `hold` will not work for triple or higher-dimensional quadrature! The user can handle this by making sure that the integrand can also be evaluated for symbolic arguments:

```
f := proc(x, y, z)  
    begin
```

```

if not testtype([args()], Type::ListOf(Type::Numeric))
  then return(procname(args()))
end_if;
if x^2 + y^2 + z^2 <= 1
  then return(1)
  else return(0)
end_if
end_proc:

```

Note that this function is not continuous, implying slow convergence of the numerical quadrature. For this reason, we use a low precision goal of only 2 digits and reduce the costs by using a low order quadrature rule:

```

DIGITS := 2:
Q(Q(Q(f(x, y, z), x=0..1, GL=5), y=0..1, GL=5), z=0..1, GL=5)

```

0.52

```
delete f, Q, DIGITS:
```

Example 6

The following example uses non-adaptive Gauss-Tschebyscheff quadrature with an increasing number of nodes. The results converge quickly to the exact value:

```

a := exp(x)/sqrt(1 - x^2), x = -1..1:
numeric::quadrature(a, Adaptive = FALSE, GT = n) $ n = 3..7

```

3.97732196, 3.977462635, 3.977463259, 3.977463261, 3.977463261

```
delete a:
```

numeric::quadrature

Example 7

The improper integral $\int_0^1 \frac{1}{x} dx = 10$ exists. Numerical convergence, however, is rather slow because of the singularity at $x = 0$:

```
numeric::quadrature(x^(-9/10), x = 0..1)
```

Warning: Precision goal is not achieved after 10000 function calls.

9.998221195

We remove the limit for the number of function calls and let `numeric::quadrature` grind along until a result is found. The time for the computation grows accordingly, the last digit is incorrect due to roundoff effects:

```
numeric::quadrature(x^(-9/10), x = 0..1, MaxCalls = infinity)
```

9.999999993

Example 8

The following integral does not exist in the Riemann sense, because the integrand is not bounded:

```
numeric::quadrature(1/x, x = -1..2)
```

Warning: Precision goal is not achieved after 10000 function calls.

116.9391252

We increase `MaxCalls`. There is no convergence of the numerical algorithm, because the integral does not exist. Consequently, some internal problem must arise: `numeric::quadrature` reaches its maximal recursive depth:

```
numeric::quadrature(1/x, x = -1..2, MaxCalls = infinity)
```

```
Warning: Precision goal is not achieved after 'MAXDEPTH=500' rec
```

```
3.262987586
```

Parameters

f(x)

An arithmetical expression in x

x

An identifier or an indexed identifier

a, b

Real or complex numerical values or $\pm\infty$

Options

GaussLegendre, GaussTschebyscheff, NewtonCotes

Options, specified as `GaussLegendre = n, GaussTschebyscheff = n, NewtonCotes = n`

The name of the underlying quadrature scheme. Each quadrature rule can be used with an arbitrary number of nodes specified by the positive integer n .

Usually there is no need to use this option to change the default method `GaussLegendre = n` with $n = 20, 40, 80$ or 160 , depending on the precision goal determined by the environment variable `DIGITS`. Due to the corresponding high quadrature orders $40, 80, 160$ or 320 , respectively, the default settings are suitable for high precision computations.

numeric::quadrature

With `GaussLegendre = n`, an adaptive version of Gauss-Legendre quadrature with n nodes is used.

For $DIGITS \leq 200$, the weights and abscissae of Gaussian quadrature with $n = 20, 40, 80$, and 160 nodes are available and the integration starts immediately.

For $DIGITS > 200$, the routine `numeric::gldata` is called to compute the Gaussian data before the actual integration starts. This will be noted by some delay in the first call of `numeric::quadrature`.

For $DIGITS$ much larger than 200, it is recommended not to use the default setting but to use `GaussLegendre = n` with sufficiently high n instead. A reasonable choice is $n \approx DIGITS$.

With `GaussTschebyscheff = n`, non-adaptive Gauss-Tschebyscheff quadrature with n nodes is used. This method may only be used in conjunction with `Adaptive = FALSE`.

Note With `NewtonCotes = n`, an adaptive version of Newton-Cotes quadrature with n nodes is used. Note that these quadrature rules become numerically unstable for large n (n much larger than 10).

Following alternative names for the methods are accepted:

`GaussLegendre`, `Gauss`, `GL`,

`GaussTschebyscheff`, `GT`, `GaussChebyshev`, `GC`,

`NewtonCotes`, `NC`.

Adaptive

Option, specified as `Adaptive = v`

v may be `TRUE` or `FALSE`. With `Adaptive = FALSE`, the internal error control is switched off.

The default setting is `Adaptive = TRUE`. An adaptive quadrature scheme with automatic control of the quadrature error is used.

The call `numeric::quadrature(f(x), x = a..b, method = n, Adaptive = FALSE)` returns the quadrature sum

$(b-a) \left(\sum_{i=1}^n B_i f(a+C_i(b-a)) \right)$ approximating $\int_a^b f(x) dx$ without any control of the quadrature error. The weights B_i and abscissae C_i are determined by the quadrature rule given by `method = n`. For the methods `GaussLegendre`, `GaussTschebyscheff` and `NewtonCotes`, these data are available via `numeric::gldata`, `numeric::gtdata` and `numeric::ncdata`, respectively.

`Adaptive = FALSE` may only be used in conjunction with `method = n`.

Usually there is no need to switch off the internal adaptive quadrature via `Adaptive = FALSE`. This option is meant to give easy access to standard non-adaptive quadrature rules of Gauss-Legendre, Gauss-Tschebyscheff and Newton-Cotes type, respectively. The user may want to build his own adaptive quadrature based on these non-adaptive rules. Cf. "Example 6" on page 18-303.

MaxCalls

Option, specified as `MaxCalls = m`

`m` must be a (large) positive integer or infinity. It is the maximal number of evaluations of the integrand, before `numeric::quadrature` gives up.

When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See "Example 7" on page 18-304. When called from inside a procedure, `numeric::quadrature` returns FAIL.

The default value is `m = MAXDEPTH*n`. The environment variable `MAXDEPTH` (default value 500) represents the maximal recursive depth of a function. `n` is the number of nodes of the basic

numeric::quadrature

quadrature rule specified by the optional argument `method = n`. If no such method is specified by the user, then Gauss-Legendre quadrature is used with $n = 20$ for $DIGITS \leq 10$, $n = 40$ for $10 < DIGITS \leq 50$, $n = 80$ for $50 < DIGITS \leq 100$, $n = 160$ for $100 < DIGITS$. Thus, for $DIGITS = 10$, the default setting is `MaxCalls = 10000`.

The default value of `m` ensures that the `MaxCalls` limit is reached before `numeric::quadrature` reaches its maximal internal recursive depth. Specifying `MaxCalls = infinity` removes this restriction and `numeric::quadrature` computes until it obtains an approximation with about `DIGITS` correct digits or until it runs into an internal error. The typical error that may occur is the evaluation of the integrand at a singularity. There also is the danger of `numeric::quadrature` reaching its maximal internal recursive depth. When called interactively, `numeric::quadrature` returns the approximation it has computed so far and issues a warning. See “Example 8” on page 18-304. When called from inside a procedure, `numeric::quadrature` returns `FAIL`.

Return Values

Floating point number is returned, unless non-numerical symbolic objects in the integrand $f(x)$ or in the boundaries a, b prevent numerical evaluation. In this case, `numeric::quadrature` returns itself symbolically. If numerical problems occur, then `FAIL` is returned.

MuPAD Functions

`int` | `numeric::gldata` | `numeric::gtdata` | `numeric::int` | `numeric::ncdata`

Purpose	Numerical estimate of the rank of a matrix
Syntax	<code>numeric::rank(A, <eps>, options)</code>
Description	<p><code>numeric::rank(A)</code> returns an integer indicating the rank of the matrix A.</p> <p>All entries of the input matrix must be numerical, i.e., they must be floating-point numbers or expressions that can be converted to floating-point numbers.</p> <p>The rank of a matrix coincides with the number of non-zero singular values.</p> <p>A numerical estimate of the rank is computed by counting all singular values that are larger than $eps s_m ax$, where $s_m ax$ is the largest singular value. (All smaller singular values are regarded as round-off artifacts and treated as zero.)</p>
Environment Interactions	The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.
Examples	<p>Example 1</p> <p>We consider a quadratic matrix of rank 2:</p> <pre>A := matrix([[1, 1, I], [1, 2, 3], [2, 4, 6]]): numeric::rank(A)</pre> <p>2</p> <p>Hilbert matrices have full rank. However, they are extremely ill-conditioned and it is difficult to compute their rank numerically. The 10×10 Hilbert matrix has rank 10. Numerically, however, some of the singular values are so small that they may be regarded as zero resulting</p>

numeric::rank

in a smaller numerical rank. In particular, with the default value `eps =`

$\frac{1}{10^{16}}$, two singular values are smaller than $eps \cdot s_{max}$ where $s_{max} = 1.7519\dots$ is the maximal singular value:

```
A := linalg::hilbert(10):  
numeric::singularvalues(A)
```

```
[1.75191967, 0.3429295485, 0.03574181627, 0.002530890769, 0.0001287496143,  
0.000004729689293, 0.0000001228967739, 0.000000002147438818, 2.26674678 10-11,  
1.093197787 10-13]
```

```
numeric::rank(A)
```

```
8
```

We specify a second argument `eps = 10-14` to allow smaller singular values to be regarded as non-zero. Now, the numerical rank is 10:

```
numeric::rank(A, 10(-14))
```

```
10
```

```
delete A:
```

Example 2

We consider a non-square matrix of rank 1:

```
A := matrix([[0, 0],  
            [I, 1],  
            [I, 1]]):
```

```
numeric::rank(A)
```

```
1
```

```
delete A:
```

Example 3

We demonstrate the difference between hardware floats and software floats:

```
A := linalg::hilbert(15):
numeric::rank(A, 10^(-20), SoftwareFloats),
numeric::rank(A, 10^(-20), HardwareFloats)
```

```
14, 15
```

```
delete A:
```

Parameters

A

An $m \times n$ matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

eps

Relative tolerance: regard all singular values s of A as zero if they satisfy $s \leq eps s_m ax$, where $s_m ax$ is the largest singular value of A .

The default value of `eps` is $\frac{1}{10^{\text{DIGITS}}}$.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled

C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

Note For ill-conditioned matrices, the results returned with `HardwareFloats` and `SoftwareFloats` may differ significantly! See “Example 3” on page 18-311.

Return Values

Positive integer.

MuPAD Functions

`linalg::rank`

numeric::rationalize

Purpose Approximate a floating-point number by a rational number

Syntax `numeric::rationalize(object, <Exact | Minimize
| Restore>, <digits>)`

Description `numeric::rationalize(object)` replaces all floating-point numbers in `object` by rational numbers.

An object of a library domain, characterized by `domtype(extop(object,0))=DOM_DOMAIN` is returned unchanged. For all other objects, `numeric::rationalize` is applied recursively to all operands. Objects of library domains can be rationalized if the domain has an appropriate `map` method. See “Example 5” on page 18-318.

A floating-point number f is approximated by a rational number r satisfying $|f - r| < \varepsilon|f|$.

Note With the options `Exact` and `Minimize`, the guaranteed precision

is $\varepsilon = \frac{1}{10^{\text{digits}}}$. With `Restore`, the guaranteed precision is only

$$\varepsilon = \frac{1}{10^{\frac{\text{digits}}{2}}}$$

The default precision is `digits = DIGITS`.

The user defined precision must not be larger than the internal floating-point precision set by `DIGITS`: an error occurs for `digits > DIGITS`.

Environment Interactions The function is sensitive to the environment variable `DIGITS`.

Examples **Example 1**

`numeric::rationalize` is applied to each operand of a composite object:

```
numeric::rationalize(0.2*a+b^(0.7*I))
```

$$\frac{a}{5} + b^{\frac{7i}{10}}$$

```
numeric::rationalize([{poly(0.2*x, [x]), sin(7.2*PI) + 1.0*I},
                      exp(3 + ln(2.0*x))])
```

$$\left[\left\{ \sin\left(\frac{36\pi}{5}\right) + i, \text{poly}\left(\frac{x}{5}, [x]\right) \right\}, e^{\ln(2x)+3} \right]$$

Example 2

We demonstrate the default strategy Exact:

```
numeric::rationalize(12.3 + 0.5*I),
numeric::rationalize(0.33333),
numeric::rationalize(1/3.0)
```

$$\frac{123}{10} + \frac{i}{2}, \frac{33333}{100000}, \frac{33333333333}{100000000000}$$

```
numeric::rationalize(10^12/13.0),
numeric::rationalize(10^(-12)/13.0)
```

$$76923076923, \frac{76923076923}{100000000000000000000000000000000000000}$$

We reduce the precision of the approximation to 5 digits:

```
numeric::rationalize(10^12/13.0, 5),
numeric::rationalize(10^(-12)/13.0, 5)
```

$$76923100000, \frac{769231}{1000000000000000000000000000000000000}$$

numeric::rationalize

Example 3

We demonstrate the strategy `Minimize` for minimizing the complexity of the resulting rational number:

```
numeric::rationalize(1/13.0, 5),
numeric::rationalize(1/13.0, Minimize, 5),
numeric::rationalize(0.333331, 5),
numeric::rationalize(0.333331, Minimize, 5),
numeric::rationalize(14.285, 5),
numeric::rationalize(14.2857, Minimize, 5),
numeric::rationalize(1234.1/56789.2),
numeric::rationalize(1234.1/56789.2, Minimize)
```

$$\frac{769231}{10000000}, \frac{1}{13}, \frac{333331}{1000000}, \frac{1}{3}, \frac{2857}{200}, \frac{100}{7}, \frac{21731244673}{1000000000000}, \frac{12341}{567892}$$

We compute rational approximations of π with various precisions:

```
numeric::rationalize(float(PI), Minimize, i) $ i = 1..10
```

$$3, \frac{22}{7}, \frac{22}{7}, \frac{355}{113}, \frac{355}{113}, \frac{355}{113}, \frac{355}{113}, \frac{102573}{32650}, \frac{104348}{33215}, \frac{208341}{66317}$$

Example 4

We demonstrate the strategy `Restore` for restoring rational numbers after elementary float operations. In many cases, also the `Minimize` strategy restores:

```
numeric::rationalize(1/7.3, Exact),
numeric::rationalize(1/7.3, Minimize),
numeric::rationalize(1/7.3, Restore)
```

$$\frac{13698630137}{100000000000}, \frac{10}{73}, \frac{10}{73}$$

However, using `Restore` improves the chances of recovering from roundoff effects:

```
numeric::rationalize(10^9/13.0, Minimize),  
numeric::rationalize(10^9/13.0, Restore)
```

$$\frac{923076923}{12}, \frac{1000000000}{13}$$

```
DIGITS:= 11:
```

```
numeric::rationalize(1234.56/12345.67, Minimize),  
numeric::rationalize(1234.56/12345.67, Restore)
```

$$\frac{88183}{881835}, \frac{123456}{1234567}$$

In some cases, `Restore` manages to recover from roundoff error propagation in composite arithmetical operations:

```
DIGITS:= 10:
```

```
x:= float(122393/75025):  
y:= float(121393/75025):  
z := (x^2 - y^2)/(x + y)
```

0.01332889037

```
numeric::rationalize(z, Restore)
```

$$\frac{40}{3001}$$

The result with `Restore` corresponds to exact arithmetic:

```
rx := numeric::rationalize(x, Restore):  
ry := numeric::rationalize(y, Restore):  
rx, ry, (rx^2 - ry^2)/(rx + ry)
```

numeric::rationalize

$$\frac{122393}{75025}, \frac{121393}{75025}, \frac{40}{3001}$$

Note that an approximation with `Restore` may have a reduced precision of only `digits/2`:

```
x := 1.0 + 1/10^6:  
numeric::rationalize(x, Exact),  
numeric::rationalize(x, Restore)
```

$$\frac{1000001}{1000000}, 1$$

```
delete x, y, z, rx, ry:
```

Example 5

The floats inside objects of library domains are not rationalized directly. However, for most domains the corresponding `map` method can forward `numeric::rationalize` to the operands:

```
Dom::Multiset(0.2, 0.2, 1/5, 0.3)
```

$$\left\{ [0.2, 2], \left[\frac{1}{5}, 1 \right], [0.3, 1] \right\}$$

```
numeric::rationalize(%), map(% , numeric::rationalize, Restore)
```

$$\left\{ [0.2, 2], \left[\frac{1}{5}, 1 \right], [0.3, 1] \right\}, \left\{ \left[\frac{1}{5}, 3 \right], \left[\frac{3}{10}, 1 \right] \right\}$$

Parameters

object

An arbitrary MuPAD object

digits

A positive integer (the number of decimal digits) not bigger than the environment variable DIGITS. It determines the precision of the rational approximation.

Options

Exact

Specifies the strategy for approximating floating-point numbers by rational numbers. This is the default strategy, so there is no real need to pass `Exact` as a parameter to `numeric::rationalize`.

Any real floating-point number $f \neq 0.0$ has a unique representation

$$f = \text{sign}(f) \text{ mantissa } 10^{\text{exponent}}$$

With integer exponent and $1.0 \leq \text{mantissa} < 10.0$. With the option `Exact`, the float mantissa is replaced by the rational approximation

$$\frac{\text{round}(\text{mantissa } 10^{\text{digits}})}{10^{\text{digits}}}$$

This guarantees a relative precision of `digits` significant decimals of the rational approximation.

Minimize

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to minimize the complexity of the rational approximation, i.e., numerators and denominators are to be small.

The guaranteed precision of the rational approximation is `digits`.

See “Example 3” on page 18-316.

Restore

Specifies the strategy for approximating floating-point numbers by rational numbers. This strategy tries to restore rational numbers

numeric::rationalize

obtained after *elementary* arithmetical operations applied to floating-point numbers. E.g., for rational r , the float division $f = 1/\text{float}(r)$ introduces additional roundoff, which the Restore algorithm tries to eliminate: `numeric::rationalize(f, Restore) = 1/r`. This strategy, however, is purely heuristic and will not succeed when significant roundoff is caused by arithmetical float operations!

Note The guaranteed precision of the rational approximation is only `digits/2!`

See “Example 4” on page 18-316.

Return Values

If the argument is an object of some kernel domain, then it is returned with all floating-point operands replaced by rational numbers. An object of some library domain is returned unchanged.

Overloaded By

object

Algorithms

Continued fraction (CF) expansion is used with the options `Minimize` and `Restore`.

With `Minimize`, the first CF approximation satisfying the precision criterion is returned.

The `Restore` algorithm stops, when large coefficients of the CF expansion are found.

Purpose

Numerical search for a real root of a real univariate function

Syntax

`numeric::realroot(f(x), x = a .. b, <SearchLevel = s>)`

Description

`numeric::realroot(f(x), x = a..b)` computes a numerical real root of $f(x)$ in the interval $[a, b]$.

The expression $f(x)$ must not contain symbolic objects other than the indeterminate x that cannot be converted to numerical values via `float`. Symbolic objects such as π or $\sqrt{2}$ etc. are accepted. The same holds true for the boundaries a , b of the search interval.

The function must produce real values. If `float(f(x))` does not yield real floating-point numbers for all real floating-point numbers x from the interval $[a, b]$, internal problems may occur. See “Example 5” on page 18-323.

`numeric::realroot` never tries to evaluate $f(x)$ outside the search interval. Consequently, singularities outside the interval do not cause any problems. In many cases also singularities inside the interval do not affect the numerical search. However, `numeric::realroot` is not guaranteed to work in such a case. An error may occur, if the internal search accidentally hits a singularity. See “Example 5” on page 18-323.

Up to roundoff effects numerical roots r with $|r| \geq \frac{1}{\text{DIGITS}}$ are computed to a relative precision of `DIGITS` significant decimal places. Roots of smaller absolute size are computed to an absolute precision

of $\frac{1}{10}$. These precision goals are not achieved, if significant roundoff occurs in the numerical evaluation of $f(x)$.

If f takes opposite signs at the endpoints a , b of the search interval and does not have zero-crossing singularities, then `numeric::realroot` is bound to find a root in the interval $[a, b]$.

User defined functions can be handled. See “Example 2” on page 18-322.

numeric::realroot

Note `numeric::realroot` approximates a point where $f(x)$ changes its sign. This is a root only if the function f is continuous. See “Example 3” on page 18-323.

Note that `numeric::realroots` may be used to isolate *all* real roots. However, this function is much slower than `numeric::realroot`, if f is not a polynomial.

For univariate polynomials we recommend to use `numeric::realroots` or `polylib::realroots` rather than `numeric::realroot`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The following functions assume different signs at the boundaries, so the searches are bound to succeed:

```
numeric::realroot(x^3 - exp(3), x = -PI..10)
```

```
2.718281828
```

```
numeric::realroot(exp(-x[1]) = x[1], x[1] = 0..1)
```

```
0.5671432904
```

Example 2

The following function cannot be evaluated for non-numerical x . So one has to delay evaluation via `hold`:

```
f := proc(x) begin
    if x<0 then 1 - x else exp(x) - 10*x end_if
end_proc:
```

```
numeric::realroot(hold(f)(x), x = -10..10)
```

```
0.1118325592
```

```
delete f:
```

Example 3

numeric::realroot approximates a point, where $f(x)$ changes its sign. For the following function this happens at the discontinuity $x = 1$:

```
f := proc(x) begin if x<1 then -1 else x end_if end_proc:
numeric::realroot(hold(f)(x), x = 0..3)
```

```
1.0
```

```
delete f:
```

Example 4

The following function does not have a real root. Consequently, numeric::realroot fails:

```
numeric::realroot(x^2 + 1, x = -2..2)
```

```
FAIL
```

The following function does not have a real root in the search interval:

```
numeric::realroot(x^2 - 1, x = 2..3)
```

```
FAIL
```

Example 5

The following function is complex valued for $x^2 < 3.5$. An error occurs, when the internal search hits such a point:

numeric::realroot

```
numeric::realroot(ln(x^2 - 3.5), x = -2..3)
```

```
Error: Cannot evaluate to Boolean. [_less]  
  Evaluating: numeric::BrentFindRoot
```

The singularity at $x = 1$ does not cause any problem in the following call:

```
numeric::realroot((x-2)/(x-1), x = -10..10)
```

```
2.0
```

However, the singularity may be hit accidentally in the internal search:

```
numeric::realroot((x-2)/(x-1), x = 0..3)
```

```
Error: Division by zero. [_power]  
  Evaluating: f
```

Example 6

The following function has a root close to 1.0, which is difficult to detect. With the default search level $s = 1$, this root is not found:

```
f := 2 - exp(-100*(x - 2)^2) - 2*exp(-1000*(x - 1)^2):  
numeric::realroot(f, x = 0..5)
```

```
FAIL
```

The root is detected with an increased search level:

```
numeric::realroot(f, x = 0..5, SearchLevel = 3)
```

1.0

delete f:

Parameters

f(x)

An arithmetical expression in one unknown x or a list, set, array, or matrix (Cat::Matrix) of expressions. Alternatively, equations in the form $f_1(x) = f_2(x)$ equivalent to the expressions $f_1(x) - f_2(x)$.

x

An identifier or an indexed identifier

a, b

Finite real numerical values

Options

SearchLevel

Option, specified as SearchLevel = s

The nonnegative integer s controls the internal refinement of the search. The default value is $s = 1$. Increasing s increases the chance of finding roots that are difficult to detect numerically. See “Example 6” on page 18-324.

Note that increasing s by 1 may quadruple the time before FAIL is returned, if no real root is found. For this reason we recommend to restrict s to small values ($s \leq 5$, say).

Return Values

Single numerical real root of domain type DOM_FLOAT. If no solution is found, then FAIL is returned.

Algorithms

A mixture of bisectioning, secant steps and quadratic interpolation is used by numeric::realroot.

numeric::realroot

MuPAD Functions

`numeric::fsolve` | `numeric::polyroots` | `numeric::realroots` |
`polylib::realroots` | `solve`

Concepts

- “Solve Equations Numerically”

Purpose

Isolate intervals containing real roots of a univariate function

Syntax

`numeric::realroots(f(x), <x = a .. b>, <eps>, <Merge = c>)`

Description

`numeric::realroots(f(x), x = a..b)` searches for real roots of $f(x)$ in the interval $[a, b]$. It returns a list of subintervals in which real roots of $f(x)$ may exist. It is guaranteed that there are no real roots in the interval $[a, b]$ lying outside the union of the returned subintervals.

With `Merge = FALSE`, all intervals returned by `numeric::realroots` have length $b_i - a_i < eps$ with a default value $eps = 0.01$. The absolute precision of the root isolation may be redefined using the optional parameter `eps`.

Note The intervals returned by `numeric::realroots` define a subset of $[a, b]$ that may contain real roots. For polynomial expressions $f(x)$, each of the subintervals of $[a, b]$ returned by `numeric::realroots` is guaranteed to contain exactly one root. For non-polynomial expressions $f(x)$, however, some of the subintervals may contain no root! Cf. “Example 6” on page 18-331.

In any case, the complement $[a, b] \setminus \left(\bigcup_{i \in \{1, \dots, n\}} [a_i, b_i] \right)$ of the subintervals $[a_i, b_i]$ returned by `numeric::realroots` is guaranteed to contain no real roots. In particular, from the return value `[]`, one may positively conclude that no root exists in the search interval $[a, b]$. Cf. “Example 2” on page 18-329.

Symbolic parameters in $f(x)$ are not allowed: `float(f(x))` must evaluate to a floating point number for all x from the interval $[a, b]$.

Infinite intervals of the form `x = -infinity..b` are not refined if $b \leq -10^5$.

Infinite intervals of the form `x = a..infinity` are not refined if $a \geq 10^5$.

numeric::realroots

Such intervals are returned directly if `numeric::realroots` thinks that they may contain roots. Cf. “Example 5” on page 18-330.

$f(x)$ may contain complex expressions. Only the search parameter x is assumed to be real. For complex expressions $f(x)$, the intervals are returned where both the real and the imaginary part of the expression vanish simultaneously.

Note The expression $f(x)$ must be suitable for interval arithmetic. In particular, MuPAD must be able to evaluate $f(a..b)$. Note that not all MuPAD functions support this kind of arithmetic.

Presently, the following special functions support interval arithmetic: `abs`, `arccos`, `arccosh`, `arccoth`, `arccot`, `arccsc`, `arccsch`, `arcsec`, `arcsech`, `arcsin`, `arcsinh`, `arctan`, `arctanh`, `arg`, `beta`, `ceil`, `cos`, `cosh`, `cot`, `coth`, `csc`, `csch`, `dirac`, `exp`, `floor`, `gamma`, `Im`, `ln`, `Re`, `round`, `sec`, `sech`, `sin`, `sinh`, `sqrt`, `tan`, `tanh`, `trunc`. Real roots can be searched for any expression that is built from these functions using the standard arithmetical operations `+`, `-`, `*`, `/`, `^`.

The default value is $eps = 0.01$. User defined precision goals must

satisfy $eps \geq \frac{1}{10^{DIGITS}}$.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The following expression has integer zeros. The solutions in the specified interval are approximated to the default precision 0.01:

```
numeric::realroots(sin(PI*x), x = -2..sqrt(2))
```

```
[[[-2.0, -1.993331614], [-1.006410506, -0.9997421204],
  [-0.006152626661, 0.000515759203], [0.9941052529, 1.000773639]]]
```

The following equation is solved with an absolute precision of 7 digits:

```
numeric::realroots(x*sin(x) = exp(-x), x = -1..1, 10^(-7))
```

```
[[0.7271005511, 0.7271006107]]
```

Example 2

The following expression does not have a real root:

```
numeric::realroots(exp(x) + x^2, x = -100..100)
```

```
[]
```

Example 3

We demonstrate the option `Merge`. If interval arithmetic can not isolate roots to the desired precision *eps* (default 0.01), then adjacent intervals are produced, each of length smaller than *eps*. This happens in the following example:

```
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10,
  Merge = FALSE)
```

```
[[[0.869140625, 0.87890625], [0.87890625, 0.888671875], [0.888671875, 0.8984375], ...,
  [1.123046875, 1.1328125], [1.1328125, 1.142578125]]]
```

With `Merge = TRUE`, these intervals are combined to a single larger interval. Since `Merge = TRUE` is the default setting for non-polynomial functions, it suffices to omit the option `Merge = FALSE`:

```
numeric::realroots(ln(x^2 -2*x + 2) = 0, x = -10..10)
```

numeric::realroots

```
[[0.869140625, 1.142578125]]
```

Example 4

The following expression has infinitely many solutions $x = \frac{1}{n}$ with $n = 1, 2, \dots$ in the search interval $[0, 1]$:

```
numeric::realroots(sin(PI/x), x = 0..1, 0.1, Merge = FALSE)
```

```
[[0.0, 0.0625], [0.0625, 0.125], [0.125, 0.1875], [0.1875, 0.25], [0.25, 0.3125], [0.3125, 0.375],  
[0.4375, 0.5], [0.5, 0.5625], [0.9375, 1.0]]
```

Omitting `Merge = FALSE`, adjacent intervals are merged to larger intervals. The first of the following intervals contains infinitely many roots:

```
numeric::realroots(sin(PI/x), x = 0..1, 0.1)
```

```
[[0.0, 0.375], [0.4375, 0.5625], [0.9375, 1.0]]
```

Example 5

If no search interval is specified, the entire real line is considered:

```
numeric::realroots(x^3 = exp(x))
```

```
[[1.841783524, 1.871585846], [4.523992538, 4.553794861], [10000.0, ∞]]
```

Apart from two finite intervals, `numeric::realroots` tells us that there may be a root close to infinity (but that there is positively no root close to $-\infty$). Analytically, it is clear that the subinterval `[10000.0, ∞]` cannot contain a root, since e^x grows much faster than x^3 as x goes to infinity. If a finite upper limit for the search interval is specified, this fact is detected:

```
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100)
[[1.842076975, 1.877795331], [4.512024084, 4.556672029]]
```

We isolate the two finite roots more closely by specifying a precision

goal of $\frac{1}{10^{\text{DIGITS}}}$:

```
numeric::realroots(x^3 = exp(x), x = -infinity .. 10^100,
                  10^(-DIGITS))
[[1.85718386, 1.85718386], [4.536403655, 4.536403655]]
```

Example 6

The following equation has no root close to 0. However, interval arithmetic does not produce realistic values of $\frac{\sin(\pi x)}{x}$ for small intervals containing $x = 0$, so an isolating interval around 0 is returned:

```
numeric::realroots(sin(PI*x)/x = 0, x = -1..1.2)
[[-1.0, -0.99140625], [-0.003125, 0.00546875], [0.99375, 1.00234375]]
```

A similar phenomenon occurs with $x^x = e^{x \ln(x)}$ in a neighbourhood of $x = 0$. An isolating interval around 0 is returned, although no solution exists there:

```
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1)
[[0.0, 0.0078125], [0.328125, 0.3359375]]
```

This cannot be cured by increasing the precision goal:

```
numeric::realroots(x^x*cos(PI*x) = tan(x), x = 0..1,
```

numeric::realroots

10^(-DIGITS)

$\left[\left[0.0, 5.820766091 \cdot 10^{-11} \right], \left[0.3334737903, 0.3334737903 \right] \right]$

Parameters

f(x)

An expression in one indeterminate x or a list, set, array, or matrix (Cat::Matrix) of expressions. Alternatively, equations in the form $f_1(x) = f_2(x)$ equivalent to the expressions $f_1(x) - f_2(x)$.

x

An identifier or an indexed identifier

a, b

Real numbers or numerical expressions satisfying $a < b$. Also -infinity and infinity may be used.

eps

A (small) positive real numerical value defining the precision goal. The default value is 0.01.

Options

Merge

Option, specified as Merge = b

b can be TRUE or FALSE. With Merge = FALSE, numeric::realroots returns subintervals of length not larger than eps. With Merge = TRUE, numeric::realroots merges adjacent subintervals to larger intervals, i.e., subintervals of length larger than eps may be returned.

The default setting is Merge = FALSE for polynomial functions $f(x)$. Otherwise, it is Merge = TRUE.

`numeric::realroots` isolates intervals $[a_i, b_i]$ that may contain roots. Internally, all these intervals satisfy $b_i - a_i < \textit{eps}$ where *eps* is the precision goal.

With `Merge = FALSE`, these intervals are returned.

With `Merge = TRUE`, adjacent intervals $[a_i, b_i], [a_{i+1}, b_{i+1}]$ with $b_i = a_{i+1}$ are combined to larger intervals $[a_i, b_{i+1}]$. See “Example 3” on page 18-329 and “Example 4” on page 18-330.

The default setting is `Merge = FALSE` for polynomial functions. Otherwise, it is `Merge = TRUE`.

Return Values

List $[[a_1, b_1], [a_2, b_2], \dots]$ of disjoint floating-point intervals

$[a_i, b_i] \subset [a, b]$ which may contain roots of $f(x)$. The empty list is returned if no root exists in the search interval $[a, b]$.

Algorithms

Let X be a subset of the real numbers. Interval arithmetic produces a set $F(X)$ such that the set of image values $\{f(x) \mid x \in X\}$ is contained in $F(X)$. The MuPAD domain `DOM_INTERVAL` facilitates this kind of arithmetic. The routine `numeric::realroots` computes $F := f(a_i \dots b_i)$ for various subintervals $[a_i, b_i]$ of $[a, b]$. If F does not contain zero, then this subinterval is eliminated from the search interval. Otherwise, the subinterval is returned as a candidate for containing zeros of $f(x)$. However, one cannot conclude that F does indeed contain at least one zero, since F is usually larger than the true image set $\{f(x) \mid x \in [a_i, b_i]\}$ (“overestimation”).

For polynomials $f(x)$, the routine `polylib::realroots` is called. Its results are intersected with the search interval $[a, b]$. No interval arithmetic is used for polynomial expressions. For polynomial equations, each isolating interval returned by `numeric::realroots` is guaranteed to contain at least one root if `Merge = TRUE` is specified. With the default setting of `Merge = FALSE` for polynomials, each isolating interval is guaranteed to contain exactly one root.

polylib::realroots | solve

Concepts

- “Solve Equations Numerically”

Purpose

Orthogonal matrix of the rotation about an axis

Syntax

`numeric::rotationMatrix(angle, axis, <Symbolic>, <ReturnType = t>)`

Description

`numeric::rotationMatrix(angle, axis)` returns an orthogonal matrix corresponding to the rotation about the given axis by the given angle.

The rotation by the angle α about the axis given by the vector $[x, y, z]$ of Euclidean length 1 is given by the rotation matrix

$$e^{\alpha \begin{pmatrix} 0 & -z & y \\ z & 0 & -x \\ -y & x & 0 \end{pmatrix}} = \begin{pmatrix} tx^2+c & txy-sz & txz+sy \\ txy+sz & ty^2+c & tyz-sx \\ txz-sy & tyz+sx & tz^2+c \end{pmatrix}$$

with $c = \cos(\alpha)$, $s = \sin(\alpha)$, and $t = 1 - c = 2 \sin\left(\frac{\alpha}{2}\right)^2$.

The rotation is implemented following the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation.

Use negative angles to rotate in the opposite direction.

The axis parameter of the routine does not need to be normalized to the Euclidean length 1. However, it must not be of zero length.

If no return type is specified via the option `ReturnType = t`, the domain type of the result depends on the type of the input matrix axis:

- If the axis is of domain type array, then the rotation matrix is returned as an array.
- If the axis is of domain type hfarray, then the result is returned as an hfarray.

numeric::rotationMatrix

- If the axis is of domain type `Dom::DenseMatrix()`, then the rotation matrix is returned as a matrix of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- If axis is of any different matrix type, the result is a matrix of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices axis of type `Dom::Matrix(...)`, `Dom::SquareMatrix(...)`, `Dom::MatrixGroup(...)` etc.
- If axis is a list with 3 elements, the rotation matrix is also returned as an `Dom::Matrix()` over the ring of MuPAD expressions.

Without the option `Symbolic`, all arguments are automatically converted to floating-point arguments (if possible). Use the option `Symbolic` if no such conversion is desired.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The rotation around the z axis by 45 degrees is given by the following matrix:

```
numeric::rotationMatrix(PI/4, [0, 0, 1])
```

$$\begin{pmatrix} 0.7071067812 & -0.7071067812 & 0 \\ 0.7071067812 & 0.7071067812 & 0 \\ 0 & 0 & 1.0 \end{pmatrix}$$

Symbolic arguments are accepted:

```
numeric::rotationMatrix(a, [1, 2, 3])
```

```
[[0.9285714286 cos(a) + 0.07142857143, 0.1428571429 - 0.8017837257 sin(a)
  - 0.1428571429 cos(a), 0.5345224838 sin(a) - 0.2142857143 cos(a) + 0.2142857143],
 [0.8017837257 sin(a) - 0.1428571429 cos(a) + 0.1428571429,
  0.7142857143 cos(a) + 0.2857142857, 0.4285714286 - 0.2672612419 sin(a)
  - 0.4285714286 cos(a)], [0.2142857143 - 0.5345224838 sin(a) - 0.2142857143 cos(a),
  0.2672612419 sin(a) - 0.4285714286 cos(a) + 0.4285714286, 0.3571428571 cos(a)
  + 0.6428571429]]
```

With the option `Symbolic`, no automatic conversion to floating-point numbers occurs:

```
numeric::rotationMatrix(a, [1, 2, 3], Symbolic)
```

$$\begin{pmatrix} \frac{13 \cos(a)}{14} + \frac{1}{14} & \frac{1}{7} - \sigma_1 - \frac{\cos(a)}{7} & \frac{\sigma_4}{7} - \sigma_2 + \frac{3}{14} \\ \sigma_1 - \frac{\cos(a)}{7} + \frac{1}{7} & \frac{5 \cos(a)}{7} + \frac{2}{7} & \frac{3}{7} - \frac{\sigma_4}{14} - \sigma_3 \\ \frac{3}{14} - \frac{\sigma_4}{7} - \sigma_2 & \frac{\sigma_4}{14} - \sigma_3 + \frac{3}{7} & \frac{5 \cos(a)}{14} + \frac{9}{14} \end{pmatrix}$$

where

$$\sigma_1 = \frac{3 \sqrt{14} \sin(a)}{14}$$

$$\sigma_2 = \frac{3 \cos(a)}{14}$$

$$\sigma_3 = \frac{3 \cos(a)}{7}$$

$$\sigma_4 = \sqrt{14} \sin(a)$$

numeric::rotationMatrix

Example 2

The return type coincides with the type of the input parameter representing the axis:

```
numeric::rotationMatrix(0.3, matrix([1,2,3]))
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix()
```

```
numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]))
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

```
domtype(%)
```

```
DOM_HFARRAY
```

The option `ReturnType` allows to specify the type of the result:

```
numeric::rotationMatrix(0.3, hfarray(1..3, [1,2,3]), ReturnType = m
```

$$\begin{pmatrix} 0.9585267399 & -0.2305627908 & 0.1675329472 \\ 0.2433237939 & 0.9680974922 & -0.05983959278 \\ -0.1483914426 & 0.0981226021 & 0.9840487461 \end{pmatrix}$$

```
domtype(%)
```

```
Dom::Matrix()
```

Example 3

The direction of the rotation is given by the “right hand rule”: Stretch the thumb of your right hand and bend the fingers. When the thumb points into the direction of the rotation axis, your finger tips indicate the direction of the rotation:

```
axis := matrix([0, 0, 1]):
vector := matrix([1, 0, 0]):
Q := numeric::rotationMatrix(PI/4, axis):
plot(plot::Arrow3d(axis, Color = RGB::Blue),
      plot::Arrow3d(vector, Color = RGB::Red),
      plot::Arrow3d(Q*vector, Color = RGB::Red),
      plot::Text3d("axis", [0.01, 0.01, 0.5]),
      plot::Text3d("vector", [1.05, 0, 0]),
      plot::Text3d("rotated vector", [0.75, 0.75, 0]),
      CameraDirection = [1, -2, 4],
      Scaling = Constrained, Axes = None):
```

numeric::rotationMatrix

Use negative angles to rotate in the opposite direction:

```
axis := matrix([0, 0, 1]):
vector := matrix([1, 0, 0]):
Q := numeric::rotationMatrix(-PI/4, axis):
plot(plot::Arrow3d(axis, Color = RGB::Blue),
      plot::Arrow3d(vector, Color = RGB::Red),
      plot::Arrow3d(Q*vector, Color = RGB::Red),
      plot::Text3d("axis", [0.01, 0.01, 0.5]),
      plot::Text3d("vector", [1.05, 0, 0]),
      plot::Text3d("rotated vector", [0.75, -0.75, 0]),
      CameraDirection = [1, -2, 4],
      Scaling = Constrained, Axes = None):
```

delete axis, vector, Q:

Parameters

angle

An arithmetical expression

axis

A vector represented by a list with 3 entries or by a 3×1 matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`

Options

Symbolic

Prevents the conversion of the input data to floating-point numbers. Exact arithmetic is used.

ReturnType

Option, specified as `ReturnType = t`

numeric::rotationMatrix

Return the result as a matrix of domain type `t`. The following return types are available: `DOM_ARRAY`, `DOM_HFARRAY`, `matrix`, or `densematrix`.

Return Values

Depending on the type of the input matrix `axis`, the 3×3 rotation matrix is returned as a matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, `Dom::Matrix()`, or `Dom::DenseMatrix()`.

Purpose

Numerical singular values of a matrix

Syntax

```
numeric::singularvalues(A, <Hard | HardwareFloats  
| Soft | SoftwareFloats>)
```

Description

`numeric::singularvalues(A)` returns numerical singular values of the matrix A .

The singular values of an $m \times n$ matrix A are the $p = \min(m, n)$ real nonnegative square roots of the eigenvalues of $A^H A$ (for $p = n$) or of AA^H (for $p = m$). The Hermitian transpose A^H is the complex conjugate of the transpose of A .

`numeric::singularvalues` returns a list of real singular values $[d_1, \dots, d_p]$ sorted by `numeric::sort`, i.e., $d_1 \geq \dots \geq d_p \geq 0.0$.

All entries of A must be numerical. Numerical expressions such as e^{π} , $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices A of a matrix domain such as `Dom::Matrix()` or `Dom::SquareMatrix()` are internally converted to arrays over expressions via `expr(A)`.

Note Singular values are approximated with an *absolute* precision

of $\frac{1}{\text{DIGITS}} r$, where r is largest singular value of A . Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

Singular values may also be computed via `map (numeric::eigenvalues(A A^H), sqrt)` or `map (numeric::eigenvalues(A^H A), sqrt)`, respectively.

The use of `numeric::singularvalues` avoids the costs of the matrix multiplication. Further, the eigenvalue routine requires about twice as

numeric::singularvalues

many DIGITS to compute small singular values with the same precision as `numeric::singularvalues`. Cf. “Example 2” on page 18-344.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The singular values of A and A^H coincide:

```
A := array(1..3, 1..2, [[1, 2*I], [2, 3],[3, sqrt(2)]]):  
numeric::singularvalues(A)  
  
[4.994802008, 2.012946323]
```

The Hermitian transpose $B = A^H$:

```
B := array(1..2, 1..3, [[1, 2, 3], [-2*I, 3, sqrt(2)]]):  
numeric::singularvalues(B)  
  
[4.994802008, 2.012946323]
```

```
delete A, B:
```

Example 2

We use `numeric::eigenvalues` to compute singular values:

```
A := matrix([[1/15, 2/15*I], [PI, 314159265358980/5000000000000*I])
```

The Hermitian transpose $B = A^H$ can be computed by the methods `conjugate` and `transpose` of the matrix domain:

```
B := A::dom::conjugate(A::dom::transpose(A)):
```

Note that $A^H A$ is positive semi-definite and cannot have negative eigenvalues. However, computing small eigenvalues is numerically ill-conditioned, and a small negative value occurs due to roundoff:

```
numeric::eigenvalues(B*A)
```

```
[69.37024423, -2.310493271 10-15]
```

Consequently, an (incorrect) imaginary singular value is computed:

```
map(%, sqrt)
```

```
[8.32888013, 0.0000004806759065 i]
```

We have to increase DIGITS in order to compute this value more accurately:

```
DIGITS := 22:
```

```
map(numeric::eigenvalues(B*A), sqrt)
```

```
[8.328880130465871055353, 3.293453726225542754196 10-15]
```

With numeric::singularvalues, the standard precision suffices:

```
DIGITS := 10:
```

```
numeric::singularvalues(A, SoftwareFloats)
```

```
[8.32888013, 3.249076763 10-15]
```

```
numeric::singularvalues(A, HardwareFloats)
```

numeric::singularvalues

```
[8.32888013, 3.6920369 10-15]
```

```
delete A, B:
```

Example 3

We demonstrate the use of hardware floats. Hilbert matrices are notoriously ill-conditioned: the computation of the small singular values is subject to severe roundoff effects. In the following results, both with HardwareFloats as well as with SoftwareFloats, the small singular values are dominated by numerical roundoff. Consequently, the results with HardwareFloats differ from those with SoftwareFloats:

```
numeric::singularvalues(linalg::hilbert(13))
```

```
[1.813830119, 0.396833076, ..., 8.878210699 10-16, 3.222901015 10-18]
```

```
[1.813830119, 0.396833076, 0.04902941942, 0.004348755075, 0.0002951777135  
0.0000156237036, 0.0000006466418563, 0.00000002076321421, 0.000000000  
9.141268657 10-12, 1.143562234 10-13, 8.877867351 10-16, 7.878607674 10-19]
```

```
A := linalg::hilbert(15):  
numeric::singularvalues(A, HardwareFloats);  
numeric::singularvalues(A, SoftwareFloats)
```

```

delete A:

Parameters

A

A numerical matrix of domain type DOM_ARRAY, DOM_HFARRAY, or of category Cat::Matrix

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled

numeric::singularvalues

C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 18-346.

