You can create a cross-validated model directly from the data, instead of creating a model followed by a cross-validated model. To do so, include

one of these options in `fitcknn`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

# ClassificationSVM.crossval

---

**Purpose** Cross-validated support vector machine classifier

**Syntax** `CVSVMModel = crossval(SVMModel)`  
`CVSVMModel = crossval(SVMModel,Name,Value)`

**Description** `CVSVMModel = crossval(SVMModel)` returns a partitioned support vector machine classifier (`CVSVMModel`) from a trained SVM classifier (`SVMModel`).

By default, `crossval` uses 10-fold cross validation on the training data to create `CVSVMModel`.

`CVSVMModel = crossval(SVMModel,Name,Value)` returns a partitioned SVM classifier with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify a holdout sample proportion.

**Tips** Assess the predictive performance of `SVMModel` on cross-validated data using the “kfold” methods and properties of `CVSVMModel`, such as `kfoldLoss`.

**Input Arguments** **SVMModel - SVM classifier**  
ClassificationSVM classifier

SVM classifier that was trained using `fitcsvm`, specified as a ClassificationSVM classifier.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **'CVPartition' - Cross-validation partition**

`cvpartition partition | []` (default)

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition as created by `cvpartition`. You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

`crossval` splits the data into subsets using `cvpartition`.

## **'Holdout' - Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Holdout',0.1

### **Data Types**

double | single

## **'KFold' - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

### **Data Types**

double

## **'Leaveout' - Leave-one-out cross-validation flag**

'off' (default) | 'on'

# ClassificationSVM.crossval

---

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'Kfold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

## Data Types

char

## Output Arguments

### CVSVMModel - Cross-validated SVM classifier

Cross-validated SVM classifier, returned as a ClassificationPartitionedModel classifier.

## Examples

### Cross Validate an SVM Classifier Using crossval

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. It is good practice to standardize the predictors and define the class order.

```
SVModel = fitsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

SVModel is a trained ClassificationSVM classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier using 10-fold cross validation.

```
CVSVMModel = crossval(SVModel)
FirstModel = CVSVMModel.Trained{1}
```

```
CVSVMModel =
```

```
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x34 cell}
  CategoricalPredictors: []
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

FirstModel =

```
classreg.learning.classif.CompactClassificationSVM
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  Alpha: [78x1 double]
  Bias: -0.2209
  KernelParameters: [1x1 struct]
  Mu: [1x34 double]
  Sigma: [1x34 double]
  SupportVectors: [78x34 double]
  SupportVectorLabels: [78x1 double]
```

CVSVMModel is a ClassificationPartitionedModel cross-validated classifier. The software:

- 1** Randomly partitions the data into 10, equally sized sets.
- 2** Trains an SVM classifier on nine of the sets.

# ClassificationSVM.crossval

---

**3** Repeats steps 1 and 2  $k = 10$  times. It leaves out one of the partitions each time, and trains on the other nine partitions.

**4** Combines generalization statistics for each fold.

`FirstModel` is the first of the 10 trained classifiers. It is a `CompactClassificationSVM` classifier.

You can estimate the generalization error by passing `CVSVMModel` to `kfoldLoss`.

## Specify a Holdout-Sample Proportion for SVM Cross Validation

By default, `crossval` uses 10-fold cross validation to cross validate an SVM classifier. You have several other options, such as specifying a different number of folds or holdout sample proportion. This example shows how to specify a holdout-sample proportion.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. It is good practice to standardize the predictors and define the class order.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMModel` is a trained `ClassificationSVM` classifier. 'b' is the negative class and 'g' is the positive class.

Cross validate the classifier by specifying a 15% holdout sample.

```
CVSVMModel = crossval(SVMModel,'Holdout',0.15)
TrainedModel = CVSVMModel.Trained{1}
```

```
CVSVMModel =
```

```
classreg.learning.partition.ClassificationPartitionedModel
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x34 cell}
  CategoricalPredictors: []
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

TrainedModel =

```
classreg.learning.classif.CompactClassificationSVM
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  Alpha: [74x1 double]
  Bias: -0.2952
  KernelParameters: [1x1 struct]
  Mu: [1x34 double]
  Sigma: [1x34 double]
  SupportVectors: [74x34 double]
  SupportVectorLabels: [74x1 double]
```

CVSVMModel is a ClassificationPartitionedModel. TrainedModel is a CompactClassificationSVM classifier trained using 85% of the data.

Estimate the generalization error.

```
kfoldLoss(CVSVMModel)
```

# ClassificationSVM.crossval

---

```
ans =  
  
    0.0769
```

The out-of-sample misclassification error is approximately 8%.

## Alternatives

Instead of creating an SVM classifier followed by a cross-validation classifier, create a cross-validated classifier directly using `fitcsvm` and by specifying any of these name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'Leaveout', or 'KFold'.

## See Also

[ClassificationSVM](#) | [CompactClassificationSVM](#) | [ClassificationPartitionedModel](#) | [fitcsvm](#)

**Purpose** Cross-validated decision tree

**Syntax**  
`cvmodel = crossval(model)`  
`cvmodel = crossval(model,Name,Value)`

**Description** `cvmodel = crossval(model)` creates a partitioned model from `model`, a fitted classification tree. By default, `crossval` uses 10-fold cross validation on the training data to create `cvmodel`.

`cvmodel = crossval(model,Name,Value)` creates a partitioned model with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- Assess the predictive performance of `model` on cross-validated data using the “kfold” methods and properties of `cvmodel`, such as `kfoldLoss`.

## Input Arguments

### **model**

A classification model, produced using `fitctree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **‘CVPartition’**

Object of class `cvpartition`, created by the `cvpartition` function. `crossval` splits the data into subsets with `cvpartition`.

Use only one of these four options at a time: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

#### **‘Holdout’**

# ClassificationTree.crossval

---

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## 'KFold'

Number of folds to use in a cross-validated tree, a positive integer.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Default:** 10

## 'Leaveout'

Set to 'on' for leave-one-out cross validation.

Use only one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## Output Arguments

### cvmodel

Partitioned model of class ClassificationPartitionedModel.

## Examples

### Create a Cross-Validation Model

Create a classification model for the ionosphere data, then create a cross-validation model. Evaluate the quality the model using `kfoldLoss`.

```
load ionosphere
tree = fitctree(X,Y);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
```

```
L =
    0.1168
```

## Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so, include one of these five options in `fitctree`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## See Also

`fitctree` | `crossval`

# RegressionEnsemble.crossval

---

**Purpose** Cross validate ensemble

**Syntax**  
`cvens = crossval(ens)`  
`cvens = crossval(ens,Name,Value)`

**Description** `cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. Default is 10-fold cross validation.

`cvens = crossval(ens,Name,Value)` creates a cross-validated ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

**ens**  
A regression ensemble created with `fitensemble`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

#### 'cvpartition'

A partition of class `cvpartition`. Sets the partition for cross validation.

Use no more than one of the name-value pairs `cvpartition`, `holdout`, `kfold`, and `leaveout`.

#### 'holdout'

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

## 'kfold'

Number of folds for cross validation, a numeric positive scalar.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## 'leaveout'

If 'on', use leave-one-out cross-validation.

Use no more than one of the name-value pairs 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## 'nprint'

Printout frequency, a positive integer scalar. Use this parameter to observe the training of cross-validation folds.

**Default:** 'off', meaning no printout

## Output Arguments

### **cvens**

A cross-validated classification ensemble of class RegressionPartitionedEnsemble.

## Alternatives

You can create a cross-validation ensemble directly from the data, instead of creating an ensemble followed by a cross-validation ensemble. To do so, include one of these five options in `fitensemble`: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## Examples

Create a cross-validated classification model for the `carsmall` data, and assess its quality using the `kfoldLoss` method:

```
X = [Acceleration Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');
cvens = crossval(rens);
L = kfoldLoss(cvens)
```

```
L =
    21.9868
```

## 'Leaveout'

Set to 'on' for leave-one-out cross-validation.

## Output Arguments

### cvmodel

A partitioned model of class RegressionPartitionedModel.

## Examples

Create a regression model of the carsmall data, and assess its accuracy with kfoldLoss:

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
cvtree = crossval(tree);
L = kfoldLoss(cvtree)
```

```
L =
    25.2432
```

## Alternatives

You can create a cross-validation tree directly from the data, instead of creating a decision tree followed by a cross-validation tree. To do so,

include one of these five options in `fitrtree`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## See Also

`fitrtree` | `crossval`

# categorical.ctranspose

---

## **Purpose**

Transpose categorical matrix

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`B = ctranspose(A)`

## **Description**

`B = ctranspose(A)` returns the transpose of the 2-D categorical matrix `A`. Note that `ctranspose` is identical to `transpose` for categorical arrays.

## **See Also**

`transpose` | `permute`

## Purpose

Cut categories

## Syntax

```
C = cutcategories(t)
C = cutcategories(t,nodes)
```

## Description

`C = cutcategories(t)` returns an  $n$ -by-2 cell array `C` of the categories used at branches in the decision tree `t`, where  $n$  is the number of nodes. For each branch node  $i$  based on a categorical predictor variable  $x$ , the left child is chosen if  $x$  is among the categories listed in `C{i,1}`, and the right child is chosen if  $x$  is among those listed in `C{i,2}`. Both columns of `C` are empty for branch nodes based on continuous predictors and for leaf nodes.

`C = cutcategories(t,nodes)` takes a vector `nodes` of node numbers and returns the categories for the specified nodes.

## Examples

Create a classification tree for car data:

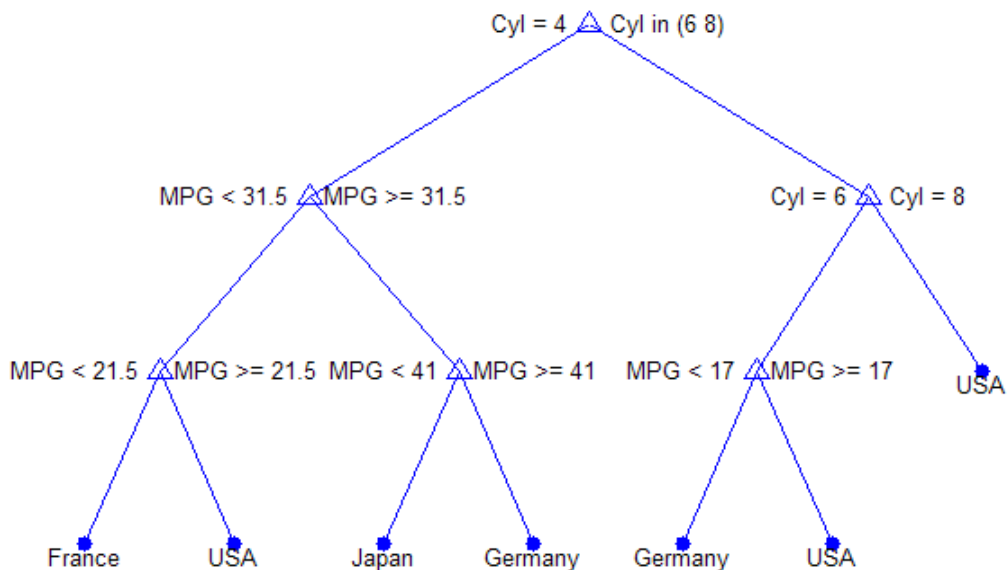

```
load carsmall

t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)
t =
Decision tree for classification
 1  if Cyl=4 then node 2 elseif Cyl in {6 8} then node 3 else USA

classregtree | cutpoint | cuttype | cutvar

# classregtree.cutpoint

---

**Purpose** Decision tree cut point values

**Syntax** `v = cutpoint(t)`  
`v = cutpoint(t,nodes)`

**Description** `v = cutpoint(t)` returns an  $n$ -element vector  $v$  of the values used as cut points in the decision tree  $t$ , where  $n$  is the number of nodes. For each branch node  $i$  based on a continuous predictor variable  $x$ , the left child is chosen if  $x < v(i)$  and the right child is chosen if  $x \geq v(i)$ .  $v$  is NaN for branch nodes based on categorical predictors and for leaf nodes.

`v = cutpoint(t,nodes)` takes a vector `nodes` of node numbers and returns the cut points for the specified nodes.

**Examples** Create a classification tree for car data:

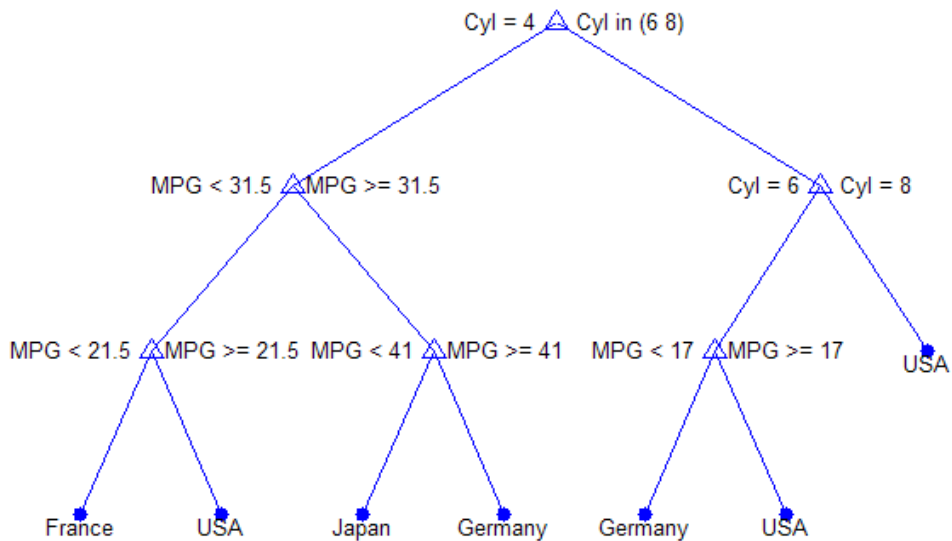

```
load carsmall

t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)

[classregtree](#) | [cutcategories](#) | [cuttype](#) | [cutvar](#)

**Purpose**

Cut types

**Syntax**

```
c = cuttype(t)
c = cuttype(t,nodes)
```

**Description**

`c = cuttype(t)` returns an  $n$ -element cell array `c` indicating the type of cut at each node in the tree `t`, where  $n$  is the number of nodes. For each node  $i$ , `c{i}` is:

- 'continuous' — If the cut is defined in the form  $x < v$  for a variable  $x$  and cut point  $v$ .
- 'categorical' — If the cut is defined by whether a variable  $x$  takes a value in a set of categories.
- '' — If  $i$  is a leaf node.

`cutvar` returns the cut points for 'continuous' cuts, and `cutcategories` returns the set of categories.

`c = cuttype(t,nodes)` takes a vector `nodes` of node numbers and returns the cut types for the specified nodes.

**Examples**

Create a classification tree for car data:

```
load carsmall

t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)

`classregtree` | `numnodes` | `cutvar` | `cutcategories`

# classregtree.cutvar

---

**Purpose** Cut variable names

**Syntax**  
`v = cutvar(t)`  
`v = cutvar(t,nodes)`  
`[v,num] = cutvar(...)`

**Description** `v = cutvar(t)` returns an  $n$ -element cell array `v` of the names of the variables used for branching in each node of the tree `t`, where  $n$  is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `v` contains an empty string.

`v = cutvar(t,nodes)` takes a vector `nodes` of node numbers and returns the cut variables for the specified nodes.

`[v,num] = cutvar(...)` also returns a vector `num` containing the number of each variable.

**Examples** Create a classification tree for car data:

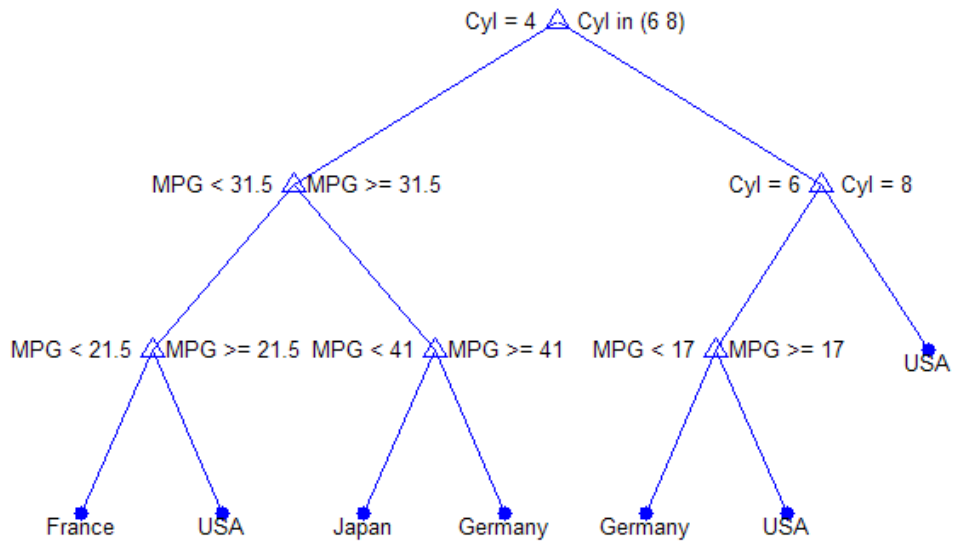

```
load carsmall

t = classregtree([MPG Cylinders],Origin,...
                'names',{'MPG' 'Cyl'},'cat',2)

```

## Description

`E = cvLoss(tree)` returns the cross-validated classification error (loss) for `tree`, a classification tree.

`[E,SE] = cvLoss(tree)` returns the standard error of `E`.

`[E,SE,Nleaf] = cvLoss(tree)` returns the number of leaves of `tree`.

`[E,SE,Nleaf,BestLevel] = cvLoss(tree)` returns the optimal pruning level for `tree`.

`[E,...] = cvLoss(tree,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### `tree`

A classification tree produced by `fitctree`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### 'subtrees'

Vector of pruning levels, with 0 representing the full, unpruned tree. `tree` must include a pruning sequence as created either by `fitctree` with 'Prune' set to 'on', or by the `prune` method.

# ClassificationTree.cvLoss

---

The returned `E`, `SE`, and `Nleaf` are vectors of the same length as subtrees; `BestLevel` is a scalar. If you set `subtrees` to 'all', `cvLoss` uses the entire pruning sequence.

**Default:** 0

## 'treesize'

One of the following strings:

- 'se' — `cvLoss` uses the smallest tree whose cost is within one standard error of the minimum cost.
- 'min' — `cvLoss` uses the minimal cost tree.

**Default:** 'se'

## 'kfold'

Number of cross-validation samples, a positive integer.

**Default:** 10

## Output Arguments

### **E**

The cross-validation classification error (loss). A vector or scalar depending on the setting of the `subtrees` name-value pair.

### **SE**

The standard error of `E`. A vector or scalar depending on the setting of the `subtrees` name-value pair.

### **Nleaf**

Number of leaf nodes in `tree`. Leaf nodes are terminal nodes, which give classifications, not splits. A vector or scalar depending on the setting of the `subtrees` name-value pair.

### **BestLevel**

By default, a scalar representing the largest pruning level that achieves a value of E within SE of the minimum error. If you set `treeSize` to 'min', `BestLevel` is the smallest value in subtrees.

## Examples

### Compute the Cross-Validation Error

Compute the cross-validation error for the default classification tree for the ionosphere data.

```
load ionosphere
tree = fitctree(X,Y);
[E,SE,Nleaf,BestLevel] = cvLoss(tree)
```

```
E =
    0.1282
```

```
SE =
    0.0178
```

```
Nleaf =
    19
```

```
BestLevel =
    0
```

Find the best level by using the subtrees name-value pair.

```
[~,~,~,BestLevel] = cvLoss(tree,'subtrees','all')
```

```
BestLevel =
    6
```

## Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvLoss`. The alternative can save time if you are going to examine the cross-validated tree more than once.

# ClassificationTree.cvLoss

---

However, unlike `cvLoss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`. `kfoldLoss` also does not allow you to examine any error other than classification error.

## See Also

`fitctree` | `crossval` | `loss` | `kfoldLoss`

## Purpose

Regression error by cross validation

## Syntax

```
E = cvLoss(tree)
[E,SE] = cvLoss(tree)
[E,SE,Nleaf] = cvLoss(tree)
[E,SE,Nleaf,BestLevel] = cvLoss(tree)
[E,...] = cvLoss(tree,Name,Value)
```

## Description

`E = cvLoss(tree)` returns the cross-validated regression error (loss) for `tree`, a regression tree.

`[E,SE] = cvLoss(tree)` returns the standard error of `E`.

`[E,SE,Nleaf] = cvLoss(tree)` returns the number of leaves (terminal nodes) in `tree`.

`[E,SE,Nleaf,BestLevel] = cvLoss(tree)` returns the optimal pruning level for `tree`.

`[E,...] = cvLoss(tree,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **tree**

A regression tree produced by `fitrtree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'subtrees'**

Vector of pruning levels, with 0 representing the full, unpruned tree. `tree` must include a pruning sequence as created either

# RegressionTree.cvLoss

---

by `fitctree` with `'prune'` set to `'on'`, or by the `prune` method. The returned `E`, `SE`, and `Nleaf` are vectors of the same length as `subtrees`; `BestLevel` is a scalar. If you set `subtrees` to `'all'`, `cvLoss` uses the entire pruning sequence.

**Default:** 0

## **'treesize'**

One of the following strings:

- `'se'` — `cvLoss` uses the smallest tree whose cost is within one standard error of the minimum cost.
- `'min'` — `cvLoss` uses the minimal cost tree.

**Default:** `'se'`

## **'kfold'**

Number of cross-validation samples, a positive integer.

**Default:** 10

## **Output Arguments**

### **E**

The cross-validation mean squared error (loss). A vector or scalar depending on the setting of the `subtrees` name-value pair.

### **SE**

The standard error of `E`. A vector or scalar depending on the setting of the `subtrees` name-value pair.

### **Nleaf**

Number of leaf nodes in `tree`. Leaf nodes are terminal nodes, which give responses, not splits. A vector or scalar depending on the setting of the `subtrees` name-value pair.

### **BestLevel**

By default, a scalar representing the largest pruning level that achieves a value of `E` within `SE` of the minimum error. If you set `treecsize` to `'min'`, `BestLevel` is the smallest value in subtrees.

## Examples

Compute the cross-validation error for the default classification tree for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
[E,SE,Nleaf,BestLevel] = cvLoss(tree)
```

```
E =
    30.7558
```

```
SE =
    6.0651
```

```
Nleaf =
    19
```

```
BestLevel =
    0
```

Find the best level by using the subtrees name-value pair:

```
[~,~,~,BestLevel] = cvLoss(tree,'subtrees','all')
```

```
BestLevel =
    15
```

## Alternatives

You can construct a cross-validated tree model with `crossval`, and call `kfoldLoss` instead of `cvLoss`. The alternative can save time if you are going to examine the cross-validated tree more than once.

However, unlike `cvLoss`, `kfoldLoss` does not return `SE`, `Nleaf`, or `BestLevel`.

## Examples

Use a 10-fold stratified cross validation to compute the misclassification error for `classify` on iris data.

```
load('fisheriris');
CVO = cvpartition(species,'k',10);
err = zeros(CVO.NumTestSets,1);
for i = 1:CVO.NumTestSets
    trIdx = CVO.training(i);
    teIdx = CVO.test(i);
    ytest = classify(meas(teIdx,:),meas(trIdx,:),...
        species(trIdx,:));
    err(i) = sum(~strcmp(ytest,species(teIdx)));
end
cvErr = sum(err)/sum(CVO.TestSize);
```

## See Also

`crossval`

## How To

- “Grouping Variables” on page 2-52

**Purpose**

Create cross validation partition for data

**Syntax**

```
c = cvpartition(n, 'kfold', k)
c = cvpartition(group, 'kfold', k)
c = cvpartition(n, 'holdout', p)
c = cvpartition(group, 'holdout', p)
c = cvpartition(n, 'leaveout')
c = cvpartition(n, 'resubstitution')
```

**Description**

`c = cvpartition(n, 'kfold', k)` constructs an object `c` of the `cvpartition` class defining a random partition for `k`-fold cross validation on `n` observations. The partition divides the observations into `k` disjoint subsamples (or *folds*), chosen randomly but with roughly equal size. The default value of `k` is 10.

`c = cvpartition(group, 'kfold', k)` creates a random partition for a stratified `k`-fold cross validation. `group` is a numeric vector, categorical array, string array, or cell array of strings indicating the class of each observation. Each subsample has roughly equal size and roughly the same class proportions as in `group`. `cvpartition` treats NaNs or empty strings in `group` as missing values.

`c = cvpartition(n, 'holdout', p)` creates a random partition for holdout validation on `n` observations. This partition divides the observations into a training set and a test (or *holdout*) set. The parameter `p` must be a scalar. When  $0 < p < 1$ , `cvpartition` randomly selects approximately  $p*n$  observations for the test set. When `p` is an integer, `cvpartition` randomly selects `p` observations for the test set. The default value of `p` is 1/10.

`c = cvpartition(group, 'holdout', p)` randomly partitions observations into a training set and a test set with stratification, using the class information in `group`; that is, both training and test sets have roughly the same class proportions as in `group`.

`c = cvpartition(n, 'leaveout')` creates a random partition for leave-one-out cross validation on `n` observations. Leave-one-out is a special case of 'kfold', in which the number of folds equals the number of observations.

# cvpartition

---

`c = cvpartition(n, 'resubstitution')` creates an object `c` that does not partition the data. Both the training set and the test set contain all of the original `n` observations.

## Examples

Use stratified 10-fold cross validation to compute misclassification rate:

```
load fisheriris;
y = species;
c = cvpartition(y, 'k', 10);

fun = @(xT,yT,xt,yt)(sum(~strcmp(yt,classify(xt,xT,yT))));

rate = sum(crossval(fun,meas,y,'partition',c)...
           /sum(c.TestSize)
rate =
    0.0200
```

## See Also

`crossval` | `repartition`

## How To

- “Grouping Variables” on page 2-52

**Purpose** Cross-validate regularization of linear discriminant

**Syntax**

```
err = cvshrink(obj)
[err,gamma] = cvshrink(obj)
[err,gamma,delta] = cvshrink(obj)
[err,gamma,delta,numpred] = cvshrink(obj)
[err,...] = cvshrink(obj,Name,Value)
```

**Description** `err = cvshrink(obj)` returns a vector of cross-validated classification error values for differing values of the regularization parameter Gamma.

`[err,gamma] = cvshrink(obj)` also returns the vector of Gamma values.

`[err,gamma,delta] = cvshrink(obj)` also returns the vector of Delta values.

`[err,gamma,delta,numpred] = cvshrink(obj)` returns the vector of number of nonzero predictors for each setting of the parameters Gamma and Delta.

`[err,...] = cvshrink(obj,Name,Value)` cross validates with additional options specified by one or more Name,Value pair arguments.

**Tips**

- Examine the `err` and `numpred` outputs to see the tradeoff between cross-validated error and number of predictors. When you find a satisfactory point, set the corresponding `gamma` and `delta` properties in the model using dot notation. For example, if  $(i, j)$  is the location of the satisfactory point, set

```
obj.Gamma = gamma(i);
obj.Delta = delta(i,j);
```

**Input Arguments**

**obj**

Discriminant analysis classifier, produced using `fitcdiscr`.

# ClassificationDiscriminant.cvshrink

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'delta'

- **Scalar delta** — `cvshrink` uses this value of `delta` with every value of `gamma` for regularization.
- **Row vector delta** — For each `i` and `j`, `cvshrink` uses `delta(j)` with `gamma(i)` for regularization.
- **Matrix delta** — The number of rows of `delta` must equal the number of elements in `gamma`. For each `i` and `j`, `cvshrink` uses `delta(i, j)` with `gamma(i)` for regularization.

**Default:** 0

### 'gamma'

Vector of `Gamma` values for cross-validation.

**Default:** 0:0.1:1

### 'NumDelta'

Number of `Delta` intervals for cross-validation. For every value of `Gamma`, `cvshrink` cross-validates the discriminant using `NumDelta + 1` values of `Delta`, uniformly spaced from zero to the maximal `Delta` at which all predictors are eliminated for this value of `Gamma`. If you set `delta`, `cvshrink` ignores `NumDelta`.

**Default:** 0

### 'NumGamma'

Number of Gamma intervals for cross-validation. `cvshrink` cross-validates the discriminant using `NumGamma + 1` values of Gamma, uniformly spaced from `MinGamma` to 1. If you set `gamma`, `cvshrink` ignores `NumGamma`.

**Default:** 10

## **'verbose'**

Verbosity level, an integer from 0 to 2. Higher values give more progress messages.

**Default:** 0

## **Output Arguments**

### **err**

Numeric vector or matrix of errors. `err` is the misclassification error rate, meaning the average fraction of misclassified data over all folds.

- If `delta` is a scalar (default), `err(i)` is the misclassification error rate for `obj` regularized with `gamma(i)`.
- If `delta` is a vector, `err(i,j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `err(i,j)` is the misclassification error rate for `obj` regularized with `gamma(i)` and `delta(i,j)`.

### **gamma**

Vector of Gamma values used for regularization. See “Gamma and Delta” on page 21-688.

### **delta**

Vector or matrix of Delta values used for regularization. See “Gamma and Delta” on page 21-688.

- If you give a scalar for the `delta` name-value pair, the output `delta` is a row vector the same size as `gamma`, with entries equal to the input scalar.
- If you give a row vector for the `delta` name-value pair, the output `delta` is a matrix with the same number of columns as the row vector, and with the number of rows equal to the number of elements of `gamma`. The output `delta(i, j)` is equal to the input `delta(j)`.
- If you give a matrix for the `delta` name-value pair, the output `delta` is the same as the input matrix. The number of rows of `delta` must equal the number of elements in `gamma`.

## **numpred**

Numeric vector or matrix containing the number of predictors in the model at various regularizations. `numpred` has the same size as `err`.

- If `delta` is a scalar (default), `numpred(i)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta`.
- If `delta` is a vector, `numpred(i, j)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta(j)`.
- If `delta` is a matrix, `numpred(i, j)` is the number of predictors for `obj` regularized with `gamma(i)` and `delta(i, j)`.

## **Definitions**

### **Gamma and Delta**

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters,  $\gamma$  and  $\delta$ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let  $\Sigma$  represent the covariance matrix of the data  $X$ , and let  $\hat{X}$  be the centered data (the data  $X$  minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix  $\tilde{\Sigma}$  is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever  $\gamma \geq \text{MinGamma}$ ,  $\tilde{\Sigma}$  is nonsingular.

Let  $\mu_k$  be the mean vector for those elements of  $X$  in class  $k$ , and let  $\mu_0$  be the global mean vector (the mean of the rows of  $X$ ). Let  $C$  be the correlation matrix of the data  $X$ , and let  $\tilde{C}$  be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where  $I$  is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point  $x$  is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = \left[ (x - \mu_0)^T D^{-1/2} \right] \left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right].$$

The parameter  $\delta$  enters into this equation as a threshold on the final term in square brackets. Each component of the vector

$\left[ \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right]$  is set to zero if it is smaller in magnitude than the threshold  $\delta$ . Therefore, for class  $k$ , if component  $j$  is thresholded to zero, component  $j$  of  $x$  does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When  $\delta \geq \text{DeltaPredictor}(i)$ , all classes  $k$  have

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when  $\delta \geq \text{DeltaPredictor}(i)$ , the regularized classifier does not use predictor  $i$ .

# ClassificationDiscriminant.cvshrink

---

## Examples

### Regularize Data with Many Predictors

Regularize a discriminant analysis classifier, and view the tradeoff between the number of predictors in the model and the classification accuracy.

Create a linear discriminant analysis classifier for the ovariancancer data. Set the `SaveMemory` and `FillCoeffs` options to keep the resulting model reasonably small.

```
load ovariancancer
obj = fitcdiscr(obs,grp,...
    'SaveMemory','on','FillCoeffs','off');
```

Use 10 levels of `Gamma` and 10 levels of `Delta` to search for good parameters. This search is time-consuming. Set `Verbose` to 1 to view the progress.

```
rng('default') % for reproducibility
[err,gamma,delta,numpred] = cvshrink(obj,...
    'NumGamma',9,'NumDelta',9,'Verbose',1);
```

```
Done building cross-validated model.
Processing Gamma step 1 out of 10.
Processing Gamma step 2 out of 10.
Processing Gamma step 3 out of 10.
Processing Gamma step 4 out of 10.
Processing Gamma step 5 out of 10.
Processing Gamma step 6 out of 10.
Processing Gamma step 7 out of 10.
Processing Gamma step 8 out of 10.
Processing Gamma step 9 out of 10.
Processing Gamma step 10 out of 10.
```

Plot the classification error rate against the number of predictors.

```
plot(err,numpred,'k.')
xlabel('Error rate');
ylabel('Number of predictors');
```

## Concepts

- “Discriminant Analysis” on page 15-3

# RegressionEnsemble.cvshrink

---

**Purpose** Cross validate shrinking (pruning) ensemble

**Syntax**

```
vals = cvshrink(ens)
[vals,nlearn] = cvshrink(ens)
[vals,nlearn] = cvshrink(ens,Name,Value)
```

**Description** `vals = cvshrink(ens)` returns an L-by-T matrix with cross-validated values of the mean squared error. L is the number of `lambda` values in the `ens.Regularization` structure. T is the number of `threshold` values on weak learner weights. If `ens` does not have a `Regularization` property filled in by the `regularize` method, pass a `lambda` name-value pair.

`[vals,nlearn] = cvshrink(ens)` returns an L-by-T matrix of the mean number of learners in the cross-validated ensemble.

`[vals,nlearn] = cvshrink(ens,Name,Value)` cross validates with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **ens**

A regression ensemble, created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'cvpartition'**

A partition created with `cvpartition` to use in a cross-validated tree. You can only use one of these four options at a time: `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.

### **'holdout'**

Holdout validation tests the specified fraction of the data, and uses the rest of the data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated tree: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## **'kfold'**

Number of folds to use in a cross-validated tree, a positive integer. If you do not supply a cross-validation method, cvshrink uses 10-fold cross validation. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

**Default:** 10

## **'lambda'**

Vector of nonnegative regularization parameter values for lasso. If empty, cvshrink does not perform cross validation.

**Default:** []

## **'leaveout'**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time: 'kfold', 'holdout', 'leaveout', or 'cvpartition'.

## **'threshold'**

Numeric vector with lower cutoffs on weights for weak learners. cvshrink discards learners with weights below threshold in its cross-validation calculation.

**Default:** 0

## **Output Arguments**

### **vals**

L-by-T matrix with cross-validated values of the mean squared error. L is the number of values of the regularization parameter

# RegressionEnsemble.cvshrink

---

'lambda', and T is the number of 'threshold' values on weak learner weights.

## nlearn

L-by-T matrix with cross-validated values of the mean number of learners in the cross-validated ensemble. L is the number of values of the regularization parameter 'lambda', and T is the number of 'threshold' values on weak learner weights.

## Examples

Create a regression ensemble for predicting mileage from the carsmall data. Cross validate the ensemble for three values each of lambda and threshold.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
[vals nlearn] = cvshrink(ens,'lambda',[.01 .1 1],...
    'threshold',[0 .01 .1])

vals =
    20.0949    19.9007    131.6316
    20.0924    19.8431    128.0989
    19.9759    19.7987    119.5574

nlearn =
    13.3000    11.6000     3.5000
    13.2000    11.5000     3.6000
    13.4000    11.4000     3.9000
```

Clearly, setting a threshold of 0.1 leads to unacceptable errors, while a threshold of 0.01 gives similar errors to a threshold of 0. The mean number of learners with a threshold of 0.1 is about 11.5, whereas the mean number is about 13.2 when the threshold is 0.

<b>Purpose</b>	Randomly sample from data, with or without replacement
<b>Syntax</b>	<pre>y = datasample(data,k) y = datasample(data,k,dim) [y,idx] = datasample(data,k,...) [y,...] = datasample(s,data,k,...) [y,...] = datasample(data,k,Name,Value) [y,...] = datasample(data,k,dim,Name,Value)</pre>
<b>Description</b>	<p><code>y = datasample(data,k)</code> returns <code>k</code> observations sampled uniformly at random, with replacement, from the data in <code>data</code>.</p> <p><code>y = datasample(data,k,dim)</code> returns a sample taken along dimension <code>dim</code> of data.</p> <p><code>[y,idx] = datasample(data,k,...)</code> returns an index vector indicating which values <code>datasample</code> sampled from <code>data</code>.</p> <p><code>[y,...] = datasample(s,data,k,...)</code> uses the random number stream <code>s</code> to generate random numbers.</p> <p><code>[y,...] = datasample(data,k,Name,Value)</code> or <code>[y,...] = datasample(data,k,dim,Name,Value)</code> samples with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• To sample random integers with replacement from a range, use <code>randi</code>.</li><li>• To sample random integers without replacement, use <code>randperm</code> or <code>datasample</code>.</li><li>• To randomly sample from data, with or without replacement, use <code>datasample</code>.</li></ul>
<b>Input Arguments</b>	<p><b>data</b></p> <p>Vector, matrix, <math>N</math>-dimensional array, table, or dataset array representing the data from which to sample. By default, <code>datasample</code> regards the rows of a data matrix, or the first nonsingleton dimension</p>

of a data array, as data elements. Change this behavior with the `dim` argument.

## **k**

Positive integer, the number of samples.

## **dim**

Integer specifying the dimension on which to take samples. For example, if `data` is a matrix and `dim` is 2, `y` contains a selection of columns in `data`. If `data` is a table or dataset array and `dim` is 2, `y` contains a selection of variables in `data`. Use `dim` to ensure sampling along a specific dimension regardless of whether `data` is a vector, matrix or  $N$ -dimensional array.

**Default:** 1

## **s**

Random number stream. Create `s` using `rng` or `RandStream`.

**Default:** The global random number stream

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **'Replace'**

Select the sample with replacement if `Replace` is true, or without replacement if `Replace` is false. If `Replace` is false, `k` must not be larger than the number of data elements in `data`.

**Default:** true

## 'Weights'

Vector with the same number of elements as data elements in `data`, and with nonnegative elements. Sample with probability proportional to the elements of `Weights`.

**Default:** `ones(datasize,1)`, where `datasize` is the number of data elements in `data`

## Output Arguments

### `y`

- If `data` is a vector, `y` is a vector containing `k` elements selected from `data`.
- If `data` is a matrix, `y` is a matrix containing `k` rows selected from `data`. Or, if `dim = 2`, `y` is a matrix containing `k` columns selected from `data`
- If `data` is an  $N$ -dimensional array, `datasample` samples along its first non-singleton dimension. Or, if you give a `dim` name-value pair, `datasample` samples along the dimension `dim`.

When the sample is taken with replacement (default), `y` can contain repeated observations from `data`. Set the `Replace` name-value pair to `false` to sample without replacement.

### `idx`

Vector of indices indicating which elements `datasample` chose from `data` to create `y`. For example:

- If `data` is a vector, `y = data(idx)`.
- If `data` is a matrix, `y = data(idx,:)`.

## Examples

Draw five unique values from the integers `1:10`.

```
y = datasample(1:10,5,'Replace',false)
```

```
y =
     6     3     7     8     5
```

# datasample

---

---

Generate a random sequence of the characters ACGT, with replacement, according to specified probabilities.

```
seq = datasample('ACGT',48,'Weights',[0.15 0.35 0.35 0.15])
```

```
seq =  
CTTCGACTGTGAGTGGGCGCACAAAGGCTACCGGCCCGGGCGGCACTC
```

---

Select a random subset of columns from a data matrix.

```
X = randn(10,1000);  
Y = datasample(X,5,2,'Replace',false)
```

```
Y =  
    0.7007    0.3382    2.1298   -0.1891    0.5026  
    0.6520   -0.6693   -0.1961   -0.9915    1.9107  
    0.1785    0.6640    2.3247   -1.1735   -1.0020  
    1.6760    2.6102   -0.8902   -0.7735    1.8676  
   -0.3251   -0.6415   -0.2572   -0.1629   -1.0523  
    0.1011    0.9323   -1.3088   -0.4477    0.8036  
   -0.5767   -0.5778   -0.8556    0.8672   -0.0727  
   -0.0615   -0.9084    0.9020   -0.4185   -1.9520  
    0.7256   -1.1228    0.7558    1.2691    2.4997  
   -1.2273    0.5754   -0.8755   -0.8224   -1.2066
```

---

Resample observations from a dataset array to create a bootstrap replicate dataset.

```
load hospital  
y = datasample(hospital,size(hospital,1));
```

---

Use the second output to sample “in parallel” from two data vectors.

```
x1 = randn(100,1);  
x2 = randn(100,1);  
[y1,idx] = datasample(x1,10);  
y2 = x2(idx);
```

## Algorithms

`datasample` uses `randperm`, `rand`, or `randi` to generate random values. Therefore, `datasample` changes the state of the MATLAB global random number generator. Control the random number generator using `rng`.

For selecting weighted samples without replacement, `datasample` uses the algorithm of Wong and Easton [1].

## References

[1] Wong, C. K. and M. C. Easton. *An Efficient Method for Weighted Sampling Without Replacement*. SIAM Journal of Computing 9(1), pp. 111–113, 1980.

## Alternatives

You can use `randi` or `randperm` to generate indices for random sampling with or without replacement, respectively. However, `datasample` can be more convenient because it samples directly from your data. `datasample` also allows weighted sampling.

# dataset

---

## Purpose

Arrays for statistical data

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

Dataset arrays are used to collect heterogeneous data and metadata including variable and observation names into a single container variable. Dataset arrays are suitable for storing column-oriented or tabular data that are often stored as columns in a text file or in a spreadsheet, and can accommodate variables of different types, sizes, units, etc.

Dataset arrays can contain different kinds of variables, including numeric, logical, character, categorical, and cell. However, a dataset array is a different class than the variables that it contains. For example, even a dataset array that contains only variables that are double arrays cannot be operated on as if it were itself a double array. However, using dot subscripting, you can operate on variable in a dataset array as if it were a workspace variable.

You can subscript dataset arrays using parentheses much like ordinary numeric arrays, but in addition to numeric and logical indices, you can use variable and observation names as indices.

## Construction

Use the `dataset` constructor to create a dataset array from variables in the MATLAB workspace. You can also create a dataset array by reading data from a text or spreadsheet file. You can access each variable in a dataset array much like fields in a structure, using dot subscripting. See the following section for a list of operations available for dataset arrays.

`dataset`

Construct dataset array

## Methods

`cat`

Concatenate dataset arrays

`cellstr`

Create cell array of strings from dataset array

<code>dataset2cell</code>	Convert dataset array to cell array
<code>dataset2struct</code>	Convert dataset array to structure
<code>datasetfun</code>	Apply function to dataset array variables
<code>disp</code>	Display dataset array
<code>display</code>	Display dataset array
<code>double</code>	Convert dataset variables to double array
<code>end</code>	Last index in indexing expression for dataset array
<code>export</code>	Write dataset array to file
<code>get</code>	Access dataset array properties
<code>horzcat</code>	Horizontal concatenation for dataset arrays
<code>intersect</code>	Set intersection for dataset array observations
<code>isempty</code>	True for empty dataset array
<code>ismember</code>	Dataset array elements that are members of set
<code>ismissing</code>	Find dataset array elements with missing values
<code>join</code>	Merge observations
<code>length</code>	Length of dataset array
<code>ndims</code>	Number of dimensions of dataset array
<code>numel</code>	Number of elements in dataset array

# dataset

---

replacedata	Replace dataset variables
replaceWithMissing	Insert missing data indicators into a dataset array
set	Set and display properties
setdiff	Set difference for dataset array observations
setxor	Set exclusive or for dataset array observations
single	Convert dataset variables to single array
size	Size of dataset array
sortrows	Sort rows of dataset array
stack	Stack data from multiple variables into single variable
subsasgn	Subscripted assignment to dataset array
subsref	Subscripted reference for dataset array
summary	Print summary of dataset array
union	Set union for dataset array observations
unique	Unique observations in dataset array
unstack	Unstack data from single variable into multiple variables
vertcat	Vertical concatenation for dataset arrays

## Properties

A dataset array `D` has properties that store metadata (information about your data). Access or assign to a property using `P = D.Properties.PropName` or `D.Properties.PropName = P`, where `PropName` is one of the following:

Description	String describing data set
DimNames	Two-element cell array of strings giving names of dimensions of data set
ObsNames	Cell array of nonempty, distinct strings giving names of observations in data set
Units	Units of variables in data set
UserData	Variable containing additional information associated with data set
VarDescription	Cell array of strings giving descriptions of variables in data set
VarNames	Cell array giving names of variables in data set

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Load a dataset array from a `.mat` file and create some simple subsets:

```
load hospital
h1 = hospital(1:10,:)
h2 = hospital(:,{'LastName' 'Age' 'Sex' 'Smoker'})

% Access and modify metadata
hospital.Properties.Description
```

# dataset

---

```
hospital.Properties.VarNames{4} = 'Wgt'  
  
% Create a new dataset variable from an existing one  
hospital.AtRisk = hospital.Smoker | (hospital.Age > 40)  
  
% Use individual variables to explore the data  
boxplot(hospital.Age,hospital.Sex)  
h3 = hospital(hospital.Age<30,...  
    {'LastName' 'Age' 'Sex' 'Smoker'})  
  
% Sort the observations based on two variables  
h4 = sortrows(hospital,{'Sex','Age'})
```

## How To

- “Dataset Arrays” on page 2-137

## Purpose

Construct dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
A = dataset(varspec, 'ParamName', Value)
A = dataset('File', filename, 'ParamName', Value)
A = dataset('XLSFile', filename, 'ParamName', Value)
A = dataset('XPTFile', xptfilename, 'ParamName', Value)
```

## Description

`A = dataset(varspec, 'ParamName', Value)` creates dataset array `A` using the workspace variable input method `varspec` and one or more optional name/value pairs (see Parameter Name/Value Pairs).

The input method `varspec` can be one or more of the following:

- `VAR` — a workspace variable. `dataset` uses the workspace name for the variable name in `A`. To include multiple variables, specify `VAR_1, VAR_2, ..., VAR_N`. Variables can be arrays of any size, but all variables must have the same number of rows. `VAR` can also be an expression. In this case, `dataset` creates a default name automatically.
- `{VAR, name}` — a workspace variable, `VAR` and a variable name, `name`. `dataset` uses `name` as the variable name. To include multiple variables and names, specify `{VAR_1, name_1}, {VAR_2, name_2}, ..., {VAR_N, name_N}`.
- `{VAR, name_1, ..., name_m}` — an `m`-columned workspace variable, `VAR`. `dataset` uses the names `name_1, ..., name_m` as variable names. You must include a name for every column in `VAR`. Each column becomes a separate variable in `A`.