Return Values

Ordered list of real floating-point values.

Algorithms

The code implements standard numerical algorithms from the Handbook of Automatic Computation by Wilkinson and Reinsch.

numeric::singularvectors

Purpose Numerical singular value decomposition of a matrix

Syntax `numeric::singularvectors(A, options)`

Description `numeric::singularvectors(A)` and the equivalent call `numeric::svd(A)` return numerical singular values and singular vectors of the matrix A .

All entries of A must be numerical. Numerical expressions such as e^{π} , $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

`Cat::Matrix` objects, i.e., matrices A of a matrix domain such as `Dom::Matrix()` or `Dom::SquareMatrix()` are internally converted to arrays over expressions via `expr(A)`.

The list `[U, d, V, resU, resV]` returned by `numeric::singularvectors` corresponds to the singular data of an $m \times n$ matrix A as described below.

Let V^H denote the Hermitian transpose of the matrix V , i.e., the complex conjugate of the transpose. The singular value decomposition of an $m \times n$ matrix A is a factorization $A = UDV^H$. D is an $m \times n$ “diagonal” matrix with real nonnegative entries $D_{ii} = d_i$, $i = 1, \dots, p$ where $p = \min(m, n)$:

$$D = \begin{pmatrix} d_1 & & 0 \\ & \dots & \\ & & d_p \\ 0 & & 0 \end{pmatrix}$$

or

$$D = \begin{pmatrix} d_1 & & 0 \\ & \dots & \\ 0 & & d_p & 0 \end{pmatrix},$$

respectively. The list $d = [d_1, \dots, d_p]$ returned by `numeric::singularvectors` are the “singular values” of A . They are sorted by `numeric::sort`, i.e., $d_1 \geq \dots \geq d_p \geq 0.0$.

U is a unitary $m \times m$ matrix. Its i -th column is an eigenvector of AA^H associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the “left singular vectors” of A . They are returned by `numeric::singularvectors` as a matrix of floating-point numbers.

V is a unitary $n \times n$ matrix. Its i -th column is an eigenvector of A^HA associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the “right singular vectors” of A . They are returned by `numeric::singularvectors` as an array of floating-point numbers. The matrix V is normalized such that, in each column, the first entry of

absolute size larger than $\frac{1}{10^{\text{DIGITS}}}$ is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors U and V depends on the type of the input matrix A :

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hffarray are returned as hffarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices A of type `Dom::Matrix()`, `Dom::SquareMatrix()`, `Dom::MatrixGroup()` etc.

$res_U = [resU_1, \dots, resU_m]$ is a list of float residues associated with the left singular vectors:

$$resU_i = \left\langle A^H u_i, A^H u_i \right\rangle - d_i^2, 1 \leq i \leq m$$

numeric::singularvectors

Here, u_i is the (normalized) i -th column of U , $\langle \dots, \dots \rangle$ is the usual complex Euclidean scalar product and $d_i = 0$ for $p < i \leq m$.

$resV = [resV_1, \dots, resV_n]$ is a list of float residues associated with the right singular vectors:

$$resV_i = \langle A v_p, A v_i \rangle - d_i^2, 1 \leq i \leq n$$

Here, v_i is the (normalized) i -th column of V , $d_i = 0$ for $p < i \leq n$.

The residues $resU$, $resV$ vanish for exact singular data U , d , V . Their sizes indicate the quality of the numerical data U , d , V .

Note Singular values are approximated with an *absolute* precision of

$\frac{1}{10^{DIGITS}}$, where r is the largest singular value of A . Consequently, large singular values should be computed correctly to DIGITS decimal places. The numerical approximations of small singular values are less accurate.

The singular values computed by `numeric::singularvectors` are identical to those computed by `numeric::svd`.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

$$d2 = [d_1^2, d_2^2, \dots, d_p^2, 0, \dots, 0]$$

The use of `numeric::singularvectors` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many DIGITS to compute the data associated with small singular values

with the same precision as `numeric::singularvectors`. Also note that the normalization of `U` and `V` may be different.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical expressions are converted to floats:

```
DIGITS := 5:
A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]):
[U, d, V, resU, resV] := numeric::singularvectors(A):
```

The singular data are:

`U, d, V`

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:

`resU, resV`

$$\left[2.247 \cdot 10^{-14}, 2.247 \cdot 10^{-14}, 3.898 \cdot 10^{-32} \right], \left[5.6175 \cdot 10^{-15}, 5.6175 \cdot 10^{-15} \right]$$

delete `DIGITS, A, U, d, V, resU, resV`:

Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as

numeric::singularvectors

matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3:
A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]):
[U, d, V, resU, resV] := numeric::singularvectors(A, NoResidues,
    ReturnType = Dom::Matrix())
```

$$\left[\begin{pmatrix} 0.514 - 0.028i & -0.788 + 0.336i \\ 0.857 + 0.014i & 0.487 - 0.168i \end{pmatrix}, [3.9, 3.27], \right. \\ \left. \begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121i & 0.55 + 0.0871i & -0.493 + 0.0785i \\ 0.418 - 0.242i & -0.81 + 0.174i & -0.236 + 0.157i \end{pmatrix}, \text{NIL}, \text{NIL} \right]$$

A “diagonal” matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitian transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via `numeric::complexRound`:

```
VH := V::dom::conjugate(V::dom::transpose(V)):
map(U*d*VH, numeric::complexRound)
```

$$\begin{pmatrix} 1.0 & 1.0i & 3.14 \\ 2.0 & 3.0 & 1.0i \end{pmatrix}$$

```
delete DIGITS, A, U, d, V, resU, resV, VH:
```

Example 3

We demonstrate the use of hardware floats. The following matrix A is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix $A^H A$, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]):
[U1, d1, V1, resU1, resV1] := numeric::singularvectors(A, HardwareFloats):
[U2, d2, V2, resU2, resV2] := numeric::singularvectors(A, SoftwareFloats):
delete V1, V2
```

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix},$$

$$\begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.1195228609 \\ 0.5345224838 & -0.04390192219 & -0.8440132318 \\ 0.8017837257 & -0.289459681 & 0.5228345342 \end{pmatrix}$$

```
delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:
```

Parameters

A

A numerical matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

numeric::singularvectors

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 18-355.

NoLeftVectors

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of U and the corresponding residues res_u . The return values for these data are `NIL`.

Depending on the size of U , this option may speed up the computation considerably.

NoRightVectors

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of V and the corresponding residues res_v . The return values for these data are `NIL`.

Depending on the size of V , this option may speed up the computation considerably.

NoResidues

Suppresses the computation of error estimates

numeric::singularvectors

If no error estimates are required, this option may be used to suppress the computation of the residues res_U and res_V . The return values for these data are NIL.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type `t`. The following return types `t` are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

NoWarning

Suppresses warnings

Return Values

List `[U, d, V, resU, resV]`. `U` is a unitary square float matrix whose columns are left singular vectors. The list `d` contains the singular values. `V` is a unitary square float matrix whose columns are right singular vectors. The lists of float residues `resU` and `resV` provide error estimates for the numerical data.

Related Examples

- “Compute Factorizations Numerically”

Purpose Numerical singular value decomposition of a matrix

Syntax numeric::svd(A, options)

Description numeric::svd(A) and the equivalent call numeric::singularvectors(A) return numerical singular values and singular vectors of the matrix A.

All entries of A must be numerical. Numerical expressions such as e^x , $\sqrt{2}$ etc. are accepted and converted to floats. Non-numerical symbolic entries lead to an error.

Cat::Matrix objects, i.e., matrices A of a matrix domain such as Dom::Matrix() or Dom::SquareMatrix() are internally converted to arrays over expressions via expr(A).

The list [U, d, V, res_U, res_V] returned by numeric::svd corresponds to the singular data of an $m \times n$ matrix A as described below.

Let V^H denote the Hermitian transpose of the matrix V, i.e., the complex conjugate of the transpose. The singular value decomposition of an $m \times n$ matrix A is a factorization $A = UDV^H$. D is an $m \times n$ “diagonal” matrix with real nonnegative entries $D_{ii} = d_i$, $i = 1, \dots, p$ where $p = \min(m, n)$:

$$D = \begin{pmatrix} d_1 & & 0 \\ & \dots & \\ & & d_p \\ 0 & & & 0 \end{pmatrix}$$

or

$$D = \begin{pmatrix} d_1 & & & 0 \\ & \dots & & \\ 0 & & d_p & 0 \end{pmatrix},$$

respectively. The list $d = [d_1, \dots, d_p]$ returned by `numeric::svd` are the “singular values” of A . They are sorted by `numeric::sort`, i.e., $d_1 \geq \dots \geq d_p \geq 0.0$.

U is a unitary $m \times m$ matrix. Its i -th column is an eigenvector of AA^H associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the “left singular vectors” of A . They are returned by `numeric::svd` as a matrix of floating-point numbers.

V is a unitary $n \times n$ matrix. Its i -th column is an eigenvector of A^HA associated with the eigenvalue d_i^2 ($d_i = 0$ for $i > p$). These are the “right singular vectors” of A . They are returned by `numeric::svd` as an array of floating-point numbers. The matrix V is normalized such that, in

each column, the first entry of absolute size larger than $\frac{1}{10^{\text{DIGITS}}}$ is real and positive.

If no return type is specified via the option `ReturnType = t`, the domain type of the singular vectors U and V depends on the type of the input matrix A :

- The singular vectors of an array are returned as arrays.
- The singular vectors of an hfarray are returned as hfarrays.
- The singular vectors of a dense matrix of type `Dom::DenseMatrix()` are returned as dense matrices of type `Dom::DenseMatrix()` over the ring of MuPAD expressions.
- For all other matrices of category `Cat::Matrix`, the singular vectors are returned as matrices of type `Dom::Matrix()` over the ring of MuPAD expressions. This includes input matrices A of type `Dom::Matrix()`, `Dom::SquareMatrix()`, `Dom::MatrixGroup()` etc.

$res_U = [resU_1, \dots, resU_m]$ is a list of float residues associated with the left singular vectors:

$$resU_i = \left\langle A^H u_i, A^H u_i \right\rangle - d_i^2, \quad 1 \leq i \leq m$$

Here, u_i is the (normalized) i -th column of U , $\langle \dots, \dots \rangle$ is the usual complex Euclidean scalar product and $d_i = 0$ for $p < i \leq m$.

$res_V = [resV_1, \dots, resV_n]$ is a list of float residues associated with the right singular vectors:

$$resV_i = \langle A v_i, A v_i \rangle - d_i^2, 1 \leq i \leq n$$

Here, v_i is the (normalized) i -th column of V , $d_i = 0$ for $p < i \leq n$.

The residues res_U , res_V vanish for exact singular data U , d , V . Their sizes indicate the quality of the numerical data U , d , V .

Note Singular values are approximated with an *absolute* precision of

$\frac{1}{10^{DIGITS}}$, where r is the largest singular value of A . Consequently, large singular values should be computed correctly to $DIGITS$ decimal places. The numerical approximations of small singular values are less accurate.

The singular values computed by `numeric::svd` are identical to those computed by `numeric::singularvalues`.

Singular data may also be computed via `[d2, U, resU] := numeric::eigenvectors(A*A^H)` or `[d2, V, resV] := numeric::eigenvectors(A^H*A)`, respectively. The list `d2` is related to the singular values by

$$d2 = [d_1^2, d_2^2, \dots, d_p^2, 0, \dots, 0]$$

The use of `numeric::svd` avoids the costs of the matrix multiplication. Further, the eigenvector routine requires about twice as many `DIGITS` to compute the data associated with small singular values with the

numeric::svd

same precision as `numeric::singularvectors`. Also note that the normalization of `U` and `V` may be different.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

Numerical expressions are converted to floats:

```
DIGITS := 5:  
A := array(1..3, 1..2, [[1, PI], [2, 3], [3, exp(sqrt(2))]]):  
[U, d, V, resU, resV] := numeric::singularvectors(A):
```

The singular data are:

`U, d, V`

$$\begin{pmatrix} 0.45729 & -0.88078 & 0.12293 \\ 0.51483 & 0.14947 & -0.84416 \\ 0.72515 & 0.44932 & 0.5218 \end{pmatrix}, [6.9986, 0.89905], \begin{pmatrix} 0.5233 & 0.85215 \\ 0.85215 & -0.5233 \end{pmatrix}$$

The small residues indicate that these results are not severely affected by roundoff:

`resU, resV`

$$\left[2.247 \cdot 10^{-14}, 2.247 \cdot 10^{-14}, 3.898 \cdot 10^{-32} \right], \left[5.6175 \cdot 10^{-15}, 5.6175 \cdot 10^{-15} \right]$$

```
delete DIGITS, A, U, d, V, resU, resV:
```

Example 2

We demonstrate how to reconstruct a matrix from its singular data. With the specified `ReturnType`, the singular vectors are returned as

matrices of type `Dom::Matrix()` and can be handled with the overloaded arithmetic:

```
DIGITS := 3:
A := array(1..2, 1..3, [[1.0, I, PI], [2, 3, I]]):
[U, d, V, resU, resV] := numeric::singularvectors(A, NoResidues,
    ReturnType = Dom::Matrix())
```

$$\left[\begin{pmatrix} 0.514 - 0.028i & -0.788 + 0.336i \\ 0.857 + 0.014i & 0.487 - 0.168i \end{pmatrix}, [3.9, 3.27], \right. \\ \left. \begin{pmatrix} 0.571 & 0.0568 & 0.819 \\ 0.652 - 0.121i & 0.55 + 0.0871i & -0.493 + 0.0785i \\ 0.418 - 0.242i & -0.81 + 0.174i & -0.236 + 0.157i \end{pmatrix}, \text{NIL}, \text{NIL} \right]$$

A “diagonal” matrix is built from the singular values:

```
d := matrix(2, 3, d, Diagonal)
```

$$\begin{pmatrix} 3.9 & 0 & 0 \\ 0 & 3.27 & 0 \end{pmatrix}$$

We use the methods `conjugate` and `transpose` of the matrix domain to compute the Hermitian transpose of `V` and reconstruct `A`. Numerical roundoff is eliminated via `numeric::complexRound`:

```
VH := V::dom::conjugate(V::dom::transpose(V)):
map(U*d*VH, numeric::complexRound)
```

$$\begin{pmatrix} 1.0 & 1.0i & 3.14 \\ 2.0 & 3.0 & 1.0i \end{pmatrix}$$

```
delete DIGITS, A, U, d, V, resU, resV, VH:
```

Example 3

We demonstrate the use of hardware floats. The following matrix A is degenerate: it has rank 1. For the double eigenvalue 0 of the matrix $A^H A$, different base vectors of the corresponding eigenspace are returned with `HardwareFloats` and `SoftwareFloats`, respectively:

```
A := array(1..2, 1..3, [[1, 2, 3], [30, 60, 90]]):
[U1, d1, V1, resU1, resV1] := numeric::singularvectors(A, HardwareFloats):
[U2, d2, V2, resU2, resV2] := numeric::singularvectors(A, SoftwareFloats):
V1, V2
```

$$\begin{pmatrix} 0.2672612419 & 0.5345224838 & 0.8017837257 \\ 0.5345224838 & -0.7745419206 & 0.3381871191 \\ 0.8017837257 & 0.3381871191 & -0.4927193213 \end{pmatrix},$$

$$\begin{pmatrix} 0.2672612419 & 0.9561828875 & 0.1195228609 \\ 0.5345224838 & -0.04390192219 & -0.8440132318 \\ 0.8017837257 & -0.289459681 & 0.5228345342 \end{pmatrix}$$

```
delete A, U1, d1, V1, resU1, resV1, U2, d2, V2, resU2, resV2:
```

Parameters

A

A numerical matrix of domain type `DOM_ARRAY`, `DOM_HFARRAY`, or of category `Cat::Matrix`.

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With `Hard` (or `HardwareFloats`), computations are done using fast hardware float arithmetic from within a MuPAD session. `Hard` and `HardwareFloats` are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With `Soft` (or `SoftwareFloats`) computations are done using software float arithmetic provided by the MuPAD kernel. `Soft` and `SoftwareFloats` are equivalent. `SoftwareFloats` is used by default if the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

The trailing digits in floating-point results computed with `HardwareFloats` and `SoftwareFloats` may differ.

Note For ill-conditioned matrices, the result is subject to roundoff errors. The results returned with `HardwareFloats` and `SoftwareFloats` may differ! See “Example 3” on page 18-364.

NoLeftVectors

Suppresses the computation of left singular vectors

If only right singular vectors are required, this option may be used to suppress the computation of U and the corresponding residues res_U . The return values for these data are `NIL`.

Depending on the size of U , this option may speed up the computation considerably.

NoRightVectors

Suppresses the computation of right singular vectors

If only left singular vectors are required, this option may be used to suppress the computation of V and the corresponding residues res_V . The return values for these data are `NIL`.

Depending on the size of V , this option may speed up the computation considerably.

NoResidues

Suppresses the computation of error estimates

If no error estimates are required, this option may be used to suppress the computation of the residues res_U and res_V . The return values for these data are NIL.

The alternative option name `NoErrors` used in previous MuPAD versions is still available.

ReturnType

Option, specified as `ReturnType = t`

Return the left and right singular vectors as matrices of domain type `t`. The following return types `t` are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

This option determines the domain type of the matrices containing the singular vectors.

NoWarning

Suppresses warnings

Return Values

List `[U, d, V, resU, resV]`. `U` is a unitary square float matrix whose columns are left singular vectors. The list `d` contains the singular values. `V` is a unitary square float matrix whose columns are right singular vectors. The lists of float residues res_U and res_V provide error estimates for the numerical data.

Related Examples

- “Compute Factorizations Numerically”

numeric::solve

Purpose Numerical solution of equations (the float attribute of solve)

Syntax
`numeric::solve(eqs, <vars>, options)`
`float(holdsolve(eqs, <vars>, options))`
`float(freezesolve(eqs, <vars>, options))`

Description `numeric::solve` computes numerical solutions of equations. For polynomial equations, *all* solutions are returned. For non-polynomial equations, only *one* solution, if any, is returned unless the option `AllRealRoots` is used.

Note Note that only for polynomial/rational equations *all* solutions are searched for. For non-polynomial/non-rational equations, only one solution, if any, is returned unless the option `AllRealRoots` is used.

If the equations contain non-polynomial expressions, it is in general not possible to isolate *all* roots numerically. Think of equations

such as $\sin\left(\frac{1}{x}\right) = 0$ that have infinitely many real solutions around the origin! If a complete set of *all* real solutions of a single non-polynomial/non-rational equation in one unknown is desired, you may try the option `AllRealRoots`. With this option, a heuristics tries to isolate all real solutions of the equation. This, however, is purely heuristical: there is no rigor in the algorithm and it is not guaranteed that all solutions are found. Alternatively, you may also use the routine `numeric::realroots` to isolate the intervals in which solutions may exist.

`numeric::solve` is a simple interface function unifying the functionality of the numerical solvers `numeric::fsolve`, `numeric::linsolve`, `numeric::polyroots`, and `numeric::polysysroots`. The return format of these routines is changed to make it consistent with the return values of the symbolic solver `solve`.

You may call the specialized numerical solvers directly. However, note the return types specific to each of these solvers.

`numeric::solve` classifies the equations as follows:

- If `eqs` is a single univariate polynomial equation, then it is directly passed to `numeric::polyroots`. Cf. “Example 2” on page 18-371. The roots are returned as a set or as a `Dom::Multiset` if `Multiple` is used.
- If `eqs` is a multivariate polynomial equation or a list or set of such equations, then the equations and the appropriate optional arguments are passed to either `numeric::linsolve` or `numeric::polysysroots`. Cf. “Example 3” on page 18-371. The roots are returned as a set or as a `Dom::Multiset` if `Multiple` is used.
- A rational equation or a set or list of rational equations is replaced by its/their numerator(s). Such equations are processed like polynomial equations.
- If `eqs` is a non-polynomial/non-rational equation or a set or list containing such an equation, then the equations and the appropriate optional arguments are passed to the numerical solver `numeric::fsolve`.

Note For non-polynomial equations, only a single numerical root is returned, unless `AllRealRoots` is specified! Cf. “Example 4” on page 18-372.

Note For non-polynomial equations, there must not be more equations than unknowns!

Using `Multiple` for non-polynomial equations leads to an error, unless the option `AllRealRoots` is specified, too!

numeric::solve

Note For systems of multivariate non-polynomial equations, MuPAD uses a Newton search. It must be able to evaluate the partial derivatives of the equations with respect to the variables to be solved for.

For a single univariate equation, first a bisectioning scheme with quadratic interpolation is used that does not require any differentiation of the equation. If this is not successful, a Newton search is started that requires the derivative of the functions involved.

For convenience, also polynomials of domain type DOM_POLY are accepted, wherever an equation is expected.

Note In contrast to the symbolic solver `solve`, the numerical solver does not react to properties of identifiers set via `assume`. To use these properties, call `float (hold(solve)(arguments))` instead.

If the user does not specify indeterminates to be solved for, then the indeterminates are internally chosen by `numeric::indets(eqs)`.

Starting points such as `x = a` or search ranges such as `x = a..b` specified in `vars` are ignored if `eqs` is a polynomial equation or a system of polynomial equations.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`, which determines the numerical working precision.

Examples

Example 1

The following three solver calls are equivalent:

```
eqs := {x^2 = sin(y), y^2 = cos(x)}:
```

```
numeric::solve(eqs, {x, y}),
float(hold(solve)(eqs, {x, y})),
float(freeze(solve)(eqs, {x,y}))
```

```
{[x = -0.8517004887, y = 0.8116062151]}, {[x = -0.8517004887, y = 0.8116062151]},
{[x = -0.8517004887, y = 0.8116062151]}
```

```
delete eqs:
```

Example 2

We demonstrate the root search for univariate polynomials:

```
numeric::solve(x^6 - PI*x^2 = sin(3), x)
```

```
{-1.339589766, 1.339589766, 1.322706295 i, 0.2120113223 i, -0.2120113223 i, -1.322706294 i}
```

Polynomials of type DOM_POLY can be used as input:

```
numeric::solve(poly((x - 1/3)^3, [x]), x)
```

```
{0.3333333333}
```

With Multiple, a Dom::Multiset is returned, indicating the multiplicity of the root:

```
numeric::solve(x^3 - x^2 + x/3 - 1/27, x, Multiple)
```

```
{[0.3333333333, 3]}
```

Example 3

We demonstrate the root search for polynomial systems. Note that the symbolic solver solve is involved if the system is nonlinear. Symbolic parameters are accepted:

numeric::solve

```
numeric::solve({x^2 + y^2 = 1, x^2 - y^2 = exp(z)}, {x, y})
```

$$\left\{ \left[x = -0.7071067812 \sqrt{e^z + 1.0}, y = -0.7071067812 \sqrt{1.0 - 1.0 e^z} \right], \dots, \right. \\ \left. \left[x = 0.7071067812 \sqrt{e^z + 1.0}, y = 0.7071067812 \sqrt{1.0 - 1.0 e^z} \right] \right\}$$

$$\left\{ \left[x = 0.7071067812 \sqrt{e^z + 1.0}, y = -0.7071067812 \sqrt{1.0 - 1.0 e^z} \right], \right.$$

$$\left[x = 0.7071067812 \sqrt{e^z + 1.0}, y = 0.7071067812 \sqrt{1.0 - 1.0 e^z} \right],$$

$$\left[x = -0.7071067812 \sqrt{e^z + 1.0}, y = 0.7071067812 \sqrt{1.0 - 1.0 e^z} \right],$$

$$\left[x = -0.7071067812 \sqrt{e^z + 1.0}, y = -0.7071067812 \sqrt{1.0 - 1.0 e^z} \right] \left. \right\}$$

Example 4

We demonstrate the root search for non-polynomial equations. Without the option `AllRealRoots`, only one solution is searched for:

```
eq := exp(-x) - 10*x^2:  
numeric::solve(eq, x)
```

```
{0.2755302947}
```

Since `numeric::solve` just calls the root finder `numeric::fsolve`, one may also use this routine directly. Note the different output format:

```
numeric::fsolve(eq, x)
```

```
[x = 0.2755302947]
```

The input syntax of `numeric::solve` and `numeric::fsolve` are identical, i.e., starting points, search ranges and options may be used. E.g., another solution of the previous equation is found by a restricted search over the interval $[-1, 0]$:

```
numeric::solve(eq, x = -1..0, RestrictedSearch)

{-0.3829657727}
```

We use the option `AllRealRoots` to isolate all real solutions of the equation:

```
numeric::solve(eq, x, AllRealRoots)

{-5.827897796, -0.3829657727, 0.2755302947}
```

With the following call we restrict the search to the negative semi-axis:

```
numeric::solve(eq, x = -infinity..0, AllRealRoots)

{-5.827897796, -0.3829657727}
```

Example 5

For the following system, `numeric::solve` finds the solution with positive y :

```
eqs := [exp(x) = 2*y^2, sin(y) = y*x^3]:
numeric::solve(eqs, [x, y])

{[x = 0.9290711314, y = 1.125201325]}
```

Another solution with negative y is found with an appropriate search range:

numeric::solve

```
numeric::solve(eqs, [x = 1, y = -infinity..0])
```

```
{[x = 0.9290711314, y = -1.125201325]}
```

```
delete eq, eqs:
```

Parameters

eqs

An equation, a list, set, array, or matrix (`Cat::Matrix`) of equations. Also arithmetical expressions are accepted and interpreted as homogeneous equations.

vars

An unknown, a list of unknowns or a set of unknowns. Unknowns may be identifiers or indexed identifiers. Also equations of the form $x=a$ or $x=a..b$ are accepted wherever an unknown x is expected. This way, starting points and search ranges are specified for the numerical search. They must be numerical; infinite search ranges are accepted.

Options

AllRealRoots

Only to be used if `eqs` is a single equation in one unknown. With this option, a *heuristics* is used to find *all* real solutions of the equation.

Note Note that there is no guarantee that all real solutions will be found.

Note Interval arithmetic is used to isolate search intervals for the solutions. The expressions in `eqs` must be suitable for such arithmetic. Internally, the procedure `numeric::realroots` is called. See the help page of `numeric::realroots` for restrictions on the expressions in `eqs`.

Note The equation must be suitable for evaluation with interval arithmetic. See `numeric::realroots` for restrictions on the expressions in the equation.

With `AllRealRoots`, only the additional options `Multiple` and `NoWarning` have an effect. All other options such as `UnrestrictedSearch` etc. are ignored.

It is highly recommend to specify a search interval by a call such as `numeric::solve(f(x), x = a..b, AllRealRoots)`. In this case, only the real solutions between `a` and `b` are searched for.

The search for all real solutions may be very time consuming!

Multiple

Only to be used if `eqs` is a polynomial equation or a system of polynomial equations or in conjunction with the option `AllRealRoots`. With this option, information on the multiplicity of degenerate polynomial roots is returned.

It changes the return type from `DOM_SET` to `Dom::Multiset`.

FixedPrecision

Only to be used if `eqs` is a single univariate polynomial. It launches a quick numerical search with fixed internal precision.

It is passed to `numeric::polyroots`, which uses a numerical search with fixed internal precision. This is fast, but degenerate

roots may be returned with a restricted precision. See the help page of `numeric::polyroots` for details.

SquareFree

Only to be used if `eqs` is a single univariate polynomial. Symbolic square free factorization is applied, before the numerical search starts.

It is passed to `numeric::polyroots`, which preprocesses the polynomial by a symbolic square free factorization. See the help page of `numeric::polyroots` for details.

Factor

Only to be used if `eqs` is a single univariate polynomial. Symbolic factorization is applied, before the numerical search starts.

It is passed to `numeric::polyroots`, which preprocesses the polynomial by a symbolic factorization. See the help page of `numeric::polyroots` for details.

RestrictedSearch

The numerical search is restricted to the search ranges specified in `vars`.

This option is passed to `numeric::fsolve`, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be used only in conjunction with search range and only for non-polynomial equations.

See `numeric::fsolve` for details.

UnrestrictedSearch

The numerical search may return results outside the search ranges specified in `vars`.

This option is passed to `numeric::fsolve`, which uses a corresponding search strategy when looking for roots in the search range specified in `vars`. It must be use only in conjunction with search ranges and only for non-polynomial equations.

See `numeric::fsolve` for details.

MultiSolutions

Only to be used for non-polynomial equations in conjunction with `RestrictedSearch`. Several roots may be returned.

It is passed to `numeric::fsolve`, which returns a sequence of all roots found in the internal search. See the help page of `numeric::fsolve` for details.

Random

Only to be used for non-polynomial equations. With this option, several calls to `numeric::solve` may lead to different solutions of the equation(s).

It is passed to `numeric::fsolve` which switches to a random search strategy. See the help page of `numeric::fsolve` for details.

NoWarning

This option only has an effect when it is used for polynomial equations in conjunction with `AllRealRoots`. When you use `AllRealRoots`, warnings are issued if interval arithmetic indicates technical difficulties such as serious overestimation (for example, when encountering multiple roots). With this option, the warnings are suppressed.

Note This option has an effect if `eqs` is a multivariate polynomial system or a univariate polynomial with a symbolic parameter.

In such a case, this option is passed to `numeric::polysysroots`.

Return Values

Set of numerical solutions. With the option `Multiple`, a set of domain type `Dom::Multiset` is returned.

Concepts

- “Solve Equations Numerically”

Purpose

Sort a numerical list

Syntax

```
numeric::sort(list)
```

Description

`numeric::sort(list)` sorts the elements in `list`.

The elements of the list are sorted such that their real parts are descending. Elements with the same real part are sorted from large absolute value to small absolute value. In case of a tie (i.e., two elements form a complex conjugate pair), the element with positive imaginary part comes first.

The elements of the list are converted to floating-point numbers via `float`. Elements that cannot be converted lead to an error.

This function is used to sort the return values of `numeric::eigenvalues`, `numeric::eigenvectors`, `numeric::polyroots`, `numeric::singularvalues`, and `numeric::singularvectors`.

Environment Interactions

The function is sensitive to the environment variable `DIGITS`.

Examples

Example 1

The elements in the sorted list have descending real parts:

```
numeric::sort([1, 2.0, I, -3, -I, PI, sqrt(2)])
[3.141592654, 2.0, 1.414213562, 1.0, 1.0 i - 1.0 i - 3.0]
```

In the following example, the sorting criterion does not seem to be satisfied. Elements with the same real part are supposed to be ordered from large absolute values to small absolute values:

```
x := sin(PI/3):
L := numeric::sort([x, sin(float(PI/3)) - I, x + I])
```

numeric::sort

```
[0.8660254038 + 1.0 i, 0.8660254038 - 1.0 i, 0.8660254038]
```

This is explained by the fact that the floating-point numbers internally have a more accurate representation than shown on the screen. The real part of the last element is indeed a little bit smaller than the other real parts:

```
DIGITS := 20:  
L
```

```
[0.8660254037844386469 + 1.0 i, 0.8660254037844386469 - 1.0 i, 0.8660254037844386469]
```

```
delete x, L, DIGITS:
```

Parameters

list

A list of numbers or numerical expressions

Return Values

Sorted list.

See Also

MuPAD Functions

sort

Purpose Spectral radius of a matrix

Syntax `numeric::spectralradius(A, <x0>, <n>, <mode>, <ReturnType = t>, <NoWarning>)`

Description `numeric::spectralradius(A)` returns data corresponding to the eigenvalue of the matrix A that has the largest absolute value.

`numeric::spectralradius` and `numeric::spectralRadius` are equivalent.

The spectral radius of a matrix with eigenvalues λ_i is $\max(|\lambda_i|)$.

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector:

$$\|x\|_2 = 1.$$

The return value `residue = \|A x - lambda x\|2` provides an error estimate for the eigenvalue. For Hermitian matrices this is a rigorous upper bound for the error $|lambda - \lambda_{exact}|$, where λ_{exact} is the exact eigenvalue.

`numeric::spectralradius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral

radius: the vector iteration $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$ “converges” towards the eigenspace associated with the spectral radius. The starting vector x_0 is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

Note The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

numeric::spectralradius

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by DIGITS. If this does not happen within n iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 18-385.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):  
numeric::spectralradius(A)
```

```
[20.09901951, ( 0.0985376181  
               0.9951333267 ), 0.000000001332123191]
```

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]):  
x0 := array(1..2, [1, 1]):  
numeric::spectralradius(A, x0, 1000)
```

```
[-10.84428877, ( 0.1665007247 -0.9860413321 ), 7.808576008 10-11]
```

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]):  
numeric::spectralradius(A, [1, 1], 1000)
```

```
[3.0 + 1.0 i [0.7071067812, 0.7071067812], 0.0]
```

```
delete A, x0:
```

Example 2

With the default setting of DIGITS = 10, the following result is computed using HardwareFloats.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50, 60]]):  
x0 := array(1..2, [1, 1]):  
numeric::spectralradius(A, x0)
```

```
[10050.0498, ( 0.9999874753 0.00500491737 ), 0.000000004820940092]
```

We request SoftwareFloats in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)
```

```
[10050.0498, ( 0.9999874753 0.00500491737 ), 0.000000004820942201]
```

```
delete DIGITS, A, x0:
```

Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):  
[1, x, residue]:= numeric::spectralradius(A);
```

```
[5.372281324, ( 0.4159735579 0.9093767091 ), 0.0000000002881934691]
```

```
domtype(x)
```

```
DOM_ARRAY
```

numeric::spectralradius

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):  
[1, x, residue]:= numeric::spectralradius(A):  
domtype(x)
```

DOM_HFARRAY

```
A:= matrix(2, 2, [[1, 2], [3, 4]]):  
[1, x, residue]:= numeric::spectralradius(A):  
domtype(x)
```

Dom::Matrix()

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):  
x0:= [1, 1]:  
[1, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

DOM_LIST

```
x0:= array(1..2, [1, 1]):  
[1, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

DOM_ARRAY

```
x0:= hfarray(1..2, [1, 1]):  
[1, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

DOM_HFARRAY

```
x0:= matrix([1, 1]):  
[l, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

[Dom::Matrix\(\)](#)

The return type can be requested explicitly:

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DO  
domtype(x)
```

[DOM_LIST](#)

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DO  
domtype(x)
```

[DOM_HFARRAY](#)

```
delete A, x0, l, x, residue:
```

Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.

```
A := array(1..2, 1..2, [[1, 0], [0, -1]]):
```

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:

```
numeric::spectralradius(A, [1, 1], 1000)
```

```
Warning: There is no convergence of vector iteration. [numeric::
```

numeric::spectralradius

[1.0, [0.7071067812, -0.7071067812], 1.414213562]

delete A:

Parameters

A

An $m \times m$ array of domain type DOM_ARRAY or DOM_HFARRAY or a matrix of category Cat::Matrix

x_0

A starting vector: a 1-dimensional array, or an hfarray, or a list of length m . Also 2-dimensional arrays (array(1..m, 1..1, ...), hfarray(1..m, 1..1, ...)) and matrices representing vectors are accepted.

n

The maximal number of iterations: a positive integer. The default value is 1000.

mode

One of the flags Hard, HardwareFloats, Soft, or SoftwareFloats

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are done using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

numeric::spectralradius

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

ReturnType

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `DOM_LIST`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

NoWarning

Suppresses warnings

Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical eigenvector corresponding to `lambda`. `residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector x_0 (i.e., it is a 1-dimensional array of type `DOM_ARRAY` or `DOM_HFARRAY`, respectively, or a list, or a column vector of type `matrix` or `densematrix`. If no starting vector is specified, the type of `x` is determined by the type of `A`.

Purpose Spectral radius of a matrix

Syntax `numeric::spectralRadius(A, <x0>, <n>, <mode>, <ReturnType = t>, <NoWarning>)`

Description `numeric::spectralRadius(A)` returns data corresponding to the eigenvalue of the matrix A that has the largest absolute value.

`numeric::spectralRadius` and `numeric::spectralradius` are equivalent.

The spectral radius of a matrix with eigenvalues λ_i is $\max(|\lambda_i|)$.

The return value `lambda` is an approximation of the corresponding eigenvalue: `abs(lambda)` is the spectral radius.

The return value `x` is the corresponding normalized eigenvector:

$$\|x\|_2 = 1.$$

The return value `residue = \|A x - lambda x\|2` provides an error estimate for the eigenvalue. For Hermitian matrices this is a rigorous upper bound for the error $|\lambda - \lambda_{exact}|$, where λ_{exact} is the exact eigenvalue.

`numeric::spectralRadius` implements the power method to compute the eigenvalue and the associated eigenvector defining the spectral

radius: the vector iteration $x_i = \frac{A^i x_0}{\|A^i x_0\|_2}$ “converges” towards the eigenspace associated with the spectral radius. The starting vector x_0 is provided by the second argument of `numeric::spectralradius`. If no starting vector is provided by the user, a randomly chosen vector is used.

Note The iteration does not converge (converges slowly), if the spectral radius is generated by several distinct eigenvalues with the same (similar) absolute value.

numeric::spectralRadius

Internally, the iteration stops, when the approximation of the eigenvalue becomes stationary within the relative precision given by DIGITS. If this does not happen within n iterations, then a warning is issued and the present values are returned. Cf. “Example 4” on page 18-393.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We let the routine choose a random starting vector:

```
A := matrix(2, 2, [[10, 1], [1, 20]]):  
numeric::spectralradius(A)
```

```
[20.09901951, ( 0.0985376181  
              0.9951333267 ), 0.000000001332123191]
```

We define a starting vector as a 1-dimensional array and allow a maximum of 1000 internal iterations:

```
A := array(1..2, 1..2, [[1, 2], [5, -10]]):  
x0 := array(1..2, [1, 1]):  
numeric::spectralradius(A, x0, 1000)
```

```
[-10.84428877, ( 0.1665007247 -0.9860413321 ), 7.808576008 10-11]
```

Next, we use a list to specify a starting vector:

```
A := array(1..2, 1..2, [[I, 3], [3, I]]):  
numeric::spectralradius(A, [1, 1], 1000)
```

```
[3.0 + 1.0 i [0.7071067812, 0.7071067812], 0.0]
```

```
delete A, x0:
```

Example 2

With the default setting of DIGITS = 10, the following result is computed using HardwareFloats.

```
A := hfarray(1..2, 1..2, [[10^4, 10^4], [50, 60]]):  
x0 := array(1..2, [1, 1]):  
numeric::spectralradius(A, x0)
```

```
[10050.0498, ( 0.9999874753 0.00500491737 ), 0.000000004820940092]
```

We request SoftwareFloats in the next call. Note the difference in the trailing digits:

```
numeric::spectralradius(A, x0, Soft)
```

```
[10050.0498, ( 0.9999874753 0.00500491737 ), 0.000000004820942201]
```

```
delete DIGITS, A, x0:
```

Example 3

The eigenvector that is returned can have various types. If no starting vector is provided, the type of the matrix determines the type of the eigenvector:

```
A:= array(1..2, 1..2, [[1, 2], [3, 4]]):  
[1, x, residue]:= numeric::spectralradius(A);
```

```
[5.372281324, ( 0.4159735579 0.9093767091 ), 0.0000000002881934691]
```

```
domtype(x)
```

```
DOM_ARRAY
```

numeric::spectralRadius

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):  
[1, x, residue]:= numeric::spectralradius(A):  
domtype(x)
```

DOM_HFARRAY

```
A:= matrix(2, 2, [[1, 2], [3, 4]]):  
[1, x, residue]:= numeric::spectralradius(A):  
domtype(x)
```

Dom::Matrix()

If a starting vector is provided, its type determines the type of the return vector:

```
A:= hfarray(1..2, 1..2, [[1, 2], [3, 4]]):  
x0:= [1, 1]:  
[1, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

DOM_LIST

```
x0:= array(1..2, [1, 1]):  
[1, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

DOM_ARRAY

```
x0:= hfarray(1..2, [1, 1]):  
[1, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

DOM_HFARRAY

```
x0:= matrix([1, 1]):  
[l, x, residue]:= numeric::spectralradius(A, x0):  
domtype(x)
```

[Dom::Matrix\(\)](#)

The return type can be requested explicitly:

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DO  
domtype(x)
```

[DOM_LIST](#)

```
[l, x, residue]:= numeric::spectralradius(A, x0, ReturnType = DO  
domtype(x)
```

[DOM_HFARRAY](#)

```
delete A, x0, l, x, residue:
```

Example 4

The following matrix has two distinct eigenvalues 1 and -1 of the same absolute value. The power method must fail.