You can combine these input methods to include as many variables and names as needed. Names must be valid, unique MATLAB identifier strings. For example input combinations, see Examples. For optional name/value pairs see Inputs.

To convert numeric arrays, cell arrays, structure arrays, or tables to dataset arrays, you can also use (respectively):

- `mat2dataset`
- `cell2dataset`
- `struct2dataset`
- `table2dataset`

---

**Note** Dataset arrays may contain built-in types or array objects as variables. Array objects must implement each of the following:

- Standard MATLAB parenthesis indexing of the form `var(i,...)`, where `i` is a numeric or logical vector corresponding to rows of the variable
  - A `size` method with a `dim` argument
  - A `vertcat` method
- 

`A = dataset('File', filename, 'ParamName', Value)` creates dataset array `A` from column-oriented data in the text file specified by the string `filename`. Variables in `A` are of type `double` if data in the corresponding column of the file, following the column header, are entirely numeric; otherwise the variables in `A` are cell arrays of strings. `dataset` converts empty fields to either `NaN` (for a numeric variable) or the empty string (for a string-valued variable). `dataset` ignores insignificant white space in the file. You cannot specify both a file and workspace variables as input. See `Name/Value Pairs` for more information.

`A = dataset('XLSFile', filename, 'ParamName', Value)` creates dataset array `A` from column-oriented data in the Excel spreadsheet specified by the string `filename`. Variables in `A` are of type `double` if data in the corresponding column of the spreadsheet, following the

column header, are entirely numeric; otherwise the variables in *A* are cell arrays of strings. See Name/Value Pairs for more information.

`A = dataset('XPTfile', xptfilename, 'ParamName', Value)` creates a dataset array from a SAS® XPORT format file. Variable names from the XPORT format file are preserved. Numeric data types in the XPORT format file are preserved but all other data types are converted to cell arrays of strings. The XPORT format allows for 28 missing data types. `dataset` represents these in the file by an upper case letter, '.' or '\_'. `dataset` converts all missing data to NaN values in *A*. See Name/Value Pairs for more information.

## Parameter Name/Value Pairs

Specify one or more of the following name/value pairs when constructing a dataset:

### VarNames

A cell array {name\_1, . . . , name\_m} naming the *m* variables in *A* with the specified variable names. Names must be valid, unique MATLAB identifier strings. The number of names must equal the number of variables in *A*. You cannot use the `VarNames` parameter if you provide names for individual variables using {VAR, name} pairs. To specify `VarNames` when using a file as input, set `ReadVarNames` to `false`.

### ObsNames

A cell array {name\_1, . . . , name\_n} naming the *n* observations in *A* with the specified observation names. The names need not be valid MATLAB identifier strings, but must be unique. The number of names must equal the number of observations (rows) in *A*. To specify `ObsNames` when using a file as input, set `ReadObsNames` to `false`.

**Name/value pairs available when using text files as inputs:**

### Delimiter

A string indicating the character separating columns in the file. Values are

- '\t' (tab, the default when no format is specified)
- ' ' (space, the default when a format is specified)
- ',' (comma)
- ';' (semicolon)
- '|' (bar)

## **Format**

A format string, as accepted by `textscan`. `dataset` reads the file using `textscan`, and creates variables in `A` according to the conversion specifiers in the format string. You may also provide any name/value pairs accepted by `textscan`. Using the `Format` parameter is much faster for large files. If `ReadObsNames` is `true`, the format string should include a format specifier for the first column of the file.

## **HeaderLines**

Numeric value indicating the number of lines to skip at the beginning of a file.

**Default:** 0

## **TreatAsEmpty**

Specifies strings to treat as the empty string in a numeric column. Values may be a character string or a cell array of strings. The parameter applies only to numeric columns in the file; `dataset` does not accept numeric literals such as '-99'.

**Name/value pairs available when using text files or Excel spreadsheets as inputs:**

## **ReadVarNames**

A logical value indicating whether (`true`) or not (`false`) to read variable names from the first row of the file. The default is `true`. If `ReadVarNames` is `true`, variable names in the column headers of the file or range (if using an Excel spreadsheet) cannot be empty.

**ReadObsNames**

A logical value indicating whether (`true`) or not (`false`) to read observation names from the first column of the file or range (if using an Excel spreadsheet). The default is `false`. If `ReadObsNames` and `ReadVarNames` are both `true`, `dataset` saves the header of the first column in the file or range as the name of the first dimension in `A.Properties.DimNames`.

When reading from an XPT format file, the `ReadObsNames` parameter name/value pair determines whether or not to try to use the first variable in the file as observation names. Specify as a logical value (default `false`). If the contents of the first variable are not valid observation names then `dataset` reads the variable into a variable of the dataset array and does not set the observation names.

**Name/value pairs available when using Excel spreadsheets as input:****Sheet**

A positive scalar value of type `double` indicating the sheet number, or a quoted string indicating the sheet name.

**Range**

A string of the form `'C1:C2'` where `C1` and `C2` are the names of cells at opposing corners of a rectangular region to be read, as for `xlsread`. By default, the rectangular region extends to the right-most column containing data. If the spreadsheet contains empty columns between columns of data, or if the spreadsheet contains figures or other non-tabular information, specify a range that contains only data.

# dataset

---

## Examples

Create a dataset array from workspace variables, including observation names:

```
load cereal
cereal = dataset(Calories,Protein,Fat,Sodium,Fiber,Carbo,...
    Sugars,'ObsNames',Name)
cereal.Properties.VarDescription = Variables(4:10,2);
```

---

Create a dataset array from a single, multi-columned workspace variable, designating variable names for each column:

```
load cities
categories = cellstr(categories);
cities = dataset({ratings,categories{:}},...
    'ObsNames',cellstr(names))
```

---

Load data from a text or spreadsheet file

```
patients = dataset('File','hospital.dat',...
    'Delimiter',' ','ReadObsNames',true)
patients2 = dataset('XLSFile','hospital.xls',...
    'ReadObsNames',true)
```

---

- 1 Load patient data from the CSV file `hospital.dat` and store the information in a dataset array with observation names given by the first column in the data (patient identification):

```
patients = dataset('file','hospital.dat', ...
    'format','%S%S%S%f%f%f%f%f%f%f%f', ...
    'Delimiter',' ','ReadObsNames',true);
```

You can also load the data without specifying a format string. `dataset` will automatically create dataset variables that are either

double arrays or cell arrays of strings, depending on the contents of the file:

```
patients = dataset('file','hospital.dat',...  
                  'delimiter',';',...  
                  'ReadObsNames',true);
```

- 2 Make the {0,1}-valued variable `smoke` nominal, and change the labels to 'No' and 'Yes':

```
patients.smoke = nominal(patients.smoke,{'No','Yes'});
```

- 3 Add new levels to `smoke` as placeholders for more detailed histories of smokers:

```
patients.smoke = addlevels(patients.smoke,...  
                           {'0-5 Years','5-10 Years','LongTerm'});
```

- 4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

```
patients.smoke = setlabels(patients.smoke,'Never','No');
```

- 5 Drop the undifferentiated 'Yes' level from `smoke`:

```
patients.smoke = droplevels(patients.smoke,'Yes');
```

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

- 6 Set each smoker to one of the new levels, by observation name:

```
patients.smoke('YPL-320') = '5-10 Years';
```

- “Create a Dataset Array from a File” on page 2-73
- “Dataset Arrays in the Variables Editor” on page 2-124

## **Concepts**

- “Dataset Arrays” on page 2-137

**Purpose**

Convert dataset array to cell array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

`C = dataset2cell(D)`

**Description**

`C = dataset2cell(D)` converts the dataset array `D` to a cell array `C`. Each variable of `D` becomes a column in `C`. If `D` is an `M`-by-`N` array, then `C` is `(M+1)`-by-`N`, with the variable names of `D` in the first row. If `D` contains observation names, then `C` is `(M+1)`-by-`(N+1)`, with the observation names in the first column.

# dataset.dataset2struct

---

## Purpose

Convert dataset array to structure

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
S = dataset2struct(D)
S = dataset2struct(D, 'AsScalar', true)
```

## Description

`S = dataset2struct(D)` converts a dataset array to a structure array. Each variable of `D` becomes a field in `S`. If `D` is an  $M$ -by- $N$  dataset array, then `S` is  $M$ -by-1 and has  $N$  fields. If `D` contains observation names, then `S` contains those names in the additional field `ObsNames`.

`S = dataset2struct(D, 'AsScalar', true)` converts a dataset array to a scalar structure. Each variable of `D` becomes a field in `S`. If `D` is an  $M$ -by- $N$  dataset array, then `S` has  $N$  fields, each of which as  $M$  rows. If `D` contains observation names, then `S` contains those names in the additional field `ObsNames`.

## Input Arguments

**D**  
 $M$ -by- $N$  dataset array.

## Output Arguments

**s**  
 $M$ -by-1 structure array, with  $N$  fields. If the input dataset array contains observation names, then `S` has an additional field `ObsNames`.  
If you specify `'AsScalar', true`, then `S` is a scalar structure, with  $N$  fields, each with  $M$  rows.

## Examples

### Convert Dataset Array to Structure Array

Load sample dataset array.

```
load('hospital')
```

Create a dataset array, D, that has only a subset of the observations and variables.

```
D = hospital(1:8,{'LastName','Sex','Age'});  
size(D)
```

```
ans =  
  
      8      3
```

The dataset array D has 8 observations and 3 variables.

Convert D to a structure array.

```
S = dataset2struct(D)
```

```
S =  
  
8x1 struct array with fields:  
  ObsNames  
  LastName  
  Sex  
  Age
```

The structure is 8x1, corresponding to the 8 observations in the dataset array. S also has the field ObsNames, since D had observation names.

Display the field data for the first element of S.

```
S(1)  
  
ans =  
  
  ObsNames: 'YPL-320'  
  LastName: 'SMITH'  
        Sex: [1x1 nominal]  
        Age: 38
```

# dataset.dataset2struct

---

This information corresponds to the first observation (row) of the dataset array.

## Convert Dataset Array to Scalar Structure

Load sample dataset array.

```
load('hospital')
```

Create a dataset array, D, that has only a subset of the observations and variables.

```
D = hospital(1:8,{'LastName','Sex','Age'});  
size(D)
```

```
ans =  
  
      8      3
```

The dataset array D has 8 observations and 3 variables.

Convert D to a scalar structure array.

```
S = dataset2struct(D,'AsScalar',true)
```

```
S =  
  
    ObsNames: {8x1 cell}  
    LastName: {8x1 cell}  
           Sex: [8x1 nominal]  
           Age: [8x1 double]
```

The data in the fields of the scalar structure is 8x1, corresponding to the 8 observations in the dataset array. S also has the field ObsNames, since D had observation names.

Display the data for the field LastName.

```
S.LastName
```

```
ans =  
  
    'SMITH'  
    'JOHNSON'  
    'WILLIAMS'  
    'JONES'  
    'BROWN'  
    'DAVIS'  
    'MILLER'  
    'WILSON'
```

The structure field `LastName` contains all of the data that was in the original dataset array variable, `LastName`.

## Concepts

- “Dataset Arrays” on page 2-137

# dataset2table

---

**Purpose** Convert dataset array to table

**Syntax** `t = dataset2table(ds)`

**Description** `t = dataset2table(ds)` converts a dataset array to a table.

**Input Arguments** **ds - Input dataset array**  
dataset array

Input dataset array to convert to a table, specified as a dataset array. Each variable in `ds` becomes a variable in the output table `t`.

**Output Arguments** **t - Output table**  
table

Output table, returned as a table. The table can store metadata such as descriptions, variable units, variable names, and row names. For more information, see [Table Properties](#).

**Examples** **Convert a Dataset Array to a Table**

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a dataset array containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);  
Protein = Protein(1:5);  
Fat = Fat(1:5);  
Name = Name(1:5);
```

```
cereal = dataset(Calories,Protein,Fat,'ObsNames',Name)  
cereal.Properties.VarDescription = Variables(4:6,2);
```

```
cereal =
```

	Calories	Protein	Fat
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Convert the dataset array to a table.

```
t = dataset2table(cereal)
```

```
t =
```

	Calories	Protein	Fat
	-----	-----	---
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

- “Dataset Arrays” on page 2-137

# dataset.datasetfun

---

## Purpose

Apply function to dataset array variables

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
b = datasetfun(fun,A)
[b,c,...] = datasetfun(fun,A)
[b,...] = datasetfun(fun,A,...,'UniformOutput',false)
[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)
[b,...] = datasetfun(fun,A,...,'DataVars',vars)
[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)
[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)
```

## Description

`b = datasetfun(fun,A)` applies the function specified by `fun` to each variable of the dataset array `A`, and returns the results in the vector `b`. The  $i$ th element of `b` is equal to `fun` applied to the  $i$ th dataset variable of `A`. `fun` is a function handle to a function that takes one input argument and returns a scalar value. `fun` must return values of the same class each time it is called, and `datasetfun` concatenates them into the vector `b`. The outputs from `fun` must be one of the following types: numeric, logical, character, structure, or cell.

To apply functions that return results that are nonscalar or of different sizes and types, use the `'UniformOutput'` or `'DatasetOutput'` parameters described below.

Do not rely on the order in which `datasetfun` computes the elements of `b`, which is unspecified.

If `fun` is bound to more than one built-in function or file, (that is, if it represents a set of overloaded functions), `datasetfun` follows MATLAB dispatching rules in calling the function. (See “Function Precedence Order”.)

`[b,c,...] = datasetfun(fun,A)`, where `fun` is a function handle to a function that returns multiple outputs, returns vectors `b`, `c`, ..., each corresponding to one of the output arguments of `fun`. `datasetfun` calls `fun` each time with as many outputs as there are in the call to

`datasetfun`. `fun` may return output arguments having different classes, but the class of each output must be the same each time `fun` is called.

`[b,...] = datasetfun(fun,A,...,'UniformOutput',false)` allows you to specify a function `fun` that returns values of different sizes or types. `datasetfun` returns a cell array (or multiple cell arrays), where the *i*th cell contains the value of `fun` applied to the *i*th dataset variable of `A`. Setting `'UniformOutput'` to `true` is equivalent to the default behavior.

`[b,...] = datasetfun(fun,A,...,'DatasetOutput',true)` specifies that the output(s) of `fun` are returned as variables in a dataset array (or multiple dataset arrays). `fun` must return values with the same number of rows each time it is called, but it may return values of any type. The variables in the output dataset array(s) have the same names as the variables in the input. Setting `'DatasetOutput'` to `false` (the default) specifies that the type of the output(s) from `datasetfun` is determined by `'UniformOutput'`.

`[b,...] = datasetfun(fun,A,...,'DataVars',vars)` allows you to apply `fun` only to the dataset variables in `A` specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[b,...] = datasetfun(fun,A,...,'ObsNames',obsnames)` specifies observation names for the dataset output when `'DatasetOutput'` is `true`.

`[b,...] = datasetfun(fun,A,...,'ErrorHandler',efun)`, where `efun` is a function handle, specifies the MATLAB function to call if the call to `fun` fails. The error-handling function is called with the following input arguments:

- A structure with the fields `identifier`, `message`, and `index`, respectively containing the identifier of the error that occurred, the text of the error message, and the linear index into the input array(s) at which the error occurred
- The set of input arguments at which the call to the function failed

The error-handling function should either re-throw an error, or return the same number of outputs as `fun`. These outputs are then returned as the outputs of `datasetfun`. If `'UniformOutput'` is true, the outputs of the error handler must also be scalars of the same type as the outputs of `fun`. For example, the following code could be saved in a file as the error-handling function:

```
function [A,B] = errorFunc(S,varargin)

warning(S.identifier,S.message);
A = NaN;
B = NaN;
```

If an error-handling function is not specified, the error from the call to `fun` is rethrown.

## Examples

### Work With Datasets Using Function Handles

Use function handles to compute the mean and plot a histogram of selected variables in a dataset array.

Load the sample data.

```
load hospital
```

Use `datasetfun` to compute the means of the `Weight` and `BloodPressure` variables, and store the results in a dataset array.

```
stats = datasetfun(@mean,hospital,...
    'DataVars',{'Weight','BloodPressure'},...
    'UniformOutput',false)
```

```
stats =

    [154]    [1x2 double]
```

The variable `BloodPressure` contains two columns: One for the systolic measurement, and one for the diastolic measurement.

Display the mean of the blood pressure variable.

```
stats{2}
```

```
ans =
```

```
122.7800  82.9600
```

Plot a histogram of the blood pressure variable.

```
datasetfun(@hist,hospital,...  
           'DataVars','BloodPressure',...  
           'UniformOutput',false);  
title('{\bf Blood Pressure}')  
legend('Systolic','Diastolic','Location','N')
```

## dataset.datasetfun

---

**See Also** `grpstats`

**Purpose**

*D*-optimal augmentation

**Syntax**

```
dCE2 = daugment(dCE,mruns)
[dCE2,X] = daugment(dCE,mruns)
[dCE2,X] = daugment(dCE,mruns,model)
[dCE2,X] = daugment(...,param1,val1,param2,val2,...)
```

**Description**

`dCE2 = daugment(dCE,mruns)` uses a coordinate-exchange algorithm to *D*-optimally add `mruns` runs to an existing experimental design `dCE` for a linear additive model.

`[dCE2,X] = daugment(dCE,mruns)` also returns the design matrix `X` associated with the augmented design.

`[dCE2,X] = daugment(dCE,mruns,model)` uses the linear regression model specified in `model`. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with  $n$  terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ...,  $n$
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1,  $n$ ), (2, 3), ..., ( $n-1$ ,  $n$ )
- 4 The squared terms in order 1, 2, ...,  $n$

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each factor and one row for each term in the model. The entries in any row of `model` are powers for the factors in the columns. For example, if a

# daugment

model has factors  $X_1$ ,  $X_2$ , and  $X_3$ , then a row  $[0 \ 1 \ 2]$  in *model* specifies the term  $(X_1.^0) \cdot (X_2.^1) \cdot (X_3.^2)$ . A row of all zeros in *model* specifies a constant term, which can be omitted.

`[dCE2,X] = daugment(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix, where <i>nfactors</i> is the number of factors. Alternatively, this value can be a cell array containing <i>nfactors</i> elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excldefun'	Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$ , where <i>S</i> is a matrix of treatments with <i>nfactors</i> columns, where <i>nfactors</i> is the number of factors, and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . $b(i)$ is true if the <i>i</i> th row <i>S</i> should be excluded.
'init'	Initial design as an <i>mrns</i> -by- <i>nfactors</i> matrix, where <i>nfactors</i> is the number of factors. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.

Parameter	Value
'options'	<p>The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with <code>statset</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"> <li>• <code>'UseParallel'</code> — If <code>true</code> and if a parpool of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is <code>false</code>, meaning serial computation.</li> <li>• <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.</li> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>daugment</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> <li>▪ You have an open Parallel pool</li> <li>▪ <code>UseParallel</code> is <code>true</code></li> <li>▪ <code>UseSubstreams</code> is <code>false</code></li> </ul>                     In that case, use a cell array the same size as the Parallel pool.                 </li> </ul>
'tries'	<p>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</p>

# daugment

---

---

**Note** The `daugment` function augments an existing design using a coordinate-exchange algorithm; the `'start'` parameter of the `candexch` function provides the same functionality using a row-exchange algorithm.

---

## Examples

The following eight-run design is adequate for estimating main effects in a four-factor model:

```
dCEmain = cordexch(4,8)
dCEmain =
    1   -1   -1    1
   -1   -1    1    1
   -1    1   -1    1
    1    1    1   -1
    1    1    1    1
   -1    1   -1   -1
    1   -1   -1   -1
   -1   -1    1   -1
```

To estimate the six interaction terms in the model, augment the design with eight additional runs:

```
dCEinteraction = daugment(dCEmain,8,'interaction')
dCEinteraction =
    1   -1   -1    1
   -1   -1    1    1
   -1    1   -1    1
    1    1    1   -1
    1    1    1    1
   -1    1   -1   -1
    1   -1   -1   -1
   -1   -1    1   -1
   -1    1    1    1
   -1   -1   -1   -1
    1   -1    1   -1
```

1	1	-1	1
-1	1	1	-1
1	1	-1	-1
1	-1	1	1
1	1	1	-1

The augmented design is full factorial, with the original eight runs in the first eight rows.

## See Also

[dcovary](#) | [cordexch](#) | [candexch](#)

**Purpose** *D*-optimal design with fixed covariates

**Syntax**

```
dCV = dcovary(nfactors, fixed)
[dCV, X] = dcovary(nfactors, fixed)
[dCV, X] = dcovary(nfactors, fixed, model)
[dCV, X] = daugment(..., param1, val1, param2, val2, ...)
```

**Description** `dCV = dcovary(nfactors, fixed)` uses a coordinate-exchange algorithm to generate a *D*-optimal design for a linear additive model with `nfactors` factors, subject to the constraint that the model include the fixed covariate factors in `fixed`. The number of runs in the design is the number of rows in `fixed`. The design `dCV` augments `fixed` with initial columns for treatments of the model terms.

`[dCV, X] = dcovary(nfactors, fixed)` also returns the design matrix `X` associated with the design.

`[dCV, X] = dcovary(nfactors, fixed, model)` uses the linear regression model specified in `model`. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of `X` for a full quadratic model with  $n$  terms is:

- 1** The constant term
- 2** The linear terms in order 1, 2, ...,  $n$
- 3** The interaction terms in order (1, 2), (1, 3), ..., (1,  $n$ ), (2, 3), ..., ( $n-1$ ,  $n$ )
- 4** The squared terms in order 1, 2, ...,  $n$

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors  $X_1$ ,  $X_2$ , and  $X_3$ , then a row  $[0 \ 1 \ 2]$  in *model* specifies the term  $(X_1.^0) \cdot (X_2.^1) \cdot (X_3.^2)$ . A row of all zeros in *model* specifies a constant term, which can be omitted.

`[dCV,X] = daugment(...,param1,val1,param2,val2,...)` specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excludefun'	Handle to a function that excludes undesirable runs. If the function is $f$ , it must support the syntax $b = f(S)$ , where $S$ is a matrix of treatments with nfactors columns and $b$ is a vector of Boolean values with the same number of rows as $S$ . $b(i)$ is true if the $i$ th row $S$ should be excluded.
'init'	Initial design as an mruns-by-nfactors matrix. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.

Parameter	Value
'options'	<p>The value is a structure that contains options specifying whether to compute multiple tries in parallel, and specifying how to use random numbers when generating the starting points for the tries. Create the options structure with <code>statset</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"> <li>• <code>'UseParallel'</code> — If true and if a parpool of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, meaning serial computation.</li> <li>• <code>UseSubstreams</code> — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.</li> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>dcovary</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> <li>▪ You have an open Parallel pool</li> <li>▪ <code>UseParallel</code> is true</li> <li>▪ <code>UseSubstreams</code> is false</li> </ul> In that case, use a cell array the same size as the Parallel pool.</li> </ul>
'tries'	<p>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</p>

## Examples

### Example 1

Suppose you want a design to estimate the parameters in a three-factor linear additive model, with eight runs that necessarily occur at different times. If the process experiences temporal linear drift, you may want to include the run time as a variable in the model. Produce the design as follows:

```
time = linspace(-1,1,8)';
[dCV1,X] = dcovary(3,time,'linear')
dCV1 =
    -1.0000    1.0000    1.0000   -1.0000
     1.0000   -1.0000   -1.0000   -0.7143
    -1.0000   -1.0000   -1.0000   -0.4286
     1.0000   -1.0000    1.0000   -0.1429
     1.0000    1.0000   -1.0000    0.1429
    -1.0000    1.0000   -1.0000    0.4286
     1.0000    1.0000    1.0000    0.7143
    -1.0000   -1.0000    1.0000    1.0000
X =
     1.0000   -1.0000    1.0000    1.0000   -1.0000
     1.0000    1.0000   -1.0000   -1.0000   -0.7143
     1.0000   -1.0000   -1.0000   -1.0000   -0.4286
     1.0000    1.0000   -1.0000    1.0000   -0.1429
     1.0000    1.0000    1.0000   -1.0000    0.1429
     1.0000   -1.0000    1.0000   -1.0000    0.4286
     1.0000    1.0000    1.0000    1.0000    0.7143
     1.0000   -1.0000   -1.0000    1.0000    1.0000
```

The column vector `time` is a fixed factor, normalized to values between  $\pm 1$ . The number of rows in the fixed factor specifies the number of runs in the design. The resulting design `dCV` gives factor settings for the three controlled model factors at each time.

### Example 2

The following example uses the `dummyvar` function to block an eight-run experiment into 4 blocks of size 2 for estimating a linear additive model with two factors:

# dcovary

---

```
fixed = dummyvar([1 1 2 2 3 3 4 4]);
dCV2 = dcovary(2, fixed(:, 1:3), 'linear')
dCV2 =
    1    1    1    0    0
   -1   -1    1    0    0
   -1    1    0    1    0
    1   -1    0    1    0
    1    1    0    0    1
   -1   -1    0    0    1
   -1    1    0    0    0
    1   -1    0    0    0
```

The first two columns of dCV2 contain the settings for the two factors; the last three columns are dummy variable codings for the four blocks.

## See Also

[daugment](#) | [cordexch](#) | [dummyvar](#)

# TreeBagger.DefaultYfit property

---

## Purpose

Default value returned by predict and oobPredict

## Description

The DefaultYfit property controls what predicted value TreeBagger returns when no prediction is possible, for example when the oobPredict method needs to predict for an observation that is in-bag for all trees in the ensemble.

For classification, you can set this property to either '' or 'MostPopular'. If you choose 'MostPopular' (default), the property value becomes the name of the most probable class in the training data.

For regression, you can set this property to any numeric scalar. The default is the mean of the response for the training data.

If you set this property to '' for classification or NaN for regression, TreeBagger excludes the in-bag observations from computation of the out-of-bagerror and margin.

## See Also

[oobPredict](#) | [Predict](#) | [OOBIndices](#)

# grandstream.delete

---

**Purpose** Delete handle object

**Syntax** `delete(h)`

**Description** `delete(h)` deletes the handle object `h`, where `h` is a scalar handle. The `delete` method deletes a handle object but does not clear the handle from the workspace. A deleted handle is no longer valid.

**See Also** `clear` | `isvalid` | `grandstream`

# TreeBagger.DeltaCritDecisionSplit property

---

- Purpose** Split criterion contributions for each predictor
- Description** The DeltaCritDecisionSplit property is a numeric array of size 1-by-Nvars of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.
- See Also** `classregtree.varimportance`

# dendrogram

---

**Purpose** Dendrogram plot

**Syntax** `dendrogram(tree)`  
`dendrogram(tree,Name,Value)`

`dendrogram(tree,P)`  
`dendrogram(tree,P,Name,Value)`

`H = dendrogram( ___ )`  
`[H,T,outperm] = dendrogram( ___ )`

**Description** `dendrogram(tree)` generates a dendrogram plot of the hierarchical binary cluster tree. A dendrogram consists of many *U*-shaped lines that connect data points in a hierarchical tree. The height of each *U* represents the distance between the two data points being connected.

- If there are 30 or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
- If there are more than 30 data points, then `dendrogram` collapses lower branches so that there are 30 leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

`dendrogram(tree,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`dendrogram(tree,P)` generates a dendrogram plot with no more than *P* leaf nodes. If there are more than *P* data points in the original data set, then `dendrogram` collapses the lower branches of the tree. As a result, some leaves in the plot correspond to more than one data point.

`dendrogram(tree,P,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`H = dendrogram( ___ )` generates a dendrogram plot and returns a vector of line handles. You can use any of the input arguments from the previous syntaxes.

`[H,T,outperm] = dendrogram( ___ )` also returns a vector containing the leaf node number for each object in the original data set, `T`, and a vector giving the order of the node labels of the leaves as shown in the dendrogram, `outperm`.

- It is useful to return `T` when the number of leaf nodes, `P`, is less than the total number of data points, so that some leaf nodes in the display correspond to multiple data points.
- The order of the node labels given in `outperm` is from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram.

## Input Arguments

### **tree - Hierarchical binary cluster tree**

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an  $(M - 1)$ -by-3 matrix that you generate using `linkage`, where  $M$  is the number of data points in the original data set.

### **P - Maximum number of leaf nodes**

30 (default) | positive integer value

Maximum number of leaf nodes to include in the dendrogram plot, specified as a positive integer value.

- If there are `P` or fewer data points in the original data set, then each leaf in the dendrogram corresponds to one data point.
- If there are more than `P` data points, then `dendrogram` collapses lower branches so that there are `P` leaf nodes. As a result, some leaves in the plot correspond to more than one data point.

If you do not specify `P`, then `dendrogram` uses 30 as the maximum number of leaf nodes. To display the complete tree, set `P` equal to 0.

# dendrogram

---

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Orientation','left','Reorder',myOrder`, specifies a vertical dendrogram with leaves in the order specified by `myOrder`.

## 'Reorder' - Order of leaf nodes

vector

Order of leaf nodes in the dendrogram plot, specified as the comma-separated pair consisting of `'Reorder'` and a vector giving the order of nodes in the complete tree. The order vector must be a permutation of the vector  $1:M$ , where  $M$  is the number of data points in the original data set. Specify the order from left to right for horizontal dendrograms, and from bottom to top for vertical dendrograms.

If  $M$  is greater than the number of leaf nodes in the dendrogram plot,  $P$  (by default,  $P$  is 30), then you can only specify a permutation vector that does not separate the groups of leaves that correspond to collapsed nodes.

**Example:**

## Data Types

single | double

## 'CheckCrossing' - Indicator for whether to check for crossing branches

true (default) | false

Indicator for whether to check for crossing branches in the dendrogram plot, specified as the comma-separated pair consisting of

'CheckCrossing' and either true or false. This option is only useful when you specify a value for Reorder.

When CheckCrossing has the value true, dendrogram issues a warning if the order of the leaf nodes causes crossing branches in the plot. If the dendrogram plot does not show a complete tree (because the number of data points in the original data set is greater than P), dendrogram only issues a warning when the order of the leaf nodes causes branch to cross in the dendrogram as shown in the plot. That is, there is no warning if the order causes crossing branches in the complete tree but not in the dendrogram as shown in the plot.

## Data Types

logical

## 'ColorThreshold' - Threshold for unique colors

'default' | scalar value in the range (0,max(tree(:,3)))

Threshold for unique colors in the dendrogram plot, specified as the comma-separated pair consisting of 'ColorThreshold' and either the string 'default' or a scalar value in the range (0,max(tree(:,3))). If ColorThreshold has the value  $T$ , then dendrogram assigns a unique color to each group of nodes in the dendrogram whose linkage is less than  $T$ .

- If ColorThreshold has the value 'default', then the threshold,  $T$ , is 70% of the maximum linkage,  $0.7*\max(\text{tree}(:,3))$ .
- If you do not specify a value for ColorThreshold, or if you specify a threshold outside the range (0,max(tree(:,3))), then dendrogram uses only one color for the dendrogram plot.

## 'Orientation' - Orientation of dendrogram

'top' (default) | 'bottom' | 'left' | 'right'

Orientation of the dendrogram in the figure window, specified as the comma-separated pair consisting of 'Orientation' and one of these strings:

# dendrogram

---

'top'	Top to bottom
'bottom'	Bottom to top
'left'	Left to right
'right'	Right to left

## Data Types

char

## 'Labels' - Label for each data point

character array | cell array of strings

Label for each data point in the original data set, specified as the comma-separated pair consisting of 'Labels' and a character array or cell array of strings. `dendrogram` labels any leaves in the dendrogram plot containing a single data point with that data point's label.

## Data Types

char | cell

## Output Arguments

### H - Handles to lines

vector

Handles to lines in the dendrogram plot, returned as a vector.

### T - Leaf node numbers

column vector

Leaf node numbers for each data point in the original data set, returned as a column vector of length  $M$ , where  $M$  is the number of data points in the original data set.

When there are fewer than  $P$  data points in the original data ( $P$  is 30, by default), all data points are displayed in the dendrogram, with each node containing a single data point. In this case,  $T$  is the identity map,  $T = (1:M)'$ .

$T$  is useful when  $P$  is less than the total number of data points. That is, when some leaf nodes in the dendrogram display correspond to multiple

data points. For example, to find out which data points are contained in leaf node  $k$  of the dendrogram plot, use `find(T==k)`.

## **outperm - Permutation of node labels**

vector

Permutation of the node labels of the leaves of the dendrogram as shown in the plot, returned as a row vector. `outperm` gives the order from left to right for a horizontal dendrogram, and from bottom to top for a vertical dendrogram. If there are  $P$  leaves in the dendrogram plot, `outperm` is a permutation of the vector  $1:P$ .

## **Examples**

### **Plot Dendrogram**

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,3);
```

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram using the default options.

```
tree = linkage(X,'average');
```

```
figure()
dendrogram(tree)
```

# dendrogram

---

## Specify Dendrogram Leaf Node Order

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,3);
```

Create a hierarchical binary cluster tree using linkage.

```
tree = linkage(X,'average');
```

```
D = pdist(X);  
leafOrder = optimalleaforder(tree,D)
```

```
leafOrder =
```

3 7 6 1 4 9 5 8 10 2

Plot the dendrogram using an optimal leaf order.

```
figure()  
dendrogram(tree, 'Reorder', leafOrder)
```

The order of the leaf nodes in the dendrogram plot corresponds—from left to right—to the permutation in `leafOrder`.

## Specify Number of Nodes in Dendrogram Plot

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(100,2);
```

# dendrogram

---

There are 100 data points in the original data set, X.

Create a hierarchical binary cluster tree using `linkage`. Then, plot the dendrogram for the complete tree (100 leaf nodes) by setting the input argument `P` equal to 0.

```
tree = linkage(X, 'average');
```

```
figure()  
dendrogram(tree, 0)
```

Now, plot the dendrogram with only 25 leaf nodes. Return the mapping of the original data points to the leaf nodes shown in the plot.

```
figure()  
[~,T] = dendrogram(tree, 25);
```

List the original data points that are in leaf node 7 of the dendrogram plot.

```
find(T==7)
```

```
ans =
```

```
7  
33  
60  
70  
74  
76  
86
```

# dendrogram

---

## Change Dendrogram Orientation and Line Width

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,3);
```

Create a hierarchical binary cluster tree using linkage. Then, plot the dendrogram with a vertical orientation, using the default color threshold. Return handles to the lines so you can change the dendrogram line widths.

```
tree = linkage(X,'average');  
  
figure()  
H = dendrogram(tree,'Orientation','left','ColorThreshold','default');  
set(H,'LineWidth',2)
```

# dataset.Description property

---

## **Purpose**

String describing data set

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Description**

Description is a string describing the data set. The default is an empty string.

# GeneralizedLinearModel.devianceTest

---

<b>Purpose</b>	Analysis of deviance				
<b>Syntax</b>	<code>tbl = devianceTest(md1)</code>				
<b>Description</b>	<code>tbl = devianceTest(md1)</code> returns an analysis of deviance table for the <code>md1</code> generalized linear model. <code>tbl</code> gives the result of a test of whether the fitted model fits significantly better than a constant model.				
<b>Input Arguments</b>	<b>md1</b> Generalized linear model, as constructed by <code>fitglm</code> or <code>stepwiseglm</code> .				
<b>Output Arguments</b>	<b>tbl</b> Table containing two rows and four columns. <ul style="list-style-type: none"><li>• The first row relates to a constant model.</li><li>• The second row relates to the full model in <code>md1</code>.</li><li>• The columns are:<table><tr><td>Deviance</td><td>Deviance is twice the difference between the log likelihoods of the corresponding model (<code>md1</code> or constant) and the saturated model. DFE	Error degrees of freedom. It is the number of observations minus the				

# GeneralizedLinearModel.devianceTest

---

chi2Stat

number of parameters in the corresponding model.

F statistic or Chi-squared statistic, depending on whether the dispersion is estimated (F statistic) or not (Chi-squared statistic)

- *Chi-squared statistic* is the difference between the deviance of the constant model and the deviance of the full model.

- *F statistic* is the difference between the deviance of the constant model and the deviance of the full model, divided by the estimated dispersion.

pValue

*p*-value associated with the test. It is the Chi-squared statistic with (number of coefficients in the model minus one) degrees of freedom, or *F* statistic with (number of coefficients in the model minus one) numerator degrees of freedom, and DFE denominator degrees of freedom.

## Definitions

### Deviance

Deviance of a model  $M_1$  is twice the difference between the loglikelihood of that model and the saturated model,  $M_S$ . The saturated model is the model with the maximum number of parameters that can be estimated.

For example, if there are  $n$  observations  $y_i, i = 1, 2, \dots, n$ , with potentially different values for  $X_i^T\beta$ , then you can define a saturated model with  $n$  parameters. Let  $L(b,y)$  denote the maximum value of the likelihood function for a model. Then the deviance of model  $M_1$  is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where  $b_1$  are the estimated parameters for model  $M_1$  and  $b_S$  are the estimated parameters for the saturated model. The deviance has a chi-square distribution with  $n - p$  degrees of freedom, where  $n$  is the number of parameters in the saturated model and  $p$  is the number of parameters in model  $M_1$ .

If  $M_1$  and  $M_2$  are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances  $D_1$  and  $D_2$  of these models. The difference of the deviances is

$$\begin{aligned} D = D_2 - D_1 &= -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom  $\nu$  equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in  $M_1$  and  $M_2$ . You can get the  $p$ -value for this test using `1 - chi2cdf(D, \nu)`, where  $D = D_2 - D_1$ .

## Examples

### Deviance Test

Perform a deviance test on a generalized linear model.

Construct a generalized linear model.

```
rng('default') % for reproducibility
X = randn(100,5);
mu = exp(X(:, [1 4 5]) * [.4; .2; .3]);
y = poissrnd(mu);
```

# GeneralizedLinearModel.devianceTest

---

```
mdl = fitglm(X,y,'linear','Distribution','poisson');
```

Test whether the model differs from a constant in a statistically significant way.

```
tbl = devianceTest(mdl)
```

```
tbl =
```

	Deviance	DFE
log(y) ~ 1	128.58	99
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5	83.726	94

	chi2Stat
log(y) ~ 1	
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5	44.858

	pValue
log(y) ~ 1	
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5	1.5502e-08

The *p*-value is very small, indicating that the model significantly differs from a constant.

**See Also** [GeneralizedLinearModel](#)

**Concepts**

- “Generalized Linear Models” on page 10-12

**Purpose** Fixed- and random-effects design matrices

**Syntax**

```
D = designMatrix(lme)

D = designMatrix(lme, 'Fixed')

D = designMatrix(lme, 'Random')
Dsub = designMatrix(lme, 'Random', gnumbers)
[Dsub, gnames] = designMatrix(lme, 'Random', gnumbers)
```

**Description** `D = designMatrix(lme)` or `D = designMatrix(lme, 'Fixed')` returns the fixed-effects design matrix for the linear mixed-effects model `lme`.

`D = designMatrix(lme, 'Random')` returns the random-effects design matrix for the linear mixed-effects model `lme`.

`Dsub = designMatrix(lme, 'Random', gnumbers)` returns a subset of the random-effects design matrix for the linear mixed-effects model `lme` corresponding to the grouping variables indicated by the integers in `gnumbers`.

`[Dsub, gnames] = designMatrix(lme, 'Random', gnumbers)` also returns the grouping variable names corresponding to the integers in `gnumbers`.

## Input Arguments

### **lme - Linear mixed-effects model**

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

### **gnumbers - Grouping variable numbers**

integer array

# LinearMixedModel.designMatrix

---

Grouping variable numbers, specified as an integer array, where  $R$  is the length of the cell array that contains the grouping variables for the linear mixed-effects model `lme`.

For example, you can specify the grouping variables  $g_1$ ,  $g_3$ , and  $g_r$  as follows.

**Example:** `[1,3,r]`

## Data Types

`double` | `single`

## Output Arguments

### D - Design matrix

`matrix`

Design matrix of a linear mixed-effects model `lme` returned as one of the following:

- Fixed-effects design matrix —  $n$ -by- $p$  matrix consisting of the fixed-effects design of `lme`, where  $n$  is the number of observations and  $p$  is the number of fixed-effects terms.
- Random-effects design matrix —  $n$ -by- $k$  matrix, consisting of the random-effects design matrix of `lme`. Here,  $k$  is equal to `length(B)`, where `B` is the random-effects coefficients vector of linear mixed-effects model `lme`.

If `lme` has  $R$  grouping variables  $g_1, g_2, \dots, g_R$ , with levels  $m_1, m_2, \dots, m_R$ , respectively, and if  $q_1, q_2, \dots, q_R$  are the lengths of the random-effects vectors that are associated with  $g_1, g_2, \dots, g_R$ , respectively, then `B` is a column vector of length  $q_1 * m_1 + q_2 * m_2 + \dots + q_R * m_R$ .

`B` is made by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1_level1; g1_level2; ...; g1_level_m1; g2_level1; g2_level2; ...; g2_level_m2; ...; gR_level1; gR_level2; ...; gR_level_mR]`'.

## Data Types

single | double

## Dsub - Submatrix of random-effects design matrix

matrix

Submatrix of random-effects design matrix corresponding to the grouping variables indicated by the integers in `gnumbers`, returned as an  $n$ -by- $k$  matrix, where  $k$  is length of the column vector `Bsub`.

`Bsub` contains the concatenated best linear unbiased predictors (BLUPs) of random-effects vectors, corresponding to each level of the grouping variables, specified by `gnumbers`.

If, for example, `gnumbers` is `[1,3,r]`, this corresponds to the grouping variables  $g_1$ ,  $g_3$ , and  $g_r$ . Then, `Bsub` contains the concatenated BLUPs of random-effects vectors corresponding to each level of the grouping variables  $g_1$ ,  $g_3$ , and  $g_r$ , such as

$$[g_{1,level_1}; g_{1,level_2}; \dots; g_{1,level_{m_1}}; g_{3,level_1}; g_{3,level_2}; \dots; g_{3,level_{m_3}}; g_{r,level_1}; g_{r,level_2}; \dots; g_{r,level_{m_r}}]'$$

Thus, `Dsub*Bsub` represents the contribution of all random effects corresponding to grouping variables  $g_1$ ,  $g_3$ , and  $g_r$  to the response of `lme`.

If `gnumbers` is empty, then `Dsub` is the full random-effects design matrix.

## Data Types

single | double

## gnames - Names of grouping variables

$k$ -by-1 cell array

Names of grouping variables corresponding to the integers in `gnumbers` if the design type is 'Random', returned as a  $k$ -by-1 cell array. If the design type is 'Fixed', then `gnames` is an empty matrix `[]`.

# LinearMixedModel.designMatrix

---

## Data Types

cell

## Examples

### Display Fixed- and Random-Effects Design Matrices

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that 5 operators manufacture during three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Display the fixed-effects design matrix.

```
designMatrix(lme)
```

```
ans =
```

```
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
1      1      0
1      0      0
1      0      1
```

The column of 1s represents the constant term in the model. `fitlme` takes the evening shift as the reference group and creates two dummy variables to represent the morning and night shifts, respectively.

Display the random-effects design matrix.

```
designMatrix(lme, 'random')
```

```
ans =
```

```
(1,1)      1
(2,1)      1
(3,1)      1
(4,2)      1
(5,2)      1
(6,2)      1
(7,3)      1
(8,3)      1
(9,3)      1
(10,4)     1
(11,4)     1
(12,4)     1
```

# LinearMixedModel.designMatrix

---

```
(13,5)      1
(14,5)      1
(15,5)      1
```

The first number,  $i$ , in the  $(i,j)$  indices corresponds to the observation number, and  $j$  corresponds to the level of the grouping variable, Operator, i.e., the operator number.

Show the full display of the random-effects design matrix.

```
full(designMatrix(lme, 'random'))
```

```
ans =
```

```
1  0  0  0  0
1  0  0  0  0
1  0  0  0  0
0  1  0  0  0
0  1  0  0  0
0  1  0  0  0
0  0  1  0  0
0  0  1  0  0
0  0  1  0  0
0  0  0  1  0
0  0  0  1  0
0  0  0  1  0
0  0  0  0  1
0  0  0  0  1
0  0  0  0  1
```

Each column corresponds to a level of the grouping variable, Operator.

## Random-Effects Design Matrix of Multiple Grouping Variables

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Store and examine the full random-effects design matrix.

```
D = full(designMatrix(lme, 'random'));
```

The first three columns of matrix `D` contain the indicator variables `fitlme` creates for the three levels (Loamy, Silty, Sandy, respectively) of the first grouping variable, `Soil`. The next 15 columns contain the indicator variables created for the second grouping variable, `Tomato` nested under `Soil`. These are basically the elementwise products of the dummy variables representing the levels of `Soil` (Loamy, Silty, and Sandy, respectively) and the levels of `Tomato` (Cherry, Grape, Heirloom, Plum, Vine, respectively).

# LinearMixedModel.designMatrix

---

## Subset of the Random-Effects Design Matrix

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds,'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

Compute the random-effects design matrix for the second grouping variable, and display the first 12 rows.

```
[Dsub,gname] = designMatrix(lme,'random',2);
full(Dsub(1:12,:))
```

```
ans =  
  
      0      0      0      0      0      0      0      0      0      0      1  
      0      0      0      0      0      0      0      0      0      0      1  
      0      0      0      0      0      0      0      0      0      0      1  
      0      0      0      0      0      0      0      0      0      0      1  
      0      1      0      0      0      0      0      0      0      0      0  
      0      1      0      0      0      0      0      0      0      0      0  
      0      1      0      0      0      0      0      0      0      0      0  
      0      0      0      0      0      0      0      0      1      0      0  
      0      0      0      0      0      0      0      0      1      0      0  
      0      0      0      0      0      0      0      0      1      0      0  
      0      0      0      0      0      0      0      0      1      0      0
```

Dsub contains the dummy variables created for the second grouping variable, that is, tomato nested under soil. These are the elementwise products of the dummy variables representing the levels of Soil (Loamy, Silty, Sandy, respectively) and the levels of Tomato (Cherry, Grape, Heirloom, Plum, Vine, respectively).

Display the name of the grouping variable.