```
A := array(1..2, 1..2, [[1, 0], [0, -1]]):
```

We allow a maximum of 1000 internal steps. The call results in a warning. The large residue also indicates that the power method did not converge:

```
numeric::spectralradius(A, [1, 1], 1000)
```

```
Warning: There is no convergence of vector iteration. [numeric::
```

numeric::spectralRadius

[1.0, [0.7071067812, -0.7071067812], 1.414213562]

delete A:

Parameters

A

An $m \times m$ array of domain type DOM_ARRAY or DOM_HFARRAY or a matrix of category Cat::Matrix

x_0

A starting vector: a 1-dimensional array, or an hfarray, or a list of length m . Also 2-dimensional arrays (array(1..m, 1..1, ...), hfarray(1..m, 1..1, ...)) and matrices representing vectors are accepted.

n

The maximal number of iterations: a positive integer. The default value is 1000.

mode

One of the flags Hard, HardwareFloats, Soft, or SoftwareFloats

Options

Hard, HardwareFloats, Soft, SoftwareFloats

With Hard (or HardwareFloats), computations are done using fast hardware float arithmetic from within a MuPAD session. Hard and HardwareFloats are equivalent. With this option, the input data are converted to hardware floats and processed by compiled C code. The result is reconverted to MuPAD floats and returned to the MuPAD session.

With Soft (or SoftwareFloats) computations are done using software float arithmetic provided by the MuPAD kernel. Soft and SoftwareFloats are equivalent. SoftwareFloats is used by default if the current value of DIGITS is larger than 15 and the input matrix A is not of domain type DOM_HFARRAY.

Compared to the `SoftwareFloats` used by the MuPAD kernel, the computation with `HardwareFloats` may be many times faster. Note, however, that the precision of hardware arithmetic is limited to about 15 digits. Further, the size of floating-point numbers may not be larger than approximately 10^{308} and not smaller than approximately 10^{-308} .

If no `HardwareFloats` or `SoftwareFloats` are requested explicitly, the following strategy is used: If the current value of `DIGITS` is smaller than 16 or if the matrix `A` is a hardware float array of domain type `DOM_HFARRAY`, then hardware arithmetic is tried. If this is successful, the result is returned.

If the result cannot be computed with hardware floats, software arithmetic by the MuPAD kernel is tried.

If the current value of `DIGITS` is larger than 15 and the input matrix `A` is not of domain type `DOM_HFARRAY`, or if one of the options `Soft`, `SoftwareFloats` or `Symbolic` is specified, MuPAD computes the result with its software arithmetic without trying to use hardware floats first.

There may be several reasons for hardware arithmetic to fail:

- The current value of `DIGITS` is larger than 15.
- The data contains symbolic objects.
- The data contains numbers larger than 10^{308} or smaller than 10^{-308} that cannot be represented by hardware floats.

If neither `HardwareFloats` nor `SoftwareFloats` is specified, the user is not informed whether hardware floats or software floats are used.

If `HardwareFloats` are specified but fail due to one of the reasons above, a warning is issued that the (much slower) software floating-point arithmetic of the MuPAD kernel is used.

Note that `HardwareFloats` can only be used if all input data can be converted to floating-point numbers.

numeric::spectralRadius

The trailing digits in floating-point results computed with HardwareFloats and SoftwareFloats may differ.

ReturnType

Option, specified as `ReturnType = t`

Return the eigenvector associated with the spectral radius as a vector of domain type `t`. The following return types are available: `DOM_ARRAY`, or `DOM_HFARRAY`, or `DOM_LIST`, or `Dom::Matrix()`, or `Dom::DenseMatrix()`.

NoWarning

Suppresses warnings

Return Values

A list `[lambda, x, residue]` is returned. The floating-point number `lambda` is an approximation of the eigenvalue of largest absolute value. The vector `x` is a numerical eigenvector corresponding to `lambda`. `residue` is a floating-point number indicating the numerical quality of `lambda` and `x`.

If no return type is requested via the `ReturnType` option, the type of the returned vector `x` coincides with the type of the input vector x_0 (i.e., it is a 1-dimensional array of type `DOM_ARRAY` or `DOM_HFARRAY`, respectively, or a list, or a column vector of type `matrix` or `densematrix`. If no starting vector is specified, the type of `x` is determined by the type of `A`.

Purpose Numerical approximation of sums (the Float attribute of Sum)

Syntax

```

numeric::sum(f(x), x = a .. b)
numeric::sum(f(x), x in {x1, x2, })
numeric::sum(f(x), x = {x1, x2, })
numeric::sum(f(x), x in RootOf(p(X), X))
numeric::sum(f(x), x = RootOf(p(X), X))
float(holdsum(f(x), x = a .. b))
float(holdsum(f(x), x in {x1, x2, }))
float(holdsum(f(x), x = {x1, x2, }))
float(holdsum(f(x), x in RootOf(p(X), X)))
float(holdsum(f(x), x = RootOf(p(X), X)))
float(freezesum(f(x), x = a .. b))
float(freezesum(f(x), x in {x1, x2, }))
float(freezesum(f(x), x = {x1, x2, }))
float(freezesum(f(x), x in RootOf(p(X), X)))
float(freezesum(f(x), x = RootOf(p(X), X)))

```

Description numeric::sum(f(i), i=a..b) computes a numerical approximation of

$$\sum_{i=a}^b f(i).$$

numeric::sum(f(x), x {x₁, x₂, }) computes a numerical

approximation of $\sum_{x \in \{x_1, x_2, \dots\}} f(x).$

numeric::sum(f(x), x in RootOf(p(X), X)) computes a numerical

approximation of $\sum_{x \in \text{RootOf}(p(X), X)} f(x).$

The call numeric::sum() is equivalent to calling the float attribute of sum via float (hold(sum)()) or float (freeze(sum)()).

If there are other symbolic parameters in $f(x)$, apart from the summation variable x , a symbolic sum is returned. Numerical expressions such as e^{π} , $\sqrt{2}$ etc. are accepted and converted to floating-point numbers.

numeric::sum

Note For infinite sums, the expression $f(i)$ with integer i must have an extension $f(x)$ to all real x in the interval $[a, b]$. Internally, the integral $\int_a^b f(x) dx$ is computed numerically and used in the approximation process.

Note For finite sums, `numeric::sum` just returns `_plus (float(f(i)$i=a..b))`. Note that numerical cancellation may occur! If $f(i)$ does not contain floating-point numbers, cancellation can be avoided summing the symbolic terms by `_plus(f(i)$i=a..b)` instead. Cf. “Example 3” on page 18-400.

Convergence is fast, if $f(x)$ decays rapidly for $x \rightarrow \infty$ or $|x| \rightarrow \infty$, respectively

Note Convergence may be slow for alternating sums containing expressions such as $(-1)^i$. Such sums are also often subject to cancellation problems!

The call `numeric::sum(f(x), x = {x1, x2, ...})` computes numerical approximations of x_1, x_2 etc., substitutes these values into $f(x)$ and adds up the results. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x = {x1, x2, ...})` and `numeric::sum(f(x), x = {x1, x2, ...})` are equivalent.

The call `numeric::sum(f(x), x in RootOf(p(X), X))` computes numerical approximations of all roots of p , substitutes these values into $f(x)$ and adds up the results. Cf. “Example 4” on page 18-400. This process may be subject to cancellation problems!

The calls `numeric::sum(f(x), x in RootOf(p(X), X))` and `numeric::sum(f(x), x = RootOf(p(X), X))` are equivalent.

Environment Interactions

The function is sensitive to the environment variable DIGITS, which determines the numerical working precision.

Examples

Example 1

We demonstrate some equivalent calls for numerical summation:

```
numeric::sum(1/i!, i = 0..infinity),
float(hold(sum)(1/i!, i = 0..infinity)),
float(freeze(sum)(1/i!, i = 0..infinity))
```

2.718281828, 2.718281828, 2.718281828

The MuPAD symbolic summation sum does not find a simple representation of the following sum:

```
sum(1/i!/(i^2+1)!, i = 0..infinity)
```

$$\sum_{i=0}^{\infty} \frac{1}{(i^2 + 1)! i!}$$

The following float evaluation calls numeric::sum:

```
float(%)
```

1.504166713

The exact value of the following sum is $\pi \coth(\pi)$:

```
numeric::sum(1/(1+i^2), i = -infinity..infinity) =
float(PI*coth(PI))
```

3.153348095 = 3.153348095

Example 2

The following sum cannot be evaluated numerically because of the symbolic parameter x :

```
numeric::sum(1/(x+i^2), i = -infinity..infinity)
```

```
numeric::sum( $\frac{1}{i^2 + x}$ , i =  $-\infty.. \infty$ )
```

Example 3

We demonstrate numerical cancellation when summing the Taylor series for e^{-20} :

```
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..100)
```

```
0.000000002061153622 ≠ 0.000000002148938644
```

Also the infinite sum suffers from cancellation:

```
exp(-20.0) <> numeric::sum((-20)^i/i!, i = 0..infinity)
```

```
0.000000002061153622 ≠ 0.000000002205327316
```

Cancellation can be avoided using a finite sum with exact terms:

```
exp(-20.0) = float(_plus((-20)^i/i! $ i = 0..100))
```

```
0.000000002061153622 = 0.000000002061153622
```

Example 4

The following call computes the numerical roots of the polynomial in the RootOf expression and sums over all the roots:

```
numeric::sum(exp(x)/x, x in RootOf(X^10 - X - PI, X))
```

```
9.681693381
```

Parameters

f(x)

An arithmetical expression in x

i, x

Summation variables: identifiers or indexed identifiers

a, b

Integers or \pm infinity satisfying $a \leq b$

x₁, x₂, ...

Numerical expressions

p(X)

A univariate polynomial expression in X

x

The indeterminate of p : an identifier or an indexed identifier

Return Values

Floating point number or a symbolic expression of type `numeric::sum`.

Algorithms

Depending on whether the series is alternating or monotone, `numeric::sum` tries a number of strategies to calculate its limit: Levin's u transformation, the Euler-MacLaurin formula or van Wijngaarden's trick.

The Euler-MacLaurin formula is

$$\sum_{i=a}^b f(i) = \frac{f(a)+f(b)}{2} + \int_a^b f(x) dx + \left(\sum_{m=1}^M \frac{B_{2m}}{(2m)!} \left(f(b)^{(2m-1)} - f(a)^{(2m-1)} \right) \right) + \dots$$

numeric::sum

involving the Bernoulli numbers B_{2m} .

numlib::checkPrimalityCertificate

Purpose Test the primality certificate

Syntax numlib::checkPrimalityCertificate(certificate)

Description numlib::checkPrimalityCertificate tests the certificate of primality returned by numlib::proveprime. For large prime numbers, the numlib::proveprime function generates certificates that provide all data you need for proving primality of a number by the Atkin-Goldwasser-Kilian-Morain algorithm. See “Example 1” on page 19-3.

For small prime numbers, numlib::proveprime does not return a certificate of primality. Instead, it returns TRUE. For nonprime numbers numlib::proveprime returns FALSE. In both cases, you do not need to use numlib::checkPrimalityCertificate.

Examples **Example 1**

Use the numlib::proveprime function to check the primality of the number 1299709. The function returns the following sequence of lists. This sequence is the certificate of primality:

```
certificate := numlib::proveprime(1299709)

[1299709, 15, [2, 2, 2, 2, 2, 107, 379], 700619, 67686, 0, 796444, [107, 379]]
```

The certificate provides all data that you need for proving primality of 1299709 by the Atkin-Goldwasser-Kilian-Morain algorithm. You can substitute the numbers into the algorithm and verify the primality of the number. Alternatively, you can verify the certificate by using the numlib::checkPrimalityCertificate function:

```
numlib::checkPrimalityCertificate(certificate)

TRUE
```

numlib::checkPrimalityCertificate

Parameters

certificate

A list or a sequence of lists returned by `numlib::proveprime`

Return Values

TRUE or FALSE

See Also

MuPAD Functions

`ifactor` | `numlib::proveprime`

Concepts

- “Primes and Factorizations”

Purpose Domain of continued fractions

Syntax numlib::contfrac(x, <n>)

Description numlib::contfrac(x) creates a continued fraction approximation for the real number x.

If x is an integer or a rational number and n is not specified, a continued fraction is returned that represents x exactly. Cf. “Example 1” on page 19-5.

Irrational numerical values x such as $1 + \sqrt{2}$ or $\text{PI}/3$ are first converted to floating-point numbers. The first n significant decimals of floating-point numbers are taken into account. If n is not specified, $n = \text{DIGITS}$ is used. The value of the continued fraction (given by numlib::contfrac ::rational) satisfies

$$|x - \text{numlib::contfrac::rational}(x)| \leq |x| \frac{1}{10^n}$$

Integers or rational numbers are also converted to floating point numbers, if a precision n is specified.

Objects of type numlib::contfrac can be handled by the usual arithmetical operations. They are sensitive to the environment variable DIGITS if floating-point numbers or irrational numerical values are involved.

Use contfrac to compute continued fraction approximations of expressions involving symbolic parameters.

Examples **Example 1**

For rational numbers, exact representations are returned:

```
numlib::contfrac(123/1234)
```

numlib::contfrac

$$\frac{1}{10 + \frac{1}{30 + \frac{1}{1 + \frac{1}{3 + \dots}}}}$$

The rational representation (the second operand of the continued fraction) coincides with the original rational:

```
numlib::contfrac::rational(%, expr(%, op(%, 2))
```

$$\frac{123}{1234}, \frac{123}{1234}, \frac{123}{1234}$$

Restricted continued fraction approximations can be computed by passing a precision as second argument:

```
numlib::contfrac(123/1234, 2),  
numlib::contfrac(123/1234, 3),  
numlib::contfrac(123/1234, 5)
```

$$\frac{1}{10 + \dots}, \frac{1}{10 + \frac{1}{30 + \dots}}, \frac{1}{10 + \frac{1}{30 + \frac{1}{1 + \frac{1}{3 + \dots}}}}$$

$$\frac{1}{10 + \dots}, \frac{1}{10 + \frac{1}{30 + \dots}}, \frac{1}{10 + \frac{1}{30 + \frac{1}{1 + \frac{1}{3 + \dots}}}}$$

Example 2

The coefficients are extracted by the method nthcoeff:

```
cf := numlib::contfrac(12/123)
```

$$\frac{1}{10 + \frac{1}{4 + \dots}}$$

`nthcoeff(cf, 1), nthcoeff(cf, 2), nthcoeff(cf, 3), nthcoeff(cf, 4)`
`0, 10, 4, FAIL`

The internal list of coefficients can also be queried via `op`:

`op(cf, 1)`

`[0, 10, 4]`

`delete cf:`

Example 3

`numlib::contfrac` can also compute continued fraction approximations of irrational numbers:

`numlib::contfrac(PI, 2),`
`numlib::contfrac(PI, 4),`
`numlib::contfrac(PI, 5)`

$$3 + \frac{1}{7 + \dots}, 3 + \frac{1}{7 + \frac{1}{15 + \dots}}, 3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \dots}}}$$

$$3 + \frac{1}{7 + \dots}, 3 + \frac{1}{7 + \frac{1}{15 + \dots}}, 3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \dots}}}$$

numlib::contfrac

A finite continued fraction approximation may be regarded as an interval of numbers (the symbol ... represents a number between 0 and 1):

```
numlib::contfrac::rationalInterval(numlib::contfrac(PI, 2));
```

$$\left[\frac{25}{8}, \frac{22}{7} \right]$$

```
float(%)
```

$$[3.125, 3.142857143]$$

Example 4

All basic arithmetical operations are available for continued fractions:

```
x := numlib::contfrac(PI, 3):  
y := numlib::contfrac(1/12):  
DIGITS:= 3: 3/x + sqrt(2)*y^(1/3)
```

$$1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{2 + \frac{1}{1 + \frac{1}{26 + \dots}}}}}}$$

$$1 + \frac{1}{1 + \frac{1}{1 + \frac{1}{2 + \frac{1}{1 + \frac{1}{26 + \dots}}}}}}$$

```
delete x, y, DIGITS:
```

Example 5

We search for a simple continued fraction in an interval:

```
numlib::contfrac::convert(1/2 - 1/10^8, 1/2 + 1/10^8)
```

$$\frac{1}{2 + \dots}$$

$$\frac{1}{2 + \dots}$$

```
numlib::contfrac::convert(PI, PI + 1/10^10)
```

$$3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \frac{1}{292 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \dots}}}}}}}}$$

$$3 + \frac{1}{7 + \frac{1}{15 + \frac{1}{1 + \frac{1}{292 + \frac{1}{1 + \frac{1}{1 + \frac{1}{1 + \dots}}}}}}}}$$

Parameters

x

A real numerical expression

n

The number of significant digits: a positive integer greater one

Methods

Mathematical Methods

_plus - Sum of two continued fractions

`_plus(x, y)`

_mult - Product of two continued fractions

`_mult(x, y)`

_invert - Reciprocal of a continued fraction

`_invert(x)`

Inverting a continued fraction means a shift of the coefficients by one to the left or to the right.

If x is an exact representation of a rational number, the continued fraction expansion of the reciprocal is also an exact representation.

_power - Power of a continued fraction

`_power(x, m)`

Access Methods

print - Print a continued fraction

`print(cf)`

See Also

MuPAD Functions

`contfrac` | `numeric::rationalize`

Purpose Periodic continued fraction expansions

Syntax `numlib::contfracPeriodic(p, q, n)`

Description `numlib::contfracPeriodic(p, q, n)` returns the continued fraction expansion of $p + q\sqrt{n}$ as a sequence of two lists: the first one contains the non-periodic part, the second one contains the periodic part of the expansion.

The non-periodic part may be an empty list. No periodic part is returned for rational input, i.e., $q = 0$ or n square.

Examples

Example 1

The non-periodic part may start with zero. All other coefficients of a continued fraction expansion are positive:

```
numlib::contfracPeriodic(2/7, 1/7, 2)
```

```
[0, 2, 19], [1, 8, 1, 18]
```

The result agrees with that one of `contfrac`:

```
op(contfrac(2/7 + 1/7 *sqrt(2)), 1)
```

```
[0, 2, 19, 1, 8, 1, 18, 1, 8, 1]
```

Example 2

The golden mean is famous for its simple continued fraction expansion:

```
numlib::contfracPeriodic(1/2, 1/2, 5)
```

```
[], [1]
```

numlib::contfracPeriodic

Example 3

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::contfracPeriodic(0, 1, 81)
```

```
[9]
```

Parameters

p

A rational number

q

A rational number

n

A positive integer

Return Values

If $p + q \sqrt{n}$ is a rational number, then `numlib::contfracPeriodic` returns one list, otherwise two lists of integers.

Algorithms

A real number has a periodic continued fraction expansion if and only if it is of the form $p + q \sqrt{n}$.

See Also

MuPAD Functions

`numlib::contfrac` | `numlib::sqrt2cfrac`

Purpose Cornachia's algorithm

Syntax `numlib::cornacchia(a, b, m)`

Description `numlib::cornacchia(a, b, m)` returns all pairs of positive and relatively prime integers x, y that solve the equation $ax^2 + by^2 = m$. The arguments a, b, m must be pairwise relatively prime.

Examples **Example 1**

We compute the solutions to $3x^2 + 5y^2 = 74533332452454382449233$:

```
numlib::cornacchia(3, 5, 74533332452454382449233)
{[22457088474, 120847316879]}
```

Example 2

For non-prime m , there may be many solutions:

```
numlib::cornacchia(1, 4, 5*13*17*29*73)
{[103, 763], [151, 761], [217, 757], [521, 719], [553, 713], [583, 707], [809, 649], [887, 623],
 [1081, 541], [1127, 517], [1159, 499], [1367, 343], [1369, 341], [1463, 223], [1481, 191],
 [1529, 19]}
```

Parameters

- a** A positive integer
- b** A positive integer
- m** A positive integer

numlib::cornacchia

Return Values

numlib::cornacchia returns a set each element of which is a list of two positive integers.

See Also

MuPAD Functions

numlib::msqrts

Purpose Infinite representation of rational numbers

Syntax `numlib::decimal(q)`

Description `numlib::decimal(q)` computes the decimal expansion of a rational number q .

If q is a nonnegative rational number whose decimal expansion is finite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of q and followed by the digits after the decimal point.

If q is a nonnegative rational number whose decimal expansion is infinite, then `numlib::decimal(q)` returns the expression sequence starting with the integral part of q , followed by the digits of the pre-period and terminated with a list, containing the digits of a minimal period.

Examples

Example 1

Computing the decimal expansion of 1999:

```
numlib::decimal(1999)
```

```
1999
```

Example 2

Computing the (finite) decimal expansion of $\frac{52187}{78125}$:

```
numlib::decimal(52187/78125)
```

```
0, 6, 6, 7, 9, 9, 3, 6
```

Example 3

Computing the (infinite) decimal expansion of $\frac{111}{7}$:

numlib::decimal

```
numlib::decimal(111/7)
```

```
15, [8, 5, 7, 1, 4, 2]
```

Example 4

Computing the (infinite) decimal expansion of $\frac{37}{28}$:

```
numlib::decimal(37/28)
```

```
1, 3, 2, [1, 4, 2, 8, 5, 7]
```

Parameters

q

Nonnegative rational number

Return Values

`numlib::decimal(q)` returns an expression sequence consisting of nonnegative integers or an expression sequence consisting of nonnegative integers and terminated by a list of nonnegative integers.

Purpose Divisors of an integer

Syntax `numlib::divisors(n)`

Description `numlib::divisors(n)` returns the list of positive divisors of `n`.
If `a` is a non-zero integer then `numlib::divisors(a)` returns the sorted list of all positive divisors of `a`.
`numlib::divisors(0)` returns `[0]`.
`numlib::divisors` returns an error if the argument evaluates to a number of wrong type.

Examples **Example 1**

We compute the list of all positive divisors of 72:

```
numlib::divisors(72)
```

```
[1, 2, 3, 4, 6, 8, 9, 12, 18, 24, 36, 72]
```

Example 2

`numlib::divisors` returns the positive divisors of negative numbers, too:

```
numlib::divisors(-63)
```

```
[1, 3, 7, 9, 21, 63]
```

Parameters **n**

Integer

Return Values `numlib::divisors` returns a list of nonnegative integers.

numlib::divisors

Algorithms

Internally, ifactor is used for factoring n.

See Also

MuPAD Functions

`ifactor` | `numlib::numdivisors` | `numlib::tau` |
`numlib::primedivisors` | `numlib::numprimedivisors` |
`polylib::divisors`

Purpose	Factorization of Gaussian integers
Syntax	<code>numlib::factorGaussInt(n)</code>
Description	<code>numlib::factorGaussInt(n)</code> returns the factorization of the Gaussian integer n into Gaussian primes. Among associate primes, that one with smallest polar angle is chosen.
Examples	<p>Example 1</p> <p>In the Gaussian integers, 3 remains prime while 5 does not:</p> <pre>numlib::factorGaussInt(3), numlib::factorGaussInt(5)</pre> <pre>[1, 3, 1], [-i, 1+2i, 1, 2+i, 1]</pre> <p>Example 2</p> <p>The argument to <code>numlib::factorGaussInt</code> may be any Gaussian integer, that is, every complex number of the form $a + bi$ where a and b are integers:</p> <pre>numlib::factorGaussInt(2+2*I)</pre> <pre>[-i, 1+i, 3]</pre>
Parameters	<p>n</p> <p>An integer, or a complex number whose real and imaginary part are integers</p>
Return Values	<p><code>numlib::factorGaussInt</code> returns a list $[u, p_1, a_1, \dots, p_k, a_k]$ where u is a unit in the Gaussian integers, the p_i are Gaussian primes and the a_i are positive integers, such that $n = u \left(\prod_{i=1}^k p_i^{a_i} \right)$.</p>

numlib::factorGaussInt

Algorithms

The function `ifactor` is used to factor the norm; this step takes most of the running time. Hence, the running time of the algorithm mainly depends on the size of the prime factors of the norm of n .

See Also

MuPAD Functions

`factor`

Purpose	Fibonacci numbers
Syntax	<code>numlib::fibonacci(n)</code>
Description	<p><code>numlib::fibonacci(n)</code> returns the n-th Fibonacci number.</p> <p>If n is a nonnegative integer then <code>numlib::fibonacci(n)</code> returns the n-th Fibonacci number.</p> <p><code>numlib::fibonacci</code> returns an error if the argument evaluates to a number of wrong type. <code>numlib::fibonacci</code> returns the unevaluated function call if n does not evaluate to a number.</p>
Examples	<p>Example 1</p> <p>We compute the 201st Fibonacci number:</p> <pre>numlib::fibonacci(201)</pre> <pre>453973694165307953197296969697410619233826</pre>
Parameters	<p>n</p> <p>A nonnegative integer</p>
Return Values	Nonnegative integer, or the function call with its arguments evaluated.
Algorithms	<p>The n-th Fibonacci number F_n is defined by the recursion formula $F_0 = 0$, $F_1 = 1$, and $F_{n+2} = F_n + F_{n+1}$.</p> <p><code>numlib::fibonacci</code> uses quadratic recursion formulas.</p>

numlib::fromAscii

Purpose Decoding of ASCII codes

Syntax numlib::fromAscii(listOfCodes)

Description If L is a list of ASCII codes then numlib::fromAscii(L) returns the string coded by L.

ASCII codes of non-printable characters, i. e., codes between 0 and 8 and between 11 and 31, are ignored.

numlib::fromAscii returns an error if its argument is not a list of integers between 0 and 127, i. e., not a list of legal ASCII codes.

Examples **Example 1**

Non-printable characters are ignored, but tabulator and newline characters are decoded.

```
L := [0,1,2,3,9,10,31,10,9,32,45,32,101,105,110,32,
      84,101,115,116,32,61,32,97,32,116,101,115,116]:
```

```
numlib::fromAscii(L)
```

```
"          - ein Test = a test"
```

Parameters **listOfCodes**
A list of ASCII codes

Return Values String

MuPAD Functions numlib::toAscii

Purpose	G-adic representation of a nonnegative integer
Syntax	<code>numlib::g_adic(number, base)</code>
Description	<p><code>numlib::g_adic(0, g)</code> returns <code>[0]</code>.</p> <p><code>numlib::g_adic</code> returns an error if the arguments evaluate to numbers which are not both of the correct type.</p> <p>If a is a natural number and g is an integer such that $g > 1$, <code>numlib::g_adic(a, g)</code> returns the g-adic representation of a as a list $[a_0, \dots, a_r]$ such that</p> $a = a_0 + a_1 g + a_2 g^2 + \dots + a_r g^r$ <p>and $0 \leq a_i < g$ für $i = 0, \dots, r - 1$ and $0 < a_r < g$.</p>
Examples	<p>Example 1</p> <p>Computing the dyadic representation of 1994:</p> <pre>numlib::g_adic(1994, 2)</pre> <pre>[0, 1, 0, 1, 0, 0, 1, 1, 1, 1, 1]</pre> <p>Example 2</p> <p>Computing the hexadecimal representation of 2001:</p> <pre>numlib::g_adic(2001, 16)</pre> <pre>[1, 13, 7]</pre>
Parameters	<p>number</p> <p>An nonnegative integer</p>

numlib::g_adic

base

An integer with absolute value is greater than 1

Return Values

List of nonnegative integers, or the function call with evaluated arguments if one of the arguments is not a number.

See Also

MuPAD Functions

`genpoly` | `int2text` | `text2int`

Purpose Chinese remainder theorem for integers

Syntax numlib::ichrem(a, m)

Description numlib::ichrem(a,m) returns the least nonnegative integer x such that $x \equiv a_i \pmod{m_i}$ for $i = 1, \dots, nops(m)$ if such a number exists; otherwise numlib::ichrem(a,m) returns FAIL.

The entries in m need not be pairwise coprime.

numlib::ichrem(a,m) returns an error if a is not a list of integers or m is not a list of natural numbers or a and m are not lists of the same length.

Examples

Example 1

Here the moduli are pairwise coprime. In this case, a solution always exists:

```
numlib::ichrem([2,3,2],[3,5,7])
```

```
23
```

Example 2

Here the moduli are not pairwise coprime, and a solution does not exist:

```
numlib::ichrem([5,6,8],[20,21,22])
```

```
FAIL
```

Example 3

Also here the moduli are not pairwise coprime, but a solution nevertheless exists:

```
numlib::ichrem([5,6,7],[20,21,22])
```

```
4605
```

numlib::ichrem

Parameters

a

A list of integers

m

A list of natural numbers of the same length as a

Return Values

Either a nonnegative integer or FAIL.

See Also

MuPAD Functions

numlib::lincongruence

Purpose Extended Euclidean algorithm for integers

Syntax `numlib::igcdmult(par1, par2,)`

Description `numlib::igcdmult` is an extension of the kernel function `igcdex`.
`numlib::igcdmult` returns an error if the arguments evaluate to numbers which are not all of the correct type.

For integers a_1, a_2, \dots, a_n , `numlib::igcdmult(a_1, a_2, \dots, a_n)` returns a list $[d, v_1, \dots, v_n]$ of integers such that d is the nonnegative greatest common divisor of a_1, a_2, \dots, a_n and $d = a_1*v_1 + a_2*v_2 + \dots + a_n*v_n$.

For integers a_1, a_2, \dots, a_n , `numlib::igcdmult(a_1, a_2, \dots, a_n)` returns a list $[d, v_1, \dots, v_n]$ of integers such that d is the nonnegative greatest common divisor of a_1, a_2, \dots, a_n and $d = a_1*v_1 + a_2*v_2 + \dots + a_n*v_n$.

Examples **Example 1**

Computing the greatest non-negative common divisor d of 455, 385, 165, 273 and integers v_1, v_2, v_3, v_4 such that $d = 455v_1 + 385v_2 + 165v_3 + 273v_4$:

```
numlib::igcdmult(455,385,165,273)
```

```
[1, -7630, 9156, -327, 2]
```

Parameters **par1**
Integer

par2, ...
Integers

Return Values List of integers, or the function call with evaluated arguments if some argument is not a number.

numlib::igcdmult

See Also

MuPAD Functions

[igcd](#) | [igcdex](#)

Purpose	Inverse of the Euler phi function
Syntax	<code>numlib::invphi(n)</code>
Description	<code>numlib::invphi(n)</code> computes all positive integers i with $\varphi(i) = n$.
Examples	<p>Example 1</p> <p>We compute all numbers i with $\varphi(i) = 500$:</p> <pre>s := numlib::invphi(500)</pre> <pre>[625, 753, 1004, 1250, 1506]</pre> <p>Test for correctness:</p> <pre>map(s, numlib::phi)</pre> <pre>[500, 500, 500, 500, 500]</pre>
Parameters	n A positive integer
Return Values	List of positive integer numbers.
See Also	
MuPAD Functions	<code>numlib::phi</code>

numlib::ispower

Purpose Test for perfect powers

Syntax numlib::ispower(n)

Description numlib::ispower(n) tests whether n is of the form a^k for some integers a, k with $a, k \geq 2$.

numlib::ispower returns FALSE if n is not a perfect power.

Among several pairs (a, k) for which $n = a^k$, that one with minimal a is returned.

Examples **Example 1**

This number is a perfect power:

```
numlib::ispower(1977326743)
```

```
7, 11
```

This number is not a perfect power:

```
numlib::ispower(1977326744)
```

```
FALSE
```

Parameters n

An integer

Return Values numlib::ispower returns a sequence of two positive integers greater than 1, or FALSE if n is not a perfect power.

See Also

**MuPAD
Functions**

`_power` | `ifactor` | `isqrt`

numlib::isquadres

Purpose Test for quadratic residues

Syntax numlib::isquadres(a, m)

Description If the integer number a is a quadratic residue modulo the natural number m numlib::isquadres(a,m) returns TRUE, and if a is a quadratic non-residue modulo m numlib::isquadres(a,m) returns FALSE.

If a and m are not coprime numlib::isquadres(a,m) returns an error.

numlib::isquadres returns an error if the arguments evaluate to numbers which are not both of the correct type.

numlib::isquadres returns the function call with its arguments evaluated if the arguments do not evaluate to numbers.

Examples

Example 1

132132 is a quadratic residue modulo 3231227:

```
numlib::isquadres(132132, 3231227)
```

TRUE

Example 2

222222 is a quadratic non-residue modulo 324899:

```
numlib::isquadres(222222,324899)
```

FALSE

Example 3

37 is a quadratic residue modulo 48884:

```
numlib::isquadres(37,48884)
```

TRUE

Parameters

a

An integer

m

A natural number coprime to a

Return Values

numlib::isquadres returns TRUE, FALSE, or the function call with its arguments evaluated.

See Also

MuPAD Functions

numlib::legendre | numlib::jacobi | numlib::msqrts

numlib::issqr

Purpose Test for perfect squares

Syntax numlib::issqr(a)

Description numlib::issqr(a) returns TRUE if a is the square of an integer, and FALSE otherwise.

Examples

Example 1

361 is the square of 19:

```
numlib::issqr(361)
```

```
TRUE
```

Example 2

362 is not a square:

```
numlib::issqr(362)
```

```
FALSE
```

Example 3

Negative integers are not squares:

```
numlib::issqr(-361)
```

```
FALSE
```

Parameters **a**

An integer

Return Values

numlib::issqr returns TRUE, FALSE, or the unevaluated call.

See Also

**MuPAD
Functions**

[isqrt](#) | [numlib::ispower](#) | [sqrt](#)

numlib::jacobi

Purpose Jacobi symbol

Syntax numlib::jacobi(a, m)

Description numlib::jacobi(a,m) returns the Jacobi symbol (a | m).
numlib::jacobi returns an error if one of its arguments evaluates to a number of wrong type.

Examples **Example 1**

Computing the Jacobi symbol (222222 | 304679):

```
numlib::jacobi(222222, 304679)
```

```
-1
```

Example 2

Computing the Jacobi-Symbol (222222 | 324889):

```
numlib::jacobi(222222, 324899)
```

```
1
```

Example 3

Computing the Jacobi symbol (222222 | 333333):

```
numlib::jacobi(222222, 333333)
```

```
0
```

Parameters **a**
 An integer
m

An odd positive integer

Return Values

numlib::jacobi(a, m) returns 0, 1, or -1, or the function call with evaluated arguments if one of the arguments is not a number.

Algorithms

numlib::jacobi doesn't use ifactor.

If a is an integer and m is an odd integer not coprime to a then by definition the Jacobi Symbol $(a | m)$ is zero.

See Also

MuPAD Functions

numlib::legendre | numlib::isquadres

numlib::Lambda

Purpose Von Mangoldt's function

Syntax `numlib::Lambda(m)`

Description `numlib::Lambda(m)` returns the value of von Mangoldt's function at m . It is an error if m is a number but not a natural number. If m is not a number, `numlib::Lambda` returns the unevaluated function call.

Examples **Example 1**

`numlib::Lambda` takes on non-zero values only for prime powers:

```
numlib::Lambda(49)
```

```
ln(7)
```

```
numlib::Lambda(48)
```

```
0
```

Example 2

`numlib::Lambda` returns the function call if its argument is not a number:

```
numlib::Lambda(3+n^4)
```

```
numlib::Lambda(n4 + 3)
```

Parameters **m**

Arithmetical expression

Return Values

numlib::Lambda returns an arithmetical expression

Algorithms

The function value of Lambda at m is defined to be $\log p$ if $m = p^n$ for some prime number p and some positive integer n , and to be zero for positive integers that are not prime powers.

See Also

MuPAD Functions

numlib::ispower

numlib::lambda

Purpose Carmichael function

Syntax `numlib::lambda(n)`

Description `numlib::lambda(n)` returns the value of the Carmichael function at n .
If m is a natural number then `numlib::lambda(m)` returns the value of the Carmichael function in m , i. e., the maximal order of an element in the group of units modulo m .
`numlib::lambda` returns an error if the argument evaluates to a number of wrong type. `numlib::lambda` returns the function call with its argument evaluated if m is not a number.

Examples **Example 1**

We compute the value of the Carmichael function λ in 97:

```
numlib::lambda(97)
```

```
96
```

Example 2

We compute the value of the Carmichael function λ in 96:

```
numlib::lambda(96)
```

```
8
```

Parameters **n**

A natural number

Return Values `numlib::lambda(n)` returns a natural number, or the function call with its argument evaluated.

Algorithms

Internally, `ifactor` is used for factoring `n`.

See Also

MuPAD Functions

`numlib::order` | `numlib::phi`

numlib::legendre

Purpose Legendre symbol

Syntax numlib::legendre(a, p)

Description numlib::legendre(a, p) returns the Legendre symbol (a | p).
numlib::legendre returns an error if one of its arguments evaluates to a number of wrong type.
numlib::legendre returns the function call with evaluated arguments if at least one of its arguments does not evaluate to a number.

Examples

Example 1

Computing the Legendre symbol (132132 | 3231277):

```
numlib::legendre(132132,3231277)
```

```
1
```

Example 2

Computing the Legendre symbol (132131 | 3231277):

```
numlib::legendre(132131,3231277)
```

```
-1
```

Example 3

Computing the Legendre symbol (-303 | 101):

```
numlib::legendre(-303,101)
```

```
0
```

Parameters**a**

An integer

p

An odd prime

Return Values

numlib::legendre(a,p) returns -1, 0, 1, or the function call with evaluated arguments.

Algorithms

If p is an odd prime and if a is an integer divisible by p then by definition the Legendre symbol $(a | p)$ is zero.

See Also**MuPAD Functions**

numlib::jacobi | numlib::isquadres

numlib::lincongruence

Purpose Linear congruence

Syntax numlib::lincongruence(a, b, m)

Description numlib::lincongruence(a,b,m) returns an error if one of the arguments evaluates to a number of wrong type.

For integers a and b and a non-zero integer m numlib::lincongruence(a,b,m) returns the sorted list of all solutions $x \in \{0, 1, \dots, m - 1\}$ of the linear congruence $ax \equiv b \pmod{m}$ if this congruence is solvable. Otherwise FAIL is returned.

For integers a and b and a non-zero integer m numlib::lincongruence(a,b,m) returns the sorted list of all solutions $x \in \{0, 1, \dots, m - 1\}$ of the linear congruence $ax \equiv b \pmod{m}$ if this congruence is solvable. Otherwise FAIL is returned.

Examples

Example 1

A linear congruence possessing one solution:

```
numlib::lincongruence(7,19,23)
```

```
[6]
```

Example 2

A linear congruence possessing several solutions:

```
numlib::lincongruence(77,209,253)
```

```
[6, 29, 52, 75, 98, 121, 144, 167, 190, 213, 236]
```

Example 3

A linear congruence possessing no solutions:

```
numlib::lincongruence(77,208,253)
```

FAIL

Parameters

a

An integer

b

An integer

m

A non-zero integer

Return Values

`numlib::lincongruence(a,b,m)` returns a list of nonnegative integers if the linear congruence is solvable.

`numlib::lincongruence(a,b,m)` returns FAIL if the linear congruence is not solvable.

`numlib::lincongruence(a,b,m)` returns the function call with its arguments evaluated if one of the arguments is a symbolic expression.

MuPAD Functions

`numlib::ichrem` | `numlib::mroots` | `numlib::msqrts`

numlib::mersenne

Purpose Mersenne primes

Syntax numlib::mersenne(n)
numlib::mersenne()

Description numlib::mersenne() returns the list of known Mersenne primes p . For these numbers, the Mersenne number $2^p - 1$ is prime.
numlib::mersenne(n) returns the n th currently known Mersenne prime. The numbers of the Mersenne primes after the 40th prime can change in the future. More Mersenne primes might be found.

Examples **Example 1**

The following primes p are known to have the property that the Mersenne number $2^p - 1$ is prime:

```
numlib::mersenne()
```

```
[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127, 521, 607, 1279, 2203, 2281, 3217, 4253, 4423, 9689, 9941, 11213, 19937, 21701, 23209, 44497, 86243, 110503, 132049, 216091, 756839, 859433, 1257787, 1398269, 2976221, 3021377, 6972593, 13466917, 20996011, 24036583, 25964951, 30402457, 32582657, 37156667, 42643801, 43112609, 57885161]
```

Example 2

Display the 10th Mersenne prime:

```
numlib::mersenne(10)
```

```
89
```

Return Values Natural number or a list of natural numbers.

References See <http://www.mersenne.org/>

Purpose Möbius function

Syntax `numlib::moebius(n)`

Description `numlib::moebius(n)` returns the value of the Möbius function at n .
`numlib::moebius` returns an error if the argument evaluates to a number of wrong type.
If n is a natural number `numlib::moebius(n)` returns the value of the Möbius function in n .
If n is not a number, `numlib::moebius(n)` returns the function call with its argument evaluated.

Examples **Example 1**

Computing the value of the Möbius function μ at 99937:

```
numlib::moebius(99937)
```

```
0
```

Example 2

`numlib::moebius` works for arbitrarily large integers:

```
numlib::moebius(453973694165307953197296969697410619233826)
```

```
-1
```

Parameters **n**

A natural number

Return Values `numlib::moebius(n)` returns a nonnegative integer.

numlib::moebius

Algorithms Internally, `ifactor` is used for factoring n .

See Also

**MuPAD
Functions** `numlib::lambda` | `numlib::phi`

Purpose	Modular roots of polynomials
Syntax	<code>numlib::mroots(P, m)</code>
Description	<p><code>numlib::mroots(P, m)</code> returns an error if P is not a polynomial over the integers or m is not a natural number.</p> <p>For a univariate polynomial P over the integers and for a natural number m the function call <code>numlib::mroots(P, m)</code> returns the sorted list of all integers $x \in \{0, 1, \dots, m - 1\}$ such that $P(x) \equiv 0 \pmod{m}$.</p> <p>For a multivariate polynomial P, <code>numlib::mroots(P, m)</code> returns a lexicographically sorted list of all lists $[x_1, \dots, x_n]$ of integers between 0 and $m - 1$ such that $P(x_1, \dots, x_n) \equiv 0 \pmod{m}$.</p> <p>For a univariate polynomial P over the integers and for a natural number m the function call <code>numlib::mroots(P, m)</code> returns the sorted list of all integers $x \in \{0, 1, \dots, m - 1\}$ such that $P(x) \equiv 0 \pmod{m}$.</p> <p>For a multivariate polynomial P, <code>numlib::mroots(P, m)</code> returns a lexicographically sorted list of all lists $[x_1, \dots, x_n]$ of integers between 0 and $m - 1$ such that $P(x_1, \dots, x_n) \equiv 0 \pmod{m}$.</p>

Examples**Example 1**

Defining a polynomial

```
P := poly(3*T^7 + 2*T^2 + T - 17, [T])
```

```
poly(3 T^7 + 2 T^2 + T - 17, [T])
```

and computing its roots modulo 1751:

```
numlib::mroots(P, 1751)
```

```
[221, 260, 612, 736, 1127, 1496]
```

numlib::mroots

The polynomial P doesn't have roots modulo 1994:

```
numlib::mroots(P, 1994)
```

```
[]
```

Example 2

We use `numlib::mroots` to find all points on a particular elliptic curve modulo 13:

```
numlib::mroots(poly(y^2 - x^3 - x - 2, [x, y]), 13)
```

```
[[1, 2], [1, 11], [2, 5], [2, 8], [6, 4], [6, 9], [7, 1], [7, 12], [9, 5], [9, 8], [12, 0]]
```

Parameters

P

A polynomial over the integers

m

A natural number

Return Values

If P is univariate, `numlib::mroots` returns a list of nonnegative integers. If P has more than one variable, `numlib::mroots` returns a list of lists of nonnegative integers.

Algorithms

`numlib::mroots` uses `factor`.

See Also

MuPAD Functions

`numlib::lincongruence` | `numlib::msqrts`

Purpose Modular square roots

Syntax `numlib::msqrts(a, m)`

Description `numlib::msqrts(a,m)` returns the list of all integers $x \in \{0, 1, \dots, m - 1\}$ such that $x^2 \equiv a \pmod{m}$.

Examples

Example 1

Computing the square roots of 132132 modulo 3231227:

```
numlib::msqrts(132132,3231227)
```

```
[219207, 3012020]
```

Example 2

There are no square roots of 222222 modulo 324899:

```
numlib::msqrts(222222,324899)
```

```
[]
```

Example 3

48884 is a composite number, so a number can have more than two square roots modulo 48884:

```
numlib::msqrts(37,48884)
```

```
[383, 585, 23857, 24059, 24825, 25027, 48299, 48501]
```

Parameters

a

An integer

m

numlib::msqrts

A natural number relatively prime to a

Return Values

`numlib::msqrts(a,m)` returns a list of nonnegative integers

Algorithms

`numlib::msqrts` uses D. Shanks' algorithm RESSOL.

See Also

MuPAD Functions

`numlib::lincongruence` | `numlib::mroots`

Purpose	Number of divisors of an integer
Syntax	<code>numlib::numdivisors(n)</code>
Description	<p><code>numlib::numdivisors(n)</code> returns the number of positive divisors of n. <code>numlib::numdivisors(0)</code> returns 0.</p> <p><code>numlib::numdivisors</code> returns the function call with evaluated argument if the argument is not a number.</p> <p><code>numlib::numdivisors</code> returns an error if the argument evaluates to a number of wrong type.</p> <p><code>numlib::numdivisors</code> is the same function as <code>numlib::tau</code>.</p>
Examples	<p>Example 1</p> <p>We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):</p> <pre>numlib::numdivisors(6746328388800)</pre> <pre>10080</pre>
Parameters	<p>n</p> <p>An integer</p>
Return Values	<code>numlib::numdivisors(n)</code> returns a nonnegative integer.
Algorithms	Internally, <code>ifactor</code> is used for factoring n .

numlib::numdivisors

See Also

MuPAD Functions

numlib::divisors | numlib::numprimedivisors |
numlib::primedivisors

Purpose Number of prime factors of an integer

Syntax `numlib::numprimedivisors(n)`

Description `numlib::numprimedivisors(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

`numlib::numprimedivisors` and `numlib::omega` are synonyms.

`numlib::numprimedivisors(0)` returns 0.

`numlib::numprimedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::numprimedivisors` returns an error if the argument evaluates to a number of wrong type.

Examples **Example 1**

We compute the number of primes dividing 6746328388800:

```
numlib::numprimedivisors(6746328388800)
```

```
9
```

Parameters **n**
An integer

Return Values `numlib::numprimedivisors(n)` returns a nonnegative integer.

Algorithms Internally, `ifactor` is used for factoring `n`.

numlib::numprimedivisors

See Also

MuPAD Functions

[numlib::omega](#) | [numlib::primedivisors](#) | [numlib::numdivisors](#)

Purpose Number of prime factors of an integer

Syntax `numlib::omega(n)`

Description `numlib::omega(n)` returns the number of prime factors of the integer `n`, counted without multiplicity.

`numlib::numprimedivisors` and `numlib::omega` are synonyms.

`numlib::omega(0)` returns 0.

`numlib::omega` returns the function call with evaluated argument if the argument is not a number.

`numlib::omega` returns an error if the argument evaluates to a number of wrong type.

Examples **Example 1**

We compute the number of primes dividing 6746328388800:

```
numlib::numprimedivisors(6746328388800)
```

```
9
```

Parameters **n**

An integer

Return Values `numlib::numprimedivisors(n)` returns a nonnegative integer.

Algorithms Internally, `ifactor` is used for factoring `n`.

numlib::omega

See Also

MuPAD Functions

numlib::numprimedivisors | numlib::primedivisors |
numlib::numdivisors

Purpose	Number of prime divisors (with multiplicity)
Syntax	<code>numlib::Omega(a)</code>
Description	<code>numlib::Omega(a)</code> returns, for a given positive integer a , the finite sum $\sum_p \alpha(p, a)$, where p runs through all primes, and $\alpha(p, a)$ denotes the highest exponent for which p^a divides a .
Examples	<p>Example 1</p> <p>In contrast to <code>numlib::numprimedivisors</code>, the prime factor 2 of 120 is counted thrice:</p> <pre>numlib::Omega(120)</pre> <p>5</p> <p>The same happens here:</p> <pre>numlib::Omega(8)</pre> <p>3</p>
Parameters	a Positive integer
Return Values	<code>numlib::Omega</code> returns a positive integer.
See Also	
MuPAD Functions	<code>numlib::numprimedivisors</code>

numlib::order

Purpose Order of a residue class

Syntax `numlib::order(a, m)`

Description `numlib::order(a,m)` returns the order of the residue class modulo `m` of `a` in the group of units modulo `m` if `a` and `m` are coprime.

`numlib::order(a,m)` returns the function call with its arguments evaluated if `a` or `m` is not a number.

`numlib::order` returns an error if one of the arguments evaluates to a number of wrong type.

Examples

Example 1

We compute the order of the residue class of 23 in the unit group modulo 2161:

```
numlib::order(23, 2161)
```

```
2160
```

Example 2

We compute the order of all elements in the unit group modulo 13:

```
map([$ 1..12], numlib::order, 13)
```

```
[1, 12, 3, 6, 4, 12, 12, 4, 3, 6, 12, 2]
```

Example 3

The residue class of 7 is not a unit in the ring modulo 21:

```
numlib::order(7, 21)
```

```
FAIL
```

Parameters**a**

An integer

m

A natural number

Return Values

`numlib::order(a,m)` returns a natural number if `a` is coprime to `m`, and FAIL if `a` is not coprime to `m`.

Algorithms

`numlib::order` uses `ifactor` and `numlib::phi`.

See Also**MuPAD Functions**

`numlib::lambda` | `numlib::phi`

numlib::phi

Purpose Euler phi function

Syntax numlib::phi(n)

Description numlib::phi(n) calculates the Euler ϕ function of the argument n, i.e. the number of numbers smaller than $|n|$ which are relatively prime to n. Cf. “Example 1” on page 19-62.

numlib::phi returns an error if the argument is a number but not an integer unequal to zero.

numlib::phi returns the function call with evaluated arguments if the argument is not a number. Cf. “Example 2” on page 19-62.

Examples **Example 1**

numlib::phi works on integers unequal zero:

```
numlib::phi(-7), numlib::phi(10)
```

```
6, 4
```

Example 2

numlib::phi is returned as a function call with evaluated argument:

```
x := a: numlib::phi(x)
```

```
numlib::phi(a)
```

Parameters n

Integer not equal to zero

Return Values numlib::phi returns a positive integer, if the argument evaluates to an integer unequal zero. If the argument cannot be evaluate to a number, the function call with evaluated arguments is returned .

**Overloaded
By** n

See Also

**MuPAD
Functions** numlib::invphi

numlib::pi

Purpose Number of primes up to a given bound

Syntax `numlib::pi(x)`

Description `numlib::pi(x)` returns the number of primes not exceeding x .

If the argument x is a real number (an integer, rational, or floating-point number), then the number of primes below x is returned. If x is a complex number, `numlib::pi` stops with an error. For every other kind of arithmetical expression x , an unevaluated call is returned.

`numlib::pi` becomes slightly faster if the internal prime number table is large. `ifactor(PrimeLimit)` displays the limit of the internal prime number table; it can be set by the user via the command line flag `-L`.

Internally, a fast kernel function with constant memory consumption is used for the computation.

Examples

Example 1

There are two primes less or equal 3:

```
numlib::pi(3)
```

```
2
```

Example 2

Also larger inputs can be handled fast:

```
numlib::pi(150000000)
```

```
8444396
```

Example 3

Floating point arguments are allowed, too.

```
numlib::pi(28.72)
```

9

Parameters**x**

An arithmetical expression

Return Values

Non-negative integer or an unevaluated call to numlib::pi

Algorithms

A Lehmer-type algorithm is used, with no precomputed sieve array and no remember tables. In contrast to the algorithm in “Computing π : The Meissel-Lehmer method”, this means constant memory consumption, at the price of slowness.

References

[1] Lagarias, J.C., V.S. Miller, and A.M. Odlyzko. “Computing π : The Meissel-Lehmer method”, Math. Comp., Vol. 44, No. 170 (1985), pp. 537-560

See Also**MuPAD Functions**

isprime | ithprime | nextprime | prevprime

numlib::proveprime

Purpose	Primality proving using elliptic curves
Syntax	<code>numlib::proveprime(n)</code>
Description	<code>numlib::proveprime(n)</code> tests whether <code>n</code> is a prime. Unlike <code>isprime</code> , <code>numlib::proveprime</code> always returns a correct answer. <code>numlib::proveprime</code> returns the following values:

- TRUE when it can prove that the number is a prime.
- FALSE when it can prove that the number is not a prime.
- FAIL when it cannot prove that the number is a prime and cannot prove otherwise. In such cases, the input most likely is a prime.
- A primality certificate, which is a list or a sequence of lists containing proof for the primality of the number. Typically, `numlib::proveprime` returns primality certificates for very large numbers.

A primality certificate is a sequence of lists of the form $[N, D, l_m, a, b, x, y, l_s]$, where

- N is a pseudoprime
- D is an integer (fundamental discriminant)
- l_m is a list of prime factors
- a, b, x, y are integers modulo N
- l_s is another list of prime factors (subset of the factors in l_m)

`numlib::checkPrimalityCertificate` checks primality certificates produced by `numlib::proveprime`.

Examples

Example 1

Proving that 1159523 is prime can be reduced to proving that 10343 is prime:

```
certificate := numlib::proveprime(1159523)
```

```
[1159523, 7, [2, 2, 2, 2, 7, 10343], 1012280, 1061361, 0, 726669, [10343]]
```

Example 2

Typically, the primality of the input is reduced to the primality of a smaller integer, the primality of that integer is reduced to the primality of an even smaller integer, and so on.

```
numlib::proveprime(179424673)
```

```
[179424673, 7, [2, 2, 2, 2, 11213771], 116768436, 77845624, 1, 110562161, [11213771]],  
[11213771, 7, [2, 2, 2, 2, 487, 1439], 9255809, 9908463, 2, 1041453, [487, 1439]]
```

Use `numlib::checkPrimalityCertificate` to check the result:

```
numlib::checkPrimalityCertificate(%)
```

```
TRUE
```

Parameters

n

Positive integer.

Return Values

TRUE, FALSE, FAIL, or a list or sequence of lists.

References

`numlib::proveprime` implements the Atkin-Goldwasser-Kilian-Morain algorithm for proving primality. For information about primality proving and this particular algorithm, see:

MuPAD Functions

`ifactor` | `isprime` | `ithprime` | `nextprime` | `prevprime`

Purpose Prime factors of an integer

Syntax `numlib::primedivisors(n)`

Description `numlib::primedivisors(n)` returns a list containing the different prime divisors of the integer `n`.

If `a` is a non-zero integer then, `numlib::primedivisors(a)` returns the sorted list of the different prime divisors of `a`.

`numlib::primedivisors(0)` returns `[0]`.

`numlib::primedivisors` returns the function call with evaluated argument if the argument is not a number.

`numlib::primedivisors` returns an error if the argument evaluates to a number of wrong type.

Examples **Example 1**

We compute the list of prime divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::primedivisors(6746328388800)
```

```
[2, 3, 5, 7, 11, 13, 17, 19, 23]
```

Parameters `n`
An integer

Return Values `numlib::primedivisors(n)` returns a list of nonnegative integers.

Algorithms Internally, `ifactor` is used for factoring `n`.

numlib::primedivisors

MuPAD Functions

`ifactor` | `isprime` | `numlib::divisors` | `numlib::numdivisors` |
`numlib::numprimedivisors` | `numlib::proveprime`

Purpose

Primitive roots

Syntax

```
numlib::primroot(m)  
numlib::primroot(a, m)
```

Description

`numlib::primroot(m)` returns the least positive primitive root modulo m if there exist primitive roots modulo m .

`numlib::primroot(a, m)` returns the least primitive root modulo m not smaller than a if there exist primitive roots modulo m .

Examples**Example 1**

We compute the least positive primitive root modulo the prime number 40487:

```
numlib::primroot(40487)
```

```
5
```

Example 2

We compute the least primitive root modulo $40487^2 = 1639197169$:

```
numlib::primroot(1639197169)
```

```
10
```

Example 3

Now we compute least primitive root modulo 40487 which is ≥ 1111111111 :

```
numlib::primroot(1111111111,40487)
```

```
111111116
```

numlib::primroot

Example 4

There are no primitive roots modulo 324013370:

```
numlib::primroot(324013370)
```

```
FAIL
```

Parameters

a

An integer

m

A natural number

Return Values

numlib::primroot returns an integer or FAIL.

Algorithms

numlib::primroot uses ifactor.

See Also

MuPAD Functions

numlib::order

- Purpose** Reconstruct a rational number from its image modulo N
- Syntax** `numlib::reconstructRational(a, n)`
- Description** `numlib::reconstructRational(a, n)` returns two integers p , q of absolute value smaller than $\sqrt{n/2}$ with p congruent to $a \cdot q$ modulo n , or FAIL if such p , q do not exist.
- `numlib::reconstructRational(a, n)` returns p , q solving $p \equiv a q \pmod{n}$. However, $p/q \pmod{n}$ equals a only if p and q are relatively prime.
- The solution p , q satisfies the following conditions: p is strictly between $-\sqrt{n/2}$ and $\sqrt{n/2}$, q is strictly between 0 and $\sqrt{n/2}$.
- Several pairs p , q satisfying these conditions may exist, in which case their ratios p/q are all the same; then the smallest of them is returned.

Examples

Example 1

We want to solve $p \equiv 7 q \pmod{12}$:

```
numlib::reconstructRational(7, 12)
```

```
2, 2
```

Modulo 98, the same congruence has no small solution. The solution $p=7$, $q=1$ is not small enough as 7 is not smaller than $\sqrt{98/2}$ but just equal.

```
numlib::reconstructRational(7, 98)
```

```
FAIL
```

Example 2

Rational number reconstruction is mostly used as the last step of a modular algorithm. Let us compute the gcd of the following polynomials:

numlib::reconstructRational

```
f:= poly(x^5 + 22/35*x^3 + 3/8*x^2 + 3/35*x + 9/56, [x]):  
g:= poly(x^5 + 2/5*x^4 + 22/35*x^3 + 153/280*x^2 + 3/35*x + 9/56,  
[x]):
```

Of course, the function `gcd` is able to do this. However, suppose we know that for some reason that the `gcd` has small coefficients with numerator and denominator both smaller than 10. Then we can use a modular algorithm with a smaller modulus than `gcd` would do: to be able to reconstruct these from their residue class modulo n , it is

sufficient that $\sqrt{\frac{n}{2}} > 10$, e.g., $n=211$.

```
gcd(poly(f, IntMod(211)), poly(g, IntMod(211)))  
  
poly(x^2 - 90, [x], IntMod(211))
```

Rational number reconstruction shows that the constant coefficient must be $3/7$:

```
numlib::reconstructRational(-90, 211)  
  
3, 7
```

This is true indeed:

```
gcd(f, g)  
  
poly(x^2 + 3/7 [x])
```

Parameters

a

Integer

n

A positive integer

Return Values

Sequence consisting of an integer and a positive integer; or FAIL

MuPAD Functions

numlib::lincongruence

numlib::sigma

Purpose Sum of divisors of an integer

Syntax numlib::sigma(n)
numlib::sigma(n, k)

Description numlib::sigma(n) returns the sum of the positive divisors of n.
numlib::sigma(n, k) returns the sum of the k-th powers of the positive divisors of n.
numlib::sigma(0) returns 0.
numlib::sigma returns the function call with evaluated argument if at least one argument is not a number.
numlib::sigma returns an error if one of its arguments evaluates to a number of wrong type.
numlib::sigma(n,0) is the same as numlib::numdivisors(n) and numlib::tau(n).
numlib::sigma(n,1) is the same function as numlib::sumdivisors(n) and numlib::sigma(n).

Examples

Example 1

The sum of the positive divisors of 120 is 360:

```
numlib::sigma(120)
```

```
360
```

Example 2

The sum of the fifth powers of the positive divisors of 120 is 25799815800:

```
numlib::sigma(120,5)
```

```
25799815800
```

Parameters**n**

An integer

k

A nonnegative integer

Return Values

numlib::sigma returns an integer.

Algorithms

Internally, ifactor is used for factoring n.

See Also**MuPAD Functions**

numlib::divisors | numlib::numdivisors

numlib::sqrt2cfrac

Purpose Continued fraction expansion of square roots

Syntax numlib::sqrt2cfrac(a)

Description numlib::sqrt2cfrac(a) returns the continued fraction expansion of the square root of a as a sequence of two lists: the first one contains the non-periodic (integer) part, the second one contains the periodic part of the expansion.

Examples **Example 1**

The square root of 87 can be written as $9 + q$, where q is a number

satisfying $q = \frac{1}{3 + \frac{1}{18 - q}}$:

```
numlib::sqrt2cfrac(87)
```

```
[9], [3, 18]
```

Example 2

Since 81 is a perfect square, there is no periodic part in the continued fraction expansion of its square root:

```
numlib::sqrt2cfrac(81)
```

```
[9]
```

Parameters **a**

A positive integer

Return Values If a is a perfect square, numlib::sqrt2cfrac returns a list with one entry; otherwise numlib::sqrt2cfrac returns a sequence of two lists, the first consisting of one integer, the second consisting of one or more integers.

MuPAD Functions

numlib::contfrac

numlib::sqrtmodp

Purpose	Square root of a quadratic residue modulo a prime
Syntax	<code>numlib::sqrtmodp(a, p)</code>
Description	<p><code>numlib::sqrtmodp(a, p)</code> computes a solution x to the congruence $x^2 \equiv a \pmod{p}$.</p> <p><code>numlib::sqrtmodp(a, p)</code> computes an integer x that satisfies $x^2 \equiv a \pmod{p}$.</p> <p>a must be a quadratic residue modulo p, and p must be a prime. This is not checked! Unless this is known to be the case, <code>numlib::msqrts</code> must be used. On the other hand, <code>numlib::sqrtmodp</code> is faster than <code>numlib::msqrts</code>.</p>
Examples	<p>Example 1</p> <p>One square root of 132132 modulo 3231227 is 3012020:</p> <pre>numlib::sqrtmodp(132132,3231227)</pre> <pre>3012020</pre>
Parameters	<p>a</p> <p>An integer</p> <p>p</p> <p>A prime unequal to 2</p>
Return Values	<code>numlib::sqrtmodp</code> returns an integer.
Algorithms	<code>numlib::sqrtmodp</code> uses D. Shanks' algorithm RESSOL.

**MuPAD
Functions**

`numlib::msqrts`

numlib::sumdivisors

Purpose Sum of divisors of an integer

Syntax numlib::sumdivisors(n)

Description numlib::sumdivisors(n) returns the sum of the positive divisors of the integer n.

numlib::sumdivisors(0) returns 0.

numlib::sumdivisors returns the function call with evaluated argument if the argument is not a number.

numlib::sumdivisors returns an error if the argument evaluates to a number of wrong type.

numlib::sumdivisors(n) is the same as numlib::sigma(n, 1).

Examples

Example 1

The sum of the positive divisors of 120 is 360:

```
numlib::sumdivisors(120)
```

```
360
```

Example 2

The sum of the positive divisors of - 63 is 104:

```
numlib::sumdivisors(-63)
```

```
104
```

Parameters n

An integer

Return Values

numlib::sumdivisors(n) returns a nonnegative integer.

Algorithms

Internally, ifactor is used for factoring n.

See Also**MuPAD Functions**

numlib::sigma | numlib::divisors | numlib::numdivisors

numlib::sumOfDigits

Purpose Sum of digits of an integer

Syntax numlib::sumOfDigits(n, <base>)

Description numlib::sumOfDigits(n, base) computes the sum of digits of n in the given base base; if the base is not given, it defaults to 10.

The sum of digits may be larger than the base. For certain purposes (testing divisibility by $b - 1$, where b is the base), it may be useful to apply numlib::sumOfDigits over and over to the result. This is not done automatically. See “Example 2” on page 19-84.

Examples **Example 1**

We compute the decimal and the binary sum of digits of 11:

```
numlib::sumOfDigits(11), numlib::sumOfDigits(11, 2)
```

```
2, 3
```

Example 2

We want to test whether 9 divides a given number, using the school method:

```
n:= 24373463462374324:  
repeat n:= numlib::sumOfDigits(n); print(n) until n < 10 end:  
delete n:
```

```
67
```

```
13
```

```
4
```

This only makes sense for demonstration purposes, as the following command achieves the same but much faster:

```
24373463462374324 mod 9
```

```
4
```

Parameters

n

Non-negative integer

base

Integer greater than one

Return Values

Non-negative integer

See Also

MuPAD Functions

numlib::g_adic

numlib::tau

Purpose Number of divisors of an integer

Syntax `numlib::tau(n)`

Description `numlib::tau(n)` returns the number of positive divisors of n .
`numlib::tau(0)` returns 0.
`numlib::tau` returns the function call with evaluated argument if the argument is not a number.
`numlib::tau` returns an error if the argument evaluates to a number of wrong type.
`numlib::tau` is the same function as `numlib::numdivisors`.

Examples **Example 1**

We compute the number of positive divisors of the number 6746328388800 (one of the highly composite numbers studied by S. Ramanujan in 1915):

```
numlib::tau(6746328388800)
```

```
10080
```

Parameters **n**

An integer

Return Values `numlib::tau` returns a nonnegative integer.

Algorithms Internally, `ifactor` is used for factoring n .

**MuPAD
Functions**

numlib::divisors | numlib::numprimedivisors |
numlib::primedivisors

numlib::toAscii

Purpose ASCII encoding of a string

Syntax numlib::toAscii(s)

Description numlib::toAscii(s) returns the list of ASCII codes of the characters in the string s.

numlib::toAscii returns an error if its argument is not a string.

Examples **Example 1**

The ASCII coding of a well-known name:

```
numlib::toAscii("MuPAD - Multi Processing Algebra Data Tool")
```

```
[77, 117, 80, 65, 68, 32, 45, 32, 77, 117, 108, 116, 105, 32, 80, 114, 111, 99, 101, 115, 115, 105, 110, 103, 32, 65, 108, 103, 101, 98, 114, 97, 32, 68, 97, 116, 97, 32, 84, 111, 111, 108]
```

and the ASCII coding of an empty string:

```
numlib::toAscii("")
```

```
[]
```

Parameters **s**

A string

Return Values numlib::toAscii(s) returns a list of nonnegative integers.

ode::symmetricPower
ode::unimodular
ode::vectorize
ode::wronskian

ode::companionSystem

Purpose Companion matrix of a linear homogeneous ordinary differential equation

Syntax `ode::companionSystem(Ly, y(x), <R>)`

Description `ode::companionSystem(Ly, y(x))` returns the companion matrix associated to Ly. If the optional argument R is given, the elements of the matrix are in R.

Examples **Example 1**

We compute the companion matrix of the following differential equation:

`Ly := 4*x^2*diff(y(x),x$3)+diff(y(x),x$2)+4*x*diff(y(x),x)-y(x)`

$$4x \frac{\partial}{\partial x} y(x) - y(x) + 4x^2 \frac{\partial^3}{\partial x^3} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

`ode::companionSystem(Ly, y(x))`

$$\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ \frac{1}{4x^2} & -\frac{1}{x} & -\frac{1}{4x^2} \end{pmatrix}$$

Parameters

Ly

A linear homogeneous ordinary differential equation.

y(x)

The dependent function of Ly.

R

A field of functions or numbers of characteristic zero, default is `Dom::ExpressionField(normal)`.

Return Values

Object of type `Dom::Matrix`.

ode::cyclicVector

Purpose Transforms a linear differential system to an equivalent linear differential system with a companion matrix.

Syntax `ode::cyclicVector(A, x, <v>)`

Description `ode::cyclicVector(A, x, v)` converts a first order homogeneous differential system $Y' = AY$ into a corresponding first order homogeneous differential system $Z' = BZ$, where B is a companion matrix, by substituting $Z = PY$ using the potential cyclic vector v. If v is not cyclic then an empty list is returned otherwise a list is returned whose first element is a list corresponding to the last row of B and second element is the invertible matrix P.

When the optional argument v is not given then the vector $[1, 0, \dots, 0]$ is tested. If it is not cyclic then a suitable one is determined randomly by the procedure.

Examples **Example 1**

We compute a differential system equivalent to the following differential system:

```
A := matrix( [ [x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2] ] )
```

$$\begin{pmatrix} x^2-1 & 1 & 0 \\ 0 & x^2+5x+\frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

```
ode::cyclicVector(A, x)
```

$$\left[\left[2x^4 + 6x^3 - \frac{49x^2}{3} - \frac{38x}{3} + \frac{19}{3}, -x^4 - 5x^3 - \frac{10x^2}{3} + x + \frac{20}{3}, 2x^2 + 5x + \frac{4}{3} \right], \right. \\ \left. \begin{pmatrix} 1 & 0 & 0 \\ x^2 - 1 & 1 & 0 \\ 2x - 2x^2 + x^4 + 1 & 5x + 2x^2 - \frac{2}{3} & 1 \end{pmatrix} \right]$$

So $[1, 0, 0]$ is a cyclic vector; $[x, 0, 0]$ is also a cyclic vector:

```
l := ode::cyclicVector(A, x, [x, 0, 0])
```

$$\left[\left[\frac{6x^7 + 21x^6 - 34x^5 - 28x^4 + 28x^3 + 10x^2 + 8x + 18}{3x^3}, \right. \right. \\ \left. \left. -\frac{3x^6 + 15x^5 + 10x^4 + 9x^3 + 10x^2 + 8x + 18}{3x^2}, \frac{6x^3 + 15x^2 + 4x + 9}{3x} \right], \right. \\ \left. \begin{pmatrix} x & 0 & 0 \\ -x + x^3 + 1 & x & 0 \\ x + 4x^2 - 2x^3 + x^5 - 2 - \frac{2x}{3} + 5x^2 + 2x^3 + 2x \end{pmatrix} \right]$$

And we can build easily a linear homogeneous differential equation associated to it (c.f. `ode::mkODE`):

```
-ode::mkODE(l[1].[-1], y, x)
```

ode::cyclicVector

$$\frac{(3x^6 + 15x^5 + 10x^4 + 9x^3 + 10x^2 + 8x + 18) \frac{\partial}{\partial x} y(x)}{3x^2} - \frac{(6x^3 + 15x^2 + 4x + 9) \frac{\partial^2}{\partial x^2} y(x)}{3x} - \frac{y(x)(6x^7 + 21x^6 - 34x^5 - 28x^4 + 28x^3 + 10x^2 + 8x + 18)}{3x^3} + \frac{\partial^3}{\partial x^3} y(x)$$

Parameters

A

A square matrix of type Dom::Matrix.

x

The independent variable.

v

A list of size the dimension of A, default is [1, 0, ..., 0].

Return Values

List, possibly empty, of two lists.

See Also

MuPAD Functions

ode::scalarEquation

Purpose D'Alembert reduction of a linear homogeneous ordinary differential equation

Syntax `ode::dAlembert(Ly, y(x), v)`

Description `ode::dAlembert(Ly, y(x), v)` returns the reduced differential equation of Ly using the method of reduction of d'Alembert and the function v. If v is a solution of Ly and u is a solution of the reduced differential equation then $v + tu$ is another solution of Ly.

Examples **Example 1**

Consider the following differential equation:

$$Ly := 2/x^3*y(x) - 2/x^2*\text{diff}(y(x),x) + 1/x*\text{diff}(y(x),x^2) + \text{diff}(y(x),x^3)$$

$$\frac{2y(x)}{x^3} - \frac{2\frac{\partial}{\partial x}y(x)}{x^2} + \frac{\frac{\partial^2}{\partial x^2}y(x)}{x} + \frac{\partial^3}{\partial x^3}y(x)$$

We easily check that x is a particular solution of Ly:

$$\text{ode::evalOde}(Ly, y(x)=x)$$

0

Then we reduce the equation Ly using this special solution:

$$R := \text{ode::dAlembert}(Ly, y(x), x)$$

$$\frac{4\frac{\partial}{\partial x}y(x)}{x} + \frac{\partial^2}{\partial x^2}y(x)$$

ode::dAlembert

The solutions of the equation R are not too hard to find:

```
ode::evalOde(R, y(x)=1), ode::evalOde(R, y(x)=1/x^3)
```

```
0, 0
```

So a basis of solutions of Ly is therefore

$\left\{ x, x \operatorname{hold}(\operatorname{int})(1, x) = x^2, x \operatorname{hold}(\operatorname{int})\left(\frac{1}{x^3}, x\right) = -\frac{1}{2x} \right\}$ which can be checked directly:

```
ode::solve(Ly, y(x))
```

```
 $\left\{ \frac{C4}{x} - \frac{x(C3 + 2 C2 x)}{6} \right\}$ 
```

Parameters

Ly

A homogeneous linear differential equation.

y(x)

The dependent function of Ly .

v

An expression.

Return Values

Expression.

Purpose	Applies an expression at a linear ordinary differential equation
Syntax	<code>ode::evalOde(Ly, y(x))</code>
Description	<code>ode::evalOde(Ly, y(x) = v)</code> evaluates Ly replacing y(x) by v and simplifying the result. This can be useful to check a solution candidate, for example.

Examples **Example 1**

We evaluate the following differential equation for various expressions:

```
Ly := (x^2+1)*diff(y(x),x$2)+x*diff(y(x),x)-4*y(x)
```

$$(x^2 + 1) \frac{\partial^2}{\partial x^2} y(x) + x \frac{\partial}{\partial x} y(x) - 4 y(x)$$

```
ode::evalOde(Ly, y(x) = 2*x^2+1),
ode::evalOde(Ly, y(x) = exp(x)),
ode::evalOde(Ly, y(x) = RootOf(Z^3+x*Z+1, Z))
```

$$0, x^2 e^x - 3 e^x + x e^x, -18 Z^2 x^4 - 54 Z^2 x^2 + 243 Z^2 x - 60 Z x^6 - 4 Z x^4 - 756 Z x^3 + 54 Z x - 2916 Z - 12 x^5 - 36 x^3 + 162 x^2$$

Parameters	Ly	A linear ordinary differential equation.
	y(x)	The dependent function of Ly.
	v	An expression.

ode::evalOde

Return Values

Expression.

Purpose Exponential solutions of a homogeneous linear ordinary differential equation

Syntax `ode::exponentialSolutions(Ly, y(x), <Generic>)`

Description `ode::exponentialSolutions(Ly, y(x))` returns a fundamental set of the exponential solutions of `Ly`, i.e. solutions z such that $\frac{z}{y}$ is a rational function of x . When the option `Generic` is given, a generic form of them is returned.

Note `ode::exponentialSolutions` does not return any eventual solution that is exponential over the algebraic closure of (x) but not over (x) .

Examples

Example 1

We compute the exponential solutions of the following differential equation :

```
Ly:=diff(y(x),x$4)-2*x*diff(y(x),x$3)+(-x+x^2-5)*diff(y(x),x$2)+
(4*x+2*x^2)*diff(y(x),x)+(2+x-x^3)*y(x)
```

$$\frac{\partial^4}{\partial x^4} y(x) - 2x \frac{\partial^3}{\partial x^3} y(x) - (-x^2 + x + 5) \frac{\partial^2}{\partial x^2} y(x) + (2x^2 + 4x) \frac{\partial}{\partial x} y(x) + y(x) (-x^3 + x + 2)$$

```
ode::exponentialSolutions(Ly, y(x)),
ode::exponentialSolutions(Ly, y(x), Generic)
```

$$\left\{ e^{\frac{x^2}{2}}, x e^{\frac{x^2}{2}} \right\}, C_2 e^{\frac{x^2}{2}} + C_1 x e^{\frac{x^2}{2}}$$

Example 2

No exponential solution over the algebraic closure of (x) is returned:

ode::exponentialSolutions

```
ode::exponentialSolutions(diff(y(x),x$2)+y(x), y(x))
```

∅

whereas $\left\{ e^{ix}, \frac{1}{e^{ix}} \right\}$ is a basis of solutions of the above differential equation.

Parameters

Ly

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

y(x)

The dependent function of Ly.

Return Values

set, possibly empty, of functions or an expression.

Purpose

Exponents of a linear ordinary differential equation

Syntax

`ode::exponents(Ly, y(x), p)`

Description

`ode::exponents` returns the set of exponents of a homogeneous linear differential equation at a given point.

`ode::exponents(Ly, y(x), p)` returns the set of (local) exponents of Ly at the place p . If the place is infinity then one uses $\frac{1}{x}$ instead. They are defined as roots (in an algebraic closure of (x)) of the indicial equation (c.f. `ode::indicialEquation`) of Ly so the set of exponents may be empty, see “Example 2” on page 20-14.

Examples**Example 1**

We compute the exponents of the following differential equation at the regular point 0 and at the singular points -1 and *infinity*:

`Ly := diff(y(x),x$2)+4/(x+1)*diff(y(x),x)+2/(x+1)^2*y(x)`

$$\frac{4 \frac{\partial}{\partial x} y(x)}{x+1} + \frac{2 y(x)}{(x+1)^2} + \frac{\partial^2}{\partial x^2} y(x)$$

`ode::exponents(Ly, y(x), x)`

`{0, 1}`

`ode::exponents(Ly, y(x), x+1)`

`{-2, -1}`

`ode::exponents(Ly, y(x), 1/x)`

ode::exponents

{1, 2}

Example 2

It may happen that at a place the set of exponents is empty; this corresponds to an irregular singular point:

```
Ly := (2*x+4)*diff(y(x),x)/(2*x+x^2-2)-2*y(x)/(2*x+x^2-2)-  
      (4*x+x^2)/(2*x+x^2-2)*diff(y(x),x$2)+diff(y(x),x$3)
```

$$\frac{(2x+4) \frac{\partial}{\partial x} y(x)}{x^2+2x-2} - \frac{(x^2+4x) \frac{\partial^2}{\partial x^2} y(x)}{x^2+2x-2} - \frac{2y(x)}{x^2+2x-2} + \frac{\partial^3}{\partial x^3} y(x)$$

```
ode::exponents(Ly, y(x), 1/x)
```

∅

```
ode::exponents(Ly, y(x), x^2+2*x-2)
```

{0, 1, 3}

Parameters

Ly

A homogeneous linear differential equation over (x) .

y(x)

The dependent function of Ly.

P

An irreducible polynomial in x or $1/x$.

Return Values

set, possibly empty.

See Also

MuPAD Functions

`ode::indicialEquation` | `ode::isFuchsian`

ode::getOrder

Purpose Order of an ordinary differential equation

Syntax `ode::getOrder(Ly, y(x))`

Description `ode::getOrder(Ly, y(x))` returns the order of Ly for the dependent function $y(x)$, i.e. the highest degree of derivative of Ly.

Examples **Example 1**

We can compute orders for linear and nonlinear ordinary differential equations:

```
ode::getOrder(diff(y(x),x$2)-x*y(x)-airyAi(x), y(x))
```

2

```
ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), y(x))
```

3

```
ode::getOrder(y(x)*diff(y(x),x$3)^2-exp(y(x)), z(x))
```

$-\infty$

Parameters **Ly**
An ordinary differential equation.

y(x)
The dependent function of Ly.

Return Values
Either -infinity or a positive integer.

Purpose Indicial equation of a linear ordinary differential equation

Syntax `ode::indicialEquation(Ly, y(x), p, u)`

Description `ode::indicialEquation(Ly, y(x), p, u)` returns the indicial equation in the variable u of Ly at the place p . If the place is infinity then one uses $\frac{1}{x}$ instead. The result is FAIL if the place corresponds to an irregular singular point of Ly .

Examples **Example 1**

We compute the indicial equations of the following differential equation at the regular point 1 and at the singular points 0 and *infinity*:

`Ly := 1/x^3*y(x)*(4*x-10)-1/x^2*(4*x^3-10)*diff(y(x),x)-9/2/x*diff(y(x),x$2)+diff(y(x),x$3)`

$$\frac{y(x)(4x-10)}{x^3} - \frac{9 \frac{\partial^2}{\partial x^2} y(x)}{2x} - \frac{(4x^3-10) \frac{\partial}{\partial x} y(x)}{x^2} + \frac{\partial^3}{\partial x^3} y(x)$$

`ode::indicialEquation(Ly, y(x), x-1, U)`

$$U^3 - 3U^2 + 2U$$

`ode::indicialEquation(Ly, y(x), 1/x, U)`

FAIL

`ode::indicialEquation(Ly, y(x), x, U)`

$$2U^3 - 15U^2 + 33U - 20$$

ode::indicialEquation

The roots of the indicial equation correspond to the (local) exponents:

```
solve(%, U), ode::exponents(Ly, y(x), x)
```

```
{1, 5/2, 4}, {1, 5/2, 4}
```

Parameters

Ly

A homogeneous linear differential equation over (x) .

y(x)

The dependent function of Ly.

P

An irreducible polynomial in x or $1/x$.

u

An element of type DOM_IDENT.

Return Values

FAIL or a polynomial expression in u.

See Also

MuPAD Functions

ode::indicialEquation | ode::isFuchsian

Purpose

Tests if a homogeneous linear ordinary differential equation is of Fuchsian type

Syntax

`ode::isFuchsian(Ly, y(x), <AllExponents>)`

Description

`ode::isFuchsian` returns TRUE if `Ly` is of Fuchsian type, i.e., all the singular points (including the point at infinity) of `Ly` are regular. It returns FALSE if at least one singular point is irregular. When the option `AllExponents` is given, either FALSE is returned or a list where each element is a table containing, at each regular singular point of `Ly` the place, the indicial equation and the exponents.

Examples**Example 1**

We test if the following differential equation is Fuchsian:

`Ly:=x*(1-x)*diff(y(x),x$2)+(1-x)*diff(y(x),x)+10*y(x)`

$$-x(x-1) \frac{\partial^2}{\partial x^2} y(x) - (x-1) \frac{\partial}{\partial x} y(x) + 10 y(x)$$

`ode::isFuchsian(Ly, y(x))`

TRUE

We can have a look of the indicial equations, exponents at each regular singular point of `Ly`:

`ode::isFuchsian(Ly, y(x), AllExponents)`

ode::isFuchsian

exponents	{0}	exponents	{0, 1}	exponents	$\{\sqrt{10}, -\sqrt{10}\}$
indicialEq	$X22^{2^2}$	indicialEq	$X22 - X22^{2^2}$	indicialEq	$-X22^2 + 10$
place	x	place	$x - 1$	place	$\frac{1}{x}$

Example 2

In this example, the Airy equation, the only singular point is at infinity and is irregular:

```
ode::isFuchsian(diff(y(x),x$2) - x*y(x), y(x))
```

```
FALSE
```

Parameters

Ly

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

y(x)

The dependent function of Ly.

Options

AllExponents

Return a list of tables of indicial equations and exponents for regular singular points.

Return Values

TRUE, FALSE or a list.

Purpose

Test for a linear ordinary differential equation

Syntax

```
ode::isLODE(Ly, y(x), <Homogeneous | HlodeOverRF |
Hlode | LodeOverRF | Lode>)
```

Description

`ode::isLODE(Ly, y(x))` returns TRUE if `Ly` is a linear ordinary differential equation in `y(x)`, FALSE otherwise. If an optional argument is given then the result is discussed as follows:

- **Homogeneous:** returns TRUE if `Ly` is homogeneous, FALSE otherwise.
- **HlodeOverRF:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous with rational functions coefficients, FALSE otherwise.
- **Hlode:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is homogeneous, FALSE otherwise.
- **LodeOverRF:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` has rational functions coefficients, FALSE otherwise.
- **Lode:** returns the sequence `Ly, y, x, n`, where `n` is the order of `Ly`, if `Ly` is a linear ordinary differential equation, FALSE otherwise.

Examples**Example 1**

We test the following differential equations:

```
ode::isLODE(y(x)^2+x^2*diff(y(x),x)+x, y(x))
```

```
FALSE
```

```
ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x))
```

```
TRUE
```

```
ode::isLODE(y(x)+x^2*diff(y(x),x)+x, y(x), Hlode)
```

ode::isLODE

FALSE

```
ode::isLODE(  
    y(x)+x^2*diff(y(x),x)+x*diff(y(x),x$2), y(x), HlodeOverRF)
```

$$y(x) + x^2 \frac{\partial}{\partial x} y(x) + x \frac{\partial^2}{\partial x^2} y(x), y, x, 2$$

```
ode::isLODE(  
    x+x^2*diff(y(x),x)+exp(x)*diff(y(x),x$2), y(x), LodeOverRF)
```

FALSE

Parameters

Ly

An expression.

y(x)

The dependent function of Ly.

Return Values

Either TRUE, FALSE or a sequence of type `_exprseq`.

Purpose Builds a linear homogeneous ordinary differential equation from a list of coefficient functions

Syntax `ode::mkODE(l, y, x)`

Description `ode::mkODE(l, y, x)` returns a linear homogeneous ordinary differential equation Ly in $y(x)$ where the coefficients are the entries of the list l . The last element of the list l corresponds to the leading coefficients of Ly .

Examples **Example 1**

We generate the linear ODE for $y(x)$ with the coefficients -1 , $4x$ and $4x^2$ of $y(x)$, $y'(x)$ and $y''(x)$, respectively:

```
ode::mkODE([-1, 4*x, 4*x^2], y, x)
```

$$4x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) + 4x \frac{\partial}{\partial x} y(x)$$

Parameters

l

A list of coefficient functions.

y

The dependent variable of the resulting differential equation.

x

The independent variable of the resulting differential equation.

Return Values

Expression.

ode::normalize

Purpose Normalized form of a linear ordinary differential equation

Syntax `ode::normalize(Ly, y, x, n)`

Description `ode::normalize(Ly, y, x, n)` computes the normalized form of the n -th order linear ordinary differential equation Ly , i.e. whose leading coefficient (the coefficient of the highest derivative of $y(x)$ in Ly) is 1.

Examples **Example 1**

We normalize the following differential equation:

```
Ly:=-diff(y(x),x,x)/x+y(x)/4/x^3-diff(y(x),x)/x^2
```

$$\frac{y(x)}{4x^3} - \frac{\frac{\partial}{\partial x} y(x)}{x^2} - \frac{\frac{\partial^2}{\partial x^2} y(x)}{x}$$

```
ode::normalize(Ly, y, x, 2)
```

$$\frac{\frac{\partial}{\partial x} y(x)}{x} - \frac{y(x)}{4x^2} + \frac{\partial^2}{\partial x^2} y(x)$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y

The dependent variable of Ly .

x

The independent variable of Ly .

n

The order of Ly .

Return Values

Expression representing a linear differential equation.

ode::polynomialSolutions

Purpose Polynomial solutions of a homogeneous linear ordinary differential equation

Syntax `ode::polynomialSolutions(Ly, y(x), <Generic>)`

Description `ode::polynomialSolutions` computes a fundamental set of polynomial solutions of a homogeneous linear ordinary differential equation.

`ode::polynomialSolutions` returns a fundamental set of the polynomial solutions of `Ly`, i.e., solutions in the ring $\mathbb{Q}[x]$. When the option `Generic` is given, a generic form of them is returned.

Examples **Example 1**

We compute the polynomial solutions of the following differential equation:

```
Ly:=3*x*diff(y(x),x,x)-x*diff(y(x),x)+9*y(x)
```

$$3x \frac{\partial^2}{\partial x^2} y(x) - x \frac{\partial}{\partial x} y(x) + 9y(x)$$

```
ode::polynomialSolutions(Ly, y(x))
```

$$\{x^9 - 216x^8 + 18144x^7 - 762048x^6 + 17146080x^5 - 205752960x^4 + 1234517760x^3 - 3174474240x^2 + 2380855680x\}$$

```
ode::polynomialSolutions(Ly, y(x), Generic)
```

$$C1 (x^9 - 216x^8 + 18144x^7 - 762048x^6 + 17146080x^5 - 205752960x^4 + 1234517760x^3 - 3174474240x^2 + 2380855680x)$$

Parameters `Ly`

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

$y(x)$

The dependent function of Ly .

Return Values

set, possibly empty, of functions or an expression

See Also

MuPAD Functions

ode::rationalSolutions

ode::rationalSolutions

Purpose Rational solutions of a homogeneous linear ordinary differential equation

Syntax `ode::rationalSolutions(Ly, y(x), <Generic>)`

Description `ode::rationalSolutions` returns a fundamental set of the rational solutions of `Ly`, i.e., solutions in the field (x) . When the option `Generic` is given, a generic form of them is returned.

Examples **Example 1**

We compute the rational solutions of the following differential equation:

```
Ly := (4*x^5+8*x^3+4*x)*diff(y(x),x,x) +  
      (36*x^4+32*x^2-4)*diff(y(x),x)+48*x^3*y(x)
```

$$48x^3 y(x) + (4x^5 + 8x^3 + 4x) \frac{\partial^2}{\partial x^2} y(x) + (36x^4 + 32x^2 - 4) \frac{\partial}{\partial x} y(x)$$

```
ode::rationalSolutions(Ly, y(x))
```

$$\left\{ \frac{1}{x^6 + 3x^4 + 3x^2 + 1}, \frac{x^4 + 2x^2}{x^6 + 3x^4 + 3x^2 + 1} \right\}$$