```
gname
```

```
gname =
```

```
'Soil:Tomato'
```

# dfittool

---

**Purpose** Open Distribution Fitting app

**Syntax**

```
dfittool
dfittool(y)
dfittool(y,cens)
dfittool(y,cens,freq)
dfittool(y,cens,freq,dsname)
```

**Description** `dfittool` opens the Distribution Fitting app or brings focus to the app if it is already open. Use the Distribution Fitting app to import data from the workspace, fit distributions to the data, and display the fitted distribution over plots of the empirical distributions.

`dfittool(y)` displays the Distribution Fitting app and creates a data set with data specified by the vector `y`.

`dfittool(y,cens)` uses the vector `cens` to specify whether the observation `y(j)` is censored, (`cens(j)==1`) and/or observed, exactly (`cens(j)==0`). If `cens` is omitted or empty, no `y` values are censored.

`dfittool(y,cens,freq)` uses the vector `freq` to specify the frequency of each element of `y`. If `freq` is omitted or empty, all `y` values have a frequency of 1.

`dfittool(y,cens,freq,dsname)` creates a data set with the name `dsname` using the data vector `y`, censoring indicator `cens`, and frequency vector `freq`.

**See Also** `mle` | `randtool` | `disttool`

**Concepts**

- “Model Data Using the Distribution Fitting App” on page 5-49

**Purpose**

Number of dimensions

**Description**

Number of dimensions in the point set. The `Dimensions` property of a point set contains a positive integer that indicates the number of dimensions for which the points have values. For example, a point set with `Dimensions=5` produces points that each have five values.

Set this property by specifying the number of dimensions when constructing a new point set. After construction, you cannot change the value. The default number of dimensions is 2.

# dataset.DimNames property

---

## **Purpose**

Two-element cell array of strings giving names of dimensions of data set

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Description**

A two-element cell array of strings giving the names of the two dimensions of the data set. The default is `{'Observations' 'Variables'}`.

**Purpose**

Display categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`disp(A)`

**Description**

`disp(A)` prints the categorical array `A` without printing the array name. In all other ways it's the same as leaving the semicolon off an expression, except that empty arrays don't display.

**See Also**

`categorical` | `display`

# classregtree.disp

---

<b>Purpose</b>	Display classregtree object
<b>Syntax</b>	<code>display(t)</code>
<b>Description</b>	<code>display(t)</code> prints the classregtree object <code>t</code> .
<b>See Also</b>	<code>classregtree</code>   <code>view</code>

<b>Purpose</b>	Display cvpartition object
<b>Syntax</b>	<code>disp(c)</code>
<b>Description</b>	<code>disp(c)</code> prints the cvpartition object <code>c</code> .

# dataset disp

---

## Purpose

Display dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
disp(ds)
```

## Description

`disp(ds)` prints the dataset array `ds`, including variable names and observation names (if present), without printing the dataset name. In all other ways it's the same as leaving the semicolon off an expression.

For numeric or categorical variables that are 2-D and have three or fewer columns, `disp` prints the actual data using either short `g`, long `g`, or bank format, depending on the current command line setting. Otherwise, `disp` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `disp` prints quoted strings. Otherwise, `disp` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `disp` prints the contents of each cell (or its size and type if too large). Otherwise, `disp` prints the size of each dataset element.

For time series variables, `disp` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `disp` prints the actual data. Otherwise, `disp` prints the size and type of each dataset element.

For other types of variables, `disp` prints the size and type of each dataset element.

**Purpose** Display generalized linear regression model

**Syntax** `disp mdl`

**Description** `disp mdl` displays the `mdl` linear model.

**Input Arguments** **mdl**  
Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

## Examples **Display a Generalized Linear Regression Model**

Create and display a generalized linear regression model.

Create a generalized linear regression model of Poisson data.

```
X = 2 + randn(100,1);  
mu = exp(1 + X/2);  
y = poissrnd(mu);  
mdl = fitglm(X,y,...  
    'y ~ x1','distr','poisson');
```

Display the model.

```
disp(mdl)
```

```
Generalized Linear regression model:
```

```
log(y) ~ 1 + x1  
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	0.9581	0.090294	10.611	2.6519e-26
x1	0.51027	0.033738	15.124	1.1179e-51

```
100 observations, 98 error degrees of freedom
```

# GeneralizedLinearModel.disp

---

Dispersion: 1  
Chi^2-statistic vs. constant model: 221, p-value = 5.77e-50

**Alternatives** Enter *mdl* at the command line to obtain a display, where *mdl* is the name of your model.

# LinearModel disp

---

**Purpose** Display linear regression model

**Syntax** `display mdl`

**Description** `display mdl` displays the `mdl` linear model.

**Input Arguments** **mdl**  
Linear model, as constructed by `fitlm` or `stepwiselm`.

## Examples **Display a Linear Regression Model**

Create and display a linear regression model.

Create a linear regression model.

```
X = randn(100,5);  
y = X*[1;2;3;4;5] + 6 + randn(100,1);  
mdl = fitlm(X,y);
```

Display the model.

```
disp(mdl)
```

Linear regression model:

```
y ~ 1 + x1 + x2 + x3 + x4 + x5
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	6.0806	0.11393	53.371	4.2509e-72
x1	1.1181	0.1154	9.6894	8.4046e-16
x2	2.0903	0.11378	18.372	7.2209e-33
x3	3.0926	0.10725	28.836	1.7967e-48
x4	3.9343	0.11489	34.244	6.9609e-55
x5	4.9538	0.10799	45.873	3.8195e-66

Number of observations: 100, Error degrees of freedom: 94

Root Mean Squared Error: 1.08  
R-squared: 0.979, Adjusted R-Squared 0.978  
F-statistic vs. constant model: 891, p-value = 1.59e-77

# LinearMixedModel.disp

---

**Purpose** Display linear mixed-effects model

**Syntax** `display(lme)`

**Description** `display(lme)` displays the fitted linear mixed-effects model `lme`.

**Input Arguments** **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

**Examples** **Randomized Block Design**

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Display the model.

```
disp(lme)
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	15
Fixed effects coefficients	3
Random effects coefficients	5
Covariance parameters	2

Formula:

```
QCDev ~ 1 + Shift + (1 | Operator)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
59.012	62.552	-24.506	49.012

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pV
'(Intercept)'	3.1196	0.88681	3.5178	12	0
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0

'(Intercept)'	'(Intercept)'	'std'	1.8297

Group: Error

Name	Estimate	Lower	Upper
------	----------	-------	-------

# LinearMixedModel.disp

---

'Res Std'                    0.76439                    0.49315                    1.1848

This display includes the model performance statistics, Akaike information criterion (AIC), Bayesian information criterion (BIC), loglikelihood, and deviance.

The fixed-effects coefficients table includes the names and estimates of the coefficients in the first two columns. The third column SE shows the standard errors of the coefficients. The column tStat includes the *t*-statistic values that correspond to each coefficient. DF is the residual degrees of freedom, and the pValue is the *p*-value that corresponds to the corresponding *t*-statistic value. The columns Lower and Upper display the lower and upper limits of a 95% confidence interval for each fixed-effects coefficient.

The first table for the random effects shows the types and the estimates of the random effects covariance parameters, with the lower and upper limits of a 95% confidence interval for each parameter. The display also shows the name of the grouping variable, operator, and the total number of levels, 5.

The second table for the random effects shows the estimate of the observation error, with the lower and upper limits of a 95% confidence interval.

## Definitions

### Akaike and Bayesian Information Criteria

Akaike information criterion (AIC) is  $AIC = -2*\log L_M + 2*(nc + p + 1)$ , where  $\log L_M$  is the maximized log likelihood (or maximized restricted log likelihood) of the model, and  $nc + p + 1$  is the number of parameters estimated in the model.  $p$  is the number of fixed-effects coefficients, and  $nc$  is the total number of parameters in the random-effects covariance excluding the residual variance.

Bayesian information criterion (BIC) is  $BIC = -2*\log L_M + \ln(n_{eff})*(nc + p + 1)$ , where  $\log L_M$  is the maximized log likelihood (or maximized restricted log likelihood) of the model,  $n_{eff}$  is the effective number of observations, and  $(nc + p + 1)$  is the number of parameters estimated in the model.

- If the fitting method is maximum likelihood (ML), then  $n_{eff} = n$ , where  $n$  is the number of observations.
- If the fitting method is restricted maximum likelihood (REML), then  $n_{eff} = n - p$ .

A lower value of deviance indicates a better fit. As the value of deviance decreases, both AIC and BIC tend to decrease. Both AIC and BIC also include penalty terms based on the number of parameters estimated,  $p$ . So, when the number of parameters increase, the values of AIC and BIC tend to increase as well. When comparing different models, the model with the lowest AIC or BIC value is considered as the best fitting model.

## Deviance

`LinearMixedModel` computes the deviance of model  $M$  as minus two times the loglikelihood of that model. Let  $L_M$  denote the maximum value of the likelihood function for model  $M$ . Then, the deviance of model  $M$  is

$$-2 * \log L_M.$$

A lower value of deviance indicates a better fit. Suppose  $M_1$  and  $M_2$  are two different models, where  $M_1$  is nested in  $M_2$ . Then, the fit of the models can be assessed by comparing the deviances  $Dev_1$  and  $Dev_2$  of these models. The difference of the deviances is

$$Dev = Dev_1 - Dev_2 = 2(\log LM_2 - \log LM_1).$$

Usually, the asymptotic distribution of this difference has a chi-square distribution with degrees of freedom  $v$  equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in  $M_1$  and  $M_2$ . You can get the  $p$ -value for this test using `1 - chi2cdf(Dev, V)`, where  $Dev = Dev_2 - Dev_1$ .

However, in mixed-effects models, when some variance components fall on the boundary of the parameter space, the asymptotic distribution of this difference is more complicated. For example, consider the hypotheses

# LinearMixedModel.disp

---

$H_0: D = \begin{pmatrix} D_{11} & 0 \\ 0 & 0 \end{pmatrix}$ ,  $D$  is a  $q$ -by- $q$  symmetric positive semidefinite matrix.  
 $H_1: D$  is a  $(q+1)$ -by- $(q+1)$  symmetric positive semidefinite matrix.

That is,  $H_1$  states that the last row and column of  $D$  are different from zero. Here, the bigger model  $M_2$  has  $q + 1$  parameters and the smaller model  $M_1$  has  $q$  parameters. And  $Dev$  has a 50:50 mixture of  $\chi^2_q$  and  $\chi^2_{(q+1)}$  distributions (Stram and Lee, 1994).

# NonLinearModel.disp

---

**Purpose** Display nonlinear regression model

**Syntax** `disp(md1)`

**Description** `disp(md1)` displays the `md1` nonlinear model at the command line.

**Input Arguments** **md1**  
Nonlinear regression model, constructed by `fitnlm`.

## Examples **Display a Nonlinear Regression Model**

Create and display a nonlinear regression model.

Load the reaction data, and specify both a model function and starting values for the iterations.

```
load reaction
modelfun = 'rate~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
beta0 = [1 .05 .02 .1 2];
```

Create a model of the data.

```
mdl = fitnlm(reactants,rate,modelfun,beta0);
```

Display the model.

```
disp(mdl)
```

```
Nonlinear regression model:
    rate ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. constant model: 1.81e+03, p-value = 7.36e-12

# piecwisedistribution.disp

---

<b>Purpose</b>	Display piecwisedistribution object
<b>Syntax</b>	<code>disp(A)</code>
<b>Description</b>	<code>disp(A)</code> prints a text representation of the piecwisedistribution object A, without printing the object name. In all other ways it's the same as leaving the semicolon off an expression.
<b>See Also</b>	<code>piecwisedistribution</code>

**Purpose** Display grandset object

**Syntax** `disp(p)`

**Description** `disp(p)` displays the properties of the quasi-random point set `s`, without printing the variable name. `disp` prints out the number of dimensions and points in the point-set, and follows this with the list of all property values for the object.

**See Also** `grandset`

# grandstream.disp

---

**Purpose**            Display grandstream object

**Syntax**            `disp(q)`

**Description**        `disp(q)` displays the quasi-random stream `q`, without printing the variable name. `disp` prints the type and number of dimensions in the stream, and follows it with the list of point set properties.

**See Also**            `grandstream`

**Purpose**

Display categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`display(A)`

**Description**

`display(A)` prints the categorical array `A`. `categorical` calls `display` when you do not use a semicolon to terminate a statement.

**See Also**

`categorical` | `disp`

# classregtree.display

---

**Purpose**            Display classregtree object

**Syntax**            display(t)  
                      display(A)

**Description**        display(t) prints the classregtree object t. classregtree  
                      callsdisplay when a you do not use a semicolon to terminate a  
                      statement.

                      display(A) prints the categorical array A. categorical callsdisplay  
                      when a you do not use a semicolon to terminate a statement.

**See Also**            classregtree | eval | prune | test

**Purpose** Display cvpartition object

**Syntax** `display(c)`

**Description** `display(c)` prints the cvpartition object `c`. `cvpartition` calls `display` when a you do not use a semicolon to terminate a statement.

**See Also** `cvpartition`

# dataset.display

---

## Purpose

Display dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

`display(ds)`

## Description

`display(ds)` prints the dataset array `ds`, including variable names and observation names (if present). `dataset` calls `display` when you do not use a semicolon to terminate a statement

For numeric or categorical variables that are 2-D and have three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For character variables that are 2-D and 10 or fewer characters wide, `display` prints quoted strings. Otherwise, `display` prints the size and type of each dataset element.

For cell variables that are 2-D and have three or fewer columns, `display` prints the contents of each cell (or its size and type if too large). Otherwise, `display` prints the size of each dataset element.

For time series variables, `display` prints columns for both the time and the data. If the variable is 2-D and has three or fewer columns, `display` prints the actual data. Otherwise, `display` prints the size and type of each dataset element.

For other types of variables, `display` prints the size and type of each dataset element.

# ProbDist.DistName property

---

**Purpose** Read-only string containing probability distribution name of ProbDist object

**Description** DistName is a read-only property of the ProbDist class. DistName is a string containing the type of distribution used to create the object.

**Values** Possible values are:

- 'kernel'
- 'beta'
- 'binomial'
- 'birnbaumsaunders'
- 'exponential'
- 'extreme value'
- 'gamma'
- 'generalized extreme value'
- 'generalized pareto'
- 'inversegaussian'
- 'logistic'
- 'loglogistic'
- 'lognormal'
- 'nakagami'
- 'negative binomial'
- 'normal'
- 'poisson'
- 'rayleigh'
- 'rician'

## ProbDist.DistName property

---

- 'tlocationscale'
- 'weibull'

Use this information to view and compare the type of distribution used to create distribution objects.

# NaiveBayes.Dist property

---

**Purpose** Distribution names

**Description** The `Dist` property is a string or a 1-by-NDims cell array of strings indicating the types of distributions for all the features. If all the features use the same type of distribution, `Dist` is a single string. Otherwise `Dist(j)` indicates the distribution type used for the `j`th feature.

The valid strings for this property are the following:

'normal'	Normal distribution.
'kernel'	Kernel smoothing density estimate.
'mvmn'	Multivariate multinomial distribution.
'mn'	Multinomial bag-of-tokens model.

## gmdistribution.DistName property

---

**Purpose** Type of distribution

**Description** The string 'gaussian mixture distribution'.

# disttool

---

<b>Purpose</b>	Interactive density and distribution plots
<b>Syntax</b>	<code>disttool</code>
<b>Description</b>	<code>disttool</code> is a graphical interface for exploring the effects of changing parameters on the plot of a cdf or pdf.
<b>See Also</b>	<code>randtool</code>   <code>dfittool</code>

- Purpose** Convert categorical array to double array
- The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.
- Syntax** `B = double(A)`
- Description** `B = double(A)` converts the categorical array `A` to a double array. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.
- See Also** `single`

# dataset.double

---

## Purpose

Convert dataset variables to double array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
b = double(A)
b = double(a,vars)
```

## Description

`b = double(A)` returns the contents of the dataset A, converted to one double array. The classes of the variables in the dataset must support the conversion.

`b = double(a,vars)` returns the contents of the dataset variables specified by vars. vars is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

## See Also

`dataset` | `single` | `replacedata`

## Purpose

Drop levels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
B = droplevels(A)
B = droplevels(A,oldlevels)
```

## Description

`B = droplevels(A)` removes unused levels from the categorical array `A`. `B` is a categorical array with the same size and values as `A`, but with a list of potential levels that includes only those present in some element of `A`.

`B = droplevels(A,oldlevels)` removes specified levels from the categorical array `A`. `oldlevels` is a cell array of strings or a 2-D character matrix specifying the levels to be removed.

`droplevels` removes levels, but does not remove elements. Elements of `B` that correspond to elements of `A` having levels in `oldlevels` all have an undefined level.

## Examples

### Example 1

Drop unused age levels from the data in `hospital.mat`:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)','%d'),{'s'});
AgeGroup = ordinal(hospital.Age,labels,[],edges);
AgeGroup = droplevels(AgeGroup);
getlabels(AgeGroup)
ans =
    '20s'    '30s'    '40s'    '50s'
```

## Example 2

- 1 Load patient data from the CSV file `hospital.dat` and store the information in a dataset array with observation names given by the first column in the data (patient identification):

```
patients = dataset('file', 'hospital.dat', ...
                  'delimiter', ',', ...
                  'ReadObsNames', true);
```

- 2 Make the  $\{0,1\}$ -valued variable `smoke` nominal, and change the labels to 'No' and 'Yes':

```
patients.smoke = nominal(patients.smoke, {'No', 'Yes'});
```

- 3 Add new levels to `smoke` as placeholders for more detailed histories of smokers:

```
patients.smoke = addlevels(patients.smoke, ...
                          {'0-5 Years', '5-10 Years', 'LongTerm'});
```

- 4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

```
patients.smoke = setlabels(patients.smoke, 'Never', 'No');
```

- 5 Drop the undifferentiated 'Yes' level from `smoke`:

```
patients.smoke = droplevels(patients.smoke, 'Yes');
```

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

- 6 Set each smoker to one of the new levels, by observation name:

```
patients.smoke('YPL-320') = '5-10 Years';
```

**See Also**

`addlevels` | `getlabels` | `islevel` | `mergelevels` | `reorderlevels`

# dummyvar

---

**Purpose** Create dummy variables

**Syntax** `D = dummyvar(group)`

**Description** `D = dummyvar(group)` returns a matrix `D` containing zeros and ones, whose columns are dummy variables for the grouping variable `group`. Columns of `group` represent categorical predictor variables, with values indicating categorical levels. Rows of `group` represent observations across variables.

`group` can be a numeric vector or categorical column vector representing levels within a single variable, a cell array containing one or more grouping variables, or a numeric matrix or cell array of categorical column vectors representing levels within multiple variables. If `group` is a numeric vector or matrix, values in any column must be positive integers in the range from 1 to the number of levels for the corresponding variable. In this case, `dummyvars` treats each column as a separate numeric grouping variable. With multiple grouping variables, the sets of dummy variable columns are in the same order as the grouping variables in `group`.

The order of the dummy variable columns in `D` matches the order of the groups defined by `group`. When `group` is a categorical vector, the groups and their order match the output of the `getlabels(group)` method. When `group` is a numeric vector, `dummyvar` assumes that the groups and their order are `1:max(group)`. In this respect, `dummyvars` treats a numeric grouping variable differently than `grp2idx`.

If `group` is  $n$ -by- $p$ , `D` is  $n$ -by- $S$ , where  $S$  is the sum of the number of levels in each of the columns of `group`. The number of levels  $s$  in any column of `group` is the maximum positive integer in the column or the number of categorical levels. Levels are considered distinct if they appear in different columns of `group`, even if they have the same value. Columns of `D` are, from left to right, dummy variables created from the first column of `group`, followed by dummy variables created from the second column of `group`, etc.

`dummyvar` treats NaN values or undefined categorical levels in `group` as missing data and returns NaN values in `D`.

Dummy variables are used in regression analysis and ANOVA to indicate values of categorical predictors.

---

**Note** If a column of 1s is introduced in the matrix D, the resulting matrix  $X = [\text{ones}(\text{size}(D,1),1) \ D]$  will be rank deficient. The matrix D itself will be rank deficient if `group` has multiple columns. This is because dummy variables produced from any column of `group` always sum to a column of 1s. Regression and ANOVA calculations often address this issue by eliminating one dummy variable (implicitly setting the coefficients for dropped columns to zero) from each group of dummy variables produced by a column of `group`.

---

## Examples

Suppose you are studying the effects of two machines and three operators on a process. Use `group` to organize predictor data on machine-operator combinations:

```
machine = [1 1 1 1 2 2 2 2]';
operator = [1 2 3 1 2 3 1 2]';
group = [machine operator]
group =
     1     1
     1     2
     1     3
     1     1
     2     2
     2     3
     2     1
     2     2
```

Use `dummyvar` to create dummy variables for a regression or ANOVA calculation:

```
D = dummyvar(group)
D =
     1     0     1     0     0
```

# dummyvar

---

1	0	0	1	0
1	0	0	0	1
1	0	1	0	0
0	1	0	1	0
0	1	0	0	1
0	1	1	0	0
0	1	0	1	0

The first two columns of D represent observations of machine 1 and machine 2, respectively; the remaining columns represent observations of the three operators.

## How To

- “Grouping Variables” on page 2-52
- “Dummy Indicator Variables” on page 2-56
- “Regression with Categorical Covariates” on page 2-60

**Purpose**

Durbin-Watson test

**Syntax**

```
p = dwtest(r,x)
p = dwtest(r,x,Name,Value)
[p,dw] = dwtest( ___ )
```

**Description**

`p = dwtest(r,x)` returns the  $p$ -value for the Durbin-Watson test of the null hypothesis that the residuals from a linear regression are uncorrelated. The alternative hypothesis is that there is autocorrelation among the residuals.

`p = dwtest(r,x,Name,Value)` returns the  $p$ -value for the Durbin-Watson test with additional options specified by one or more name-value pair arguments. For example, you can conduct a one-sided test or calculate the  $p$ -value using a normal approximation.

`[p,dw] = dwtest( ___ )` also returns the Durbin-Watson test statistic, `dw`, using any of the input arguments from the previous syntaxes.

**Input Arguments****x - Design matrix**

matrix

Design matrix for a linear regression, specified as a matrix. Include a column of 1 values in the design matrix so the model contains a constant term.

**Data Types**

single | double

**r - Regression residuals**

vector

Regression residuals, specified as a vector. Obtain `r` by performing a linear regression using a function such as `regress`, or by using the backslash operator.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Tail','right','Method','approximate'` specifies a right-tailed hypothesis test and calculates the  $p$ -value using a normal approximation.

## 'Method' - Computation method for $p$ -value

'exact' | 'approximate'

Computation method for the  $p$ -value, specified as the comma-separated pair consisting of 'Method' and one of the following.

'exact' Calculate an exact  $p$ -value using the Pan algorithm.  
This is the default if the sample size is less than 400.

'approximate' Calculate the  $p$ -value using a normal approximation.  
This is the default if the sample size is 400 or larger.

**Example:** `'Method','exact'`

## 'Tail' - Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternate hypothesis that autocorrelation among the residuals is not zero.
'right'	Test the alternative hypothesis that autocorrelation among the residuals is greater than zero.
'left'	Test the alternative hypothesis that autocorrelation among the residuals is less than zero.