```
ode::rationalSolutions(Ly, y(x), Generic)
```

$$\frac{C1}{x^6 + 3x^4 + 3x^2 + 1} + \frac{C2(x^4 + 2x^2)}{x^6 + 3x^4 + 3x^2 + 1}$$

Parameters `Ly`

A homogeneous linear ordinary differential equation with coefficients in the field (x) of rational functions over the rationals.

$y(x)$

The dependent function of Ly .

**Return
Values**

set, possibly empty, of functions or an expression

See Also

**MuPAD
Functions**

`ode::polynomialSolutions`

ode::ratSys

Purpose Rational solutions of a first order homogeneous linear differential system

Syntax `ode::ratSys(M, x)`

Description `ode::ratSys(M, x)` computes a fundamental set of rational solutions of the first order homogeneous linear differential system $Y' = MY$. This method uses a cyclic vector and therefore is not optimal.

Examples **Example 1**

We compute the rational solutions of the following differential system:

```
A := matrix([ [2*(x+x^2-9)/x/(x-2), 2*(x^2-6)/x/(x-2)],  
              [-3*(2*x+x^2-12)/x/(x-2), -(2*x+3*x^2-24)/x/(x-2)] ])
```

$$\begin{pmatrix} \frac{2x^2+2x-18}{x(x-2)} & \frac{2x^2-12}{x(x-2)} \\ -\frac{3x^2+6x-36}{x(x-2)} & -\frac{3x^2+2x-24}{x(x-2)} \end{pmatrix}$$

```
v := ode::ratSys(A, x)
```

$$\left\{ \left(\begin{array}{c} \frac{x+2}{x^3} \\ -\frac{x+4}{x^3} \end{array} \right) \right\}$$

And we can check the result:

```
diff(v[1], x) = normal(A*v[1])
```

$$\begin{pmatrix} -\frac{2(x+3)}{x^4} \\ \frac{2(x+6)}{x^4} \end{pmatrix} = \begin{pmatrix} -\frac{2(x+3)}{x^4} \\ \frac{2(x+6)}{x^4} \end{pmatrix}$$

Parameters**M**

A square matrix of type `Dom::Matrix` with coefficients in the field (x) of rational functions over the rationals.

x

The independent function.

Return Values

set, possibly empty, of objects of type `Dom::Matrix`.

See Also**MuPAD Functions**

`ode::rationalSolutions` | `ode::cyclicVector` | `ode::scalarEquation`

ode::scalarEquation

Purpose Transforms a linear differential system to an equivalent scalar linear differential equation

Syntax `ode::scalarEquation(A, x, y, <Transform>)`

Description `ode::scalarEquation` converts a first order homogeneous linear differential system to an equivalent homogeneous scalar linear differential equation using the method of cyclic vector.

`ode::scalarEquation(A, x, y)` returns a scalar homogeneous linear differential equation in $y(x)$ equivalent to the first order homogeneous differential system $Y' = AY$ using the method of the cyclic vector. If the option `Transform` is given then a list is returned whose first element is the corresponding differential equation Ly and second element is an invertible matrix P such that $C = P'P^{-1} + PAP^{-1}$ is the companion matrix associated to Ly ; hence if Z is a solution of the differential system $Y' = AY$ then PZ is a solution of the system $Y' = CY$.

Examples **Example 1**

We compute a linear differential equation equivalent to the following differential system:

```
A := matrix( [ [x^2-1,1,0], [0,x^2+5*x+1/3,1], [0,0,2] ] )
```

$$\begin{pmatrix} x^2-1 & 1 & 0 \\ 0 & x^2+5x+\frac{1}{3} & 1 \\ 0 & 0 & 2 \end{pmatrix}$$

```
l := ode::scalarEquation(A, x, y, Transform)
```

$$\left[\frac{\partial^3}{\partial x^3} y(x) - \left(2x^2 + 5x + \frac{4}{3} \right) \frac{\partial^2}{\partial x^2} y(x) + \left(x^4 + 5x^3 + \frac{10x^2}{3} - x - \frac{20}{3} \right) \frac{\partial}{\partial x} y(x) - y(x) \left(2x^4 + 6x^3 - \frac{49x^2}{3} - \frac{38x}{3} + \frac{19}{3} \right), \begin{pmatrix} 1 & 0 & 0 \\ x^2 - 1 & 1 & 0 \\ 2x - 2x^2 + x^4 + 1 & 5x + 2x^2 - \frac{2}{3} & 1 \end{pmatrix} \right]$$

And we can check that, for $P=1[2]$, $P' P^{-1} + P A P^{-1}$ is the companion matrix associated to $1[1]$:

```
P := 1[2]:
bool( diff(P,x)*P^(-1)+P*A*P^(-1) =
      ode::companionSystem(1[1], y(x)) )
```

TRUE

Parameters

A

A square matrix of type `Dom::Matrix`.

x

The independent variable of the resulting scalar differential equation.

y

The dependent variable of the resulting scalar differential equation.

Return Values

Expression or a list.

ode::scalarEquation

See Also

MuPAD Functions

`ode::cyclicVector`

Purpose

Series solutions of an ordinary differential equation

Syntax

```
ode::series(Ly, y(x), x | x = x0, <order>)
ode::series({Ly, <inits>}, y(x), x | x = x0, <order>)
```

Description

`ode::series(Ly, y(x), x = x0)` computes the first terms of the series expansions of the solutions of `Ly` with respect to the variable `x` around the point `x0`.

`ode::series` tries to compute either the Taylor series, the Laurent series or the Puiseux series of the solutions of the differential equation `Ly` around the point `x=x0`.

Suppose that `Ly` is a nonlinear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed otherwise an expression of type "series" is returned. If initial conditions are given at the point `x0` then the answer is expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0`. See "Example 1" on page 20-35.

Suppose that `Ly` is a linear differential equation. If `x0` is an ordinary point of `Ly` then a Taylor series is computed, if `Ly` is furthermore homogeneous and `x0` is a regular point then a Puiseux series is computed (containing possible logarithmic terms), otherwise an expression of type "series" is returned. If initial conditions are given at the point `x0` then the answer is either expressed in terms of the function `y(x)` and its derivatives evaluated at the point `x0` or it may be expressed in terms of arbitrary constants.

Examples**Example 1**

Consider the following nonlinear differential equation:

$$Ly := x^2 \text{diff}(y(x), x) + y(x) - x$$

$$y(x) - x + x^2 \frac{\partial}{\partial x} y(x)$$

We compute the series solutions at the point 0 which is a singular point:

```
ode::series(Ly, y(x), x=0)
```

$$\text{series}\left(y(x) - x + x^2 \frac{\partial}{\partial x} y(x), y(x), x=0\right)$$

Then we compute the series solutions at the regular point 1:

```
ode::series(Ly, y(x), x=1)
```

$$\left\{ y(1) - (x-1)(y(1)-1) + \left(\frac{3y(1)}{2} - 1\right)(x-1)^2 - \left(\frac{13y(1)}{6} - \frac{4}{3}\right)(x-1)^3 \right. \\ \left. + \left(\frac{73y(1)}{24} - \frac{11}{6}\right)(x-1)^4 - \left(\frac{167y(1)}{40} - \frac{5}{2}\right)(x-1)^5 + \mathcal{O}((x-1)^6) \right\}$$

And we can also put some initial conditions at the point 1:

```
ode::series({y(1)=1, Ly}, y(x), x=1)
```

$$\left\{ 1 + \frac{(x-1)^2}{2} - \frac{5(x-1)^3}{6} + \frac{29(x-1)^4}{24} - \frac{67(x-1)^5}{40} + \mathcal{O}((x-1)^6) \right\}$$

Example 2

Consider the following linear differential equation:

```
Ly := (2*x+x^3)*diff(y(x),x$2)-diff(y(x),x)-6*x*y(x)
```

$$(x^3 + 2x) \frac{\partial^2}{\partial x^2} y(x) - \frac{\partial}{\partial x} y(x) - 6x y(x)$$

We compute the series solutions at the regular point 1:

```
ode::series(Ly, y(x), x=1)
```

$$\left\{ y(1) + y'(1)(x-1) + (x-1)^2 \left(\frac{y''(1)}{6} + y(1) \right) - \left(\frac{y(1)}{9} - \frac{7y'(1)}{27} \right) (x-1)^3 \right. \\ \left. + \left(\frac{y(1)}{12} - \frac{y'(1)}{36} \right) (x-1)^4 + \left(\frac{y(1)}{90} - \frac{2y'(1)}{135} \right) (x-1)^5 + O((x-1)^6) \right\}$$

The series solutions at the regular singular point 0:

```
ode::series(Ly, y(x), x=0)
```

$$\left\{ 1 + 3x^2 + \frac{3x^4}{5} + O(x^6), x^{3/2} + \frac{3x^{7/2}}{8} - \frac{3x^{11/2}}{128} + O(x^{15/2}) \right\}$$

Also the series solutions at the regular singular point *infinity*:

```
ode::series(Ly, y(x), x=infinity)
```

$$\left\{ \frac{1}{x^2} - \frac{1}{x^4} + \frac{11}{9x^6} + O\left(\frac{1}{x^8}\right), 2880x^3 + 4320x - \frac{1080}{x} + O\left(\frac{1}{x^3}\right) \right\}$$

Example 3

Consider the following linear differential equation:

```
Ly := x^2*diff(y(x),x$2) - x*diff(y(x),x) + (1-x)*y(x)
```

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x)(x-1) - x \frac{\partial}{\partial x} y(x)$$

We compute the series solutions at the regular singular point 0:

```
ode::series(Ly, y(x), x)
```

ode::series

$$\left\{ x \ln(x) + x^2 (\ln(x) - 2) + x^3 \left(\frac{\ln(x)}{4} - \frac{3}{4} \right) + x^4 \left(\frac{\ln(x)}{36} - \frac{11}{108} \right) + x^5 \left(\frac{\ln(x)}{576} - \frac{25}{3456} \right) + x^6 \left(\frac{\ln(x)}{14400} - \frac{137}{432000} \right) + O(x^7), x + x^2 + \frac{x^3}{4} + \frac{x^4}{36} + \frac{x^5}{576} + \frac{x^6}{14400} + O(x^7) \right\}$$

And at the same point we look for solutions satisfying the initial condition $y(0) = 1$ and $y'(0) = 0$:

`ode::series({y(0)=1, Ly}, y(x), x)`

\emptyset

`ode::series({y(0)=0, Ly}, y(x), x)`

$$\left\{ C4 x \ln(x) + C4 x^2 (\ln(x) - 2) + C4 x^3 \left(\frac{\ln(x)}{4} - \frac{3}{4} \right) + C4 x^4 \left(\frac{\ln(x)}{36} - \frac{11}{108} \right) + C4 x^5 \left(\frac{\ln(x)}{576} - \frac{25}{3456} \right) + C4 x^6 \left(\frac{\ln(x)}{14400} - \frac{137}{432000} \right) + O(x^7), C3 x + C3 x^2 + \frac{C3 x^3}{4} + \frac{C3 x^4}{36} + \frac{C3 x^5}{576} + \frac{C3 x^6}{14400} + O(x^7) \right\}$$

Parameters

Ly

An ordinary differential equation.

y(x)

The dependent function of Ly.

x

The independent variable of Ly.

x0

The expansion point: an arithmetical expression. If not specified, the default expansion point 0 is used .

inits

The initial or boundary conditions: a sequence of equations.

order

The number of terms to be computed: a nonnegative integer.
The default order is given by the environment variable ORDER (default value 6).

Return Values

Either a `list`, maybe empty, of objects of type `Series::Puisseux` or an expression of type `"series"`.

ode::solve

Purpose Solving ordinary differential equations

Syntax `ode::solve(o, options)`
`solve(o, options)`

Description `ode::solve` computes solutions for ordinary differential equations.

`ode::solve(o)` returns the set of solutions of the ordinary differential equation `o`. You can also call the generic function `solve(o)`.

The solver detects the type of the differential equation and chooses an algorithm according to the detected equation type. If you know the type of the equation, you can use the option `Type = OdeType` to pass the equation type to the solver. Passing the equation type to the solver increases performance.

The solver recognizes the following values of `OdeType`:

- `Abel` - Abel differential equation
- `Bernoulli` - Bernoulli differential equation
- `Chini` - Chini differential equation
- `Clairaut` - Clairaut differential equation
- `ExactFirstOrder` - exact first order ordinary differential equation
- `ExactSecondOrder` - exact second order ordinary differential equation
- `Homogeneous` - homogeneous first order ordinary differential equation
- `Lagrange` - Lagrange differential equation
- `Riccati` - Riccati differential equation

See the Background section for more details on the classes of ordinary differential equations.

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value `FAIL`.

To solve an ordinary differential equation disregarding possible conditions on the parameters of the equation, use `IgnoreSpecialCases` option. This option eliminates receiving a set of special cases as an answer.

To solve an ordinary differential equation in a simplified manner, use the `IgnoreAnalyticConstraints` option. This option can provide simple solutions for the equations for which the direct use of the solver gives complicated results. If you use the `IgnoreAnalyticConstraints` option, always check the answer. This option can lead to wrong or incomplete results. See “Example 3” on page 20-43.

The solutions of ordinary differential equations can contain arbitrary constants of integration. The solver generates the constants of integration using the format of an uppercase letter `C` followed by an automatically generated number, for example `C13`.

The solver does not always verify the uniqueness and completeness of the returned solution. For example:

- The solver does not validate the Lipschitz-conditions on the ordinary differential equation for the Picard-Lindelöf Theorem.
- For some complex nonlinear systems of differential equations the solver returns constant solutions and does not warn you that other solutions exist.

The solver might ignore assumptions that you set on symbolic parameters and variables or use them only partially. More precisely, `ode::solve` passes assumptions to the functions that it calls internally. While these functions can use the specified assumptions, `ode::solve` itself does not use them in most of its internal algorithms. The same happens if you define an ordinary differential equation using `ode` and solve it using `solve`.

Examples

Example 1

To define an ordinary differential equation, use the `ode` command:

ode::solve

```
o:= ode(y'(x) = y(x)^2, y(x))
```

```
ode(y'(x) - y(x)^2, y(x))
```

To solve the equation, enter:

```
ode::solve(o)
```

```
{0, - 1 / C3 + x}
```

or more efficiently:

```
solve(o)
```

```
{0, - 1 / C7 + x}
```

Internally, the function `ode::solve` calls the function `solve`.

Example 2

You can solve an ordinary differential equation with a symbolic parameter and an initial condition:

```
o:= ode({y'(x) = a*y(x)^2, y(a) = ln(a)}, y(x)):  
solve(o)
```

```
{ {0} if a = 1  
  { 1 / ln(a) - a x + a^2 } if a ≠ 1 }
```

To reduce the number of returned solutions, use the option `IgnoreSpecialCases`. For example, you can drop the solution for the parameter $a = 1$:

```
solve(o, IgnoreSpecialCases)
```

$$\left\{ \frac{1}{\frac{1}{\ln(a)} - ax + a^2} \right\}$$

With the `IgnoreSpecialCases` option, a returned set of solutions can be incomplete.

Example 3

The solver can return piecewise solutions:

```
o:= ode(y'(x) = a/y(x)^2 + b*y(x), y(x)):
solve(o)
```

ode::solve

$$\left\{ \begin{array}{ll} \{\text{C18}\} & \text{if } a = 0 \wedge b = 0 \\ \left\{ \frac{\sigma_1}{b^{1/3}}, \sigma_3, \sigma_4, \frac{\sigma_1 \left(-\frac{1}{2} + \sigma_5\right)}{b^{1/3}} \right\} & \text{if } a \neq 0 \wedge b \neq 0 \\ \left\{ \sigma_2, -\frac{\sigma_1 \left(\frac{1}{2} + \sigma_5\right)}{b^{1/3}} \right\} & \\ \emptyset & \text{if } (a = 0 \vee b = 0) \wedge (a = 0 \vee b \neq 0) \wedge (a \neq 0 \vee b = 0) \\ & \wedge (a \neq 0 \vee b \neq 0) \\ \{\sigma_3, \sigma_4, \sigma_2\} & \text{if } ((a = 0 \wedge b \neq 0) \vee (a \neq 0 \wedge b = 0)) \wedge (a = 0 \vee b = 0) \\ & \wedge (a \neq 0 \vee b \neq 0) \end{array} \right.$$

where

$$\sigma_1 = (-a)^{1/3}$$

$$\sigma_2 = -\left(\frac{1}{2} + \sigma_5\right) \sigma_4$$

$$\sigma_3 = \left(-\frac{1}{2} + \sigma_5\right) \sigma_4$$

$$\sigma_4 = \left(-\frac{a - e^3 b (C19 + x)}{b}\right)^{1/3}$$

$$\sigma_5 = \frac{\sqrt{3} i}{2}$$

This solution is complete and mathematically correct for all possible values of the parameter a and variable x . Also you can try the option

IgnoreAnalyticConstraints to obtain a particular solution that is correct under a set of common assumptions:

`solve(o, IgnoreAnalyticConstraints)`

$$\left\{ \frac{\sigma_2}{b^{1/3}}, \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \sigma_1, \sigma_1, \frac{\sigma_2 \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right)}{b^{1/3}}, -\left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \sigma_1, -\frac{\sigma_2 \left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right)}{b^{1/3}} \right\}$$

where

$$\sigma_1 = \left(-\frac{a - e^{3bx} C_{24}}{b} \right)^{1/3}$$

$$\sigma_2 = (-a)^{1/3}$$

The solver accepts several options:

`solve(o, Type = Bernoulli, IgnoreAnalyticConstraints)`

$$\left\{ \left(-\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \sigma_1, \sigma_1, -\left(\frac{1}{2} + \frac{\sqrt{3}i}{2}\right) \sigma_1 \right\}$$

where

$$\sigma_1 = \left(-\frac{a - C_{26} b e^{3bx}}{b} \right)^{1/3}$$

Example 4

Suppose, you want to solve an ordinary differential equation from the class of Bernoulli equations:

`o := ode(y'(x) = (-1/x + 2*I)*y(x) + 1/x*y(x)^2, y(x)):`

ode::solve

```
solve(o)
```

$$\left\{ 0, \frac{e^{-\ln(x)+2xi}}{C28 + 2 \operatorname{Ei}(1, -2xi) i + \frac{e^{2xi}}{x}} \right\}$$

The solver recognizes the type of the equation and uses the algorithm for solving Bernoulli equations. To improve performance, you can explicitly pass the type of the equation to the solver:

```
solve(o, Type = Bernoulli)
```

$$\left\{ 0, \frac{x e^{-\ln(x)+2xi}}{e^{2xi} + C29 x + 2 x \operatorname{Ei}(1, -2xi) i} \right\}$$

To solve the Clairaut equation with the initial conditions, enter:

```
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)):
solve(o, Type = Clairaut)
```

```
{1}
```

If the solver cannot identify the equation with the type you indicated, it issues a warning and returns the special value FAIL:

```
o:= ode({(x*y'(x)-y(x))^2 - y'(x)^2 - 1 = 0, y(1) = 1}, y(x)):
solve(o, Type = Lagrange)
```

```
Warning: Cannot detect the Lagrange ODE. [ode::lagrange]
```

```
FAIL
```

Example 5

Some ordinary differential equations belong to several classes. For example, some Chini equations are also homogeneous and some Lagrange equations are also Clairaut equations. If an equation belongs to several classes simultaneously, the solver can present its solution in different forms. The form of a solution depends on the class with which an equation is identified. For example, suppose you want to solve the Chini differential equation. You can explicitly pass the type of the equation to the solver:

```
o:= ode(y'(x) = 1/x*y(x)^2 + 1/x*y(x) + x, y(x)):
L:= solve(o, Type = Chini)
```

$$\{x \tan(C31 + x), -x i, x i\}$$

You also can let the solver recognize the type of the equation:

```
solve(o)
```

$$\left\{ -x i, -x i + \frac{2 e^{2xi} e^{\ln(x)-2xi}}{2 C33 e^{2xi} - i} \right\}$$

The solver does not return the type with which an ordinary differential equation is internally identified. If you want to verify that both solution sets are equivalent, use the `rewrite` function with target `exp` on the first set of solutions:

```
rewrite(L, exp)
```

$$\left\{ -x i, x i - \frac{x \left(e^{2 C31 i + 2xi} i - i \right)}{e^{2 C31 i + 2xi} + 1} \right\}$$

Example 6

MuPAD solves some classes of Riccati ordinary differential equations that involve arbitrary functions. For example, the following equation contains the arbitrary function $f(x)$:

$$\text{eq} := \text{diff}(y(x), x) - f(x) \cdot y(x)^2 + a^2 x^{2n} f(x) - a n x^{n-1}$$

$$\frac{\partial}{\partial x} y(x) - f(x) y(x)^2 + a^2 x^{2n} f(x) - a n x^{n-1}$$

For this equation the solver returns:

$$\text{solve}(\text{ode}(\text{eq}, y(x)))$$

$$\left\{ a x^n, a x^n + \frac{e^{\int 2 a x^n f(x) dx}}{C35 - \int e^{\int 2 a x^n f(x) dx} f(x) dx} \right\}$$

You also can solve an equation with more than one arbitrary function. For example, the following equations contain $f(x)$ and $g(x)$:

$$\text{eq} := \text{diff}(y(x), x) - g(x) \cdot f(x) \cdot y(x) - g(x) - \text{diff}(f(x), x) \cdot y(x)^2$$

$$- y(x)^2 \frac{\partial}{\partial x} f(x) + \frac{\partial}{\partial x} y(x) - f(x) g(x) y(x) - g(x)$$

The returned solution is:

$$\text{solve}(\text{ode}(\text{eq}, y(x)))$$

$$\left\{ \frac{e^{\int f(x) g(x) dx - 2 \ln(f(x))}}{C37 - \int e^{\int f(x) g(x) dx - 2 \ln(f(x))} \frac{\partial}{\partial x} f(x) dx} - \frac{1}{f(x)}, -\frac{1}{f(x)} \right\}$$

Example 7

Suppose, you want to solve the following second-order ordinary differential equation:

$$\text{eq} := x^2(x^2+1) \frac{\partial^2 y(x)}{\partial x^2} + x(2x^2+1) \frac{\partial y(x)}{\partial x} - (\nu^2 + \nu)x^2 y(x)$$

$$x(2x^2+1) \frac{\partial}{\partial x} y(x) - y(x)(\nu^2 + \nu)x^2 + x^2(x^2+1) \frac{\partial^2}{\partial x^2} y(x)$$

The solver returns the result in terms of the hypergeometric function ${}_2F_2$ (see hypergeom):

$$\text{solve}(\text{ode}(\text{eq}, y(x)))$$

$$\left\{ \frac{C39 {}_2F_2\left(\frac{\nu}{2} - \frac{n}{2} + \frac{1}{2}, \frac{n}{2} + \frac{\nu}{2} + \frac{1}{2}; \nu + \frac{3}{2}; \sigma_1\right)}{x^{\nu+1}} + C40 x^{\nu} {}_2F_1\left(-\frac{n}{2} - \frac{\nu}{2}, \frac{n}{2} - \frac{\nu}{2}; \frac{1}{2} - \nu; \sigma_1\right) \right\}$$

where

$$\sigma_1 = -\frac{1}{x^2}$$

Example 8

The solver can handle some third- and higher-order ordinary differential equations. For example, solve the following third-order linear differential equations:

$$\text{eq} := \text{ode}(\sin(x) y'''(x) + \cos(x) y(x), y(x)):$$

$$\text{solve}(\text{eq})$$

$$\{C42 \sin(x)\}$$

$$\text{eq} := \text{ode}(6y(x) + x^3 y'''(x), y(x)):$$

ode::solve

`solve(eq)`

$$\left\{ C47 \sigma_1 - \frac{\sigma_1 \left(\frac{C46}{22} + \frac{3\sqrt{2} C46 i}{44} \right)}{x^3 + \sqrt{2} i} + \frac{\sqrt{2} C48 \sigma_2 \sigma_1 i}{4} + \frac{\sqrt{2} \sigma_2 \sigma_1 \left(\frac{3 C46}{11} + \frac{\sqrt{2} C46 i}{11} \right) i}{4x^3 - \sqrt{2} i} \right\}$$

where

$$\sigma_1 = x^{2 + \sqrt{2} i}$$

$$\sigma_2 = \frac{1}{x^2 \sqrt{2} i}$$

Example 9

The solver also can handle some nonlinear first-order ordinary differential equations. For example, solve the following first-order linear differential equations:

```
eq := ode(y(x)*diff(y(x), x) - y(x) - x^3 - 4*x^4 - 4*x^7, y(x)):
solve(eq)
```

$$\left\{ x^4 + x + \frac{1}{4} \right\}$$

```
eq := ode(exp(x/2)/4 - 2*exp(x) - y(x) + x*exp(x/2) + y(x)*y'(x), y):
solve(eq)
```

$$\left\{ x - 2 e^{\frac{x}{2}} + \frac{1}{4} \right\}$$

Parameters

•

An ordinary differential equation, an object of the type `ode`.

Options

Type

Option, specified as `Type = OdeType`

Indicates the type of the ordinary differential equation and accepts the following arguments: `Abel`, `Bernoulli`, `Chini`, `Clairaut`, `ExactFirstOrder`, `ExactSecondOrder`, `Homogeneous`, `Lagrange`, `Riccati`.

MaxDegree

Option, specified as `MaxDegree = n`

Pass the option to the generic solver, which is called internally for all intermediate equations. See the list of options for the `solve` function for further information.

IgnoreSpecialCases

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator `int`, which is called for computing all intermediate integrals. See the list of options for the `solve` function for further information.

IgnoreAnalyticConstraints

Pass the option to the generic solver, which is called internally for all intermediate equations, and to the integrator `int`, which is called for computing all intermediate integrals. See the list of options for the `solve` function for further information.

Return Values

Set of solutions of the ordinary differential equation or the special value `FAIL`. For additional information on the return values, see the `solve` help page.

Concepts

- “Solve Ordinary Differential Equations and Systems”

Purpose Symmetric power of a homogeneous linear ordinary differential equation

Syntax `ode::symmetricPower(Ly, y(x), m)`

Description `ode::symmetricPower(Ly, y(x), m)` computes the m -th symmetric power of Ly . This is the lowest order linear ordinary differential equation whose solution space consists exactly of all possible m -th powerproducts of solutions of Ly .

Examples **Example 1**

We compute the second symmetric power of the following differential equation:

$$Ly := x^2 \operatorname{diff}(y(x), x) - (36x^6 \exp(4x^3) + 9x^6 + 2)y(x)$$

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - y(x) \left(36x^6 e^{4x^3} + 9x^6 + 2 \right)$$

$$\operatorname{ode}::\operatorname{symmetricPower}(Ly, y(x), 2)$$

$$\begin{aligned} & \frac{\partial^3}{\partial x^3} y(x) - \left(144x^4 e^{4x^3} + \frac{8}{x^2} + 36x^4 \right) \frac{\partial}{\partial x} y(x) \\ & - y(x) \left(288x^3 e^{4x^3} + 864x^6 e^{4x^3} - \frac{8}{x^3} + 72x^3 \right) \end{aligned}$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y(x)

The dependent function of Ly .

m

ode::symmetricPower

A positive integer.

Return Values

Linear differential equation

Purpose Unimodular transformation of a linear ordinary differential equation

Syntax `ode::unimodular(Ly, y(x), <Transform>)`

Description `ode::unimodular(Ly, y(x))` tests if the linear homogeneous differential equation `Ly` has a unimodular Galois group (i.e. the wronskian lies in the base field (x)), if not transforms `Ly` into a unimodular one (by changing the second highest coefficient to zero) and returns a table with index equation and `factorOfTransformation` containing respectively the transformed differential equation and the factor of transformation `Wn` such that a solution of the transformed equation multiplied by `Wn` is a solution of `Ly`.

If the option `Transform` is given then `Ly` is transformed unconditionally even if `Ly` has yet a unimodular Galois group.

Examples **Example 1**

We test if the following differential equation has a unimodular Galois group:

`Ly := y(x)*6+x*diff(y(x),x)*(-2)+diff(y(x),x$2)*(-x^2+1)`

$$-(x^2 - 1) \frac{\partial^2}{\partial x^2} y(x) - 2x \frac{\partial}{\partial x} y(x) + 6y(x)$$

`ode::unimodular(Ly, y(x))`

equation	$6y(x) - 2x \frac{\partial}{\partial x} y(x) - (x^2 - 1) \frac{\partial^2}{\partial x^2} y(x)$
factorOfTransformation	1

It is unimodular since the factor of transformation is 1. We can also check this by computing the wronskian of `Ly` which is a rational function:

ode::unimodular

`ode::wronskian(Ly, y(x))`

$$\frac{1}{x^2-1}$$

Now we transform Ly into a differential equation whose wronskian is 1:

`ode::unimodular(Ly, y(x), Transform)`

equation	$\frac{\partial^2}{\partial x^2} y(x) - \frac{y(x)(6x^2-7)}{-2x^2+x^4+1}$
factorOfTransformation	$\sqrt{\frac{1}{x^2-1}}$

`ode::wronskian(%[equation], y(x))`

1

Parameters

Ly

A homogeneous linear differential equation over (x) .

y(x)

The dependent function of Ly.

Return Values

table.

See Also

MuPAD Functions

`ode::wronskian`

Purpose Coefficients of a homogeneous linear ODE

Syntax `ode::vectorize(Ly, y, x, n)`

Description `ode::vectorize(Ly, y, x, n)` returns the list of coefficients of the n -th order homogeneous linear ordinary differential equation `Ly`.

Examples **Example 1**

We compute the list of coefficients of the following differential equation:

```
Ly := 4*x^2*diff(y(x), x$3)+exp(x^2)*diff(y(x),x$2)+
      4*x*diff(y(x),x)-y(x)
```

$$4x \frac{\partial}{\partial x} y(x) - y(x) + e^{x^2} \frac{\partial^2}{\partial x^2} y(x) + 4x^2 \frac{\partial^3}{\partial x^3} y(x)$$

```
ode::vectorize(Ly, y, x, 3)
```

$$\left[-1, 4x, e^{x^2}, 4x^2 \right]$$

Parameters

Ly

A homogeneous linear ordinary differential equation.

y

The dependent variable of `Ly`.

x

The independent variable of `Ly`.

n

The order of `Ly`, a positive integer.

ode::vectorize

Return Values

list

Purpose Wronskian of functions or of a linear homogeneous ordinary differential equation

Syntax `ode::wronskian(l, x, <R>)`
`ode::wronskian(Ly, y(x), <R>)`

Description `ode::wronskian` computes the wronskian (determinant) of functions or of a linear homogeneous ordinary differential equation.

`ode::wronskian(l, x)` returns the wronskian, i.e. the determinant of the wronskian matrix, of the elements of `l` with respect to `x`.

`ode::wronskian(Ly, y(x))` returns the wronskian of `Ly` defined as the element w such that $w' = -a_{n-1} w$, where a_{n-1} is the coefficient of `Ly` of degree $n - 1$ and n the order of `Ly`.

If the optional argument `R` is given, then the specified differential ring will be chosen for representing the entries of the wronskian matrix.

Examples **Example 1**

We compute the wronskian of `[2*x^2+1, x*sqrt(1+x^2), y(x)]` which is a linear differential equation in `y(x)`:

```
Ly:=ode::wronskian([2*x^2+1, x*sqrt(1+x^2), y(x)], x)
```

ode::wronskian

$$4x\sigma_4 \frac{\partial}{\partial x} y(x) - 4x^2\sigma_4 \frac{\partial^2}{\partial x^2} y(x) - 4y(x)\sigma_3 - \sigma_1\sigma_2 \frac{\partial}{\partial x} y(x) + 4xy(x)\sigma_2 + \sigma_1\sigma_3 \frac{\partial^2}{\partial x^2} y(x)$$

where

$$\sigma_1 = 2x^2 + 1$$

$$\sigma_2 = \frac{3x}{\sigma_4} - \frac{x^3}{(x^2+1)^{3/2}}$$

$$\sigma_3 = \sigma_4 + \frac{x^2}{\sigma_4}$$

$$\sigma_4 = \sqrt{x^2 + 1}$$

`Ly := numer(normal(Ly))`

$$x^2 \frac{\partial^2}{\partial x^2} y(x) - 4y(x) + x \frac{\partial}{\partial x} y(x) + \frac{\partial^2}{\partial x^2} y(x)$$

And we can check that a basis of solutions of Ly is as expected:

`ode::solve(Ly, y(x))`

$$\left\{ C2 \left(x + \sqrt{x^2 + 1} \right)^2 + \frac{C3}{\left(x + \sqrt{x^2 + 1} \right)^2} \right\}$$

We can also compute the wronskian of Ly, which is, up to a constant, the wronskian of x^2+1 and $x*\text{sqrt}(x^2+1)$:

```
ode::wronskian(Ly, y(x)),
simplify(ode::wronskian([x^2+1/2,x*sqrt(1+x^2)], x))
```

$$\frac{1}{\sqrt{x^2+1}}, \frac{1}{2\sqrt{x^2+1}}$$

Parameters**I**

A list of functions of the variable x .

Ly

A homogeneous linear ordinary differential equation.

y(x)

The dependent function of Ly .

R

A differential ring, default is `Dom::ExpressionField(id, iszero@normal)`.

Return Values

Expression in x .

ode::wronskian

orthpoly – Orthogonal Polynomials

orthpoly::chebyshev1
orthpoly::chebyshev2
orthpoly::curtz
orthpoly::gegenbauer
orthpoly::hermite
orthpoly::jacobi
orthpoly::laguerre
orthpoly::legendre

orthpoly::chebyshev1

Purpose The Chebyshev polynomials of the first kind

Syntax `orthpoly::chebyshev1(n, x)`

Description `orthpoly::chebyshev1(n, x)` computes the value of the n -th degree Chebyshev polynomial of the first kind at the point x .

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values x from the interval $[-1.0, 1.0]$. Cf. “Example 2” on page 21-3.

`orthpoly::chebyshev2` implements the Chebyshev polynomials of the second kind.

Examples **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::chebyshev1(2, x)
```

```
poly(2 x2 - 1, [x])
```

```
orthpoly::chebyshev1(3, x[1])
```

```
poly(4 x13 - 3 x1, [x1])
```

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::chebyshev1(2, 6*x)
```

```
72 x2 - 1
```

```
orthpoly::chebyshev1(3, x[1] + 2)
```

$$4x_1^3 + 24x_1^2 + 45x_1 + 26$$

“Arithmetical expressions” include numbers:

```
orthpoly::chebyshev1(2, sqrt(2)),
orthpoly::chebyshev1(3, 8 + I),
orthpoly::chebyshev1(1000, 0.3)
```

$$3, 1928 + 761i - 0.9991251116$$

If no integer degree is specified, `orthpoly::chebyshev1` returns itself symbolically:

```
orthpoly::chebyshev1(n, x), orthpoly::chebyshev1(1/2, x)
```

$$\text{orthpoly::chebyshev1}(n, x), \text{orthpoly::chebyshev1}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::chebyshev1(200, 0.3)
```

$$-0.3169632681$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
T200 := orthpoly::chebyshev1(200, x):
```

```
DIGITS := 10: evalp(T200, x = 0.3)
```

$$-3912167.235$$

orthpoly::chebyshev1

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 20: evalp(T200, x = 0.3)
```

```
-0.31710101442512309682
```

```
delete DIGITS, T200:
```

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type "_index").

Return Values

If x is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If x is an arithmetical expression, then the value of the Chebyshev polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then orthpoly::chebyshev1 returns itself symbolically.

Algorithms

The Chebyshev polynomials are given by $T(n, x) = \cos(n \arccos(x))$ for real x $[-1, 1]$. This representation is used by orthpoly::chebyshev1 for floating-point values in this range.

These polynomials satisfy the recursion formula

$$T(n, x) = 2x T(n-1, x) - T(n-2, x)$$

with $T(0, x) = 1$ and $T(1, x) = x$.

They are orthogonal on the interval $[-1, 1]$ with respect to the weight

function $w(x) = \frac{1}{\sqrt{1-x^2}}$.

$T(n, x)$ is a special (Jacobi) polynomial:

$$T(n, x) = \frac{2^{2n} n!^2}{(2n)!} P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right)$$

MuPAD Functions

`orthpoly::chebyshev2` | `orthpoly::jacobi`

orthpoly::chebyshev2

Purpose The Chebyshev polynomials of the second kind

Syntax `orthpoly::chebyshev2(n, x)`

Description `orthpoly::chebyshev2(n, x)` computes the value of the n -th degree Chebyshev polynomial of the second kind at the point x .

These polynomials have integer coefficients.

Evaluation is fast and numerically stable for real floating point values x from the interval $[-1.0, 1.0]$. Cf. “Example 2” on page 21-7.

`orthpoly::chebyshev1` implements the Chebyshev polynomials of the first kind.

Examples

Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::chebyshev2(2, x)
```

```
poly(4 x2 - 1, [x])
```

```
orthpoly::chebyshev2(3, x[1])
```

```
poly(8 x13 - 4 x1, [x1])
```

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::chebyshev2(2, 6*x)
```

```
144 x2 - 1
```

```
orthpoly::chebyshev2(3, x[1] + 2)
```

$$8x_1^3 + 48x_1^2 + 92x_1 + 56$$

“Arithmetical expressions” include numbers:

```
orthpoly::chebyshev2(2, sqrt(2)),
orthpoly::chebyshev2(3, 8 + I),
orthpoly::chebyshev2(1000, 0.3)
```

$$7, 3872 + 1524i, -1.012277265$$

If no integer degree is specified, then `orthpoly::chebyshev2` returns itself symbolically:

```
orthpoly::chebyshev2(n, x), orthpoly::chebyshev2(1/2, x)
```

$$\text{orthpoly::chebyshev2}(n, x), \text{orthpoly::chebyshev2}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::chebyshev2(200, 0.3)
```

$$-0.01869337443$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
U200 := orthpoly::chebyshev2(200, x):
```

```
DIGITS := 10: evalp(U200, x = 0.3)
```

$$-3872355.739$$

orthpoly::chebyshev2

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 20: evalp(U200, x = 0.3)
```

```
-0.018233184138451814741
```

```
delete DIGITS, U200:
```

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type "_index").

Return Values

If x is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If x is an arithmetical expression, then the value of the Chebyshev polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then orthpoly::chebyshev2 returns itself symbolically.

Algorithms

The Chebyshev polynomials of the second kind are given by

$$U(n, x) = \frac{\sin((n+1) \arccos(x))}{\sin(\arccos(x))}$$

for real x $[-1, 1]$. This representation is used by orthpoly::chebyshev2 for floating-point values in this range.

These polynomials satisfy the recursion formula

$$U(n, x) = 2xU(n-1, x) - U(n-2, x)$$

with $U(0, x) = 1$ and $U(1, x) = 2x$.

They are orthogonal on the interval $[-1, 1]$ with respect to the weight

function $w(x) = \sqrt{1-x^2}$.

$U(n, x)$ coincides with the Gegenbauer polynomial $G(n, 1, x)$.

$U(n, x)$ is a special Jacobi polynomial:

$$U(n, x) = \frac{2^{2n} n! (n+1)!}{(2n+1)!} P\left(n, \frac{1}{2}, \frac{1}{2}, x\right)$$

MuPAD Functions

orthpoly::chebyshev1 | orthpoly::gegenbauer | orthpoly::jacobi

orthpoly::curtz

Purpose The Curtz polynomials

Syntax `orthpoly::curtz(n, x)`

Description `orthpoly::curtz(n,x)` computes the value of the n -th degree Curtz polynomial at the point x .

These polynomials have rational coefficients.

Evaluation for real floating-point values x is numerically stable. Cf. “Example 2” on page 21-11.

Examples

Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::curtz(2, x)
```

$$\text{poly}\left(x^2 - x + \frac{1}{3}, [x]\right)$$

```
orthpoly::curtz(3, x[1])
```

$$\text{poly}\left(x_1^3 - \frac{3x_1^2}{2} + \frac{11x_1}{12} - \frac{1}{4}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::curtz(2, 6*x)
```

$$36x^2 - 6x + \frac{1}{3}$$

```
orthpoly::curtz(3, x[1] + 2)
```

$$x_1^3 + \frac{9x_1^2}{2} + \frac{83x_1}{12} + \frac{43}{12}$$

“Arithmetical expressions” include numbers:

```
orthpoly::curtz(2, sqrt(2)), orthpoly::curtz(3, 8 + I),
orthpoly::curtz(100, 0.3)
```

$$\frac{7}{3} - \sqrt{2}, \frac{4807}{12} + \frac{2015i}{12}, 0.001395122936$$

If no integer degree is specified, then `orthpoly::curtz` returns itself symbolically:

```
orthpoly::curtz(n, x), orthpoly::curtz(1/2, x)
```

$$\text{orthpoly::curtz}(n, x), \text{orthpoly::curtz}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::curtz(50, 1.2)
```

```
0.0003843630923
```

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
orthpoly::curtz(50, x): evalp(%, x = 1.2)
```

```
0.0003849036173
```

orthpoly::curtz

Note that only 3 digits are correct due to numerical round-off.

Parameters **n**

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type "_index").

Return Values

If x is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If x is an arithmetical expression, then the value of the Curtz polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then `orthpoly::curtz` returns itself symbolically.

Algorithms

The Curtz polynomials are given by the recursion formula

$$C(n, x) = x^n + x \left(\sum_{i=1}^{n-1} \frac{(-1)^i}{i+1} C(n-i-1, x) \right) + \frac{(-1)^n}{n+1}$$

with $C(0, x) = 1$.

Purpose The Gegenbauer (ultraspherical) polynomials

Syntax `orthpoly::gegenbauer(n, a, x)`

Description `orthpoly::gegenbauer(n, a, x)` computes the value of the n -th degree Gegenbauer polynomial with parameter a at the point x .

Evaluation for real floating-point values x from the interval $[-1.0, 1.0]$ is numerically stable. See “Example 2” on page 21-14.

Examples **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::gegenbauer(2, a, x)
```

```
poly((2 a + 2 a^2) x^2 - a, [x])
```

```
orthpoly::gegenbauer(3, 2, x[1])
```

```
poly(32 x_1^3 - 12 x_1, [x_1])
```

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::gegenbauer(2, a, 6*x)
```

```
72 a^2 x^2 + 72 a x^2 - a
```

```
orthpoly::gegenbauer(3, 2, x[1] + 2)
```

```
32 x_1^3 + 192 x_1^2 + 372 x_1 + 232
```

orthpoly::gegenbauer

“Arithmetical expressions” include numbers:

```
orthpoly::gegenbauer(2, a, sqrt(2)),  
orthpoly::gegenbauer(3, 0.4, 8 + I),  
orthpoly::gegenbauer(1000, -1/3, 0.3)
```

```
4 a2 + 3 a, 865.536 + 341.152 i, 0.00006046127974
```

If no integer degree is specified, then `orthpoly::gegenbauer` returns itself symbolically:

```
orthpoly::gegenbauer(n, a, x), orthpoly::gegenbauer(1/2, 2, x)
```

```
orthpoly::gegenbauer(n, a, x), orthpoly::gegenbauer( $\frac{1}{2}$ , 2, x)
```

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::gegenbauer(200, 4, 0.3)
```

```
165549.7263
```

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
G200 := orthpoly::gegenbauer(200, 4, x):
```

```
DIGITS := 10: evalp(G200, x = 0.3)
```

```
-6.270612376 1011
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 20: evalp(G200, x = 0.3)
```

```
165454.59819021060509
```

```
delete DIGITS, G200:
```

Parameters

n

A nonnegative integer: the degree of the polynomial.

a

An arithmetical expression.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type "_index").

Return Values

If x is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If x is an arithmetical expression, then the value of the Gegenbauer polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then orthpoly::gegenbauer returns itself symbolically.

Algorithms

The Gegenbauer polynomials are given by the recursion formula

$$G(n, a, x) = \frac{2(n-1+a)}{n} x G(n-1, a, x) - \frac{n-2+2a}{n} G(n-2, a, x)$$

with $G(0, a, x) = 1$, $G(1, a, x) = 2ax$.

For fixed real $a > -\frac{1}{2}$ these polynomials are orthogonal on the interval $[-1, 1]$ with respect to the weight function $w(x) = (1-x^2)^{a-\frac{1}{2}}$.

$G\left(n, \frac{1}{2}, x\right)$ coincides with the Legendre polynomial $P(n, x)$.

$G(n, 1, x)$ coincides with the Chebyshev polynomial $U(n, x)$ of the second kind.

The polynomials $G(n, 0, x)$ are trivial.

orthpoly::hermite(n, x), orthpoly::hermite(1/2, x)
```

```
orthpoly::hermite(n, x), orthpoly::hermite( $\frac{1}{2}$ , x)
```

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type `DOM_POLY` is returned. If `x` is an arithmetical expression, then the value of the Hermite polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::hermite` returns itself symbolically.