Example: 'Tail', 'right'

## Output Arguments

### **p - p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

### **dw - Test statistic**

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

## Examples

### **Test Residuals for Correlation**

Load the sample census data.

```
load census;
```

Create a design matrix using the census date (cdate) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among the residuals,  $r$ .

```
[p,dw] = dwtest(r,x)
```

```
p =  
    0
```

```
dw =  
    0.1308
```

The returned value  $p = 0$  indicates rejection of the null hypothesis at the 5% significance level.

## One-Sided Hypothesis Test

Load the sample census data.

```
load census;
```

Create a design matrix using the census date (`cdate`) as the predictor. Add a column of 1 values to include a constant term.

```
n = length(cdate);  
x = [ones(n,1),cdate];
```

Fit a linear regression to the data.

```
[b,bint,r] = regress(pop,x);
```

Test the null hypothesis that there is no autocorrelation among regression residuals, against the alternative hypothesis that the autocorrelation is greater than zero.

```
[p,dw] = dwtest(r,x,'Tail','right')
```

```
p =  
    0
```

dw =  
0.1308

The returned value  $p = 0$  indicates rejection of the null hypothesis at the 5% significance level, in favor of the alternative hypothesis that the autocorrelation among residuals is greater than zero.

## Definitions

### Durbin-Watson Test

The Durbin-Watson test is used to test if linear regression residuals are uncorrelated, against the alternative that autocorrelation exists.

The test statistic is

$$d = \frac{\sum_{t=2}^T (e_t - e_{t-1})^2}{\sum_{t=1}^T e_t^2},$$

where  $T$  is the number of observations, and  $e_t$  is the residual at time  $t$ .

The  $p$ -value can be calculated exactly using the Pan algorithm. Alternatively, the  $p$ -value can be estimated using a normal approximation. Significantly small  $p$ -values indicate correlation among residuals.

regress

# LinearModel.dwtest

---

**Purpose** Durbin-Watson test of linear model

**Syntax**

```
P = dwtest mdl
[P,DW] = dwtest mdl
[P,DW] = dwtest mdl,method
[P,DW] = dwtest mdl,method,tail
```

**Description**

`P = dwtest(mdl)` returns the  $p$ -value of the Durbin-Watson test on the `mdl` linear model.

`[P,DW] = dwtest(mdl)` returns the Durbin-Watson statistic.

`[P,DW] = dwtest(mdl,method)` specifies the method `dwtest` uses to compute the  $p$ -value.

`[P,DW] = dwtest(mdl,method,tail)` specifies the alternative hypothesis.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **method**

Algorithm for computing the  $p$ -value:

- 'exact' — Calculates an exact  $p$ -value using Pan's algorithm.
- 'approximate' — Calculates the  $p$ -value using a normal approximation.

**Default:** 'exact' when the sample size is less than 400, 'approximate' otherwise

### **tail**

`dwtest` tests whether `mdl` has no serial correlation against one of these alternative hypotheses:

Tail	Alternative Hypothesis
'both'	Serial correlation is not 0.
'right'	Serial correlation is greater than 0 (right-tailed test).
'left'	Serial correlation is less than 0 (left-tailed test).

**Default:** 'both'

## Output Arguments

### P

*p*-value of the test, a scalar. `dwtest` tests if the residuals are uncorrelated, against the alternative that there is autocorrelation among them. Small values of P indicate that the residuals are correlated.

### DW

Value of the Durbin-Watson statistic, a scalar.

## Definitions

### Durbin-Watson Statistic

Let  $r$  be the vector of residuals (in `mdl.residuals.response`). The Durbin-Watson statistic is

$$DW = \frac{\sum_{i=1}^{n-1} (r_{i+1} - r_i)^2}{\sum_{i=1}^n r_i^2}.$$

## Examples

### Test Residuals for Autocorrelation

Examine whether the residuals from a fitted model of census data over time have autocorrelated residuals.

Load the census data and create a linear model.

# LinearModel.dwtest

---

```
load census
mdl = fitlm(cdate, pop);
```

Find the  $p$ -value of the Durbin-Watson autocorrelation test.

```
P = dwtest(mdl)
```

```
P =
```

```
0
```

There is significant autocorrelation in the residuals.

## Algorithms

Approximate calculation of the  $p$ -value uses a normal approximation [1]. Exact calculation uses Pan's algorithm [2].

LinearModel

## How To

- “Linear Regression” on page 9-12

**Purpose**

Empirical cumulative distribution function

**Syntax**

```
[f,x] = ecdf(y)
[f,x] = ecdf(y,Name,Value)
[f,x,flo,fup] = ecdf( ___ )
```

```
ecdf( ___ )
ecdf(ax, ___ )
```

**Description**

`[f,x] = ecdf(y)` returns the empirical cumulative distribution function (cdf), `f`, evaluated at the points in `x`, using the data in the vector `y`.

In survival and reliability analysis, this empirical cdf is called the Kaplan-Meier estimate. And the data might correspond to survival or failure times.

`[f,x] = ecdf(y,Name,Value)` returns the empirical function values, `f`, evaluated at the points in `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the type of function to evaluate or which data is censored.

`[f,x,flo,fup] = ecdf( ___ )` also returns the 95% lower and upper confidence bounds for the evaluated function values. You can use any of the input arguments in the previous syntaxes.

`ecdf` computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

`ecdf( ___ )` plots the evaluated function.

`ecdf(ax, ___ )` plots the evaluated function using axes with the handle, `ax`, instead of the current axes returned by `gca`.

## Input Arguments

### **y** - Input data

column vector

Input data, specified as a column vector. For example, in survival or reliability analysis, data might be survival or failure times for each item or individual.

### **Data Types**

single | double

### **ax** - Axes handle

handle

Axes handle for the figure `ecdf` plots to, specified as a handle.

For instance, if `h` is a handle for a figure, then `ecdf` can plot to that figure as follows.

**Example:** `ecdf(h,x)`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'censoring',c,'function','cumulative hazard','alpha',0.025,'bounds','on'` specifies that `ecdf` returns the cumulative hazard function and plots the 97.5% confidence bounds, accounting for the censored data specified by vector `c`.

### **'censoring' - Indicator of censored data**

array of 0s (default) | vector of 0s and 1s

Indicator of censored data, specified as the comma-separated pair including `'censoring'` and a Boolean array of the same size as `x`. Enter 1 for observations that are right-censored and 0 for observations that are fully observed. Default is all observations are fully observed.

For instance, if vector `cdata` stores the censored data information, you can enter the censoring information as follows.

**Example:** `'censoring',cdata`

### **Data Types**

logical

### **'frequency' - Frequency of observations**

array of 1s (default) | vector of nonnegative scalars

Frequency of observations, specified as the comma-separated pair consisting of `'frequency'` and a vector containing nonnegative integer counts. This vector is the same size as the vector `x`. The  $j$ th element of this vector gives the number of times the  $j$ th element of `x` was observed. Default is one observation per element of `x`.

For instance, if `failurefreq` is a vector of frequencies, then you can enter it as follows.

**Example:** `'frequency',failurefreq`

### **Data Types**

single | double

### **'alpha' - Confidence level**

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of the evaluated function, specified as the comma-separated pair consisting of `'alpha'` and a scalar value between in the range (0,1). Default is 0.05 for 95% confidence. For a given value `alpha`, the confidence level is  $100(1 - \alpha)\%$ .

For instance, for a 99% confidence interval, you can specify the `alpha` value as follows.

**Example:** `'alpha',0.01`

### **Data Types**

single | double

### **'function' - Type of function returned**

'cdf' (default) | 'survivor' | 'cumulative hazard'

Type of function that `ecdf` evaluates and returns, specified as the comma-separated pair consisting of 'function' and one of the following.

'cdf'	Default. Cumulative distribution function.
'survivor'	Survivor function.
'cumulative hazard'	Cumulative hazard function.

**Example:** 'function', 'cumulative hazard'

### Data Types

char

### 'bounds' - Indicator for including bounds

'off' (default) | 'on'

Indicator for including bounds, specified as the comma-separated pair consisting of 'bounds' and one of the following.

'off'	Default. Specify to omit bounds.
'on'	Specify to include bounds.

---

**Note** This name-value argument is used only for plotting.

---

**Example:** 'bounds', 'on'

### Data Types

char

## Output Arguments

### **f - Function values**

column vector

Function values evaluated at the points in **x**, returned as a column vector.

### **x - Distinct observed points**

column vector

Distinct observed points in data vector **y**, returned as a column vector.

### **flo - Lower confidence bound**

column vector

Lower confidence bound for the evaluated function, returned as a column vector. **ecdf** computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

### **fup - Upper confidence bound**

column vector

Upper confidence bound for the evaluated function, returned as a column vector. **ecdf** computes the confidence bounds using Greenwood's formula. They are not simultaneous confidence bounds.

## Examples

### **Compute Empirical Cumulative Distribution Function**

Compute the Kaplan-Meier estimate of the cumulative distribution function (cdf) for simulated survival data.

Generate survival data from a Weibull distribution with parameters 3 and 1.

```
rng('default') % for reproducibility
failuretime = random('wbl',3,1,15,1);
```

Compute the Kaplan-Meier estimate of the cdf for survival data.

# ecdf

---

```
[f,x] = ecdf(failuretime);  
[f,x]
```

```
ans =
```

0	0.0895
0.0667	0.0895
0.1333	0.1072
0.2000	0.1303
0.2667	0.1313
0.3333	0.2718
0.4000	0.2968
0.4667	0.6147
0.5333	0.6684
0.6000	1.3749
0.6667	1.8106
0.7333	2.1685
0.8000	3.8350
0.8667	5.5428
0.9333	6.1910
1.0000	6.9825

Plot the estimated cdf.

```
figure()  
plot(x,f)
```

### Empirical Hazard Function of Right-Censored Data

Compute and plot the hazard function of simulated right-censored survival data.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, generate a logical array that indicates simulated failure times that are larger than 0.9 as censored data, and store this information in a vector.

```
T = 0.9;  
cens = (failuretime>T);
```

Plot the empirical hazard function for the data.

```
ecdf(failuretime,'function','cumulative hazard',...  
'censoring',cens,'bounds','on');
```

### Compare Empirical Cumulative Distribution Function (CDF) with Known CDF

Generate right-censored survival data and compare the empirical cumulative distribution function (cdf) with the known cdf.

Generate failure times from an exponential distribution with mean failure time of 15.

```
rng('default')
```

```
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Generate the observed failure times. They are the minimum of the generated failure times and the drop-out times.

```
t = min(y,d);
```

Create a logical array that indicates generated failure times that are larger than the drop-out times. The data for which this is true are censored.

```
censored = (y>d);
```

Compute the empirical cdf and confidence bounds.

```
[f,x,flo,fup] = ecdf(t,'censoring',censored);
```

Plot the cdf and confidence bounds.

```
figure()  
ecdf(t,'censoring',censored,'bounds','on');  
hold on
```

Superimpose a plot of the known population cdf.

```
xx = 0:.1:max(t);  
yy = 1-exp(-xx/15);  
plot(xx,yy,'g-','LineWidth',2)  
axis([0 50 0 1])  
legend('Empirical','LCB','UCB','Population',...  
      'Location','SE')  
hold off
```

## Empirical Survivor Function with 99% Confidence Bounds

Generate survival data and plot the empirical survivor function with 99% confidence bounds.

Generate lifetime data from a Weibull distribution with parameters 100 and 2.

```
rng('default') % For reproducibility  
R = wblrnd(100,2,100,1);
```

Plot the survivor function for the data with 99% confidence bounds.

```
ecdf(R,'function','survivor','alpha',0.01,'bounds','on')  
hold on
```

Fit the Weibull survivor function.

```
x = 1:1:250;  
wblsurv = 1-cdf('weibull',x,100,2);
```

```
plot(x,wblsurv,'g-', 'LineWidth',2)  
legend('Empirical','LCB','UCB','Population',...  
      'Location','NE')
```

The survivor function based on the actual distribution is within the confidence bounds.

## Definitions

### Greenwood's Formula

Approximation for the variance of Kaplan-Meier estimator.

The variance estimate is given by

$$V(S(t)) = S^2(t) \sum_{t_i < T} \frac{d_i}{r_i(r_i - d_i)},$$

where  $r_i$  is the number at risk at time  $t_i$ , and  $d_i$  is the number of failures at time  $t_i$ .

## See Also

`cdfplot` | `ecdfhist`

# ecdfhist

---

**Purpose** Histogram based on empirical cumulative distribution function

**Syntax** `[n,c] = ecdfhist(f,x)`  
`[n,c] = ecdfhist(f,x,m)`

`n = ecdfhist(f,x,centers)`

`ecdfhist( ___ )`

**Description** `[n,c] = ecdfhist(f,x)` returns the heights, `n`, of histogram bars for 10 equally spaced bins and the position of the bin centers, `c`.

`ecdfhist` computes the bar heights from the increases in the empirical cumulative distribution function, `f`, at evaluation points, `x`. It normalizes the bar heights so that the area of the histogram is equal to 1. In contrast, `hist` produces bars with heights representing bin counts.

`[n,c] = ecdfhist(f,x,m)` returns the histogram bars using `m` bins.

`n = ecdfhist(f,x,centers)` returns the heights of the histogram bars with bin centers specified by `centers`.

`ecdfhist( ___ )` plots the histogram bars.

## Input Arguments

### **f** - Empirical cdf values

vector

Empirical cdf values at given evaluation points, `x`, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

**Example:** `[f,x] = ecdf(failure); ecdfhist(f,x);`

### **Data Types**

single | double

**x - Evaluation points**

vector

Evaluation points at which empirical cdf values, *f*, are calculated, specified as a vector.

For instance, you can use `ecdf` to obtain the empirical cdf values and enter them in `ecdfhist` as follows.

**Example:** `[f,x] = ecdf(failure); ecdfhist(f,x);`

**Data Types**

single | double

**m - Number of bins**

scalar

Number of bins, specified as a scalar.

For instance, you can draw a histogram with 8 bins as follows.

**Example:** `ecdfhist(f,x,8)`

**Data Types**

single | double

**centers - Center points of bins**

vector

Center points of bins, specified as a vector.

**Example:** `centers = 2:2:10; ecdfhist(f,x,centers);`

**Data Types**

single | double

**Output Arguments****n - Heights of histogram bars**

row vector

Heights of histogram bars `ecdfhist` calculates based on the empirical cdf values, returned as a row vector.

**c - Position of bin centers**

row vector

Position of bin centers, returned as a row vector.

## Examples

### Return Histogram Bar Heights and Bin Centers

Compute the histogram bar heights based on the empirical cumulative distribution function.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

Compute the empirical cumulative distribution function for the data.

```
[f,x] = ecdf(failuretime,'censoring',cens);
```

Now, find the bar heights of the histogram using the cumulative distribution function estimate.

```
[n,c] = ecdfhist(f,x);
[n' c']
```

```
ans =
```

```
2.3529    0.0715
1.7647    0.1565
1.4117    0.2415
1.5294    0.3265
1.0588    0.4115
```

```

0.4706    0.4965
0.4706    0.5815
0.9412    0.6665
0.2353    0.7515
0.2353    0.8365

```

### Return Bar Heights and Bin Centers for a Given Number of Bins

Compute the bar heights for six bins using the empirical cumulative distribution function and also return the bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```

rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);

```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```

T = 0.9;
cens = (failuretime>T);

```

First, compute the empirical cumulative distribution function for the data.

```

[f,x] = ecdf(failuretime,'censoring',cens);

```

Now, estimate the histogram with six bins using the cumulative distribution function estimate.

```

[n,c] = ecdfhist(f,x,6);
[n' c']

```

```

ans =

```

```
1.9764    0.0998
1.7647    0.2415
1.1294    0.3831
0.4235    0.5248
0.7764    0.6665
0.2118    0.8081
```

## Draw Histogram for Given Bin Centers

Draw the histogram of the empirical cumulative distribution histogram for specified bin centers.

Generate failure times from a Birnbaum-Saunders distribution.

```
rng('default') % for reproducibility
failuretime = random('birnbaumsaunders',0.3,1,100,1);
```

Assuming that the end of the study is at time 0.9, mark the generated failure times that are larger than 0.9 as censored data and store that information in a vector.

```
T = 0.9;
cens = (failuretime>T);
```

Define bin centers.

```
centers = 0.1:0.1:1;
```

Compute the empirical cumulative distribution function for the data and draw the histogram for specified bin centers.

```
[f,x] = ecdf(failuretime,'censoring',cens);
ecdfhist(f,x,centers)
axis([0 1 0 2.5])
```

### Compare Histogram with Known Probability Distribution Function

Generate right-censored survival data and compare the histogram from cumulative distribution function with the known probability distribution function.

Generate failure times from an exponential distribution with mean failure time of 15.

# ecdfhist

---

```
rng('default') % For reproducibility  
y = exprnd(15,75,1);
```

Generate drop-out times from an exponential distribution with mean failure time of 30.

```
d = exprnd(30,75,1);
```

Record the minimum of these times as the observed failure times.

```
t = min(y,d);
```

Generate censoring by finding the generated failure times that are greater than the drop-out times.

```
censored = (y>d);
```

Calculate the empirical cdf and plot a histogram using the empirical cumulative distribution function.

```
[f,x] = ecdf(t,'censoring',censored);  
ecdfhist(f,x)  
set(get(gca,'Children'),'FaceColor',[.8 .8 1])  
hold on
```

Superimpose a plot of the known population pdf.

```
xx = 0:.1:max(t);  
yy = exp(-xx/15)/15;  
plot(xx,yy,'r-','LineWidth',2)  
hold off
```

# ecdfhist

<b>Purpose</b>	Edge of $k$ -nearest neighbor classifier
<b>Syntax</b>	<code>E = edge(md1,X,Y)</code> <code>E = edge(md1,X,Y,Name,Value)</code>
<b>Description</b>	<code>E = edge(md1,X,Y)</code> returns the classification edge for <code>md1</code> with data <code>X</code> and classification <code>Y</code> . <code>E = edge(md1,X,Y,Name,Value)</code> computes the edge with additional options specified by one or more <code>Name,Value</code> pair arguments.
<b>Input Arguments</b>	<b>md1 - Classifier model</b> classifier model object  $k$ -nearest neighbor classifier model, returned as a classifier model object.  Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class <code>ClassificationPartitionedModel</code> . You cannot use a partitioned tree for prediction, so this kind of tree does not have a <code>predict</code> method.  Otherwise, <code>md1</code> is of class <code>ClassificationKNN</code> , and you can use the <code>predict</code> method to make predictions.  <b>X - Matrix of predictor values</b> matrix  Matrix of predictor values. Each column of <code>X</code> represents one variable, and each row represents one observation.  <b>Y - Categorical variables</b> categorical array   cell array of strings   character array   logical vector   numeric vector  A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as <code>X</code> . Each row of <code>Y</code> represents the classification of the corresponding row of <code>X</code> .

# ClassificationKNN.edge

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'weights'

Observation weights, a numeric vector of length `size(X,1)`. If you supply `weights`, `edge` computes weighted classification edge.

**Default:** `ones(size(X,1))`

## Output Arguments

**E**

Classification edge, a scalar that is the mean classification margin (see "Margin" on page 21-840).

## Definitions

### Edge

The *edge* is the mean value of the classification *margin*.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

Margin is a column vector with the same number of rows as `X`.

### Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see "Posterior Probability" on page 21-2997.

## Examples

### Edge Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for five-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the edge of the classifier for minimum, mean, and maximum observations classified 'setosa', 'versicolor', and 'virginica' respectively.

```
NewX = [min(X);mean(X);max(X)];
Y = {'setosa';'versicolor';'virginica'};
E = edge(mdl,NewX,Y)
```

```
E =
```

```
1
```

The classifier has no doubt that the Y entries are correct classifications (all five nearest neighbors of each NewX point classify as the corresponding Y entry).

# CompactClassificationDiscriminant.edge

---

<b>Purpose</b>	Classification edge
<b>Syntax</b>	<code>E = edge(obj,X,Y)</code> <code>E = edge(obj,X,Y,Name,Value)</code>
<b>Description</b>	<code>E = edge(obj,X,Y)</code> returns the classification edge for <code>obj</code> with data <code>X</code> and classification <code>Y</code> . <code>E = edge(obj,X,Y,Name,Value)</code> computes the edge with additional options specified by one or more <code>Name,Value</code> pair arguments.
<b>Input Arguments</b>	<b>obj</b> Discriminant analysis classifier of class <code>ClassificationDiscriminant</code> or <code>CompactClassificationDiscriminant</code> , typically constructed with <code>fitcdiscr</code> . <b>X</b> Matrix where each row represents an observation, and each column represents a predictor. The number of columns in <code>X</code> must equal the number of predictors in <code>obj</code> . <b>Y</b> Class labels, with the same data type as exists in <code>obj</code> . The number of elements of <code>Y</code> must equal the number of rows of <code>X</code> . <b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code> . <b>'weights'</b> Observation weights, a numeric vector of length <code>size(X,1)</code> . If you supply weights, <code>edge</code> computes the weighted classification edge.

**Default:** `ones(size(X,1))`

## Output Arguments

**E**

Edge, a scalar representing the weighted average value of the margin.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification *margin*. The weights are the class probabilities in `Obj.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

### Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

## Examples

Compute the classification edge and margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
E = edge(obj,X,species)
```

# CompactClassificationDiscriminant.edge

---

```
E =  
    0.4980  
  
M = margin(obj,X,species);  
M(end-10:end)  
  
ans =  
    0.6551  
    0.4838  
    0.6551  
   -0.5127  
    0.5659  
    0.4611  
    0.4949  
    0.1024  
    0.2787  
   -0.1439  
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);  
E = edge(obj,meas,species)  
  
E =  
    0.9454  
  
M = margin(obj,meas,species);  
M(end-10:end)  
  
ans =  
    0.9983  
    1.0000  
    0.9991  
    0.9978  
    1.0000  
    1.0000
```

0.9999  
0.9882  
0.9937  
1.0000  
0.9649

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.edge

---

**Purpose** Classification edge

**Syntax**  
E = edge(ens,X,Y)  
E = edge(ens,X,Y,Name,Value)

**Description**  
E = edge(ens,X,Y) returns the classification edge for ens with data X and classification Y.  
E = edge(ens,X,Y,Name,Value) computes the edge with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### ens

A classification ensemble constructed with fitensemble, or a compact classification ensemble constructed with compact.

### X

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in X must equal the number of predictors in ens.

### Y

Class labels, with the same data type as exists in ens. The number of elements of Y must equal the number of rows of X.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. edge uses only these learners for calculating loss.

**Default:** 1:NumTrained

## **'mode'**

String representing the meaning of the output E:

- 'ensemble' — E is a scalar value, the edge for the entire ensemble.
- 'individual' — E is a vector with one element per trained learner.
- 'cumulative' — E is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## **'UseObsForLearner'**

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i,j)` is true, learner j is used in predicting the class of row i of X.

**Default:** `true(N,T)`

## **'weights'**

Observation weights, a numeric vector of length `size(X,1)`. If you supply weights, `edge` computes weighted classification edge.

**Default:** `ones(size(X,1))`

# CompactClassificationEnsemble.edge

---

## Output Arguments

**E**

The classification edge, a vector or scalar depending on the setting of the `mode` name-value pair. Classification edge is weighted average classification margin.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`. If you supply weights in the `weights` name-value pair, those weights are used instead of class probabilities.

## Examples

Make a boosted ensemble classifier for the `ionosphere` data, and find the classification edge for the last few rows:

```
load ionosphere
ens = fitensemble(X,Y,'AdaboostM1',100,'Tree');
E = edge(ens,X(end-10:end,:),Y(end-10:end))
```

E =  
8.3310

**See Also** margin | edge

# CompactClassificationSVM.edge

---

## Purpose

Classification edge

## Syntax

```
e = edge(SVMModel,X,Y)
e = edge(SVMModel,X,Y,Name,Value)
```

## Description

`e = edge(SVMModel,X,Y)` returns the classification edge (`e`) for the support vector machine (SVM) classifier `SVMModel` using predictor data `X` and class labels `Y`.

`e = edge(SVMModel,X,Y,Name,Value)` computes the edge with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **SVMModel - SVM classifier**

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier that was trained using `fitcsvm`, specified as a ClassificationSVM or CompactClassificationSVM classifier.

### **X - Predictor data**

matrix of numeric values

Predictor data, specified as a matrix of numeric values.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows of `X` must be equal.

If you set `'Standardize',true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

### **Data Types**

double | single

## Y - Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of SVMModel.Y.

The length of Y and the number of rows of X must be equal.

## Data Types

cell | char | double | logical

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## 'Weights' - Observation weights

ones(size(X,1)) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector. Weights must have the same length as the number of rows of X, i.e., size(X,1).

If you supply weights, edge computes the weighted classification edge.

## Output Arguments

### e - Classification edge

scalar

Classification edge, returned as a scalar. e represents the (weighted) mean of the classification margins.

## Definitions

### Edge

The *edge* is the weighted mean of the *classification margins*.

# CompactClassificationSVM.edge

---

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

## Classification Margins

The *margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [2].

## Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Estimate the Test Sample Edge of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
```

```
'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact c
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample edge.

```
e = edge(CompactSVMModel,XTest,YTest)
```

```
e =
```

```
5.0765
```

The estimated test sample margin average is approximately 5.

## **Estimate the Test Sample Weighted Margin Mean of SVM Classifiers**

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Suppose that the observations were measured sequentially, and that the last 150 observations were better quality due to a technology upgrade. One way to incorporate this advancement is to weigh the better quality observations more than the other observations.

Define a weight vector that weighs the better quality observations two times the other observations.

# CompactClassificationSVM.edge

---

```
n = size(X,1);
weights = [ones(n-150,1);2*ones(150,1)];
```

Train an SVM classifier. Specify the weighting scheme and a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Weights',weights,'Holdout',0.15,...
    'ClassNames',{'b','g'],'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1};
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
```

CVSVMModel is a trained ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

```
e = edge(CompactSVMModel,XTest,YTest,'Weights',wTest)
```

```
e =
```

```
4.8341
```

The test sample weighted average margin is approximately 5.

## Select SVM Classifier Features by Comparing Test Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- fullX contains all predictors (except the removed column of 0s).
- partX contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVModel = PartCVSVMModel.Trained{1};
```

FullCVSVMModel and PartCVSVMModel are ClassificationPartitionedModel classifiers. They contain the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```
fullEdge = edge(FCSVMModel,XTest,YTest)
partEdge = edge(PCSVModel,XTest(:,end-20:end),YTest)
```

```
fullEdge =
    2.8319
```

```
partEdge =
    1.5540
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained using all of the predictors is better.

## Algorithms

For binary classification, the software defines the margin for observation  $j$ ,  $m_j$ , as

$$m_j = 2y_j f(x_j),$$

where  $y_j \in \{-1,1\}$ , and  $f(x_j)$  is the predicted score of observation  $j$  for the positive class. However, the literature commonly uses  $m_j = y_j f(x_j)$  to define the margin.

If you supply <code>weights</code> , <code>edge</code> computes weighted classification edge. <b>Default:</b> <code>ones(size(X,1))</code>

## Output Arguments

**E**

The edge, a scalar representing the weighted average value of the margin.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as the matrix  $X$ .

### Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

Generate 100 random points and classify them:

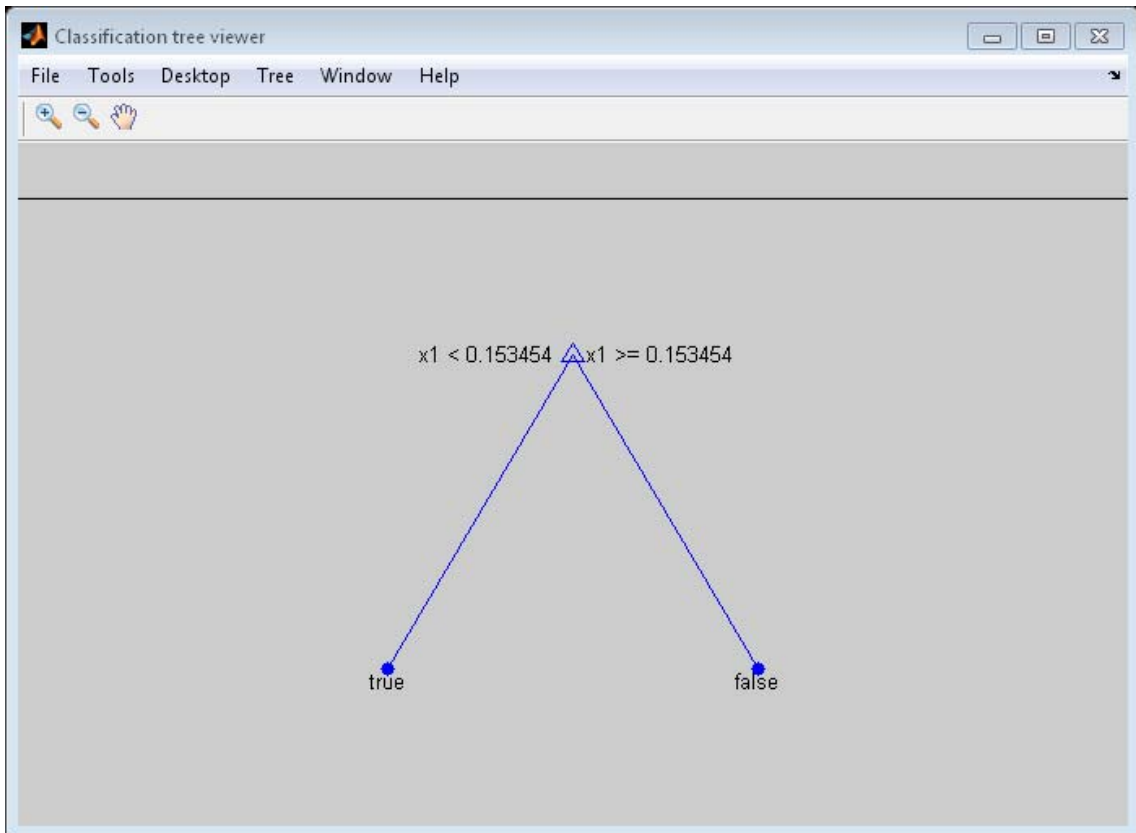

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

# CompactClassificationTree.edge

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

# CompactClassificationTree.edge

---

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

## Examples

Compute the classification margin and edge for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris  
X = meas(:,1:2);  
tree = fitctree(X,species);  
E = edge(tree,X,species)
```

```
E =  
    0.6299  
  
M = margin(tree,X,species);  
M(end-10:end)
```

```
ans =  
    0.1111  
    0.1111  
    0.1111  
   -0.2857  
    0.6364  
    0.6364  
    0.1111  
    0.7500  
    1.0000  
    0.6364  
    0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);  
E = edge(tree,meas,species)
```

```
E =  
    0.9384
```

```
M = margin(tree,meas,species);  
M(end-10:end)
```

```
ans =  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565  
    0.9565
```

# CompactClassificationTree.edge

- Purpose** Last index in indexing expression for categorical array
- The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.
- Syntax** `end(A,k,n)`
- Description** `end(A,k,n)` indexes expressions involving the categorical array `A` when `end` is part of the `k`-th index out of `n` indices. For example, the expression `A(end-1,:)` calls `A`'s `end` method with `end(A,1,2)`.
- See Also** `single`

# dataset.end

---

## **Purpose**

Last index in indexing expression for dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Syntax**

`end(A,k,n)`

## **Description**

`end(A,k,n)` is called for indexing expressions involving the dataset `A` when `end` is part of the `k`-th index out of `n` indices. For example, the expression `A(end-1,:)` calls `A`'s `end` method with `end(A,1,2)`.

## **See Also**

`size`

**Purpose** Last index in indexing expression for point set

**Syntax** `end(p,k,n)`

**Description** `end(p,k,n)` is called for indexing expressions involving the point set `p` when `end` is part of the `k`-th index out of `n` indices. For example, the expression `p(end-1,:)` calls `p`'s `end` method with `end(p,1,2)`.

**See Also** `grandset`

# RepeatedMeasuresModel.epsilon

---

**Purpose** Epsilon adjustment for repeated measures anova

**Syntax**  
`tbl = epsilon(rm)`  
`tbl = epsilon(rm,C)`

**Description** `tbl = epsilon(rm)` returns the epsilon adjustment factors for repeated measures model `rm`.

`tbl = epsilon(rm,C)` returns the epsilon adjustment factors for the test based on the contrast matrix `C`.

**Tips**

- The `mauchly` method tests for sphericity.
- The `ranova` method contains  $p$ -values based on each epsilon value.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **C - Contrasts**

matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

### **Data Types**

single | double

## Output Arguments

### **tbl - Epsilon adjustment factors**

table

Epsilon adjustment factors for the repeated measures model `rm`, returned as a table. `tbl` contains four different adjustments for `epsilon`.

Correction	Definition
Uncorrected	No adjustments, $\epsilon = 1$
Greenhouse-Geiser	Greenhouse-Geiser approximation
Huynh-Feldt	Huynh-Feldt approximation
Lower bound	Lower bound on the $p$ -value

For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 8-56.

### **Data Types**

table

## Examples

### **Epsilon Corrections for Repeated Measures ANOVA**

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

# RepeatedMeasuresModel.epsilon

---

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = anova(rm)
```

```
ranovatbl =
```

	SumSq	DF	MeanSq	F	pVal
Measurements	1656.3	3	552.09	6873.3	
species:Measurements	282.47	6	47.078	586.1	1.4271
Error	35.423	441	0.080324		

`anova` computes the last three  $p$ -values using Greenhouse-Geisser, Huynh-Feldt, and lower bound corrections, respectively.

Display the epsilon correction values.

```
epsilon(rm)
```

```
ans =
```

	epsilon
Uncorrected	1
Greenhouse-Geisser	0.75179
Huynh-Feldt	0.77448
Lower bound	0.33333

You can check the compound symmetry (sphericity) assumption using the `mauchly` method.

## Algorithms

`ranova` computes the regular  $p$ -value (in the `pValue` column of the `rmanova` table) using the  $F$ -statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor epsilon,  $\epsilon$ , to compute the corrected  $p$ -values as follows:

$$p\text{-value\_corrected} = 1 - \text{fcdf}(F, \epsilon^*v_1, \epsilon^*v_2).$$

The `epsilon` method returns the epsilon adjustment values.

## Concepts

- “Compound Symmetry Assumption and Epsilon Corrections” on page 8-56
- “Mauchly’s Test of Sphericity” on page 8-58

**Purpose** Extreme value cumulative distribution function

**Syntax**

```
p = evcdf(x,mu,sigma)
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = evcdf( __ , 'upper' )
```

**Description** `p = evcdf(x,mu,sigma)` returns the cumulative distribution function (cdf) for the type 1 extreme value distribution, with location parameter `mu` and scale parameter `sigma`, at each of the values in `x`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is a 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies  $100(1 - \alpha)\%$  confidence bounds. `plo` and `pup` are arrays of the same size as `p`, containing the lower and upper confidence bounds.

`[p,plo,pup] = evcdf( __ , 'upper' )` returns the complement of the type 1 extreme value distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The function `evcdf` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `P`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $X$  and subtracting the resulting distribution values from 1. See “Extreme Value Distribution” on page B-37 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

**See Also**

[cdf](#) | [evpdf](#) | [evinv](#) | [evstat](#) | [evfit](#) | [evlike](#) | [evrnd](#)

**How To**

- “Extreme Value Distribution” on page B-37

**Purpose** Extreme value parameter estimates

**Syntax**

```
parmhat = evfit(data)
[parmhat,parmci] = evfit(data)
[parmhat,parmci] = evfit(data,alpha)
[...] = evfit(data,alpha,censoring)
[...] = evfit(data,alpha,censoring,freq)
[...] = evfit(data,alpha,censoring,freq,options)
```

**Description** `parmhat = evfit(data)` returns maximum likelihood estimates of the parameters of the type 1 extreme value distribution given the data in the vector `data`. `parmhat(1)` is the location parameter,  $\mu$ , and `parmhat(2)` is the scale parameter,  $\sigma$ .

`[parmhat,parmci] = evfit(data)` returns 95% confidence intervals for the parameter estimates on the  $\mu$  and  $\sigma$  parameters in the 2-by-2 matrix `parmci`. The first column of the matrix of the extreme value fit contains the lower and upper confidence bounds for the parameter  $\mu$ , and the second column contains the confidence bounds for the parameter  $\sigma$ .

`[parmhat,parmci] = evfit(data,alpha)` returns  $100(1 - \text{alpha})\%$  confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = evfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = evfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = evfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood

estimates. You can create options using the function `statset`. Enter `statset('evfit')` to see the names and default values of the parameters that `evfit` accepts in the options structure. See the reference page for `statset` for more information about these options.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $X$ . See “Extreme Value Distribution” on page B-37 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

**How To**

- “Extreme Value Distribution” on page B-37

**Purpose** Extreme value inverse cumulative distribution function

**Syntax**  
`X = evinv(P,mu,sigma)`  
`[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)`

**Description** `X = evinv(P,mu,sigma)` returns the inverse cumulative distribution function (cdf) for a type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` is a scalar that specifies  $100(1 - \alpha)\%$  confidence bounds for the estimated parameters, and has a default value of 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `evinv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where  $q$  is the  $P$ th quantile from an extreme value distribution with parameters  $\mu = 0$  and  $\sigma = 1$ . The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $X$ . See “Extreme Value Distribution” on page B-37 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

# grandstream.eq

---

**Purpose** Test handle equality

**Syntax**  
`h1 == h2`  
`tf = eq(h1, h2)`

**Description** `h1 == h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise equality result. If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = eq(h1, h2)` stores the result in a logical array of the same dimensions.

**See Also** `grandstream` | `ge` | `gt` | `le` | `lt` | `ne`

**Purpose** Error (misclassification probability or MSE)

**Syntax**  
`err = error(B,X,Y)`  
`err = error(B,X,Y,'param1',val1,'param2',val2,...)`

**Description** `err = error(B,X,Y)` computes the misclassification probability (for classification trees) or mean squared error (MSE, for regression trees) for each tree, for predictors `X` given true response `Y`. For classification, `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

<code>'mode'</code>	String indicating how the method computes errors. If set to <code>'cumulative'</code> (default), error computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
<code>'trees'</code>	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.

# CompactTreeBagger.error

---

- 'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
- 'useifort' Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

## Purpose

Error (misclassification probability or MSE)

## Syntax

```
err = error(B,X,Y)
err = error(B,X,Y,'param1',val1,'param2',val2,...)
```

## Description

`err = error(B,X,Y)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for predictors `X` given true response `Y`. For classification, `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

- 'mode' String indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and `err` is a vector of length `NTrees`, where the first element gives error from `trees(1)`, second element gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to 'individual', `err` is a vector of length `NTrees`, where each element is an error from each tree in the ensemble. If set to 'ensemble', `err` is a scalar showing the cumulative error for the entire ensemble.
- 'trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

# TreeBagger.error

---

- 'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
- 'useifort' Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`CompactTreeBagger.error`

<b>Purpose</b>	Predicted responses
<b>Syntax</b>	<pre> yfit = eval(t,X) yfit = eval(t,X,s) [yfit,nodes] = eval(...) [yfit,nodes,cnums] = eval(...) [...] = t(X) [...] = t(X,s) </pre>
<b>Description</b>	<p><code>yfit = eval(t,X)</code> takes a classification or regression tree <code>t</code> and a matrix <code>X</code> of predictors, and produces a vector <code>yfit</code> of predicted response values. For a regression tree, <code>yfit(i)</code> is the fitted response value for a point having the predictor values <code>X(i,:)</code>. For a classification tree, <code>yfit(i)</code> is the class into which the tree assigns the point with data <code>X(i,:)</code>.</p> <p><code>yfit = eval(t,X,s)</code> takes an additional vector <code>s</code> of pruning levels, with 0 representing the full, unpruned tree. <code>t</code> must include a pruning sequence as created by <code>classregtree</code> or by <code>prune</code>. If <code>s</code> has <math>k</math> elements and <code>X</code> has <math>n</math> rows, the output <code>yfit</code> is an <math>n</math>-by-<math>k</math> matrix, with the <math>j</math>th column containing the fitted values produced by the <code>s(j)</code> subtree. <code>s</code> must be sorted in ascending order.</p> <p>To compute fitted values for a tree that is not part of the optimal pruning sequence, first use <code>prune</code> to prune the tree.</p> <p><code>[yfit,nodes] = eval(...)</code> also returns a vector <code>nodes</code> the same size as <code>yfit</code> containing the node number assigned to each row of <code>X</code>. Use <code>view</code> to display the node numbers for any node you select.</p> <p><code>[yfit,nodes,cnums] = eval(...)</code> is valid only for classification trees. It returns a vector <code>cnum</code> containing the predicted class numbers.</p> <p>NaN values in <code>X</code> are treated as missing. If <code>eval</code> encounters a missing value when it attempts to evaluate the split rule at a branch node, it cannot determine whether to proceed to the left or right child node. Instead, it sets the corresponding fitted value equal to the fitted value assigned to the branch node.</p> <p><code>[...] = t(X)</code> or <code>[...] = t(X,s)</code> also invoke <code>eval</code>.</p>

# classregtree.eval

---

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})

t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```

Click to display:  Magnification:  Pruning level:

Find assigned class names:

```
sfit = eval(t,meas);
```

Compute that proportion is correctly classified:

```
pct = mean(strcmp(sfit,species))
pct =
    0.9800
```

# classregtree.eval

## Purpose

Evaluate clustering solutions

## Syntax

```
eva = evalclusters(x,clust,criterion)
eva = evalclusters(x,clust,criterion,Name,Value)
```

## Description

`eva = evalclusters(x,clust,criterion)` creates a clustering evaluation object containing data used to evaluate the optimal number of data clusters.

`eva = evalclusters(x,clust,criterion,Name,Value)` creates a clustering evaluation object using additional options specified by one or more name-value pair arguments.

## Input Arguments

### **x** - Input data

matrix

Input data, specified as an  $N$ -by- $P$  matrix.  $N$  is the number of observations, and  $P$  is the number of variables.

### **Data Types**

single | double

### **clust** - Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in $x$ using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in $x$ using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in $x$ using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using the function\_handle (@) operator. The function must be of the form  $C = \text{clustfun}(\text{DATA}, K)$ , where DATA is the data to be clustered, and  $K$  is the number of clusters. The output of clustfun must be one of the following:

- A vector of integers representing the cluster index for each observation in DATA. There must be  $K$  unique values in this vector.
- A numeric  $n$ -by- $K$  matrix of score for  $n$  observations and  $K$  classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify clust as a  $n$ -by- $K$  matrix containing the proposed clustering solutions.  $n$  is the number of observations in the sample data, and  $K$  is the number of proposed clustering solutions. Column  $j$  contains the cluster indices for each of the  $N$  points in the  $j$ th clustering solution.

### **criterion - Clustering evaluation criterion**

'CalinskiHarabasz' | 'DaviesBouldin' | 'gap' | 'silhouette'

Clustering evaluation criterion, specified as one of the following.

'CalinskiHarabasz'	Create a <code>CalinskiHarabaszEvaluation</code> clustering evaluation object containing Calinski-Harabasz index values.
'DaviesBouldin'	Create a <code>DaviesBouldinEvaluation</code> cluster evaluation object containing Davies-Bouldin index values.
'gap'	Create a <code>GapEvaluation</code> cluster evaluation object containing gap criterion values.
'silhouette'	Create a <code>SilhouetteEvaluation</code> cluster evaluation object containing silhouette values.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

**Example:** `'KList', [1:5], 'Distance', 'cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

### For All Criteria

#### 'KList' - List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string

or a function handle. When `criterion` is 'gap', `clust` must be a string or a function handle, and you must specify `KList`.

**Example:** 'KList',[1:6]

## For Silhouette and Gap

### 'Distance' - Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (@) operator. The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by- $n$  vector corresponding to a single row of the input matrix `X`, and `XJ` is an  $m_2$ -by- $n$  matrix corresponding to multiple rows of `X`. `distfun` must return an  $m_2$ -by-1 vector of distances `d2`, whose  $k$ th element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is `'silhouette'`, you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

**Example:** `'Distance', 'Euclidean'`

### For Silhouette Only

#### **'ClusterPriors' - Prior probabilities for each cluster**

`'empirical'` (default) | `'equal'`

Prior probabilities for each cluster, specified as the comma-separated pair consisting of `'ClusterPriors'` and one of the following.

- |                          |   |
|--------------------------|---|
| <code>'empirical'</code> | Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.              |
| <code>'equal'</code>     | Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes |

equally to the overall silhouette value, regardless of its size.

**Example:** 'ClusterPriors', 'empirical'

## For Gap Only

### **'B' - Number of reference data sets**

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of 'B' and a positive integer value.

**Example:** 'B', 150

### **'ReferenceDistribution' - Reference data generation method**

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix $x$ .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix $x$ .

**Example:** 'ReferenceDistribution', 'uniform'

### **'SearchMethod' - Method for selecting optimal number of clusters**

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

`'globalMaxSE'`

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters,  $\text{GAPMAX}$  is the largest gap value, and  $\text{SE}(\text{GAPMAX})$  is the standard error corresponding to the largest gap value.

`'firstMaxSE'`

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters, and  $\text{SE}(K + 1)$  is the standard error of the clustering solution with  $K + 1$  clusters.

**Example:** `'SearchMethod', 'globalMaxSE'`

## Output Arguments

### **eva - Clustering evaluation data**

clustering evaluation object

Clustering evaluation data, returned as a clustering evaluation object.

## Examples

### **Evaluate the Clustering Solution Using Calinski-Harabasz Criterion**

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using kmeans.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
  InspectedK: [1 2 3 4 5 6]
CriterionValues: [1x6 double]
  OptimalK: 3
```

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

## Evaluate a Matrix of Clustering Solutions

Use an input matrix of proposed clustering solutions to evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use kmeans to create an input matrix of proposed clustering solutions for the sepal length measurements, using 1, 2, 3, 4, 5, and 6 clusters.