Algorithms

The Hermite polynomials are given by the recursion formula

$$H(n, x) = 2x H(n-1, x) - 2(n-1) H(n-2, x)$$

with $H(0, x) = 1$ and $H(1, x) = 2x$.

These polynomials are orthogonal on the real line with respect to the

weight function $w(x) = \frac{1}{e^{x^2}}$.

orthpoly::jacobi

Purpose The Jacobi polynomials

Syntax `orthpoly::jacobi(n, a, b, x)`

Description `orthpoly::jacobi(n, a, b, x)` computes the value of the n -th degree Jacobi polynomial with parameters a and b at the point x .

Evaluation for real floating-point values x from the interval $[-1.0, 1.0]$ is numerically stable. Cf. “Example 2” on page 21-21.

Examples **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

`orthpoly::jacobi(2, a, b, x)`

$$\text{poly}\left(\left(\frac{7a}{8} + \frac{7b}{8} + \frac{ab}{4} + \frac{a^2}{8} + \frac{b^2}{8} + \frac{3}{2}\right)x^2 + \left(\frac{3a}{4} - \frac{3b}{4} + \frac{a^2}{4} - \frac{b^2}{4}\right)x - \frac{a}{8} - \frac{b}{8} - \frac{ab}{4} + \frac{a^2}{8} + \frac{b^2}{8} - \frac{1}{2}, [x]\right)$$

`orthpoly::jacobi(3, 4, 5, x[1])`

$$\text{poly}\left(\frac{455x_1^3}{8} - \frac{91x_1^2}{8} - \frac{91x_1}{8} + \frac{7}{8}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

`orthpoly::jacobi(2, 4, b, 6*x)`

$$\frac{9b^2x^2}{2} - \frac{3b^2x}{2} + \frac{b^2}{8} + \frac{135bx^2}{2} - \frac{9bx}{2} - \frac{9b}{8} + 252x^2 + 42x + 1$$

```
orthpoly::jacobi(2, 0, I, x[1] + 2)
```

$$x_1^2 \left(\frac{11}{8} + \frac{7i}{8} \right) + x_1 \left(\frac{23}{4} + \frac{11i}{4} \right) + \frac{43}{8} + \frac{15i}{8}$$

“Arithmetical expressions” include numbers:

```
orthpoly::jacobi(2, 1/2, -1/2, sqrt(2)),
orthpoly::jacobi(3, 2, 5, 8 + I),
orthpoly::jacobi(1000, 1, 2, 0.3);
```

$$\frac{3\sqrt{2}}{4} + \frac{21}{8}, \frac{31733}{2} + \frac{12859i}{2}, -0.06546648097$$

If no integer degree is specified, then `orthpoly::jacobi` returns itself symbolically:

```
orthpoly::jacobi(n, a, b, x), orthpoly::jacobi(1/2, 0, 1, 1)
```

$$\text{orthpoly::jacobi}(n, a, b, x), \text{orthpoly::jacobi}\left(\frac{1}{2}, 0, 1, 1\right)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::jacobi(100, 1/2, 3/2, 0.9)
```

```
0.2560339406
```

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
P100 := orthpoly::jacobi(100, 1/2, 3/2, x):
```

orthpoly::jacobi

```
evalp(P100, x = 0.9)
```

```
- 8.6781052 1015
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 30: evalp(P100, x = 0.9)
```

```
0.256030968488207303016930946513
```

```
delete P100, DIGITS:
```

Parameters

n

A nonnegative integer: the degree of the polynomial.

a, b

Arithmetical expressions.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type DOM_IDENT) or an indexed identifier (of type "_index").

Return Values

If x is an indeterminate, then a polynomial of domain type DOM_POLY is returned. If x is an arithmetical expression, then the value of the Jacobi polynomial at this point is returned as an arithmetical expression. If n is not a nonnegative integer, then `orthpoly::jacobi` returns itself symbolically.

Algorithms

The Jacobi polynomials are given by the recursion formula

$$2 n c_n c_{2 n-2} P(n, a, b, x) = c_{2 n-1} \left(c_{2 n-2} c_{2 n} x + a^2 - b^2 \right) P(n-1, a, b, x) - 2 (n-1+a) (n-1+b) c_{2 n} P(n-2, a, b, x)$$

with $c_i = i + a + b$ and

$$P(0, a, b, x) = 1, P(1, a, b, x) = \frac{a-b}{2} + \left(1 + \frac{a+b}{2} \right) x$$

For fixed real $a > -1$, $b > -1$ the Jacobi polynomials are orthogonal on the interval $[-1, 1]$ with respect to the weight function $w(x) = (1-x)^a(1+x)^b$.

For special values of the parameters a, b the Jacobi polynomials are related to the Legendre polynomials

$$P(n, x) = P(n, 0, 0, x),$$

to the Chebyshev polynomials of the first kind

$$T(n, x) = \frac{2^{2 n} n!^2}{(2 n)!} P\left(n, -\frac{1}{2}, -\frac{1}{2}, x\right),$$

to the Chebyshev polynomials of the second kind

$$U(n, x) = \frac{2^{2 n} n! (n+1)!}{(2 n+1)!} P\left(n, \frac{1}{2}, \frac{1}{2}, x\right),$$

and to the Gegenbauer polynomials, respectively:

orthpoly::jacobi

$$G(n, a, x) = \frac{\Gamma\left(a + \frac{1}{2}\right) \Gamma(n + 2a)}{\Gamma(2a) \Gamma\left(n + a + \frac{1}{2}\right)} P\left(n, a - \frac{1}{2}, a - \frac{1}{2}, x\right)$$

MuPAD Functions

orthpoly::chebyshev1 | orthpoly::chebyshev2 |
orthpoly::gegenbauer | orthpoly::legendre

Purpose The (generalized) Laguerre polynomials

Syntax `orthpoly::laguerre(n, a, x)`

Description `orthpoly::laguerre(n, a, x)` computes the value of the generalized n -th degree Laguerre polynomial with parameter a at the point x .

The standard Laguerre polynomials correspond to $a = 0$. They have rational coefficients.

Examples **Example 1**

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::laguerre(2, a, x)
```

$$\text{poly}\left(\frac{x^2}{2} + (-a-2)x + \frac{3a}{2} + \frac{a^2}{2} + 1, [x]\right)$$

```
orthpoly::laguerre(3, a, x[1])
```

$$\text{poly}\left(-\frac{x_1^3}{6} + \left(\frac{a}{2} + \frac{3}{2}\right)x_1^2 + \left(-\frac{5a}{2} - \frac{a^2}{2} - 3\right)x_1 + \frac{11a}{6} + a^2 + \frac{a^3}{6} + 1, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::laguerre(2, 4, 6*x)
```

$$18x^2 - 36x + 15$$

```
orthpoly::laguerre(2, 2/3*I, x[1] + 2)
```

orthpoly::laguerre

$$\frac{x_1^2}{2} - \frac{2x_1 i}{3} - \frac{11}{9} - \frac{i}{3}$$

“Arithmetical expressions” include numbers:

```
orthpoly::laguerre(2, a, sqrt(2)),  
orthpoly::laguerre(3, 0.4, 8 + I),  
orthpoly::laguerre(1000, 3, 0.3);
```

$$\frac{3a}{2} - \sqrt{2}a - 2\sqrt{2} + \frac{a^2}{2} + 2, -4.969333333 - 8.713333333i - 15691.69498$$

If no integer degree is specified, then `orthpoly::laguerre` returns itself symbolically:

```
orthpoly::laguerre(n, a, x), orthpoly::laguerre(1/2, a, x)
```

$$\text{orthpoly::laguerre}(n, a, x), \text{orthpoly::laguerre}\left(\frac{1}{2}, a, x\right)$$

Parameters

n

A nonnegative integer: the degree of the polynomial.

a

An arithmetical expression.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type `DOM_POLY` is returned. If `x` is an arithmetical expression, then the value of the Laguerre polynomial at this point is returned as an arithmetical

expression. If n is not a nonnegative integer, then `orthpoly::laguerre` returns itself symbolically.

Algorithms

The Laguerre polynomials are given by the recursion formula

$$L(n, a, x) = \frac{2n + a - 1 - x}{n} L(n-1, a, x) - \frac{n + a - 1}{n} L(n-2, a, x)$$

with $L(0, a, x) = 1$ and $L(1, a, x) = 1 + a - x$.

For fixed real $a > -1$ these polynomials are orthogonal on the interval

$[0, \infty)$ with respect to the weight function $w(x) = \frac{1}{(x^a e^{-x})}$.

orthpoly::legendre

Purpose The Legendre polynomials

Syntax `orthpoly::legendre(n, x)`

Description `orthpoly::legendre(n, x)` computes the value of the n -th degree Legendre polynomial at the point x .

These polynomials have rational coefficients.

Evaluation for real floating-point values x from the interval $[-1.0, 1.0]$ is numerically stable. Cf. “Example 2” on page 21-29.

Use `numeric::gldata` to compute the roots of the Legendre polynomials. Cf. “Example 3” on page 21-30.

Examples

Example 1

Polynomials of domain type `DOM_POLY` are returned, if identifiers or indexed identifiers are specified:

```
orthpoly::legendre(2, x)
```

$$\text{poly}\left(\frac{3x^2}{2} - \frac{1}{2}, [x]\right)$$

```
orthpoly::legendre(3, x[1])
```

$$\text{poly}\left(\frac{5x_1^3}{2} - \frac{3x_1}{2}, [x_1]\right)$$

However, using arithmetical expressions as input the “values” of these polynomials are returned:

```
orthpoly::legendre(2, 6*x)
```

$$54x^2 - \frac{1}{2}$$

```
orthpoly::legendre(3, x[1] + 2)
```

$$\frac{5x_1^3}{2} + 15x_1^2 + \frac{57x_1}{2} + 17$$

“Arithmetical expressions” include numbers:

```
orthpoly::legendre(2, sqrt(2)), orthpoly::legendre(3, 8 + I),  
orthpoly::legendre(1000, 0.3)
```

$$\frac{5}{2} 1208 + 476 i - 0.02566916751$$

If no integer degree is specified, then `orthpoly::legendre` returns itself symbolically:

```
orthpoly::legendre(n, x), orthpoly::legendre(1/2, x)
```

$$\text{orthpoly::legendre}(n, x), \text{orthpoly::legendre}\left(\frac{1}{2}, x\right)$$

Example 2

If a floating-point value is desired, then a direct call such as

```
orthpoly::legendre(100, 0.9)
```

$$0.1022658206$$

is appropriate and yields a correct result. One should not evaluate the symbolic polynomial at a floating-point value, because this may be numerically unstable:

```
P100 := orthpoly::legendre(100, x):
```

```
evalp(P100, x = 0.9)
```

```
8.284745953 10-14
```

This result is caused by numerical round-off. Also with increased DIGITS only a few leading digits are correct:

```
DIGITS := 30: evalp(P100, x = 0.9)
```

```
0.102276303910546875548266967112
```

```
delete P100, DIGITS:
```

Example 3

We recommend to use `numeric::gldata` for computing roots of the Legendre polynomial $P(n, x)$. This routine provides all roots of the function $Q(n, y) = P(n, 2y - 1)$:

```
QRoots := numeric::gldata(5, DIGITS)[2]
```

```
[0.04691007703, 0.2307653449,  $\frac{1}{2}$ , 0.7692346551, 0.953089923]
```

These values are easily transformed to roots of $P(n, x)$:

```
PRoots := map(QRoots, y -> 2*y - 1)
```

```
[-0.9061798459, -0.5384693101, 0, 0.5384693101, 0.9061798459]
```

```
orthpoly::legendre(5, r) $ r in PRoots
```

```
-1.080385781 10-14, -1.387778781 10-18, 0, 1.387778781 10-18, 1.081218448 10-14
```

```
delete QRoots, PRoots:
```

Parameters

n

A nonnegative integer: the degree of the polynomial.

x

An indeterminate or an arithmetical expression. An indeterminate is either an identifier (of domain type `DOM_IDENT`) or an indexed identifier (of type `"_index"`).

Return Values

If `x` is an indeterminate, then a polynomial of domain type `DOM_POLY` is returned. If `x` is an arithmetical expression, then the value of the Legendre polynomial at this point is returned as an arithmetical expression. If `n` is not a nonnegative integer, then `orthpoly::legendre` returns itself symbolically.

Algorithms

The Legendre polynomials are given by $P(n, x) = \frac{1}{2^n n!} \frac{d^n}{dx^n} (x^2 - 1)^n$. They satisfy the recursion formula

$$P(n, x) = \frac{2n-1}{n} x P(n-1, x) - \frac{n-1}{n} P(n-2, x)$$

with $P(0, x) = 1$ and $P(1, x) = x$.

They are orthogonal on the interval $[-1, 1]$ with respect to the weight function $w(x) = 1$.

$P(n, x)$ coincides with the Gegenbauer polynomial $G\left(n, \frac{1}{2}, x\right)$.

$P(n, x)$ coincides with the Jacobi polynomial $P(n, 0, 0, x)$.

output – Formatted Output

output::asciiAbbreviate
output::fence
output::mathText
output::ordinal
output::roman
output::subexpr
output::tableForm
output::tree

output::asciiAbbreviate

Purpose Generates a procedure for creating an ASCII formatted output

Syntax `output::asciiAbbreviate(<varname>)`

Description `output::asciiAbbreviate` generates a procedure for creating ASCII formatted outputs of expressions

By default, MuPAD generates ASCII abbreviations using the # symbol followed by numbers. Using the argument `varname` you can customize the names of abbreviated subexpressions. See “Example 2” on page 22-3.

If you want to use abbreviations in all ASCII PrettyPrint output expressions, pass the procedure generated by `output::asciiAbbreviate` to `Pref::output`. See “Example 3” on page 22-3.

Examples Example 1

The generated procedure `ascii` produces ASCII code for MuPAD expressions:

```
ascii:=output::asciiAbbreviate():
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
ascii(y)
```

```
{
{
{
{ #1 - -----, -----, -----, -----, -----
{      3 #1   6 #1   2          2          6 #1   2          sqrt(
{                                     / 1 \
sqrt(3) | ----- + #1 | I
\ 3 #1   /
```

where

```
#1 = | / sqrt(31) sqrt(108) 1 \1/3
\      108          2 /
```

Example 2

You can customize the names of abbreviated subexpressions:

```
ascii:=output::asciiAbbreviate(t):
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
ascii(y)
```

$$\left\{ \left\{ \left\{ t_1 - \frac{1}{3 t_1}, \frac{1}{6 t_1} - \frac{t_1}{2} + \frac{\sqrt{3} \sqrt{\frac{1}{3 t_1} + t_1}}{2}, \frac{1}{6 t_1} - \frac{t_1}{2} + \dots \right. \right. \right.$$

where

$$t_1 = \sqrt{\frac{\sqrt{31} \sqrt{108}}{108} - \frac{1}{2}}^{1/3}$$

Example 3

The generated procedure can serve as an input for Pref::output:

```
Pref::output(output::asciiAbbreviate(u)):
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3)
```

$$\left\{ \left\{ \left\{ u_1 - \frac{1}{3 u_1}, \frac{1}{6 u_1} - \frac{u_1}{2} + \frac{\sqrt{3} \sqrt{\frac{1}{3 u_1} + u_1}}{2}, \frac{1}{6 u_1} - \frac{u_1}{2} + \dots \right. \right. \right.$$

output::asciiAbbreviate

where

$$u1 = \left| \frac{\sqrt{31} \sqrt{108}}{108} - \frac{1}{2} \sqrt{\frac{1}{3}} \right|$$

Parameters

varname

A base name for the abbreviation variables

Return Values

Procedure for creating an ASCII formatted output

See Also

MuPAD Functions

output::subexpr | Pref::abbreviateOutput | Pref::output

Purpose

Put delimiters around multiline strings

Syntax

```
output::fence(left, right, string, <width, <base>>)
```

Description

`output::fence(left, right, string)` encloses the multiline string in the delimiters indicated by `left` and `right`

You can use `output::fence` in combination with `strprint` to overload `print` (and thereby, standard screen output) for pretty-printing. Note that it does not affect typeset output.

Examples

Example 1

Set `TEXTWIDTH` to 75:

```
TEXTWIDTH := 75:
```

First, define a domain that uses `output::fence` for output:

```
domain Fence
  print := x -> output::fence("(", ")", extop(x, 1));
  new   := x -> new(dom, x);
end_domain:
```

`Fence` expects a string in its constructor. The output uses `output::fence` to put parentheses around the input:

```
print(Plain, Fence("abc"))
```

```
(abc)
```

Strings of height two are only partly placed inside parentheses, for consistency with the pretty-printer:

```
print(Plain, Fence("abc\ndef"), sin(x^2))
```

output::fence

```
abc      2  
(def), sin(x )
```

Strings of height more than two are fully bracketed:

```
print(Plain, Fence("abc\ndef\nghi"))
```

```
/ abc \  
| def |  
\ ghi /
```

Example 2

Set TEXTWIDTH to 75:

```
TEXTWIDTH := 75:
```

The next step in using `output::fence` is to enclose expressions in parentheses. For this, the information from `strprint` is useful:

```
domain FenceExpr  
  print := proc(x)  
    local str, h1, w1, h, w, b;  
    begin  
      [str, h1, w1, h, w, b] := strprint(All, extop(x));  
      output::fence("{", "]", str, w, b);  
    end_proc;  
  new := x -> new(dom, x);  
end_domain:
```

The sixth operand of the return value of `strprint(All,)` must be given to `output::fence` to align baselines properly:

```
print(Plain, FenceExpr(x), FenceExpr(x^2), FenceExpr(x^2/2*y))
```

```
{ x^2, { x^2 y^2 } }
{ x^2, { x^2 y^2 } }
```

strprint reacts to TEXTWIDTH and can return a string consisting of more than one logical line. In this case, fencing the returned string leads to strange results:

```
print(Plain, FenceExpr(_plus(x.i $ i = 0..30)))
```

```
{ x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11 +
  --
  {
    |
  {   + x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23
25  |
  {
    |
  {   + x26 + x27 + x28 + x29 + x30
  --
```

Here, the string with added delimiter symbols is too wide for TEXTWIDTH. Also, output::fence does not let you control line breaks. Therefore, it is a good practice to avoid putting large delimiters to the left and right of long strings. For example, abs prints in functional notation for long arguments:

```
print(Plain, abs(_plus(x.i $ i = 0..30)))
```

```
abs(x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9 + x10 + x11
```

output::fence

```
+ x13 + x14 + x15 + x16 + x17 + x18 + x19 + x20 + x21 + x22 + x23 + x24  
+ x25 + x26 + x27 + x28 + x29 + x30)
```

Parameters

left, right

Strings indicating the type of delimiter: "(,)", "[,]", "[+", "+]", "{, }", "|, | ", or " |".

string

The string to enclose

width

The width of the string to enclose. Defaults to the width of the widest line in `string`.

base

The baseline of the string, counted from the first line. Defaults to the bottom line of the string. If set to `-1`, the baseline is vertically centered.

Return Values

String

See Also

MuPAD Functions

`strprint`

Purpose Pretty output of text combined with formulas

Syntax `output::mathText(str1, expr1, <str2, <expr2>, >)`

Description `output::mathText(str1, expr1, str2,)` creates an object of combined strings and expressions. This object prints itself nicely in various output formats.

Examples **Example 1**

`output::mathText` creates an object representing combined text and formulas:

```
messageWithMath := output::mathText("The integral ",
                                     hold(int(sin(x)*cos(x), x)),
                                     " is equal to ", int(sin(x)*cos(x),
```

The integral $\int \cos(x) \sin(x) dx$ is equal to $\frac{\sin(x)^2}{2}$

They can be printed with the ASCII pretty-printer as well:

```
print(Plain, messageWithMath)
```

The integral $\int \sin(x) \cos(x) dx$ is equal to $\frac{\sin(x)^2}{2}$

Same for the ASCII lineprint output:

```
PRETTYPRINT := FALSE:
print(Plain, messageWithMath):
delete PRETTYPRINT:
```

output::mathText

The integral `int(sin(x)*cos(x), x)` is equal to `(1/2)*sin(x)^2`

Parameters

str₁, **str₂**

Strings

expr₁, **expr₂**

Expressions

Return Values

Object of type `output::mathText`

See Also

MuPAD Functions

`strprint`

Purpose Ordinal numbers

Syntax `output::ordinal(i)`

Description `output::ordinal` converts an integer to the corresponding english ordinal number. The return value is a string and can be used in messages.

Examples **Example 1**

Convert some numbers to the corresponding english ordinal string:

```
map([0, 1, 2, 3, 4, 22, 134, 2001], output::ordinal)
["0th", "1st", "2nd", "3rd", "4th", "22nd", "134th", "2001st"]
```

Parameters **i**
An integer number

Return Values String with the English ordinal number

See Also

MuPAD Functions `info` | `print`

output::roman

Purpose Roman numerals

Syntax `output::roman(n)`

Description `output::roman` converts an integer to the corresponding roman numeral. The return value is a string and can be used in messages.

Examples **Example 1**

Convert some numbers to the corresponding roman numerals:

```
map([1, 2, 3, 4, 22, 134, 2001], output::roman)
```

```
["I", "II", "III", "IV", "XXII", "CXXXIV", "MMI"]
```

Now, thanks to alias backsubstitution, we can trick MuPAD into computing with roman numerals:

```
alias(`I`=1): // I is a reserved word in MuPAD, so we use `I` instead
for i from 2 to 1000 do
    eval(text2expr("alias(".output::roman(i)."]=" .expr2text(i).)");")
end_for:
II+II;
XIII*XXIV
```

```
IV
```

```
CCCXII
```

```
unalias(`I`):
for i from 2 to 1000 do
    eval(text2expr("unalias(".output::roman(i).)");");
end_for:
```

Parameters **n**
Positive integer

Return Values String containing the roman numeral

See Also

MuPAD Functions `info | print`

output::subexpr

Purpose Abbreviates a expression

Syntax `output::subexpr(e, <varname>)`

Description `output::subexpr` rewrites symbolic expression in terms of common subexpressions.

If an expression `e` contains common subexpressions, `output::subexpr(e)` returns a list that contains the abbreviated expression and the abbreviations in a form of equations. With `output::subexpr` you get the same abbreviations as you see in the outputs. See “Example 1” on page 22-14.

An output of this command does not depend on the current setting of `Pref::abbreviateOutput`.

By default, MuPAD generates abbreviations using the # symbol followed by numbers. Using the argument `varname`, you can customize the names of abbreviated subexpressions. See “Example 2” on page 22-15.

Examples

Example 1

You can abbreviate an expression:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):  
output::subexpr(y)
```

$$\left[\left\{ \#_1 - \frac{1}{3 \#_1}, \frac{1}{6 \#_1} - \frac{\#_1}{2} + \frac{\sqrt{3} \left(\frac{1}{3 \#_1} + \#_1 \right) i}{2}, \frac{1}{6 \#_1} - \frac{\#_1}{2} - \frac{\sqrt{3} \left(\frac{1}{3 \#_1} + \#_1 \right) i}{2} \right\}, \right. \\ \left. \#_1 = \left(\frac{\sqrt{31} \sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} \right]$$

Example 2

You can customize the names of abbreviated subexpressions:

```
y := solve(x^3 + x + 1 = 0, x, MaxDegree = 3):
output::subexpr(y, t)
```

$$\left[\left\{ t1 - \frac{1}{3 t1}, \frac{1}{6 t1} - \frac{t1}{2} - \frac{\sqrt{3} \left(\frac{1}{3 t1} + t1 \right) i}{2}, \frac{1}{6 t1} - \frac{t1}{2} + \frac{\sqrt{3} \left(\frac{1}{3 t1} + t1 \right) i}{2} \right\}, \right. \\ \left. t1 = \left(\frac{\sqrt{31} \sqrt{108}}{108} - \frac{1}{2} \right)^{1/3} \right]$$

Parameters**e**

A MuPAD expression

varname

A base name for the abbreviation variables

Return Values

List that contains the abbreviated expression and the abbreviations as equations

See Also**MuPAD Functions**

`Pref::abbreviateOutput` | `output::asciiAbbreviate`

output::tableForm

Purpose Printing objects in table form

Syntax `output::tableForm(obj, <separator>, options)`

Description `output::tableForm(obj)` prints the elements of the given object `obj` in table form.

The width of the table and the number of columns depends on the size of `TEXTWIDTH` (see options `Width` and `Columns`). The width of a column depends on the widest entry in this column.

`output::tableForm` determines the number of columns, that the total width of the table fits into `TEXTWIDTH`.

The columns are separated by one space by default.

If `separator` is given, then it is printed between each column (instead of one space). Appending spaces to the separator results additionally space between columns. By default the separator is one space.

If the first argument `obj` is a table or a domain, `output::tableForm` uses the option `Columns = 2` (two columns) and the separator `"= "` as default.

Without the option `Sort` the objects are converted to strings and then sorted alphabetically. To avoid any sorting the option `Sort = FALSE` must be given.

Examples

Example 1

For all examples on this page we assume the `TEXTWIDTH 75`:

```
TEXTWIDTH := 75:
```

Print some random numbers in table form:

```
SEED := -1:  
output::tableForm([random(100000)() $ k = 1..30])
```

```
11647 12826 26280 26292 28315 30908 36523 42073 4682 47334 52640 5
```

```
5829 615    62580 65904 66223 6719  69451 69903 77904 78221 80528
86068 89016 90516 91008 92791 9532
```

Some random strings are created. The columns should have all the same width (Unique) and be printed centered. The strings should not be sorted:

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20],
                  Unique, Center, Sort = FALSE)
```

```
"*****" "*****" "*****" "*****" " " " "
"*****" "*****" "*****" "*****" "*****" "*****"
"*****" "*****" "*****" "*****" " " " " " " " "
```

The option Unquoted prevents printing of quotes (see fprint):

```
output::tableForm([_concat("*" $ random(10)()) $ k = 1..20],
                  Unique, Center, Sort = FALSE, Unquoted)
```

```
***** * ***** ***** ***** ***** ** *
***** * ***** ***** ** ***** ***** *
* *****
```

Example 2

The next object is a MuPAD table and should be printed as a table with two columns. The table contains some random numbers and their sum of the digits:

```
SEED := -1:
T := table(op(map([random(10000000)() $ k = 1..10],
                  proc(X)
                    local Xs, k;
```

output::tableForm

```
begin
  Xs := expr2text(X);
  X = _plus(text2expr(substring(Xs, k))
            $ k = 1..length(Xs))
end_proc)):
output::tableForm(T)
```

19962580 = 40

25878221 = 35

37777904 = 44

41281013 = 20

43856426 = 38

46169451 = 36

66926292 = 42

80330908 = 31

89306719 = 43

94386068 = 44

Domains are also printed in this form by default:

```
output::tableForm(newDomain("Test",
                             table("type" = "Test",
                                     "info" = "only a testdomain")))
```

"info" = "only a testdomain"

"key" = "Test"

```
"type" = "Test"
```

Example 3

The next table should consist of four columns:

```
SEED := -1:  
output::tableForm([random(100000)() $ k = 1..30], Columns = 4)
```

```
11647 12826 26280 26292
```

```
28315 30908 36523 42073
```

```
4682 47334 52640 56426
```

```
5829 615 62580 65904
```

```
66223 6719 69451 69903
```

```
77904 78221 80528 81013
```

```
86068 89016 90516 91008
```

```
92791 9532
```

The next table should have a maximal width of 50 characters:

```
SEED := -1:  
output::tableForm([random(100000)() $ k = 1..30], Width = 50)
```

```
11647 12826 26280 26292 28315 30908 36523 42073
```

```
4682 47334 52640 56426 5829 615 62580 65904
```

```
66223 6719 69451 69903 77904 78221 80528 81013
```

```
86068 89016 90516 91008 92791 9532
```

output::tableForm

delete T:

Example 4

The next examples show different usage of separators. First one single separator:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], "|")

11647|12826|26280|26292|28315|30908|36523|42073|4682 |47334|52640|5
5829|615 |62580|65904|66223|6719 |69451|69903|77904|78221|80528|81
86068|89016|90516|91008|92791|9532
```

Now a list with a separator character between each column. If the list is too short, the characters are used from beginning of the list again etc.:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], ["|", " ", " "])

11647|12826 26280 26292|28315 30908 36523|42073 4682 47334|52640 5
5829|615 62580 65904|66223 6719 69451|69903 77904 78221|80528 81
86068|89016 90516 91008|92791 9532
```

Only the first both columns should be separated by a vertical line:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], ["|", " " $ 10])

11647|12826 26280 26292 28315 30908 36523 42073 4682 47334 52640 5
5829|615 62580 65904 66223 6719 69451 69903 77904 78221 80528 81
86068|89016 90516 91008 92791 9532
```

Additionally a character can be appended to each entry:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
                  ["|", " " $ 10], Append = ",")

11647,|12826, 26280, 26292, 28315, 30908, 36523, 42073, 4682, 4
56426,|5829, 615, 62580, 65904, 66223, 6719, 69451, 69903, 7
80528,|81013, 86068, 89016, 90516, 91008, 92791, 9532,
```

Example 5

The next examples show different usage of sorting. Without the option Sort the numbers are sorted as strings in lexicographical order:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30])

11647 12826 26280 26292 28315 30908 36523 42073 4682 47334 5264
5829 615 62580 65904 66223 6719 69451 69903 77904 78221 80528
86068 89016 90516 91008 92791 9532
```

Sort = FALSE avoids any sorting:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30], Sort = FALSE)

30908 6719 26292 56426 81013 69451 77904 78221 86068 62580 4733
9532 5829 28315 65904 42073 80528 4682 52640 69903 92791 36523
89016 91008 615 66223 90516 11647
```

output::tableForm

Any sorting can be done with a special defined procedure, e.g., sort the numbers in reverse order:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
                  Sort = ((X,Y) -> Y < X))
```

```
92791 91008 90516 89016 86068 81013 80528 78221 77904 69903 69451 6
65904 62580 56426 52640 47334 42073 36523 30908 28315 26292 26280 1
11647 9532 6719 5829 4682 615
```

At last a user defined procedure is given that sorts the numbers by the sum of their digits ascending:

```
SEED := -1:
output::tableForm([random(100000)() $ k = 1..30],
                  Sort = proc(X,Y)
                        local crossfoot;
                        begin
                          crossfoot :=
                            proc(X)
                              local Xs, k;
                              begin
                                Xs := expr2text(X);
                                _plus(text2expr(substring(Xs, k))
                                      $ k = 1..length(Xs))
                              end_proc;
                              crossfoot(X) < crossfoot(Y)
                            end_proc)
```

```
615 81013 42073 52640 91008 26280 36523 11647 12826 66223 9532 283
30908 4682 78221 26292 90516 47334 62580 56426 80528 6719 5829 65
89016 69451 77904 69903 92791 86068
```

Parameters

obj

A list, set or table of any MuPAD objects or a domain

separator

A string between columns

Options

Unquoted

Strings are printed without quotes

The output function `fprint` is called with the option `Unquoted`.

Unique

All columns are of the same width

All columns are printed with the same width, the widest column determines the width of each column.

Width

Option, specified as `Width = w`

The maximal width of the table is set to `w` (instead of `TEXTWIDTH`).
`w` must be a positive integer.

Columns

Option, specified as `Columns = c`

The number of columns is set to `c`. The width of the table depends on the width of any column.

Note `output::tableForm` called with this option takes not care about the value of `TEXTWIDTH`.

`c` must be a positive integer.

Center, Left, Right

output::tableForm

The entries of each column are aligned left-justified, centered or justified.

Sort

Option, specified as `Sort = procedure`

The entries are sorted with the given procedure. Entries can be printed unsorted, when procedure is the object `FALSE`.

Output

Option, specified as `Output = file`

Output into a file. If `file` is a string, a file named `file` is opened and overwritten and closed after writing. If `file` is a file descriptor (the return value of `fopen`), the table is appended to `file` without closing `file`.

String

Return as a string that can be printed

The string contains line breaks, and can be printed with `print` or `fprint` and option `Unquoted`.

Append

Option, specified as `Append = string`

Character string is appended to each entry of the list

Return Values

Void object `null()`

See Also

MuPAD Functions

`output::tree` | `print` | `fopen` | `fprint` | `fclose` | `sort`

Purpose

Display of trees

Syntax

`output::tree(Tree, <indentdepth>, <charlist>, <Small>>)`

Description

`output::tree` displays trees given as specially MuPAD lists.

The first object of the list is the root of the tree. All further objects are nodes or subtrees of the tree. A subtree is again a special list (as described), and any other MuPAD object will be interpreted as node of the tree.

The elements of the tree will be printed by MuPAD, when the tree will be displayed, so it's recommended to use strings as objects or objects with a well defined display.

The return value is a string that contains all chars to display the tree. With functions `print` and `fprint` and the option `Unquoted` the tree can be displayed.

The parameter `charlist` is a list with five characters. The default value is `["|", "+", "-", " ", " "]`. The characters have the following meaning (described in the order of the list).

The vertical lines of the tree, the connection between vertical and horizontal line (i.e., an arm, but not the last arm), an arm (vertical line), the last connection to an arm in a subtree, a char between an arm and the description of the arm.

Examples**Example 1**

`output::tree` displays special nested lists as trees:

```
TREE := ["a1", "a2", ["b1", "b2", ["c1", "c2"], "b3"],
        ["d1", "d2", "d3"]]:
print(Unquoted, output::tree(TREE))
```

```
a1
|
+-- a2
```

output::tree

```
|
+-- b1
|   |
|   +-- b2
|   |   |
|   |   +-- c1
|   |   |   |
|   |   |   \-- c2
|   |   \-- b3
|   \-- d1
|       |
|       +-- d2
|       \-- d3
```

```
print(Unquoted, output::tree(TREE, 3, Small)):
```

```
a1
+- a2
+- b1
|   +- b2
|   +- c1
|   |   \-- c2
|   \-- b3
\-- d1
    +- d2
    \-- d3
```

The chars can be defined by the user:

```
print(Unquoted, output::tree(TREE, 6, [ "|", "|", ".", "\\ ", " " ])):
```

Parameters

Tree

The tree, given as a special list

indentdepth

Indent depth for each subtree

charlist

The chars that illustrate the tree structure

Options

Small

Suppresses the display of a space line between every tree entry to reduce the height of the tree

output::tree

Return Values

String object to display

RGB::ColorNames

Purpose Find predefined colors by name

Syntax `RGB::ColorNames()`
`RGB::ColorNames(subname)`

Description `RGB::ColorNames(str)` returns a list of names of colors in the RGB name space whose names contain `str`.
`RGB::ColorNames` goes through the list of predefined color names and returns those whose names contain the string or identifier given as input, if any.

Environment Interactions `RGB::plotColorPalette` plots a list of color samples with names.

Examples **Example 1**

The following call returns all predefined color names containing “Olive”:

```
RGB::ColorNames("Olive")
```

```
[Olive, OliveDrab, OliveGreen, OliveGreenDark]
```

The RGB values of these colors are:

```
RGB::Olive, RGB::OliveDrab, RGB::OliveGreen,  
RGB::OliveGreenDark
```

```
[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0],  
[0.333293, 0.419599, 0.184301]
```

Example 2

The following call plots all predefined colors containing “Olive”:

```
RGB::plotColorPalette("Olive")
```

When the list of colors found gets larger, they are distributed over more lines:

```
RGB::plotColorPalette("Blue")
```

RGB::ColorNames

Colors containing 'Blue'

				
AliceBlue	AirForceBlue			
				
BlueMedium	BlueLight	BlueGrey	Blue	AzureBlueDark
				
CornflowerBlue	CeruleanBlue	BondiBlue	BlueViolet	BluePale
				
ManganeseBlue	LightBlue	InternationalKleinBlue	DodgerBlue	DarkBlue

RoyalBlue	RobinEggBlue	PrussianBlue	PowderBlueLight	PowderBlue
				
SlateBlueDark	SlateBlue	SkyBlueLight	SkyBlueDeep	SkyBlue
				
UnitedNationsBlue	SteelBlueLight	SteelBlue	SlateBlueMedium	SlateBlueLight

**Return
Values**

RGB::ColorNames returns a list of predefined color names.
RGB::plotColorPalette returns the empty object, null().

See Also**MuPAD
Functions**

RGB::plotColorPalette

RGB::plotColorPalette

Purpose	Display predefined colors
Syntax	<code>RGB::plotColorPalette(subname)</code>
Description	<code>RGB::plotColorPalette(str)</code> displays the colors in the RGB name space whose names contain <code>str</code> . <code>RGB::plotColorPalette</code> uses <code>RGB::ColorNames</code> and plots samples of the colors found by this routine, in tabular fashion.
Environment Interactions	<code>RGB::plotColorPalette</code> plots a list of color samples with names.

Examples

Example 1

The following call returns all predefined color names containing “Olive”:

```
RGB::ColorNames("Olive")
```

```
[Olive, OliveDrab, OliveGreen, OliveGreenDark]
```

The RGB values of these colors are:

```
RGB::Olive, RGB::OliveDrab, RGB::OliveGreen,  
RGB::OliveGreenDark
```

```
[0.230003, 0.370006, 0.170003], [0.419599, 0.556902, 0.137303], [0.2, 0.2, 0.0],  
[0.333293, 0.419599, 0.184301]
```

Example 2

The following call plots all predefined colors containing “Olive”:

```
RGB::plotColorPalette("Olive")
```

When the list of colors found gets larger, they are distributed over more lines:

```
RGB::plotColorPalette("Blue")
```

RGB::plotColorPalette

Colors containing 'Blue'

**Return
Values**

RGB::ColorNames returns a list of predefined color names.
RGB::plotColorPalette returns the empty object, null().

See Also**MuPAD
Functions**

RGB::ColorNames

RGB::colorName

Purpose Find names of predefined colors

Syntax `RGB::colorName(rgb, <Exact>)`

Description `RGB::colorName([r, g, b])` looks for the predefined color with values closest to [r, g, b] and returns its name.

`RGB::colorName([r, g, b], Exact)` looks for a predefined color with values exactly [r, g, b] and returns its name.

The RGB namespace contains predefined color names, accessible as `RGB::Blue` etc. `RGB::colorName` performs a reverse lookup, finding the name of a color given as RGB values.

Since rather often, colors will stem from calculations with floating-point numbers, no exact matches can be expected in this reverse lookup. Therefore, by default, `RGB::colorName` will perform a “fuzzy” search, returning the predefined color which is closest (in Euclidean distance in RGB space) to the input. Cf. “Example 2” on page 23-18.

Examples

Example 1

`RGB::colorName` returns the symbolic name of predefined colors:

```
RGB::colorName([0, 1, 0])
```

```
RGB::Green
```

```
RGB::colorName([0, 1, 0, 0.5])
```

```
RGB::Green.[0.5]
```

Example 2

When performing calculations on color values, the results will rarely be exact, even if the unavoidable round-off errors are too small to be displayed on the screen:

```
a := RGB::Olive;  
b := RGB::fromHSV(RGB::toHSV(RGB::Olive))
```

```
[0.230003, 0.370006, 0.170003]
```

```
[0.230003, 0.370006, 0.170003]
```

```
bool(a = b)
```

```
FALSE
```

Therefore, `RGB::colorName` by default searches in a “fuzzy” fashion:

```
RGB::colorName(a);  
RGB::colorName(b)
```

```
RGB::Olive
```

```
RGB::Olive
```

In cases where this is undesirable, the option `Exact` can be used to switch to exact searching:

```
RGB::colorName(a, Exact);  
RGB::colorName(b, Exact)
```

```
RGB::Olive
```

```
FAIL
```

The predefined color names do not fill RGB space uniformly, therefore, the color found by `RGB::colorName` may be quite different from the one entered. The following plot shows the predefined colors in RGB space:

RGB::colorName

```
plot(plot::Scene3d(  
  plot::PointList3d([c.[c] $ c in RGB::ColorList]),  
  ZXRatio = 1, BackgroundStyle = TopBottom,  
  BackgroundColor = RGB::Grey,  
  BackgroundColor2 = RGB::White,  
  Margin=0))
```

Parameters **rgb**

An RGB or RGBA color specification: A list of three or four real numbers in the interval $[0, 1]$.

Options **Exact**

Only return an exact match, FAIL if none exists.

Return Values

If a color was found, `RGB::colorName` returns an expression of the form `RGB::Name` or `RGB::Name.[a]`. If given `Exact` and no match was found, `FAIL` is returned. If given symbolic input parameters, an unevaluated call is returned.

MuPAD Functions

RGB

RGB::fromWaveLength

Purpose Get the RGB color of monochromatic light

Syntax `RGB::fromWaveLength(o, <a>)`

Description `RGB::fromWaveLength(o)` returns an approximative RGB specification for light of wavelength λnm .

Light consists of photons, each of which has a distinct wavelength. These different wavelengths cause color perception. `RGB::fromWaveLength` calculates an RGB triple corresponding to a given wave length.

Different displays show the same RGB color in slightly different ways. For this reason, the so-called “gamma correction” has been invented. `RGB::fromWaveLength` accepts a second argument, for fine-tuning the assumed gamma correction that enters the calculation.

Color perception depends on a number of factors, including individual differences. Therefore, such a calculation can only return an approximation. `RGB::fromWaveLength` uses the model published by Dan Bruton for the conversion.

For wavelengths outside the visible spectrum (which ranges from $380nm$ to $780nm$), `RGB::fromWaveLength` returns black.

Examples

Example 1

White light, when sent through a prism, is split into the commonly known spectrum, because the prism refracts different wavelengths differently. This spectrum can easily be reproduced by `RGB::fromWaveLength`:

```
plot(plot::Raster([[RGB::fromWaveLength(i) $ i=380..780]]),  
      Scaling = Unconstrained, Height = 20)
```

Example 2

Bruton's conversion model looks like this:

```
plotfunc2d(  
  plot::Raster([[RGB::fromWaveLength(i) $ i = 380..780]],  
    x = 380..780, y = -0.2..0),  
  (x -> RGB::fromWaveLength(x)[i]) $ i = 1..3,  
  x = 380..780,  
  Colors = [RGB::Red, RGB::Green, RGB::Blue],  
  LegendVisible = FALSE,  
  XTicksNumber = Low,  
  Scaling = Unconstrained,  
  Axes = Automatic)
```

RGB::fromWaveLength

Parameters

The wavelength: a real-valued constant (interpreted as nanometers) or a length expression

The “gamma correcture” for the display, defaults to 0.8

Return Values

RGB color: a list of three floating-point values

See Also

MuPAD Functions

RGB | RGB::fromHSV

Purpose Pick a color uniformly at random in RGB color space

Syntax `RGB::random()`

Description `RGB::random()` returns a random color. The colors returned are distributed independently and uniformly in the RGB color space.

Examples **Example 1**

`RGB::random` can be used to produce high-frequency noise:

```
plot(plot::Raster([[RGB::random() $ x = 0..42] $ y = 0..42]))
```

Example 2

It is possible to use `RGB::random` directly as a color function, but the result may be unexpected:

RGB::random

```
plot(plot::Waterman(5, FillColorFunction = RGB::random))
```

The reason is that the color function will be called repeatedly if the same point is met again. It is a better idea to create a bunch of random colors and then use the parameters passed into the color functions to get some consistency into the choice of colors:

```
colors := [RGB::random() $ i = 1..42]:  
plot(plot::Waterman(5, FillColorFunction=((x,y,z,i) -> colors[i])))
```

Return Values

RGB color: A list of three floating-point values.

MuPAD Functions

RGB | frandom

RGB::toHSV

Purpose Convert RGB colors to HSV

Syntax RGB::toHSV([r, g, b, <a>])

Description RGB::toHSV(RGBcolor) returns RGBcolor expressed in HSV values, with hue in the range **0..360** (i.e., in degrees) and saturation and value in the range **0..1**.

Examples **Example 1**

With the RGB::fromHSV utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values [290, 0.4, 0.6], whereas “dark green” is given by the HSV specification [120, 1, 0.4]. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

```
plot(plot::Sphere(1, [0, 0, 0],
                  Color = RGB::fromHSV([290, 0.4, 0.6]).[0.5]),
      plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1,
                    Mesh = [2, 2],
                    Color = RGB::fromHSV([120, 1, 0.4]))
):
```

Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example `plot::Conformal`. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use `plot::Density`, providing the following color function:

```
f_color := (x, y, fz, a) ->
    RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):
```

The identity function is thus shown as follows:

```
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1,
    XMesh = 50, YMesh = 50,
    FillColorFunction = f_color))
```

RGB::toHSV

$z \rightarrow z^2$ doubles the argument of a complex function, resulting in the following picture:

```
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1,  
      XMesh = 50, YMesh = 50,  
      FillColorFunction = f_color))
```

To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of the origin to be of interest:

```
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2,  
  XMesh = 50, YMesh = 50,  
  FillColorFunction = f_color))
```

RGB::toHSV

$z \rightarrow z^{4/3}$ is clearly discontinuous along the negative real axis:

```
plot(plot::Density((x, y) -> (x + I*y)^(4/3),  
  x = -1..1, y = -1..1,  
  XMesh = 50, YMesh = 50,  
  FillColorFunction = f_color))
```

Parameters

r, g, b

The red, green, and blue contributions of an RGB color: numerical values between 0 and 1.

a

The translucency (alpha) value: a numerical value between 0 and 1.

Return Values

a list with three or four floating-point values, depending on whether a was given in the input.

RGB::fromHSV

RGB::fromHSV

Purpose Convert HSV colors to RGB

Syntax RGB::fromHSV([h, s, v, <a>])

Description RGB::fromHSV(HSVcolor) is the inverse of RGB::toHSV: Given color coordinates in HSV, this function returns the corresponding RGB color. Cf. “Example 2” on page 23-35.

Examples **Example 1**

With the RGB::fromHSV utility, all colors in a MuPAD graphics can be specified easily as HSV colors. For example, the color “violet” is given by the HSV values [290, 0.4, 0.6], whereas “dark green” is given by the HSV specification [120, 1, 0.4]. Hence, a semi-transparent violet sphere intersected by an opaque dark green plain may be specified as follows:

```
plot(plot::Sphere(1, [0, 0, 0],
                Color = RGB::fromHSV([290, 0.4, 0.6]).[0.5]),
      plot::Surface([x, y, 0.5], x = -1 .. 1, y = -1 .. 1,
                Mesh = [2, 2],
                Color = RGB::fromHSV([120, 1, 0.4]))
):
```

Example 2

There are numerous ways of displaying complex-valued functions of a complex argument, see for example `plot::Conformal`. One of these is to use a color scheme that interprets the complex plane as a section through HSV color space at a fixed value, say, 1. To plot this scheme in MuPAD, we use `plot::Density`, providing the following color function:

```
f_color := (x, y, fz, a) ->
    RGB::fromHSV([180/float(PI)*arg(fz), abs(fz), 1]):
```

The identity function is thus shown as follows:

```
plot(plot::Density((x, y) -> x + I*y, x = -1..1, y = -1..1,
    XMesh = 50, YMesh = 50,
    FillColorFunction = f_color))
```

RGB::fromHSV

$z \rightarrow z^2$ doubles the argument of a complex function, resulting in the following picture:

```
plot(plot::Density((x, y) -> (x + I*y)^2, x = -1..1, y = -1..1,  
  XMesh = 50, YMesh = 50,  
  FillColorFunction = f_color))
```

To plot the complex sine function, we choose a larger rectangle, since the sine is too similar to the identity in small neighborhoods of the origin to be of interest:

```
plot(plot::Density((x, y) -> sin(x + I*y), x = -2..2, y = -2..2,
  XMesh = 50, YMesh = 50,
  FillColorFunction = f_color))
```

RGB::fromHSV

$z \rightarrow z^{4/3}$ is clearly discontinuous along the negative real axis:

```
plot(plot::Density((x, y) -> (x + I*y)^(4/3),  
             x = -1..1, y = -1..1,  
             XMesh = 50, YMesh = 50,  
             FillColorFunction = f_color))
```

Parameters

a

The translucency (alpha) value: a numerical value between 0 and 1.

h

The “hue” in an HSV specification: a numerical value between 0 and 360

s

The “saturation” in an HSV specification: a numerical value between 0 and 1

v

The “value” in an HSV specification: a numerical value between 0 and 1

RGB::fromHSV

Return Values

a list with three or four floating-point values, depending on whether a was given in the input.

RGB::toHSV

Purpose	Easy plotting
Syntax	<code>plot::easy(<arg, >, options)</code>
Description	<p><code>plot::easy(arg , <options>,)</code> transforms data and expressions into graphical objects.</p> <p><code>plot::easy</code> accepts graphical objects and graphical attributes as input and returns them unchanged.</p> <p><code>plot::easy</code> supports the options listed above. Additionally, it accepts arbitrary data and expressions and tries to transform them into valid graphical objects.</p> <p><code>plot::easy</code> supports the option <code>Colors=[c₁,...c₂]</code> for automatically coloring newly generated graphical objects. The given list is used instead of the internally defined default color list.</p> <p><code>plot::easy</code> accepts the options <code>Mesh</code> and <code>Submesh</code> and uses them for each newly generated graphical object.</p> <p>The function <code>plot</code> calls <code>plot::easy</code> for preprocessing its input before plotting.</p> <p><code>plot::easy</code> tries to handle standard situations intuitively in order to make plotting as easy as possible. However, it supports only a small subset of the graphical objects, attributes and expressions available in MuPAD and thus does not claim to be complete.</p> <p>Users that want to plot other objects or control specific details of their graphics explicitly, still have to create their graphical objects manually, e.g. using <code>plot::Function2d</code> and <code>plot::Point2d</code>, and to use graphical attributes like <code>LineStyle =Dashed</code> directly.</p> <p><code>plot::easy</code> sets a new color for each object that it creates, if no color is predefined in the given context.</p> <p><code>plot::easy</code> accepts sets <code>{...}</code> as group definition and transforms them into graphical objects of type <code>plot::Group2d(...)</code> or <code>plot::Group3d(...)</code>, respectively. All elements of a group share the</p>

same color, if colors were not specified explicitly for single objects. Note that, regular graphical objects usually have a predefined color.

`plot::easy` accepts a nested set `{{...}}` as scene definition and transforms it into the graphical object `plot::Scene2d(...)` or `plot::Scene3d(...)`, respectively.

Creating a graphical object may require the specification of value ranges for variables. If they are not specified explicitly then `plot::easy` tries use ranges specified for other variables and/or uses the default value range `-5..5`.

Examples

Example 1

`plot::easy` tries to transform all given data and expressions into valid graphical objects and attributes:

```
plot::easy(sin(x), [PI/2,1])
```

```
plot::Function2d(sin(x), x = -5..5), plot::Point2d( $\frac{\pi}{2}$ , 1, PointColor = RGB::Red, LegendText = "[PI/2, 1]")
```

Since the function `plot` calls the function `plot::easy` for preprocessing its input data, scenes like above can directly be plotted using `plot`:

```
plot(sin(x), [PI/2,1], #x=PI/2, #y=1)
```

Now, it is only a small step to animate this scene:

```
plot(sin(x), {[x,sin(x)], #Points}, #x=x, #y=sin(x))
```

Note: Graphical objects and attributes, as well as data that `plot::easy` cannot transform, are returned unchanged:

```
plot::easy(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject")
```

```
plot::Function2d(x, x = -5..5), plot::Point2d(1, 1), LineStyle = Dashed, "UnknownObject"
```

This is why `plot` returns the following error message when it is executed with the above arguments:

```
plot(x, plot::Point2d(1,1), LineStyle=Dashed, "UnknownObject");
```

```
Error: The arguments 'UnknownObject' are unexpected. [plot::Canvas:
```

Example 2

Points can be entered as lists with two or three values. Alternatively, a corresponding column vector in combination with the option `#Points` (alias `#P`, see “Example 18” on page 23-74) can be used.

Note that for plotting animated points the option `#Points` is required. Otherwise a curve (when entered a list) or an arrow (when entered a vector) is plotted:

```
plot([0,1], [s,s^2], {[s,s^2], #Points}, s=-2..2,  
      matrix([t,t^2]), {matrix([t,t^2]), #Points}, t= 2..-2  
)
```

See also: `plot::Point2d`, `plot::Point3d`.

Example 3

Arrows can be specified as column vectors with two or three elements. Alternatively, a list in combination with the option #Arrows (alias #A, see “Example 13” on page 23-69) can be used:

```
plot(matrix([0,1]), matrix([s,s^2]), s=2..-2,  
      [t,t^2], {[t,t^2], #Arrows}, t=-2..2  
)
```

If an arrow should start at coordinates other than (0,0) or (0,0,0), respectively, then a list of two column vectors or a corresponding list of lists in combination with the option #Arrows (alias #A, see “Example 13” on page 23-69) can be used:

```
u:= matrix([3,2]):  
v:= matrix([1,4]):  
w:= (1-a)*u + a*v:
```

```
u, v, w;
```

$$\begin{pmatrix} 3 \\ 2 \end{pmatrix}, \begin{pmatrix} 1 \\ 4 \end{pmatrix}, \begin{pmatrix} 3-2a \\ 2a+2 \end{pmatrix}$$

```
plot(u, v, [u,w], a=0.1..1, #Arrows)
```

```
delete u, v, w;
```

See also: `plot::Arrow2d`, `plot::Arrow3d`.

Example 4

Polygons can be specified as lists, tables or matrices. In the following example, polygons are plotted using different input styles. The option `#Origin` (alias `#0`, see “Example 17” on page 23-73) ensures that the origin of the coordinate system is visible in the scene as well:

```
plot([[1,3],[2,5],[3,3],[4,8]],  
      table(1=4,2=6,3=4,4=9),  
      [matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],  
      matrix([[1,6],[2,8],[3,6],[4,11]]),  
      #Origin)
```

Note that polygons are displayed as points when option `#Points` (alias `#P`, see “Example 18” on page 23-74) is used:

```
plot([[1,3],[2,5],[3,3],[4,8]],  
      table(1=4,2=6,3=4,4=9),  
      [matrix([1,5]),matrix([2,7]),matrix([3,5]),matrix([4,10])],  
      matrix([[1,6],[2,8],[3,6],[4,11]]),  
      #Points, #Origin)
```

Note that the following polygons with two elements are displayed as arrows when option `#Arrows` (alias `#A`, see “Example 13” on page 23-69) is used:

```
plot([[1,4],[2,6]],  
      [matrix([1,5]),matrix([2,7])],  
      matrix([[1,6],[2,8]]),  
      #Arrows, #Origin)
```

See also: `plot::Polygon2d`, `plot::Polygon3d`.

Example 5

Point lists can be specified as lists, tables or matrices. For each point an RGBA color has to be specified. In the following example, point lists are plotted using different input styles. The option `#Origin` (alias `#0`, see “Example 17” on page 23-73) ensures that the origin of the coordinate system is visible in the scene as well:

```
plot([[1,2,RGB::Red], [2,4,[0,1,0]], [3,3,[0,0,1,0.5]]],  
      [matrix([1,3,RGB::Red]),matrix([2,5,[0,1,0]]),matrix([3,4,[0,0,1,0.5]]),  
      matrix([1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]])],  
      table(1=[5,RGB::Red], 2=[7,[0,1,0]], 3=[6,[0,0,1,0.5]]),  
      #Origin)
```

Note that the following point lists are displayed as arrows when option `#Arrows` (alias `#A`, see “Example 13” on page 23-69) is used:

```
plot([[1,2,RGB::Red], [2,4,[0,1,0]] ,[3,3,[0,0,1,0.5]]],
      [matrix([1,3,RGB::Red]),matrix([2,5,[0,1,0]]),matrix([3,4,[0,0,1,0.5]]),
      matrix([1,4,RGB::Red], [2,6,[0,1,0]], [3,5,[0,0,1,0.5]])],
      table(1=[5,RGB::Red], 2=[7,[0,1,0]] ,3=[6,[0,0,1,0.5]]),
      #Arrows, #Origin)
```

See also: `plot::PointList2d`, `plot::PointList2d`.

Example 6

For drawing horizontal and vertical infinite lines, the short syntax `#x = e` and `#y = e` with `e` is a real expression, can be used:

```
plot(sin(x), [PI/2,1], #x=PI/2, #y=1, #Legend)
```

For drawing horizontal and vertical infinite planes, the short syntax $\#x = e$, $\#y = e$ and $\#z = e$, with e is a real expression, can be used.

Both, lines and planes can also be animated:

```
plot([t,0,t^2], {[t,0,t^2], #Points}, #x=t, #z=t^2, #Legend)
```

See also: `plot::Line2d`, `plot::Plane`.

Example 7

A curve can be specified as list with two or three elements, where at least one element depends on a free variable. If option `#Points` (alias `#P`, see “Example 18” on page 23-74) is set, then instead of a curve, an animated point is plotted that moves along the curve.

```
plot([t,sin(t)], {[t,sin(t)], #Points}, t=0..2*PI)
```

See also: `plot::Curve2d`, `plot::Curve3d`.

Example 8

`plot::easy` tries to transform expressions that are no lists, sets, matrices, equations or inequalities into graphs of 2D or 3D functions. We plot some graphs of 2D functions:

```
plot(sin(x), tan(x), x)
```

We plot a simple 3D function. Note that the option #3D (alias #3, see “Example 12” on page 23-66) is required in the following example for plotting a 3D function. Otherwise, an animated 2D function is created.

```
plot(m*x, #3D)
```

We plot a simple 2D animation: a point and the corresponding tangent of the sine function move along the sine function graph:

```
f:= x -> sin(x):  
plot(f(x), x = -PI..PI,  
      {[a, f(a)], #Points}, f'(a)*(x-a) + f(a), a = -PI/2..PI/2)
```

We plot a piecewise defined function:

```
plot(piecewise([x < 1, -x^2 + 1], [x >= 1, x + 5]), #x=1, #Legend)
```

The same piecewise defined function is now written in a shorter syntax. Note the difference between defining one function with two branches (left) and defining two functions (right):

```
plot({{[[x < 1, -x^2 + 1], [x >= 1, x + 5]], #x=1}},
     {{ [x < 1, -x^2 + 1], [x >= 1, x + 5] , #x=1}},
     #Legend)
```

See also: `plot::Function2d`, `plot::Function3d`.

Example 9

An implicit function can be specified as an equation:

```
plot(u^5 + x^2 = 1 - u^3)
```

Note that the option #3D (alias #3, see “Example 12” on page 23-66) may be required to plot planes given as cartesian equations. Otherwise, an animated 2D graph might be created. This depends on the number of variable of the equation.

```
E1:= 2*x + 30*y - 2*z = 5:  
E2:= -x + 7*y - z = 12:  
E3:= -4*x + 2*y + z = 0:  
plot(E1, E2, E3, #3D, #Legend)
```

delete E1, E2, E3:

See also: `plot::Implicit2d`, `plot::Implicit3d`.

Example 10

An inequality can be displayed directly:

```
plot(u^5+x^2 < 1-u^3)
```

The same is true for a list of inequalities and equations:

```
plot([x < 3, x > 1, y < 4, y > -4])
```

See also: `plot::Inequality`.

Example 11

To display a 2D text at a certain position, an equation of a coordinate tuple and a character string or a procedure can be entered:

```
plot([t, t^2],  
     {[t, t^2], #Points},  
     [t, t^2] = "moving text")
```

We display a 3D text. As in any other context of `plot::easy`, we can use regular graphical attributes like `TextFont =Center` as well:

```
DIGITS := 2:  
plot([t, t^2, 1],  
      {[t, t^2, 1], #Points},  
      [t, t^2, 1] = (t->" x = ".[t, t^2, 1.0]),  
      TextFont=[Bold]):  
delete DIGITS:
```

See also: `plot::Text2d`, `plot::Text3d`.

Example 12

Usually `plot::easy` creates a 2D scene, unless one of the arguments is a 3D object or can only be transformed to a 3D object or the option `#3D` is used.

```
plot(sin(x), #3)
```

However, the option #3D is only a hint. It is ignored if the current scene can only be a 2D scene. In the following example, the 2D point determines the dimension of the scene:

```
plot([PI/2,1], sin(x), #3)
```

In the following example, the 3D point determines the dimension of the scene. There is no need to use option `#3D` in order to create a 3d scene:

```
plot([PI/2,1,0], sin(x))
```

Example 13

With option `#Arrows`, arrows instead of points or curves are created. When used within a `{...}`-group, it affects the elements of this group or scene only.

```
plot({{ [-5,25], [5,25], [x,x^2]      }},  
     {{ [-5,25], [5,25], [x,x^2], #A }})
```

Example 14

Option `#Constrained` creates a coordinate system with constrained scaled axes. This is a shortcut for `Scaling = Constrained`.

```
plot({{ x^2 }}, {{ x^2, #C }})
```

Example 15

Option `#Grid` creates a coordinate system with grid lines. This is a shortcut for `GridVisible = TRUE`.

```
plot({{ x^2 }}, {{ x^2, #G }})
```

Example 16

Option `#Legend` creates a legend. This is a shortcut for `LegendVisible = TRUE` in combination with `LegendEntry = TRUE`. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

```
plot([0,-6], x^2-5, [t,t^2], #L)
```

Example 17

Option `#Origin` includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

```
plot({[2,2], [3,3]}, {[2,2], [3,3], #0})
```

Example 18

Using option `#Points`, points instead of arrows or curves are created. Furthermore, this option sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a `{...}`-group, it affects the elements of this group or scene only.

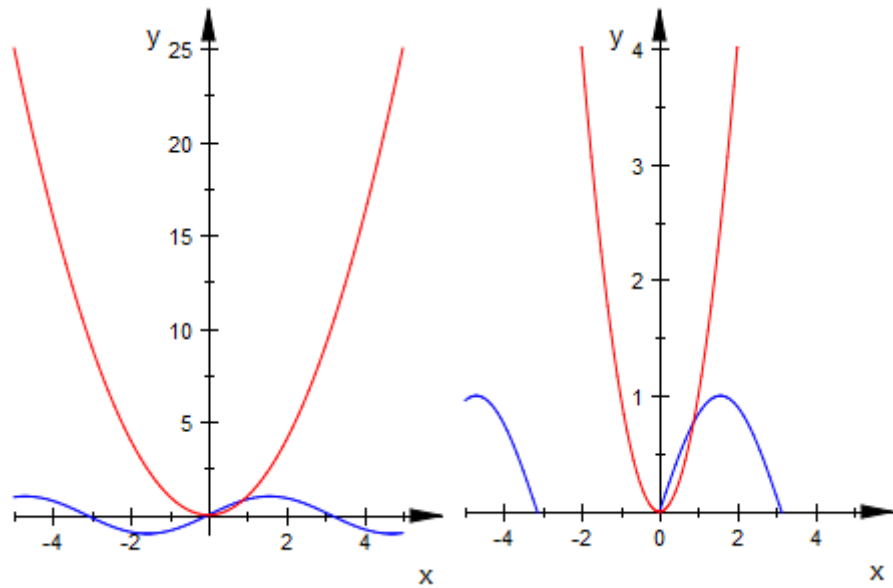

```
plot({[-5,25], [x,x^2], #Gray}, {matrix([5,25]), [x,x^2], #P})
```

Example 19

`#X / #Y / #Z = a..b` sets the x- / y- / z-range of the viewing box of the scene to a..b. This is a shortcut for `ViewingBoxXRange / ViewingBoxYRange / ViewingBoxZRange = a..b`.

```
plot({x^2, sin(x)}), {x^2, sin(x), #Y=0..4}}
```

We draw a 3D scene with a restricted viewing box. Therefore, only a quarter of the sphere is visible:

```
plot({{plot::Sphere(1)}},  
      {{plot::Sphere(1), #X=0..1, #Y=0..1, #Z=0..1}})
```

Parameters

arg

Any object

Options

#3D

Alias #3. Creates a 3D instead of a 2D scene, if possible. Usually, a 2D scene is created unless one of the arguments is a 3D object or can only be transformed into one.

#Arrows

Alias #A. Creates arrows instead of points. When used within a {...}-group, it affects the elements of this group or scene only.

#Constrained

Alias #C. Creates a coordinate system with axes having the same scaling. This is a shortcut for `Scaling =Constrained`.

#Grid

Alias #G. Creates a coordinate system with grid lines. This is a shortcut for `GridVisible =TRUE`.

#Legend

Alias #L. Creates a legend. This is a shortcut for `LegendEntry =TRUE` and `LegendVisible =TRUE`. When used within a {...}-group, it affects the elements of this group or scene only. Note that `plot::easy` explicitly sets a legend text for each graphical object it creates.

#Origin

Alias #O. Includes the coordinates (0,0) or (0,0,0), respectively, into the viewing box of the current scene.

#Points

Alias #P. Creates points instead arrows or curves. Furthermore, it sets the attributes `PointsVisible =TRUE` and `LinesVisible =FALSE`. When used within a {...}-group, it affects the elements of this group or scene only.

#XRange

Option, specified as `#XRange = a .. b`

Alias `#X = a .. b`. Sets the x-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxXRange =a..b`.

#YRange

Option, specified as `#YRange = a .. b`

Alias `#Y = a .. b`. Sets the y-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxYRange =a..b`.

#ZRange

Option, specified as `#ZRange = a .. b`

Alias `#Z = a .. b`. Sets the z-range of the viewing box of the scene to `a..b`. This is a shortcut for `ViewingBoxZRange =a..b`.

#<Colorname>

If RGB ::<Colorname> is a valid color name in MuPAD, #<Colorname> is transformed to: Color = RGB ::<Colorname>, LineColorType =Flat and for 3D objects additionally FillColorType =Flat. Transparent RGB colors can be specified as #<Colorname>.[t], with t is in 0..1. If #<Colorname> is a valid color following the html conventions then instead of RGB ::<Colorname>, the corresponding RGB or RGBA color value is inserted. When used within a {...}-group, it affects the elements of this group or scene only.

#<Colorname1> .. #<Colorname2>

If RGB ::<Colorname1> and RGB ::<Colorname2> are valid color names in MuPAD, this option is transformed to:

Color = RGB ::<Colorname1>, LineColorType =Dichromatic, LineColor2 = RGB ::<Colorname2> in 2D scenes and to:

Color = RGB ::<Colorname1>, FillColorType =Dichromatic, FillColor2 = RGB ::<Colorname2> in 3D scenes.

Transparent RGB colors can be specified as #<Colorname>.[t], with t is in 0..1. If #<Colorname1> and/or #<Colorname2> are valid colors following the html conventions then instead of RGB ::<Colorname1> and/or, RGB ::<Colorname2> the corresponding RGB or RGBA color values are inserted. When used within a {...}-group, it affects the elements of this group or scene only.

Return Values

A sequence of graphical objects and graphical attributes as well as objects that could not be transformed by plot::easy.

Overloaded By

arg

Algorithms

Let c_i be real constants and f and f_i be real functions. plot::easy automatically carries out the following transformations:

Graphical object	Data or mathematical expression
plot::Point2d:	$[c_1, c_2], \{[f_1(x), f_2(x)], \#Points\}, \{matrix([f_1(x), f_2(x)]), \#Points\}.$
plot::Point3d:	$[c_1, c_2, c_3], \{[f_1(x), f_2(x), f_3(x)], \#Points\}, \{matrix([f_1(x), f_2(x), f_3(x)]), \#Points\}.$
plot::Arrow2d:	$matrix([c_1, c_2]), \{[c_1, c_2], \#Arrows\}, \{matrix([f_1(x), f_2(x)]), matrix([f_3(x), f_4(x)]), \#Arrows\}, \{matrix([f_1(x), f_2(x), [f_3(x), f_4(x)]), \#Arrows\}, \{[f_1(x), f_2(x)], [f_3(x), f_4(x)]\}, \#Arrows\}.$

MuPAD Functions

plot

Purpose Get current default setting of attributes

Syntax `plot::getDefault(type::attr)`

Description `plot::getDefault(plot::Object::Attribute)` enquires the current default.

Examples **Example 1**

By default, function plots use relatively thin lines:

```
plotfunc2d(sin(x))
```

For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:

plot::getDefault

```
plotfunc2d(sin(x), LineWidth = 1*unit::mm)
```

However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):  
plotfunc2d(sin(x))
```

One thing you should know in this context: `plotfunc2d` and `plotfunc3d` use `plot::Function2d` and `plot::Function3d` for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since `plotfunc2d` and `plotfunc3d` set color and legend settings explicitly.

Parameters

type

A domain of the plot library, i.e., an object type such as `plot::Function2d`

attr

Attributes admissible for the object type `type`

Return Values

`plot::setDefault` returns the previous default value(s).
`plot::getDefault` returns the current default value.

plot::getDefault

Algorithms

“Admissible attributes” includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as “mandatory,” default values are read and used the moment an object is created. Default values of attributes marked as “optional” or “inherited” are read when the object is plotted and can therefore be changed after creating an object.

See Also

MuPAD Functions

`plot::setDefault`

Purpose Set default setting of attributes

Syntax `plot::setDefault(type::attr = value,)`

Description `plot::setDefault(plot::Object::Attribute = Value)` sets the default of the attribute `Attribute` for objects of type `plot::Object` to `Value`.

While not all attributes have defaults, it is in general possible to set defaults for them, although some examples like setting a default function to plot for `plot::Function2d` are probably more exotic than others, to say the least.

Defaults are set and retrieved per object; with the exception of `OutputFile` and `OutputOptions`, the attribute must be prefixed with the name of the object type the setting shall be valid for. There is, e.g., no function to turn of all lines on all 3D objects. `OutputFile` and `OutputOptions` are not associated with an object and must be set directly.

To delete a default (which is not recommended for attributes having a default in the standard installation), set value to `FAIL`.

Examples **Example 1**

By default, function plots use relatively thin lines:

```
plotfunc2d(sin(x))
```

plot::setDefault

For some applications, this is undesirable, for example when projecting graphics for a larger audience. It is always possible to set thicker lines in the call:

```
plotfunc2d(sin(x), LineWidth = 1*unit::mm)
```

However, this is distracting and cumbersome. Using `plot::setDefault`, we change the default setting once and for the whole session:

```
plot::setDefault(plot::Function2d::LineWidth = 1*unit::mm):  
plotfunc2d(sin(x))
```

plot::setDefault

One thing you should know in this context: `plotfunc2d` and `plotfunc3d` use `plot::Function2d` and `plot::Function3d` for the actual plotting. Changing color and legend settings of the latter two does not influence the former, however, since `plotfunc2d` and `plotfunc3d` set color and legend settings explicitly.

Parameters

type

A domain of the plot library, i.e., an object type such as `plot::Function2d`

attr

Attributes admissible for the object type `type`

value

The new default value: a value admissible for `attr` in objects of type `type`

Return Values

`plot::setDefault` returns the previous default value(s).
`plot::getDefault` returns the current default value.

Algorithms

“Admissible attributes” includes all the attributes the object itself reacts to. Hints cannot be set or changed with `plot::setDefault`.

For attributes marked as “mandatory,” default values are read and used the moment an object is created. Default values of attributes marked as “optional” or “inherited” are read when the object is plotted and can therefore be changed after creating an object.

MuPAD Functions

`plot::getDefault`

plot::copy

Purpose Make a physical copy of a plot object

Syntax `plot::copy(obj)`

Description Plot objects usually have a reference effect. `plot::copy` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect*: If you make another reference to some object, say by calling `o2 := o1`; and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1)`;

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE)`;

Examples

Example 1

The following call does *not* create two points, but rather one which we can access by two names:

```
A := plot::Point2d(0, 0):  
B := A:
```

This surfaces as soon as we try to modify ‘one of the points’:

```
B::Position := [1, 1]:  
A
```

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:

```
B := plot::modify(A, Position = [2, 2]):  
A, B
```

`plot::Point2d(1, 1), plot::Point2d(2, 2)`

Note Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

Parameters**obj**

Plot objects

Return ValuesObject of the same type as `obj`**See Also****MuPAD Functions**`plot::modify`

plot::modify

Purpose Make a physical copy of a plot object setting new values of attributes in the same call

Syntax `plot::modify(obj, <attr, >)`

Description Plot objects usually have a reference effect. `plot::modify` creates copies which are independent of the original.

Objects created from inside the `plot` library have a *reference effect*: If you make another reference to some object, say by calling `o2 := o1`; and then change an attribute of `o2`, e.g., setting `o2::Visible := FALSE`, this change will also effect the object referred to by `o1`, since they actually refer to the same object. To create an actual copy of an object instead, use `o2 := plot::copy(o1)`;

The function `plot::modify` is a variant of `plot::copy`. It allows setting new values of attributes in the same call, as in `o2 := plot::modify(o1, Visible = FALSE)`;

Examples

Example 1

The following call does *not* create two points, but rather one which we can access by two names:

```
A := plot::Point2d(0, 0):  
B := A:
```

This surfaces as soon as we try to modify ‘one of the points’:

```
B::Position := [1, 1]:  
A
```

```
plot::Point2d(1, 1)
```

Instead, we can use `plot::modify` to achieve the desired effect:

```
B := plot::modify(A, Position = [2, 2]):
```

A, B

`plot::Point2d(1, 1), plot::Point2d(2, 2)`

Note Note that `plot::modify` does not modify its argument, but returns a modified copy instead, whatever the name may suggest.

Parameters

obj

Plot objects

attr

Attributes admissible for the object `obj`, in the form `Attribute = Value`

Return Values

Object of the same type as `obj`

MuPAD Functions

`plot::copy`

plot::delaunay

Purpose Compute the Delaunay triangulation of a set of points

Syntax `plot::delaunay(L)`

Description `plot::delaunay` computes the Delaunay triangulation of a list of points in arbitrary dimension.

The Delaunay triangulation of a list of points is a triangulation of their convex hull such that for each edge of the triangulation, there is a circle containing the two endpoints of this edge but no other point of the list.

Environment Interactions Although `plot::delaunay` accepts and returns floating-point values, the actual computations take place in hardware floating-points and are therefore *not* affected by the value of DIGITS.

Examples **Example 1**

Delaunay triangulation does not introduce new points:

```
n0 := 10:  
l := [[Re, Im](exp(float(2*I*PI*n)/n0)) $ n = 1.. n0]:  
d := plot::delaunay(l):  
plot(plot::PointList2d(l, PointSize=3),  
      plot::Polygon2d(t, Closed) $ t in d)
```

Parameters

L

A list of points, which are given as lists of real values

Return Values

List of simplices in the dimension of the points in L, given as lists of lists of floating-point values.

Algorithms

plot::delaunay uses qhull from the Geometry Center of the University of Minnesota, see www.qhull.org.

plot::hull

Purpose Compute the convex hull of a set of points

Syntax `plot::hull(L)`

Description `plot::hull` computes the convex hull of a list of points in any dimension, i.e., the smallest convex region containing all the points. Such a region is bounded by simplices (straight lines in the plane, triangles in 3D) and it is these simplices which `plot::hull` returns.

Environment Interactions Although `plot::hull` accepts and returns floating point values, the actual computations take place in hardware floating points and are therefore *not* affected by the value of DIGITS.

Examples **Example 1**

We generate a list of random points and compute their convex hull:

```
X := stats::uniformRandom(0, 20):  
l := [[X(), X()] $ i = 1..10]:  
h := plot::hull(l):
```

The convex hull is returned as lists of lists, as accepted by `plot::Polygon2d`:

```
h[1]
```

```
[[17.58320254, 18.38769696], [3.063130321, 19.89625562]]
```

```
plot(plot::PointList2d(l),  
      plot::Polygon2d(t) $ t in h,  
      Closed, PointSize=2)
```

Example 2

The convex hull of a list of points in 3D is also easy to visualize:

```
l := [[x, y, z] $ y = z..x $ z = -x..x $ x = 0..10]:
h := plot::hull(l):
plot(plot::PointList3d(l, PointSize=1),
      plot::Polygon3d(t) $ t in h,
      Closed, Filled, FillColor=RGB::LightOrange.[0.6])
```

plot::hull

Parameters **L**

A list of points, which are given as lists of real values

Return Values

List of simplices of dimension one less than that of the points in L, given as lists of lists of floating-point values.

Algorithms

plot::hull uses qhull from the Geometry Center of the University of Minnesota, see www.qhull.org.

Purpose Circular and elliptical arcs in 2D

Syntax

```
plot::Arc2d(r, <[cx, cy]>, <Æ .. >, <a =
amin .. amax>, options)
plot::Arc2d([r1, r2], <[cx, cy]>, <Æ .. >, <a =
amin .. amax>, options)
```

Description `plot::Arc2d(r, [x, y], Æ ..)` creates a circular arc with radius r and center (x, y) with a polar angle between a and β .

`plot::Arc2d([r1, r2], [x, y], Æ ..)` creates a corresponding elliptical arc with semi-axes r_1, r_2 .

The angle of a point on the arc is the usual polar angle to the positive x -axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center $[0, 0]$ is created.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Angle	rotation angle	0
AngleEnd	end of angle range	PI/2
AngleBegin	begin of angle range	0
AngleRange	angle range	0 .. PI/2
AntiAliased	antialiased lines and points?	TRUE
Center	center of objects, rotation center	[0, 0]

plot::Arc2d

Attribute	Purpose	Default Value
CenterX	center of objects, rotation center, x-component	0
CenterY	center of objects, rotation center, y-component	0
Closed	open or closed polygons	FALSE
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	

Attribute	Purpose	Default Value
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
SemiAxes	semi axes of ellipses and ellipsoids	[1, 1]
SemiAxisX	first semi axis of ellipses and ellipsoids	1
SemiAxisY	second semi axis of ellipses and ellipsoids	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

plot::Arc2d

Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

An arc is a segment of a circle:

```
circle := plot::Circle2d(3, [0, 0]):
arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red,
                  LineWidth = 1.5*unit::mm):
plot(circle, arc)
```

```
delete circle, arc:
```

Example 2

The center of an arc may be given as the second argument to `plot::Arc2d`:

```
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE):  
arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE):  
plot(arc1, arc2)
```

plot::Arc2d

The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:

```
arc2::Center := [1, 3]:  
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

Example 3

A filled arc is a segment of a circle, like a piece of pie:

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))
```

plot::Arc2d

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))
```

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE,  
              FillPattern = Solid, LinesVisible = FALSE),  
      AxesInFront = TRUE)
```

plot::Arc2d

Example 4

When giving a list of two radii, `plot::Arc2d` draws a segment of an ellipse with the corresponding semi-axes:

```
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue):  
arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red):  
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

Example 5

To plot or animate segments of a tilted ellipse, use the attribute `Angle`:

```
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=So
plot(plot::Arc2d(arc, Angle=a+0,      a=0..2*PI, FillColor=RGB::
      plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::
      plot::Arc2d(arc, Angle=a+PI,     a=0..2*PI, FillColor=RGB::
      plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::
```

plot::Arc2d

delete arc:

Example 6

Further examples of animated 2D arcs:

```
plot(plot::Arc2d(1, a .. PI, a = 0..PI))
```

```
plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))
```

Example 7

We plot an animated 3D arc:

```
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))
```

Example 8

We plot a colored 3D arcs:

```
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled,  
      LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType =  
      FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType =  
      ))
```

Parameters r

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter a .

r is equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

r_1 , r_2

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter a .

r_1 , r_2 are equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

c_x , c_y

The center point. The coordinates c_x , c_y must be real numerical values or arithmetical expressions of the animation parameter a . If no center is specified, an arc centered at the origin is created.

c_x , c_y are equivalent to the attribute Center.

..

The angle range in radians: Δ and AngleRange must be real numerical values or arithmetical expressions of the animation parameter a . The default range is $0 \dots 2*PI$.

Δ .. is equivalent to the attribute AngleRange.

a

Animation parameter, specified as $a = a_{\min} \dots a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

MuPAD Functions

`plot` | `plot::copy`

MuPAD Graphical Primitives

`plot::Arc3d` | `plot::Circle2d` | `plot::Ellipse2d` |
`plot::Ellipse3d`

plot::Arc3d

Purpose Circular and elliptical arcs in 3D

Syntax
`plot::Arc3d(r, <[cx, cy, cz], <[nx, ny, nz]>>, <Æ .. >, <a = amin .. amax>, options)`
`plot::Arc3d([r1, r2], <[cx, cy, cz], <[nx, ny, nz]>>, <Æ .. >, <a = amin .. amax>, options)`

Description `plot::Arc3d(r, [x, y, z], [nx, ny, nz], Æ ..)` creates a circular arc with radius r and center (x, y, z) with a polar angle between α and β in the plane with the normal vector (nx, ny, nz) .

`plot::Arc3d([r1, r2], [x, y, z], [nx, ny, nz], Æ ..)` creates a corresponding elliptical arc with semi-axes r_1, r_2 .

The angle of a point on the arc is the usual polar angle to the positive x -axis known from polar coordinates. It is measured in radians.

If no range for the polar angle is specified, a full circle/ellipse is created.

If no center point is specified, an arc with center $[0, 0, 0]$, is created.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Angle	rotation angle	0
AngleEnd	end of angle range	PI/2
AngleBegin	begin of angle range	0
AngleRange	angle range	0 .. PI/2
Center	center of objects, rotation center	[0, 0, 0]
CenterX	center of objects, rotation center, x-component	0

Attribute	Purpose	Default Value
CenterY	center of objects, rotation center, y-component	0
CenterZ	center of objects, rotation center, z-component	0
Closed	open or closed polygons	FALSE
Filled	filled or transparent areas and surfaces	FALSE
FillColor	color of areas and surfaces	RGB::LightBlue
FillColor2	second color of areas and surfaces for color blends	RGB::CornflowerBlue
FillColorType	surface filling types	Flat
FillColorDirection	the direction of color transitions on surfaces	[0, 0, 1]
FillColorDirectionX	x-component of the direction of color transitions on surfaces	0
FillColorDirectionY	y-component of the direction of color transitions on surfaces	0

plot::Arc3d

Attribute	Purpose	Default Value
FillColorDirectionZ	z-component of the direction of color transitions on surfaces	1
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineColor2	color of lines	RGB::DeepPink
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorType	line coloring types	Flat
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0

Attribute	Purpose	Default Value
LineColorDirectionZ	z-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
Normal	normal vector of circles and discs, etc. in 3D	[0, 0, 1]

Attribute	Purpose	Default Value
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

An arc is a segment of a circle:

```
circle := plot::Circle2d(3, [0, 0]):
arc := plot::Arc2d(3, [0, 0], 0 .. PI/4, LineColor = RGB::Red,
    LineWidth = 1.5*unit::mm):
plot(circle, arc)
```

plot::Arc3d

```
delete circle, arc:
```

Example 2

The center of an arc may be given as the second argument to `plot::Arc2d`:

```
arc1 := plot::Arc2d(3, [1, 3], 0..PI/2, Closed = TRUE):  
arc2 := plot::Arc2d(3, [3, 1], -PI ..0, Closed = TRUE):  
plot(arc1, arc2)
```

The center is accessible as the attribute `Center` of the arc object. We change the center of the second arc:

```
arc2::Center := [1, 3]:  
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

Example 3

A filled arc is a segment of a circle, like a piece of pie:

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE))
```

plot::Arc3d

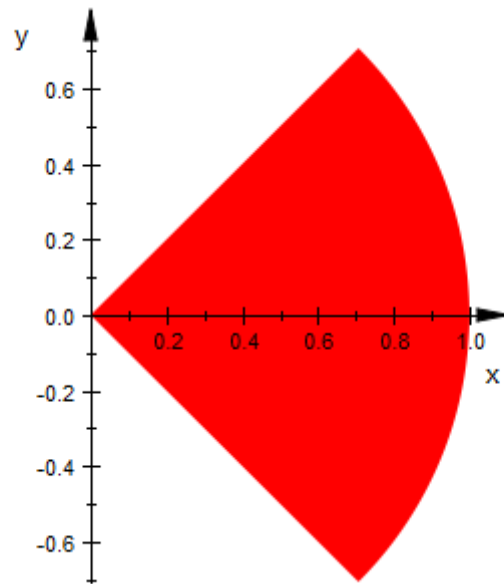

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE, Closed = TRUE))
```

```
plot(plot::Arc2d(1, -PI/4..PI/4, Filled = TRUE,  
            FillPattern = Solid, LinesVisible = FALSE),  
      AxesInFront = TRUE)
```

plot::Arc3d

Example 4

When giving a list of two radii, `plot::Arc2d` draws a segment of an ellipse with the corresponding semi-axes:

```
arc1 := plot::Arc2d([2, 1], 0 .. PI, Color = RGB::Blue):  
arc2 := plot::Arc2d([2, 1], -PI .. 0, Color = RGB::Red):  
plot(arc1, arc2)
```

```
delete arc1, arc2:
```

Example 5

To plot or animate segments of a tilted ellipse, use the attribute `Angle`:

```
arc:= [1, 1], [0, 0], PI/4..PI/2, Filled, Closed, FillPattern=So
plot(plot::Arc2d(arc, Angle=a+0,      a=0..2*PI, FillColor=RGB::
      plot::Arc2d(arc, Angle=a+1/2*PI, a=0..2*PI, FillColor=RGB::
      plot::Arc2d(arc, Angle=a+PI,     a=0..2*PI, FillColor=RGB::
      plot::Arc2d(arc, Angle=a+3/2*PI, a=0..2*PI, FillColor=RGB::
```

plot::Arc3d

delete arc:

Example 6

Further examples of animated 2D arcs:

```
plot(plot::Arc2d(1, a .. PI, a = 0..PI))
```

```
plot(plot::Arc2d([1 + a^2/2, 1 + a], -PI/2 .. PI/2, a = 0..4))
```

Example 7

We plot an animated 3D arc:

```
plot(plot::Arc3d(1, [0,0,0], [0,a,1-a], 0..3/2*PI, a = 0..1))
```

Example 8

We plot a colored 3D arcs:

```
plot(plot::Arc3d(1, [0,0,0], 0.1..2*PI-0.1, Filled,  
      LineColor=RGB::Yellow, LineColor2=RGB::Red, LineColorType =  
      FillColor=RGB::Yellow, FillColor2=RGB::Red, FillColorType =  
    ))
```

Parameters r

The radius of the circle. This must be a real numerical value or an arithmetical expression of the animation parameter a .

r is equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

r_1 , r_2

The semi-axes of an elliptical arc. They must be real numerical values or arithmetical expressions of the animation parameter a .

r_1 , r_2 are equivalent to the attributes `SemiAxisX`, `SemiAxisY`.

c_x , c_y , c_z

The center point. The coordinates c_x , c_y , c_z must be real numerical values or arithmetical expressions of the animation parameter a . If no center is specified, an arc centered at the origin is created.

c_x , c_y , c_z are equivalent to the attribute Center.

n_x , n_y , n_z

The normal vector. The coordinates n_x , n_y , n_z must be real numerical values or arithmetical expressions of the animation parameter a . If no normal vector is specified, the arc is created in the xy-plane.

n_x , n_y , n_z are equivalent to the attribute Normal.

..

The angle range in radians: Δ and δ must be real numerical values or arithmetical expressions of the animation parameter a . The default range is $0 \dots 2*PI$.

$\Delta \dots \delta$ is equivalent to the attribute AngleRange.

a

Animation parameter, specified as $a = a_{\min} \cdot a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

plot::Ellipse3d

plot::Arrow2d

Purpose 2D arrows

Syntax `plot::Arrow2d(<[x1, y1]>, [x2, y2], <a = amin .. amax>, options)`

Description `plot::Arrow2d([x1, y1], [x2, y2])` creates a 2D arrow from the point (x₁, y₁) to the point (x₂, y₂).

`plot::Arrow2d([x2, y2])` creates a 2D arrow from the point (0, 0) to the point (x₂, y₂).

The points defining an arrow can also be passed as vectors.

The appearance of arrows can be controlled by various attributes:

- `Color` sets the color.
- `LineWidth` and `LineStyle` set the width and the style (solid, dashed, dotted).
- `TipLength`, `TipAngle`, and `TipStyle` control the arrow tip.

Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Color</code>	the main color	<code>RGB::Blue</code>
<code>Frames</code>	the number of frames in an animation	50
<code>From</code>	starting point of arrows and lines	[0, 0]

Attribute	Purpose	Default Value
FromX	starting point of arrows and lines, x-coordinate	0
FromY	starting point of arrows and lines, y-coordinate	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

plot::Arrow2d

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
TipAngle	opening angle of arrow heads	$(2*PI) / 15$
TipStyle	presentation style of arrow heads	Filled
TipLength	length of arrow heads	4
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	

Attribute	Purpose	Default Value
To	end point of arrows and lines	[1, 0]
ToX	end point of arrows and lines, x-coordinate	1
ToY	end point of arrows and lines, y-coordinate	0
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

We create and plot some arrows:

```
plot(plot::Arrow2d([1, 1]), plot::Arrow2d([1, 3]),
      plot::Arrow2d([1, 1], [1, 3]))
```

plot::Arrow2d

Various attributes are available to control the presentation style of an arrow:

```
plot(plot::Arrow2d([1, 1], Color = RGB::Red,  
                  TipStyle = Open, TipLength = 10*unit::mm),  
      plot::Arrow2d([-1, 1], Color = RGB::Green,  
                  LineWidth = 0.8*unit::mm,  
                  TipStyle = Closed, TipAngle = PI/2),  
      plot::Arrow2d([0, -sqrt(2)], Color = RGB::Blue,  
                  LineStyle = Dashed),  
      Axes = None)
```

Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,  
                  TipStyle = Open, TipLength = 10*unit::mm),  
      plot::Arrow3d([-1, 1, 0], Color = RGB::Green,  
                  LineWidth = 0.8*unit::mm,  
                  TipStyle = Closed, TipAngle = PI/2),  
      plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue,  
                  LineStyle = Dashed),  
      CameraDirection = [0, -1, 1000])
```

plot::Arrow2d

We use `Tubular = TRUE`:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,  
  TipLength = 10*unit::mm),  
  plot::Arrow3d([-1, 1, 0], Color = RGB::Green,  
  TubeDiameter = 1.5*unit::mm,  
  TipAngle = PI/2),  
  plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue),  
  Tubular = TRUE, CameraDirection = [0, -1, 1000])
```

Example 2

We plot an arrow with fixed starting point and animated end point:

```
plot(plot::Circle2d(2, [1, 2]),  
      plot::Arrow2d([1, 2], [1 + 2*cos(a), 2 + 2*sin(a)],  
                    a = 0..2*PI))
```

Parameters

x_1, y_1

The coordinates of the starting point: real numerical values or arithmetical expressions of the animation parameter a . If no starting point is specified, an arrow starting at the origin is created.

x_1, y_1 are equivalent to the attributes FromX, FromY.

x_2, y_2

The coordinates of the end point: real numerical values or arithmetical expressions of the animation parameter a .

x_2, y_2 are equivalent to the attributes ToX, ToY.

a

Animation parameter, specified as $a = a_{\min} . . a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

Examples

Example 1

We create and plot some arrows:

```
plot(plot::Arrow2d([1, 1]), plot::Arrow2d([1, 3]),  
      plot::Arrow2d([1, 1], [1, 3]))
```

Various attributes are available to control the presentation style of an arrow:

```
plot(plot::Arrow2d([1, 1], Color = RGB::Red,
                  TipStyle = Open, TipLength = 10*unit::mm),
      plot::Arrow2d([-1, 1], Color = RGB::Green,
                  LineWidth = 0.8*unit::mm,
                  TipStyle = Closed, TipAngle = PI/2),
      plot::Arrow2d([0, -sqrt(2)], Color = RGB::Blue,
                  LineStyle = Dashed),
      Axes = None)
```

Here are corresponding arrows in 3D:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,
                  TipStyle = Open, TipLength = 10*unit::mm),
      plot::Arrow3d([-1, 1, 0], Color = RGB::Green,
```

plot::Arrow3d

```
LineWidth = 0.8*unit::mm,  
TipStyle = Closed, TipAngle = PI/2),  
plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue,  
LineStyle = Dashed),  
CameraDirection = [0, -1, 1000])
```

We use Tubular = TRUE:

```
plot(plot::Arrow3d([1, 1, 0], Color = RGB::Red,  
TipLength = 10*unit::mm),  
plot::Arrow3d([-1, 1, 0], Color = RGB::Green,  
TubeDiameter = 1.5*unit::mm,  
TipAngle = PI/2),  
plot::Arrow3d([0, -sqrt(2), 0], Color = RGB::Blue),  
Tubular = TRUE, CameraDirection = [0, -1, 1000])
```

Example 2

We plot an arrow with fixed starting point and animated end point:

```
plot(plot::Circle2d(2, [1, 2]),  
      plot::Arrow2d([1, 2], [1 + 2*cos(a), 2 + 2*sin(a)],  
                    a = 0..2*PI))
```

plot::Arrow3d

Parameters

x_1, y_1, z_1

The coordinates of the starting point: real numerical values or arithmetical expressions of the animation parameter a . If no starting point is specified, an arrow starting at the origin is created.

x_1, y_1, z_1 are equivalent to the attributes FromX, FromY, FromZ.

x_2, y_2, z_2

The coordinates of the end point: real numerical values or arithmetical expressions of the animation parameter a .

x_2, y_2, z_2 are equivalent to the attributes ToX, ToY, ToZ.

a

Animation parameter, specified as $a = a_{\min} \cdot a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

MuPAD Graphical Primitives

`plot::Arrow2d` | `plot::Line2d` | `plot::Line3d` |
`plot::VectorField2d`

plot::Bars2d

Purpose 2D bar chart

Syntax
`plot::Bars2d([[a1, a2,], [b1, b2,],], <a = amin .. amax>, options)`
`plot::Bars2d([a1, a2,], <a = amin .. amax>, options)`

Description `plot::Bars2d([[a1, a2, ...], [b1, b2, ...], ...])` generates a bar chart with bar heights a₁, b₁, ..., a₂, b₂, ...

`plot::Bars2d([a1, a2, ...])` creates a bar chart with bars of height a₁, a₂, ...

With `plot::Bars2d([[a1, a2, ...], [b1, b2, ...], ...])`, bars are plotted in the order a₁, b₁, ..., a gap, a₂, b₂, ... Cf. “Example 2” on page 23-160.

The horizontal positions and the widths of the bars may be controlled by the attributes `BarCenters` and `BarWidths`, respectively.

The attribute `GroupStyle` provides grouping options.

Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	FALSE
<code>BarStyle</code>	display style of bar plots	Boxes
<code>BarWidths</code>	widths of bars	[[1.0]]
<code>BarCenters</code>	position of bars	
<code>Color</code>	the main color	

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	Vertical
Filled	filled or transparent areas and surfaces	TRUE
FillPatterns	list of area fill types	[Solid]
Frames	the number of frames in an animation	50
GroupStyle	grouping options in 2D bar plots	MultipleBars
Legend	makes a legend entry	

plot::Bars2d

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
Shadows	display “shadows” for bar plots?	FALSE
TimeEnd	end time of the animation	10.0

Attribute	Purpose	Default Value
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

plot::Bars2d

Examples

Example 1

Given a single list of values, `plot::Bars2d` plots bars of the corresponding height, filled solidly in one color:

```
plot(plot::Bars2d([1, 2, 3, 4, 5]))
```

Example 2

When asked to plot a list of lists of values, `plot::Bars2d` will group the first entries of all lists, the second entries and so on, with a small gap between the groups:

```
plot(plot::Bars2d([[ 5, 10, 24, -3],  
                  [ 6,  5,  2, 18],  
                  [19, 45, 12, -10]]))
```

Example 3

The appearance of the plots can be controlled with a number of attributes. For example, `Colors` accepts a list of colors for the bars and `Shadows` switches on “shadows,” giving a slight impression of depth:

```
plot(plot::Bars2d([[ 5, 10, 24, -3],  
                  [ 6,  5,  2, 18],  
                  [19, 45, 12, -10]],  
      Colors = [RGB::Red, RGB::Green, RGB::Blue],  
      Shadows = TRUE))
```

plot::Bars2d

Using `DrawMode`, `plot::Bars2d` can be made to draw horizontal bars instead of vertical ones:

```
plot(plot::Bars2d([[ .5, 1.0, 2.4,  -.3],  
                  [ .6,  .5,  .2,  1.8],  
                  [1.9, 4.5, 1.2, -1.0]],  
      Colors = [RGB::Red,RGB::Green,RGB::Blue],  
      Shadows = TRUE, DrawMode = Horizontal))
```

BarStyle is used to plot points or lines instead of rectangles:

```
plot(plot::Bars2d([[ 5, 10, 24, -3],  
                  [ 6,  5,  2, 18],  
                  [19, 45, 12, -10]], BarStyle = Lines))
```

plot::Bars2d

Example 4

We demonstrate alternative grouping styles:

```
plot(plot::Bars2d([[ 5, 10, 15, 20],  
                  [ 6,  5,  4,  3],  
                  [10,  5,  3,  1]], GroupStyle = MultipleBars))
```

```
plot(plot::Bars2d([[ 5, 10, 15, 20],  
                  [ 6,  5,  4,  3],  
                  [10,  5,  3,  1]], GroupStyle = SingleBars))
```

plot::Bars2d

Example 5

To plot a single group of data with different colors, they must be placed in individual lists:

```
plot(plot::Bars2d([[binomial(15,i)] $ i = 0..15],  
                  Colors = [[1-j/15, j/15, 0.9] $ j = 0..15]),  
      XAxisVisible)
```

Example 6

plot::Bars2d accepts input in form of lists (as above), as a matrix, or as a one- or two-dimensional array:

```
L := [ [2, 1, 2, 4, 5],
        [1, 2, 3, 2, 1],
        [2, -1, -3, 1, 2],
        [5, 4, 3, 2, 1],
        [2, 1, 2, 1, 2]]:
M := matrix(L):
A :=array(1..5, 1..5,
          (1,1) = 2, (1,2) = 1, (1,3) = 2, (1,4) = 4, (1,5) = 5,
          (2,1) = 1, (2,2) = 2, (2,3) = 3, (2,4) = 2, (2,5) = 1,
          (3,1) = 2, (3,2) = 1, (3,3) = -3, (3,4) = 1, (3,5) = 2,
          (4,1) = 5, (4,2) = 4, (4,3) = 3, (4,4) = 2, (4,5) = 1,
          (5,1) = 2, (5,2) = 1, (5,3) = 2, (5,4) = 1, (5,5) = 2)
plot(plot::Bars2d(L))
```

plot::Bars2d

```
plot(plot::Bars2d(M))
```

```
plot(plot::Bars2d(A))
```

plot::Bars2d

Example 7

Here is a real life example of a bar plot taken from a German magazine. It visualizes data related to waste management. We reproduce the plot via MuPAD. The main ingredient is a bar plot generated via `plot::Bars2d` with the option `GroupStyle = SingleBars`. Generating the annotations is somewhat tricky:

```
data := [[25 , 24.6, 30.8 ],
         [ 2 ,  2.8, 11  ],
         [ 7.1,  3.3, 4.05]]:

sw := 1.5:
bw := 2.0:
n := nops(data):
w := sw + bw:
myticks := [(i-1)* w + sw + bw/2 $ i = 1..n]:
```

```

m := nops(data[1]):

datalabels := ["Prognos", "LAGA", "BDE"]:

// cumulative data for the groups
datasums := _concat(datalabels[i].": ".
                    expr2text(_plus(data[j][i]$j=1..m)).
                    " megatons " $i=1..n):

// generate a list of text objects containing the data values
// and place them in the centers of the bars:
datatext := []:
for i from 1 to n do
  h := 0;
  for j from 1 to m do
    d := data[j][i];
    datatext := datatext, plot::Text2d(expr2text(d),
                                       [myticks[i], h + d/2],
                                       TextFont = [8, RGB::White],
                                       VerticalAlignment = Center,
                                       HorizontalAlignment = Center)

    h := h + d
  end
end
end:

```

Here is the bar plot with the annotations. Many scene options are used to fine tune the graphics:

```

S1:=plot::Scene2d(
  plot::Bars2d(data,
    Colors=[RGB::LimeGreen, RGB::Blue, RGB::Red],
    GroupStyle = SingleBars,
    BarCenters = [myticks[i] $ i=1..n],
    BarWidths = [[bw]],
    DrawMode = Vertical),

  // scene options:

```

```
ViewingBox = [0 .. w*n + sw, 0 .. 50],

// options for the grid
XGridVisible = FALSE,
YGridVisible = TRUE,
XSubgridVisible = FALSE,
YSubgridVisible = TRUE,
GridLineColor = RGB::DarkGrey,
SubgridLineColor = RGB::DarkGrey,

// options for the axes
Axes = Boxed,
AxesTips = FALSE,
AxesInFront = TRUE,
AxesTitleFont = ["Arial", 12, Bold],
XAxisVisible = TRUE,
YAxisTitleOrientation = Vertical,
YAxisTitleAlignment = Center,
YAxisTitle = "megatons",
XAxisTitle = "",

// options for the ticks along the axes
TicksLabelFont = ["Arial", 10],
XTicksVisible = FALSE,
XTicksNumber = None,
XTicksAt = [myticks[i] = datalabels[i] $ i=1..n],

// layout
RightMargin = 50,

// annotation
datatext,

// header and footer
Header = "Capacities in megatons",
HeaderFont = ["Arial", 12, Bold],
```

```

Footer = "\n\nAmount of waste taken into account:\n".datasu
FooterFont = ["Arial", 8],
FooterAlignment = Left,

// use a yellowish background
BackgroundColor = [0.886275, 0.870588, 0.294118]
):

plot(S1)

```

Next, we build a legend made of colored rectangles and text objects:

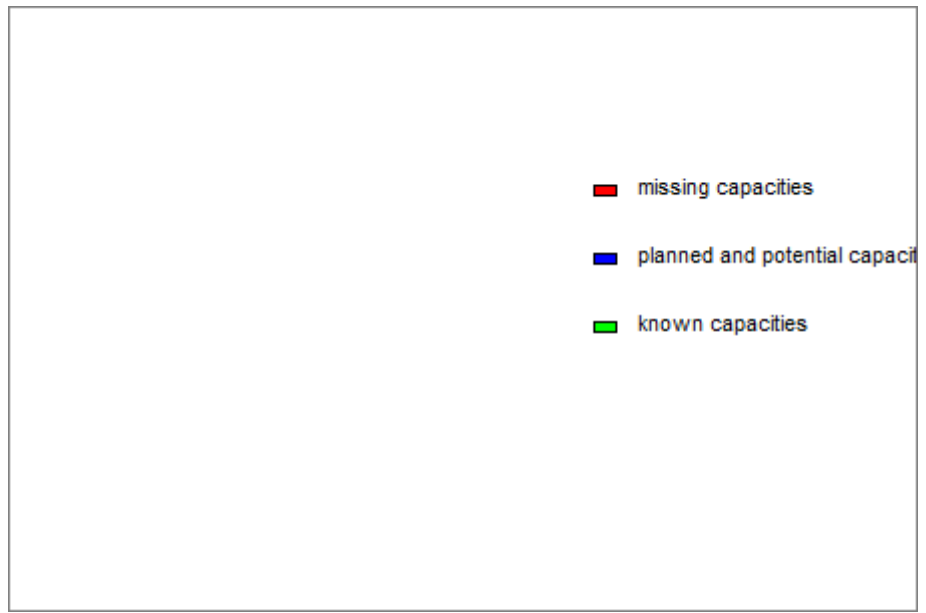

```

S2 := plot::Scene2d(
  ViewingBox = [0..20, 0..50],
  Axes = None,
  plot::Rectangle(13..13.5, 35..36,
    Filled = TRUE,

```

plot::Bars2d

```
        FillPattern = Solid,
        FillColor = RGB::Red,
        LineColor = RGB::Black),
plot::Text2d("missing capacities", [14, 35],
            HorizontalAlignment = Left,
            TextFont = ["Arial", 8]),
plot::Rectangle(13..13.5, 29..30,
               Filled = TRUE,
               FillPattern = Solid,
               FillColor = RGB::Blue,
               LineColor = RGB::Black),
plot::Text2d("planned and potential capacities", [14, 29],
            HorizontalAlignment = Left, TextFont = ["Arial", 8])
plot::Rectangle(13..13.5, 23..24,
               Filled = TRUE,
               FillPattern = Solid,
               FillColor = RGB::Green,
               LineColor = RGB::Black),
plot::Text2d("known capacities", [14, 23],
            HorizontalAlignment = Left,
            TextFont = ["Arial", 8])
):
plot(S2, BorderWidth = 0.2)
```

The final picture consists of the bar plot S1 and the legend S2. We just put S2 on top of S1, making the background of S2 transparent:

```
S1::Width := 1: S1::Height := 1:  
S2::Width := 1: S2::Height := 1:  
S1::Bottom := 0: S1::Left := 0:  
S2::Bottom := 0: S2::Left := 0:  
S1::BackgroundTransparent := FALSE:  
S2::BackgroundTransparent := TRUE:  
  
plot(S1, S2, Layout = Relative)
```

plot::Bars2d

`delete data, datalabels, datasums, datatext, myticks, sw, bw, n, m, w, i, h, j, d, S1, S2:`

Parameters

$a_1, a_2, \dots, b_1, b_2, \dots, \dots$

Real-valued expressions, possibly in the animation parameter.

$a_1, a_2, \dots, b_1, b_2, \dots, \dots$ is equivalent to the attribute Data.

a

Animation parameter, specified as $a = a_{\min} \cdot a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

[plot::Bars3d](#) | [plot::Histogram2d](#) | [plot::Scatterplot](#)

plot::Bars3d

Purpose

3D bar chart of matrix data

Syntax

```
plot::Bars3d(A, <x = xmin .. xmax, y = ymin .. ymax>,
<a = amin .. amax>, options)
plot::Bars3d(L, <x = xmin .. xmax, y = ymin .. ymax>,
<a = amin .. amax>, options)
```

Description

`plot::Bars3d(A)` generates a 3D bar chart with bar heights given by the entries of the matrix `A`.

The rows of the matrix are plotted along the x coordinate, the columns along the y coordinate.

Different rows may be regarded as different classes of data. Each row has a different color determined by the attribute `Colors = [c1, c2, ...]` with RGB or RGBa colors c_1, c_2 etc.

The simplest way to obtain a uniform coloring of all rows with the color `c` is to specify the attribute `Color = c`.

Arrays/matrices do not need to be indexed from 1. E.g.,

```
A = array( `i_{min}` .. `i_{max}`, `j_{min}` ..
`j_{max}`, [..data..])
```

yields a bar chart with $i_{\max} - i_{\min} + 1$ rows and $j_{\max} - j_{\min} + 1$ columns, stretching from x_{\min} to x_{\max} in x direction and from y_{\min} to y_{\max} in y direction.

If no plot range ``x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`` is specified, $x_{\min} = j_{\min} - 1$, $x_{\max} = j_{\max}$, $y_{\min} = i_{\min} - 1$, $y_{\max} = i_{\max}$ is used.

When the values are specified by a list of lists `L` and no plot range ``x_{min}` .. `x_{max}`, `y_{min}` .. `y_{max}`` is specified, $x_{\min} = 0$, $x_{\max} = m$, $y_{\min} = 0$, $y_{\max} = n$ is used, where n is the length of `L` and m is the (common) length of the sublists in `L`. All sublists (“rows”) must have the same length.

The attribute `BarStyle` allows to switch the style of the bars between `Boxes` (bars), `Lines` (vertical lines), `LinesPoints` (vertical lines and points), and `Points`(points only). See “Example 1” on page 23-183.

The attribute `Gap = [gx, gy]` or, equivalently, `XGap = gx`, `YGap = gy` allows to introduce gaps between adjacent bars. The values `gx`, `gy` may be real numerical values between 0 and 1 or expressions of the animation parameter `a`. These values set the fraction of the space reserved for a bar that is not filled by the bar.

With `gx = 0`, `gy = 0`, there are no gaps. With `gx = 0.5`, `gy = 0.5`, the gaps between adjacent bars are of the same size as the bars. With `gx = 1`, `gy = 1`, there bars become lines.

Values of `gx`, `gy` larger than 1 are treated like 1, negative values like 0.

The `Gap` attribute has an effect only for `BarStyle = Boxes`.

The attribute `Ground = z0` determines the `z` value of the lower or upper face of the bars. Matrix values `m > z0` are displayed as bars stretching in `z` direction from the lower face `z0` to the upper face `m`. Matrix values `m < z0` are displayed as bars stretching in `z` direction from the upper face `z0` down to the lower face `m`.

The parameter `z0` has to be a numerical real value or an expression of the animation parameter `a`.

If the attribute `Ground = z0` is not specified, the default value `z0 = 0` is used.

Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>BarStyle</code>	display style of bar plots	Boxes
<code>Color</code>	the main color	

plot::Bars3d

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson, RGB::Aqua, RGB::Lavender, RGB::SeaGreen, RGB::AureolineYellow, RGB::Banana, RGB::Beige, RGB::YellowGreen, RGB::Wheat, RGB::IndianRed, RGB::Black]
Data	the (statistical) data to plot	
Filled	filled or transparent areas and surfaces	TRUE
Frames	the number of frames in an animation	50
Gap	gaps between the bars of a bar chart	[0, 0]
Ground	base value	0
Legend	makes a legend entry	
LegendText	short explanatory text for legend	

Attribute	Purpose	Default Value
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
PointSize	the size of points	1.5
PointStyle	the presentation style of points	FilledCircles
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	

plot::Bars3d

Attribute	Purpose	Default Value
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE
XGap	gaps in x direction between the bars of a bar chart	0

Attribute	Purpose	Default Value
XMax	final value of parameter “x”	
XMin	initial value of parameter “x”	
XName	name of parameter “x”	
XRange	range of parameter “x”	
YGap	gaps in y direction between the bars of a bar chart	0
YMax	final value of parameter “y”	
YMin	initial value of parameter “y”	
YName	name of parameter “y”	
YRange	range of parameter “y”	

Examples

Example 1

We create some random matrix data and plot them as a bar chart:

```
A := matrix::random(5, 10, frandom) :
plot(plot::Bars3d(A, Gap = [0.4, 0.7]))
```

plot::Bars3d

We create bar charts of the data with different `BarStyle` options:

```
plot(plot::Scene3d(plot::Bars3d(A, BarStyle = Boxes)),  
      plot::Scene3d(plot::Bars3d(A, BarStyle = Lines)),  
      plot::Scene3d(plot::Bars3d(A, BarStyle = Points)),  
      plot::Scene3d(plot::Bars3d(A, BarStyle = LinesPoints)),  
      PointSize = 2.0*unit::mm, LineWidth = 0.5*unit::mm  
):
```

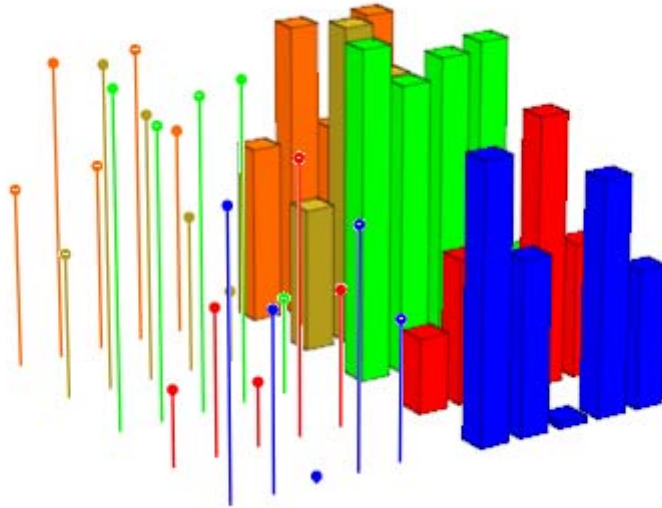

delete A:

Example 2

We demonstrate the positioning of bar charts by specifying ranges for the x and the y coordinate. The following two bar charts are plotted in one scene. They are placed side by side via suitable x ranges:

```
A := matrix::random(5, 5, frandom):
plot(plot::Bars3d(A, x = 0 .. 0.9, y = 0 .. 1,
  BarStyle = LinesPoints),
  plot::Bars3d(A, x = 1.1 .. 2, y = 0 .. 1,
  Gap = [0.3, 0.7])):
```

plot::Bars3d

delete A:

Example 3

We demonstrate the attributes Ground and Color:

```
A := matrix::random(5, 10, frandom):  
plot(plot::Scene3d(plot::Bars3d(A, Ground = 0,  
                                Color = RGB::Grey)),  
      plot::Scene3d(plot::Bars3d(A, Ground = 0.5,  
                                Color = RGB::Grey)),  
      Layout = Horizontal):
```

In the next call, the ground level is animated. Note that in animations one must specify ranges for the x and y coordinates. We include a transparent plane visualizing the ground level:

```
plot(plot::Bars3d(A, x = 0 .. 1, y = 0 .. 1, a = 0 .. PI,  
                Color = RGB::Grey, Gap = [0.5, 0.5],  
                Ground = sin(a)),  
      plot::Surface([x, y, sin(a) + 0.001],  
                  x = 0 .. 1, y = 0 .. 1, a = 0 .. PI,  
                  Mesh = [2, 2], Color = RGB::Blue.[0.5]))):
```

delete A:

Parameters **A**

An array of domain type `DOM_ARRAY` or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) containing real numerical values or expressions of the animation parameter a . Rows/columns of the array, respectively matrix, correspond to rows/columns of the bar chart.

A is equivalent to the attribute `Data`.

L

A list of lists of real numerical values or expressions of the animation parameter a . Each sublist of L represents a row of the bar chart.

L is equivalent to the attribute `Data`.

x

Name of the horizontal variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in x direction.

x is equivalent to the attribute XName.

 x_{\min} .. x_{\max}

The range of the horizontal variable: x_{\min} , x_{\max} must be numerical real value or expressions of the animation parameter a .

x_{\min} .. x_{\max} is equivalent to the attribute XRange.

y

Name of the vertical variable: an identifier or an indexed identifier. It is used as the title of the coordinate axis in y direction.

y is equivalent to the attribute YName.

 y_{\min} .. y_{\max}

The range of the vertical variable: y_{\min} , y_{\max} must be numerical real value or expressions of the animation parameter a .

y_{\min} .. y_{\max} is equivalent to the attribute YRange.

a

Animation parameter, specified as $a = a_{\min} \cdot a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

plot::Bars3d

MuPAD
Graphical
Primitives

`plot::Bars2d` | `plot::Histogram2d` | `plot::Matrixplot`

Purpose Boxes in 3D

Syntax `plot::Box(xmin .. xmax, ymin .. ymax, zmin .. zmax, <a = amin .. amax>, options)`
`plot::Box([xmin, ymin, zmin], [xmax, ymax, zmax], <a = amin .. amax>, options)`

Description `plot::Box(`x_{min}`..`x_{max}``, `y_{min}`..`y_{max}``, `z_{min}`..`z_{max}``)` creates the 3D box

$$\{(x \ y \ z) \mid x_{m \min} \leq x \leq x_{m \max}, y_{m \min} \leq y \leq y_{m \max}, z_{m \min} \leq z \leq z_{m \max}\}$$

`plot::Box([xmin, ymin, zmin], [xmax, ymax, zmax])` produces the same box.

`plot::Box` creates 3D boxes with edges parallel to the coordinate axes. Using `plot::Rotate3d` or `plot::Transform3d` one can create boxes and parallelepipeds with arbitrary orientation. Cf. examples “Example 3” on page 23-196 and “Example 4” on page 23-199.

Attributes

Attribute	Purpose	Default Value
AffectViewingBox	influence of objects on the ViewingBox of a scene	TRUE
Color	the main color	RGB::LightBlue
Filled	filled or transparent areas and surfaces	TRUE
FillColor	color of areas and surfaces	RGB::LightBlue
Frames	the number of frames in an animation	50
Legend	makes a legend entry	

Attribute	Purpose	Default Value
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Black.[0.25]
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	0
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	

Attribute	Purpose	Default Value
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
TitlePositionZ	position of object titles, z component

YMax	final value of parameter "y"	1
YMin	initial value of parameter "y"	-1
YRange	range of parameter "y"	-1 .. 1
ZMax	final value of parameter "z"	1
ZMin	initial value of parameter "z"	-1
ZRange	range of parameter "z"	-1 .. 1

Examples

Example 1

We draw a box consisting of its edges and a filled box:

```
plot(plot::Box(-3..-1, 0..2, 0..1, Filled = FALSE,  
             LineColor = RGB::Black),
```

```
plot::Box(1..3, 0..2, 0..1, Filled = TRUE,  
          FillColor = RGB::Red),  
Axes = None, Scaling = Constrained)
```

Example 2

The borders of a box can be animated:

```
plot(plot::Box([1, 1, 1], [2, 2, 2 + sin(r)], r = 0..2*PI)):
```

Example 3

We want to display a cube “standing” on one of its corners. First, we define the cube:

```
b0 := plot::Box(0..1, 0..1, 0..1)
```

```
plot::Box(0..1, 0..1, 0..1)
```

Now, rotating the cube to stand on a corner is equivalent to first rotating around the x-axis by 45 degrees, then rotating around the y-axis:

```
b1 := plot::Rotate3d(b0, Axis = [1, 0, 0], Angle = -PI/4):  
plot(b1, Scaling = Constrained)
```

```
b2 := plot::Rotate3d(b1, Axis = [0, 1, 0], Angle = 7*PI/36):  
plot(b2, Scaling = Constrained)
```

plot::Box

Finally, we let it rotate around the z -axis:

```
plot(plot::Rotate3d(b2, Axis = [0, 0, 1], Angle = a,  
                  a = 0..2*PI/3),  
      Scaling = Constrained)
```

delete b0, b1, b2:

Example 4

A parallelepiped can be obtained from a `plot::Box` by a linear transformation:

```
plot(plot::Transform3d([0, 0, 0], [1, 1, 0,
                                1, 1, 3,
                                0, 3, 1],
                      plot::Box(0..1, 0..1, 0..1)),
      Scaling = Constrained,
      CameraDirection = [-27, -12, 22])
```

Parameters

x_{min} , y_{min} , z_{min}

The lower borders: numerical real values or arithmetical expressions of the animation parameter a .

x_{min} , y_{min} , z_{min} are equivalent to the attributes XMin, YMin, ZMin.

x_{max} , y_{max} , z_{max}

The upper borders: numerical real values or arithmetical expressions of the animation parameter a .

x_{max} , y_{max} , z_{max} are equivalent to the attributes XMax, YMax, ZMax.

a

Animation parameter, specified as $a = a_{min} \cdot a_{max}$, where a_{min} is the initial parameter value, and a_{max} is the final parameter value.

plot::Boxplot

Purpose Statistical box plots

Syntax

```
plot::Boxplot(L1, , <a = amin .. amax>, options)
plot::Boxplot([L1, ], <a = amin .. amax>, options)
plot::Boxplot(A, <a = amin .. amax>, options)
plot::Boxplot(s, <c1, >, <a = amin .. amax>, options)
plot::Boxplot(s, <[c1, ]>, <a = amin .. amax>, options)
```

Description plot::Boxplot(data) creates a box plot of the given data.

plot::Boxplot creates a box plot of discrete data samples. Box plots reduce data samples to a number of descriptive parameters and are a useful means of comparing statistical data.

In particular, each data sample is represented as one box. A typical box consists of the following subparts:

- A “central box” representing the central 50% of the data. Its lower and upper boundary lines are at the 25%/75% quantile of the data. A central line indicates the median of the data.
- Two vertical lines extending from the central box indicating the remaining data outside the central box that are not regarded as outliers. These lines extend maximally to $\frac{3}{2}$ times the height of the central box but not past the range of the data.
- Outliers: these are points indicating the remaining data.

plot::Boxplot

With the special attribute `Notched = TRUE`, the sides of the boxes can be notched, thus providing additional information on the data sample. The horizontal width of the notches may be set by the attribute `NotchWidth`.

The special attributes `BoxCenters` and `BoxWidths` allow to center the boxes at arbitrary positions along the horizontal axis and to set the horizontal width of the boxes, respectively.

The special attribute `Averaged` determines whether the quantile values are computed with or without the option `Averaged` (cf. `stats::empiricalQuantile`).

Specifying `DrawMode = Horizontal`, the boxes are rotated by 90 degrees.

The attribute `Colors` allows to specify the color of each box in a box plot. A common color for all boxes may be specified via `Color`.

Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	FALSE
<code>Averaged</code>	mode for computing quantile lines in box plots	TRUE
<code>BoxWidths</code>	widths of boxes in a box plot	[0.8]
<code>BoxCenters</code>	position of boxes in a box plot	[1]
<code>Color</code>	the main color	

Attribute	Purpose	Default Value
Colors	list of colors to use	[RGB::Blue, RGB::Red, RGB::Green, RGB::MuPADGold, RGB::Orange, RGB::Cyan, RGB::Magenta, RGB::LimeGreen, RGB::CadmiumYellowLight, RGB::AlizarinCrimson]
Data	the (statistical) data to plot	
DrawMode	orientation of boxes and bars	Vertical
Filled	filled or transparent areas and surfaces	TRUE
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE

plot::Boxplot

Attribute	Purpose	Default Value
Name	the name of a plot object (for browser and legend)	
Notched	notched boxes in box plots	FALSE
NotchWidth	width of notches in box plots	0.2
ParameterEnd	end value of the animation parameter	
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center

Attribute	Purpose	Default Value
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

Just to show basic usage of `plot::Boxplot`, we plot some data samples chosen arbitrarily:

```
data1 := [5, 10, 24, -4, 13]:
data2 := [7, 9, -1, 4, 10, 8, 12, 10, 15]:
b := plot::Boxplot(data1, data2):
plot(b)
```

plot::Boxplot

We can modify the appearance of the box plot in various ways:

```
b::Notched := TRUE:  
b::Colors := [RGB::Green, RGB::Black]:  
b::BoxCenters := [2, 3]:  
b::FillPattern := XCrossedLines:  
  
plot(b)
```

delete b:

Example 2

It is possible to shift the whole plot in x -direction by providing a center for the first box via `BoxCenters`:

```
A := matrix([[ 5,  6, 19],
             [10,  5, 45],
             [24,  2, 12],
             [-3, 18, -10],
             [-4,  0, - 4]]):
```

```
plot(plot::Boxplot(A, BoxCenters = [2], Notched = TRUE,
                  FillPattern = Solid))
```

plot::Boxplot

delete A:

Example 3

The primary use of `plot::Boxplot` is comparing data sets. We shall do this for data produced by the following random number generators:

```
f := stats::normalRandom(1, 0.2):  
g := stats::uniformRandom(0, 2):
```

Now, we create small samples and compare their boxes:

```
data1 := [f() $ k = 1..100]: // Red  
data2 := [f() $ k = 1..100]: // Green  
data3 := [g() $ k = 1..100]: // Blue  
plot(plot::Boxplot(data1, data2, data1, data3, data2, data3,  
  Colors = [RGB::Red, RGB::Green, RGB::Red, RGB::Blue,  
           RGB::Green, RGB::Blue],
```

```
BoxCenters = [1, 2, 4, 5, 7, 8], Notched = TRUE))
```

Comparing the central boxes, the blue data differ significantly from the red and the green data. The red and green boxes, however, are quite similar – as they should, given that the red and green data were produced by the same random generator `f`.

```
delete f, g, data1, data2, data3:
```

Example 4

For symmetric input data, the images generated by `plot::Boxplot` are symmetric, too:

```
plot(plot::Boxplot([$0..10], [5+5*sin(PI*n/20) $ n=-10..10], Not
```

plot::Boxplot

Example 5

By default, the quantile lines of the boxes are computed with the option `Averaged` (see `stats::empiricalQuantile` for details). When using `Averaged = FALSE`, the quantiles are computed without this option:

```
r := random(0..10):  
SEED := 123:  
data := [r() $ k = 1..250]:  
plot(plot::Boxplot(data, Averaged = TRUE, BoxCenters = 0.5, Color =  
  plot::Boxplot(data, Averaged = FALSE, BoxCenters = 1.5, Color  
  )):
```

```
delete r, SEED, data:
```

Example 6

Box plots can be animated. We create two data samples and fuse them to a symbolic superposition:

```
f1 := stats::normalRandom(0, 1):
f2 := stats::normalRandom(4, 8):
data0 := sort([f1() $ k = 1..100]):
data1 := sort([f2() $ k = 1..100]):
data01 := [(1 - a)*data0[i] + a*data1[i] $ i = 1..100]:
```

The box associated with the data sample `data01` changes from the box associated with `data0` to the box associated with `data1` as the animation parameter increases from $a = 0$ to $a = 1$:

```
plot(plot::Boxplot(data0, data01, data1, a = 0..1))
```

plot::Boxplot

`delete f1, f2, data0, data1, data01:`

Parameters

L_1, \dots

Data samples: lists of numerical real values or arithmetical expressions of the animation parameter a .

L_1, \dots is equivalent to the attribute `Data`.

A

An array of domain type `DOM_ARRAY` or a matrix of category `Cat::Matrix` (e.g., of type `matrix` or `densematrix`) providing numerical real values or arithmetical expressions of the animation parameter a . The columns are regarded as separate data samples. Also a 1-dimensional array, regarded as a single data sample, is accepted.

A is equivalent to the attribute `Data`.

s

A data collection of domain type `stats::sample`. The columns in `s` are regarded as separate data samples.

`s` is equivalent to the attribute `Data`.

c₁, ...

Column indices into `s`: positive integers. These indices, if given, indicate that only the specified columns in `s` should be used as data samples. If no column indices are specified, *all* columns in `s` are used as data samples.

a

Animation parameter, specified as $a = a_{\min} \cdot a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

`plot::Scatterplot`

plot::Circle2d

Purpose 2D circles

Syntax `plot::Circle2d(r, <[x, y]>, <a = amin .. amax>, options)`

Description `plot::Circle2d(r, [x, y])` creates a 2D circle with radius r and center (x, y) .

Per default circles are drawn as lines both in 2D and 3D. The attribute `LineColor` or, equivalently, `Color` serves for setting the line color.

Use the attribute `Filled = TRUE` to create filled circles in 2D.

In 2D, one can choose between hatched and solidly filled circles via the attribute `FillPattern`. The fill color is determined by `FillColor`. The circumferential line can be “switched off” via `LinesVisible = FALSE`.

Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	TRUE
<code>AntiAliased</code>	antialiased lines and points?	TRUE
<code>Center</code>	center of objects, rotation center	[0, 0]
<code>CenterX</code>	center of objects, rotation center, x-component	0
<code>CenterY</code>	center of objects, rotation center, y-component	0
<code>Color</code>	the main color	RGB::Blue
<code>Filled</code>	filled or transparent areas and surfaces	FALSE

Attribute	Purpose	Default Value
FillColor	color of areas and surfaces	RGB::Red
FillPattern	type of area filling	DiagonalLines
Frames	the number of frames in an animation	50
Legend	makes a legend entry	
LegendText	short explanatory text for legend	
LegendEntry	add this object to the legend?	FALSE
LineColor	color of lines	RGB::Blue
LineWidth	width of lines	0.35
LineStyle	solid, dashed or dotted lines?	Solid
LinesVisible	visibility of lines	TRUE
LineColorDirection	the direction of color transitions on lines	[0, 1]
LineColorDirectionX	x-component of the direction of color transitions on lines	0
LineColorDirectionY	y-component of the direction of color transitions on lines	1
Name	the name of a plot object (for browser and legend)	
ParameterEnd	end value of the animation parameter	

plot::Circle2d

Attribute	Purpose	Default Value
ParameterName	name of the animation parameter	
ParameterBegin	initial value of the animation parameter	
ParameterRange	range of the animation parameter	
Radius	radius of circles, spheres etc.	1
TimeEnd	end time of the animation	10.0
TimeBegin	start time of the animation	0.0
TimeRange	the real time span of an animation	0.0 .. 10.0
Title	object title	
TitleFont	font of object titles	[" sans-serif ", 11]
TitlePosition	position of object titles	
TitleAlignment	horizontal alignment of titles w.r.t. their coordinates	Center
TitlePositionX	position of object titles, x component	
TitlePositionY	position of object titles, y component	
Visible	visibility	TRUE
VisibleAfter	object visible after this time value	

Attribute	Purpose	Default Value
VisibleBefore	object visible until this time value	
VisibleFromTo	object visible during this time range	
VisibleAfterEnd	object visible after its animation time ended?	TRUE
VisibleBeforeBegin	object visible before its animation time starts?	TRUE

Examples

Example 1

Circles centered at the origin are created if only a radius is specified:

```
plot(plot::Circle2d(3)):
```

plot::Circle2d

A center may be given as a list of coordinates:

```
plot(plot::Circle2d(1, [1, 1]),  
      plot::Circle2d(2, [1, 2]),  
      plot::Circle2d(3, [1, 3])):
```

Example 2

Radius and center of a circle can be animated. We plot an animated circle with a changing radius and a center moving on a spiral:

```
plot(plot::Curve2d([a*cos(2*a), a*sin(2*a)], a = 0..PI),  
      plot::Point2d([a*cos(2*a), a*sin(2*a)], a = 0..PI,  
                    PointSize = 2*unit:mm),  
      plot::Circle2d(0.2 + sin(a), [a*cos(2*a), a*sin(2*a)],  
                    a = 0..PI))
```

Example 3

In three dimensions, a circle requires a normal vector. We animate this vector:

```
normal_ := plot::Arrow3d(  
    [0, 0, 0],  
    [sin(2*a), sin(a)*cos(2*a), cos(a)*cos(2*a)],  
    a = 0..2*PI):  
circle := plot::Circle3d(1, [0, 0, 0], normal_::To,  
    a = 0..2*PI, Filled):  
plot(normal_, circle)
```

Parameters **r**

The radius: a real numerical value or an arithmetical expression in the animation parameter a .

r is equivalent to the attribute Radius.

x, y

The center. The coordinates x, y must be real numerical values or arithmetical expressions in the animation parameter a . If no center is specified, a circle centered at the origin is created.

x, y are equivalent to the attributes CenterX, CenterY.

a

Animation parameter, specified as $a = a_{\min}..a_{\max}$, where a_{\min} is the initial parameter value, and a_{\max} is the final parameter value.

MuPAD Functions

`plot` | `plot::copy`

MuPAD Graphical Primitives

`plot::Circle3d` | `plot::Cone` | `plot::Sphere`

Purpose 3D circles

Syntax `plot::Circle3d(r, <[x, y, z]>, <a = amin .. amax>, options)`
`plot::Circle3d(r, [x, y, z], [nx, ny, nz], <a = amin .. amax>, options)`

Description `plot::Circle3d(r, [x, y, z], [nx, ny, nz])` creates a 3D circle with radius r , center (x, y, z) , and normal vector (n_x, n_y, n_z) .

Per default circles are drawn as lines both in 2D and 3D. The attribute `LineColor` or, equivalently, `Color` serves for setting the line color.

Use the attribute `Filled = TRUE` to create circular discs in 3D.

Attributes

Attribute	Purpose	Default Value
<code>AffectViewingBox</code>	influence of objects on the <code>ViewingBox</code> of a scene	<code>TRUE</code>
<code>Center</code>	center of objects, rotation center	<code>[0, 0, 0]</code>