```
clust = zeros(size(meas,1),6);
for i=1:6
```

```

clust(:,i) = kmeans(meas,i,'emptyaction','singleton',...
    'replicate',5);
end

```

Each row of `clust` corresponds to one sepal length measurement. Each of the six columns corresponds to a clustering solution containing 1 to 6 clusters.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,clust,'CalinskiHarabasz')
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150
```

```
InspectedK: [1 2 3 4 5 6]
```

```
CriterionValues: [NaN 513.9245 561.6278 530.7658 459.5058 473.6577]
```

```
OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

### Specify Clustering Algorithm with a Function Handle

Use a function handle to specify the clustering algorithm, then evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use a function handle to specify the clustering algorithm.

```
myfunc = @(X,K)(kmeans(X, K, 'emptyaction','singleton',...
```

```
'replicate',5));
```

Evaluate the optimal number of clusters for the sepal length data using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,myfunc,'CalinskiHarabasz',...  
    'klist',[1:6])
```

```
eva =
```

```
CalinskiHarabaszEvaluation with properties:
```

```
NumObservations: 150  
    InspectedK: [1 2 3 4 5 6]  
CriterionValues: [NaN 513.9245 561.6278 530.7658 459.5058 473.6577]  
    OptimalK: 3
```

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

# evpdf

---

**Purpose** Extreme value probability density function

**Syntax**  $Y = \text{evpdf}(X, \mu, \sigma)$

**Description**  $Y = \text{evpdf}(X, \mu, \sigma)$  returns the pdf of the type 1 extreme value distribution with location parameter  $\mu$  and scale parameter  $\sigma$ , evaluated at the values in  $X$ .  $X$ ,  $\mu$ , and  $\sigma$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for  $\mu$  and  $\sigma$  are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating  $X$ . See “Extreme Value Distribution” on page B-37 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

# evstat

---

**Purpose** Extreme value mean and variance

**Syntax** `[M,V] = evstat(mu,sigma)`

**Description** `[M,V] = evstat(mu,sigma)` returns the mean of and variance for the type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input. The default values for `mu` and `sigma` are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima. See “Extreme Value Distribution” on page B-37 for more details. If  $x$  has a Weibull distribution, then  $X = \log(x)$  has the type 1 extreme value distribution.

<b>Superclasses</b>	ToolboxFittableParametricDistribution
<b>Purpose</b>	Exponential probability distribution object
<b>Description</b>	<p>prob.ExponentialDistribution is an object consisting of parameters, a model description, and sample data for an exponential probability distribution.</p> <p>Create a probability distribution object with specified parameter values using <code>makedist</code>. Alternatively, fit a distribution to data using <code>fitdist</code> or the Distribution Fitting app.</p>
<b>Construction</b>	<p><code>pd = makedist('Exponential')</code> creates an exponential probability distribution object using the default parameter values.</p> <p><code>pd = makedist('Exponential','mu',mu)</code> creates an exponential probability distribution object using the specified parameter value.</p>
	<b>Input Arguments</b>
	<b>mu - Mean</b> 1 (default)   positive scalar value  Mean of the exponential distribution, specified as a positive scalar value.
	<b>Data Types</b> single   double
<b>Properties</b>	<b>mu - Mean</b> positive scalar value  Mean of the exponential distribution, stored as a positive scalar value.
	<b>Data Types</b> single   double
	<b>DistributionName - Probability distribution name</b> probability distribution name string

# prob.ExponentialDistribution

---

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

### **Data Types**

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

### **Data Types**

char

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

# prob.ExponentialDistribution

---

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object

var	Variance of probability distribution object

## Definitions

### Exponential Distribution

The exponential distribution is used to model events that occur randomly over time, and its main application area is studies of lifetimes. It is a special case of the gamma distribution with the shape parameter  $\alpha = 1$ .

The exponential distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$\mu > 0$

The probability density function (pdf) is

# prob.ExponentialDistribution

---

$$f(x|\mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}} \quad ; \quad x \geq 0.$$

## Examples

### Create an Exponential Distribution Object Using Default Parameters

Create an exponential distribution object using the default parameter values.

```
pd = makedist('Exponential')
```

```
pd =
```

```
ExponentialDistribution
```

```
Exponential distribution
```

```
mu = 1
```

### Create an Exponential Distribution Object Using Specified Parameters

Create an exponential distribution object by specifying the parameter values.

```
pd = makedist('Exponential','mu',2)
```

```
pd =
```

```
ExponentialDistribution
```

```
Exponential distribution
```

```
mu = 2
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =
```

# expcdf

---

**Purpose** Exponential cumulative distribution function

**Syntax**  
`p = expcdf(x,mu)`  
`[p,plo,pup] = expcdf(x,mu,pcov,alpha)`  
`[p,plo,pup] = expcdf( __ , 'upper' )`

**Description** `p = expcdf(x,mu)` computes the exponential cdf at each of the values in `x` using the corresponding mean parameter `mu`. `x` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

`[p,plo,pup] = expcdf(x,mu,pcov,alpha)` produces confidence bounds for `Pp` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies  $100(1 - \alpha)\%$  confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper endpoints of that interval.

`[p,plo,pup] = expcdf( __ , 'upper' )` returns the complement of the exponential cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the prior syntaxes.

The exponential cdf is

$$p = F(x | u) = \int_0^x \frac{1}{\mu} e^{-\frac{t}{\mu}} dt = 1 - e^{-\frac{x}{\mu}}$$

The result,  $p$ , is the probability that a single observation from an exponential distribution will fall in the interval  $[0, x]$ .

**Examples****Compute the Exponential CDF**

The following code shows that the median of the exponential distribution is  $\mu \log(2)$ .

```
mu = 10:10:60;  
p = expcdf(log(2)*mu,mu)
```

```
p =  
0.5000 0.5000 0.5000 0.5000 0.5000 0.5000
```

What is the probability that an exponential random variable is less than or equal to the mean,  $\mu$ ?

```
mu = 1:6;  
x = mu;  
p = expcdf(x,mu)
```

```
p =  
0.6321 0.6321 0.6321 0.6321 0.6321 0.6321
```

**See Also**

[cdf](#) | [exppdf](#) | [expinv](#) | [expstat](#) | [expfit](#) | [explike](#) | [exprnd](#)

**How To**

- “Exponential Distribution” on page B-33

# expfit

---

**Purpose** Exponential parameter estimates

**Syntax**

```
muhat = expfit(data)
[muhat,muci] = expfit(data)
[muhat,muci] = expfit(data,alpha)
[...] = expfit(data,alpha,censoring)
[...] = expfit(data,alpha,censoring,freq)
```

**Description** `muhat = expfit(data)` estimates the mean of an exponentially distributed sample data. Each entry of `muhat` corresponds to the data in a column of `data`.

`[muhat,muci] = expfit(data)` returns 95% confidence intervals for the mean parameter estimates in matrix `muci`. The first row of `muci` contains the lower bounds of the confidence intervals, and the second row contains the upper bounds.

`[muhat,muci] = expfit(data,alpha)` returns  $100(1 - \alpha)\%$  confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = expfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = expfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

**Examples** The following estimates the mean  $\mu$  of exponentially distributed data, and returns a 95% confidence interval for the estimate:

```
mu = 3;
data = exprnd(mu,100,1); % Simulated data
```

```
[muhat,muci] = expfit(data)
muhat =
    2.7511
muci =
    2.2826
    3.3813
```

# ExhaustiveSearcher

---

**Superclasses** NeighborSearcher

**Purpose** Nearest neighbors search using exhaustive search

**Description** An ExhaustiveSearcher object performs  $k$ NN ( $k$ -nearest neighbor) search using exhaustive search. Search objects store information about the data used, and the distance metric and parameters. The search performance for this object, compared with the KDTreeSearcher object, tends to be better for larger dimensions (10 or more) and worse for smaller dimensions. For more information on search objects, see “What Are Search Objects?” on page 16-17.

**Construction** `NS = ExhaustiveSearcher(X, 'Name', Value)` constructs an ExhaustiveSearcher object based on `X`, where rows of `X` correspond to observations and columns correspond to variables, using one or more optional name/value pairs. You can then use this object to find neighbors in `X` nearest to the query points.

`NS = createns(X, 'NSMethod', 'exhaustive', 'Name', Value)` creates an ExhaustiveSearcher object based on `X` using `createns`, where rows of `X` correspond to observations and columns correspond to variables, using one or more optional name/value pairs. You can use this object to find neighbors in `X` nearest to the query points.

## Name-Value Pair Arguments

Both the ExhaustiveSearcher and the createns functions accept one or more of the following optional name/value pairs as input:

### 'Distance'

A string or function handle specifying the default distance metric used when you call the `knnsearch` method.

- 'euclidean' — Euclidean distance (default).
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in `X` and the query matrix is scaled by dividing by the corresponding element of the standard

deviation computed from  $X$ ,  $S = \text{nanstd}(X)$ . To specify another value for  $S$ , use the `Scale` argument.

- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance.
- `'mahalanobis'` — Mahalanobis distance, computed using a positive definite covariance matrix  $C$ . The default value of  $C$  is `nancov(X)`. To change the value of  $C$ , use the `Cov` parameter.
- `'cosine'` — One minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- `'hamming'` — Hamming distance, percentage of coordinates that differ.
- `'jaccard'` — One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
- `custom distance function` — A distance function specified using `@` (for example, `@distfun`). A distance function must be of the form `function D2 = distfun(ZI, ZJ)`, taking as arguments a 1-by- $n$  vector  $ZI$  containing a single row from  $X$  or from the query points  $Y$ , an  $m2$ -by- $n$  matrix  $ZJ$  containing multiple rows of  $X$  or  $Y$ , and returning an  $m2$ -by-1 vector of distances  $D2$ , whose  $j$ th element is the distance between the observations  $ZI$  and  $ZJ(j,:)$ .

For more information on these distance metrics, see “Distance Metrics” on page 16-9.

# ExhaustiveSearcher

---

## **'P'**

A positive scalar indicating the exponent of Minkowski distance. This parameter is only valid when `Distance` is `'minkowski'`. Default is 2.

## **'Cov'**

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when `Distance` is `'mahalanobis'`. Default is `nancov(X)`.

## **'Scale'**

A vector `S` with the length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This parameter is only valid when `Distance` is `'seuclidean'`. Default is `nanstd(X)`.

## **Properties**

### **X**

A matrix used to create the object

### **Distance**

A string specifying a built-in distance metric or a function handle that you provide when you create the object. This property is the default distance metric used when you call the `knnsearch` method to find nearest neighbors for future query points.

### **DistParameter**

Specifies the additional parameter for the chosen distance metric. The value is:

- If `'Distance'` is `'minkowski'`: A positive scalar indicating the exponent of the Minkowski distance.
- If `'Distance'` is `'mahalanobis'`: A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance.

- If 'Distance' is 'seuclidean': A vector representing the scale value of the data when computing the 'seuclidean' distance.
- Otherwise: Empty.

## Methods

knnsearch	Find $k$ -nearest neighbors using ExhaustiveSearcher object
rangearch	Find all neighbors within specified distance using object

## Examples

Create an ExhaustiveSearcher object using the constructor:

```
load fisheriris
x = meas(:,3:4);
NS = ExhaustiveSearcher(x,'distance','minkowski')
```

```
NS =
```

```
ExhaustiveSearcher
```

```
Properties:
```

```
    X: [150x2 double]
  Distance: 'minkowski'
DistParameter: 2
```

---

Create an ExhaustiveSearcher object using createns:

```
load fisheriris
x = meas(:,3:4);
NS = createns(x,'NsMethod','exhaustive',...
             'distance','minkowski')
```

# ExhaustiveSearcher

---

NS =

ExhaustiveSearcher

Properties:

X: [150x2 double]  
Distance: 'minkowski'  
DistParameter: 2

For more in-depth examples using the `knnsearch` method, see the method reference page or see “Classifying Query Data Using `knnsearch`” on page 16-18.

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12
- “Distance Metrics” on page 16-9

**Purpose** Exponential inverse cumulative distribution function

**Syntax**  
`X = expinv(P,mu)`  
`[X,XLO,XUP] = expinv(X,mu,pcov,alpha)`

**Description** `X = expinv(P,mu)` computes the inverse of the exponential cdf with parameters specified by mean parameter `mu` for the corresponding probabilities in `P`. `P` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive and the values in `P` must lie on the interval `[0 1]`.

`[X,XLO,XUP] = expinv(X,mu,pcov,alpha)` produces confidence bounds for `X` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is `0.05`. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper end points of that interval.

The inverse of the exponential cdf is

$$x = F^{-1}(p | \mu) = -\mu \ln(1 - p)$$

The result, `x`, is the value such that an observation from an exponential distribution with parameter `μ` will fall in the range `[0 x]` with probability `p`.

**Examples** Let the lifetime of light bulbs be exponentially distributed with `μ = 700` hours. What is the median lifetime of a bulb?

```
expinv(0.50,700)
ans =
```

485.2030

Suppose you buy a box of “700 hour” light bulbs. If 700 hours is the mean life of the bulbs, half of them will burn out in less than 500 hours.

## How To

- “Exponential Distribution” on page B-33

**Purpose**

Exponential negative log-likelihood

**Syntax**

```
nlogL = explike(param,data)
[nlogL,avar] = explike(param,data)
[...] = explike(param,data,censoring)
[...] = explike(param,data,censoring,freq)
```

**Description**

`nlogL = explike(param,data)` returns the negative of the log-likelihood for the exponential distribution. `param` is the mean parameter, `mu`. `nlogL` is a scalar.

`[nlogL,avar] = explike(param,data)` returns the inverse of Fisher’s information, `avar`, a scalar. If the input parameter value in `param` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher’s information, not the expected information.

`[...] = explike(param,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = explike(param,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

# dataset.export

---

## Purpose

Write dataset array to file

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
export(DS,'file',filename)
export(DS)
export(DS,'file',filename,'Delimiter',delim)
export(DS,'XLSfile',filename)
export(DS,'XPTfile',filename)
export(DS,...,'WriteVarNames',false)
export(DS,...,'WriteObsNames',false)
```

## Description

`export(DS,'file',filename)` writes the dataset array `DS` to a tab-delimited text file, including variable names and observation names, if present. If the observation names exist, the name in the first column of the first line of the file is the first dimension name for the dataset (by default, 'Observations'). `export` overwrites any existing file named `filename`.

`export(DS)` writes to a text file whose default name is the name of the dataset array `DS` appended by `'.txt'`. If `export` cannot construct the file name from the dataset array input, it writes to the file `'dataset.txt'`. `export` overwrites any existing file.

`export(DS,'file',filename,'Delimiter',delim)` writes the dataset array `DS` to a text file using the delimiter `delim`. `delim` must be one of the following:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

`export(DS, 'XLSfile', filename)` writes the dataset array `DS` to a Microsoft® Excel spreadsheet file, including variable names and observation names (if present). You can specify the `'Sheet'` and `'Range'` parameter name/value pairs, with parameter values as accepted by the `xlsread` function.

`export(DS, 'XPTFile', filename)` writes the dataset array `DS` to a SAS XPORT format file. When writing to an XPORT format file, variables must be scalar valued. `export` saves observation names to a variable called `obsnames`, unless the `WriteObsNames` parameter described below is `false`. The XPORT format restricts the length of variable names to eight characters; longer variable names are truncated.

`export(DS, ..., 'WriteVarNames', false)` does not write the variable names to the text file. `export(DS, ..., 'WriteVarNames', true)` is the default, writing the names as column headings in the first line of the file.

`export(DS, ..., 'WriteObsNames', false)` does not write the observation names to the text file.

`export(DS, ..., 'WriteObsNames', true)` is the default, writing the names as the first column of the file.

In some cases, `export` creates a text file that does not represent `A` exactly, as described below. If you use `dataset` to read the file back into MATLAB, the new dataset array may not have exactly the same contents as the original dataset array. Save `A` as a MAT-file if you need to import it again as a dataset array.

`export` writes out numeric variables using long `g` format, and categorical or character variables as unquoted strings.

For non-character variables with more than one column, `export` writes out multiple delimiter-separated fields on each line, and constructs suitable column headings for the first line of the file.

`export` writes out variables that have more than two dimensions as a single empty field in each line of the file.

# dataset.export

---

For cell-valued variables, `export` writes out the contents of each cell only when the cell contains a single row, and writes out a single empty field otherwise.

In some cases, `export` creates a file that cannot be read back into MATLAB using `dataset`. Writing a dataset array that contains a cell-valued variable whose cell contents are not scalars results in a mismatch in the file between the number of fields on each line and the number of column headings on the first line. Writing a dataset array that contains a cell-valued variable whose cell contents are not all the same length results in a different number of fields on each line in the file. Therefore, if you might need to import a dataset array again, save it as a `.mat` file.

## Examples

Move data between external text files and dataset arrays in the MATLAB workspace:

```
A = dataset('file','sat2.dat','delimiter','(',')')
```

```
A =
```

Test	Gender	Score
'Verbal'	'Male'	470
'Verbal'	'Female'	530
'Quantitative'	'Male'	520
'Quantitative'	'Female'	480

```
export(A(A.Score > 500,:), 'file', 'HighScores.txt')
```

```
B = dataset('file', 'HighScores.txt', 'delimiter', '\t')
```

```
B =
```

Test	Gender	Score
'Verbal'	'Female'	530
'Quantitative'	'Male'	520

## See Also

`dataset`

**Purpose** Exponential probability density function

**Syntax** `Y = exppdf(X,mu)`

**Description** `Y = exppdf(X,mu)` returns the pdf of the exponential distribution with mean parameter `mu`, evaluated at the values in `X`. `X` and `mu` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

The exponential pdf is

$$y = f(x | \mu) = \frac{1}{\mu} e^{\frac{-x}{\mu}}$$

The exponential pdf is the gamma pdf with its first parameter equal to 1.

The exponential distribution is appropriate for modeling waiting times when the probability of waiting an additional period of time is independent of how long you have already waited. For example, the probability that a light bulb will burn out in its next minute of use is relatively independent of how many minutes it has already burned.

**Examples**

```
y = exppdf(5,1:5)
y =
    0.0067    0.0410    0.0630    0.0716    0.0736
```

```
y = exppdf(1:5,1:5)
y =
    0.3679    0.1839    0.1226    0.0920    0.0736
```

# exprnd

---

**Purpose** Exponential random numbers

**Syntax**  
R = exprnd(mu)  
R = exprnd(mu,m,n,...)  
R = exprnd(mu,[m,n,...])

**Description** R = exprnd(mu) generates random numbers from the exponential distribution with mean parameter mu. mu can be a vector, a matrix, or a multidimensional array. The size of R is the size of mu.  
R = exprnd(mu,m,n,...) or R = exprnd(mu,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the exponential distribution with mean parameter mu. mu can be a scalar or an array of the same size as R.

**Examples**

```
n1 = exprnd(5:10)
n1 =
    7.5943  18.3400  2.7113  3.0936  0.6078  9.5841

n2 = exprnd(5:10,[1 6])
n2 =
    3.2752  1.1110  23.5530  23.4303  5.7190  3.9876

n3 = exprnd(5,2,3)
n3 =
    24.3339  13.5271  1.8788
     4.7932   4.3675  2.6468

# prob.ExtremeValueDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Extreme value probability distribution object

**Description** prob.ExtremeValueDistribution is an object consisting of parameters, a model description, and sample data for an extreme value probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('ExtremeValue')` creates an extreme value probability distribution object using the default parameter values.

`pd = makedist('ExtremeValue','mu',mu,'sigma',sigma)` creates an extreme value probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Location parameter**

0 (default) | scalar value

Location parameter of the extreme value distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma - Scale parameter**

1 (default) | nonnegative scalar value

Scale parameter of the extreme value distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

## Properties

### **mu - Location parameter**

scalar value

Location parameter of the extreme value distribution, stored as a scalar value.

#### **Data Types**

single | double

### **sigma - Scale parameter**

nonnegative scalar value

Scale parameter of the extreme value distribution, stored as a nonnegative scalar value.

#### **Data Types**

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

#### **Data Types**

char

### **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

#### **Data Types**

struct

# prob.ExtremeValueDistribution

---

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## **Data Types**

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## **Data Types**

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

### **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

### **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

### **ParameterValues - Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

### **Truncation - Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

# prob.ExtremeValueDistribution

<code>var</code>	Variance of probability distribution object

## Definitions

### Extreme Value Distribution

The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

The extreme value distribution uses the following parameters.

Parameter	Description	Support
mu	Location parameter	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right) ; \quad -\infty < x < \infty.$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

## Examples

### Create an Extreme Value Distribution Object Using Default Parameters

Create an extreme value distribution object using the default parameter values.

```
pd = makedist('ExtremeValue')
```

```
pd =
```

```
ExtremeValueDistribution
```

```
Extreme Value distribution  
mu = 0
```

# prob.ExtremeValueDistribution

---

```
sigma = 1
```

## Create an Extreme Value Distribution Object Using Specified Parameters

Create an extreme value distribution object by specifying the parameter values.

```
pd = makedist('ExtremeValue', 'mu', -1, 'sigma', 2)
```

```
pd =
```

```
ExtremeValueDistribution
```

```
Extreme Value distribution
```

```
mu = -1
```

```
sigma = 2
```

Compute the standard deviation for the distribution.

```
s = std(pd)
```

```
s =
```

```
2.5651
```

## Concepts

- “Extreme Value Distribution” on page B-37
- Class Attributes
- Property Attributes

**Purpose**

Factor analysis

**Syntax**

```
lambda = factoran(X,m)
[lambda,psi] = factoran(X,m)
[lambda,psi,T] = factoran(X,m)
[lambda,psi,T,stats] = factoran(X,m)
[lambda,psi,T,stats,F] = factoran(X,m)
[...] = factoran(...,param1,val1,param2,val2,...)
```

**Definitions**

factoran computes the maximum likelihood estimate (MLE) of the factor loadings matrix  $\Lambda$  in the factor analysis model

$$x = \mu + \Lambda f + e$$

where  $x$  is a vector of observed variables,  $\mu$  is a constant vector of means,  $\Lambda$  is a constant  $d$ -by- $m$  matrix of factor loadings,  $f$  is a vector of independent, standardized common factors, and  $e$  is a vector of independent specific factors.  $x$ ,  $\mu$ , and  $e$  are of length  $d$ .  $f$  is of length  $m$ .

Alternatively, the factor analysis model can be specified as

$$\text{cov}(x) = \Lambda\Lambda^T + \Psi$$

where  $\Psi = \text{cov}(e)$  is a  $d$ -by- $d$  diagonal matrix of specific variances.

**Description**

`lambda = factoran(X,m)` returns the maximum likelihood estimate, `lambda`, of the factor loadings matrix, in a common factor analysis model with  $m$  common factors.  $X$  is an  $n$ -by- $d$  matrix where each row is an observation of  $d$  variables. The  $(i, j)$ th element of the  $d$ -by- $m$  matrix `lambda` is the coefficient, or loading, of the  $j$ th factor for the  $i$ th variable. By default, `factoran` calls the function `rotatefactors` to rotate the estimated factor loadings using the 'varimax' option.

`[lambda,psi] = factoran(X,m)` also returns maximum likelihood estimates of the specific variances as a column vector `psi` of length  $d$ .

`[lambda,psi,T] = factoran(X,m)` also returns the  $m$ -by- $m$  factor loadings rotation matrix `T`.

# factoran

`[lambda,psi,T,stats] = factoran(X,m)` also returns a structure `stats` containing information relating to the null hypothesis,  $H_0$ , that the number of common factors is  $m$ . `stats` includes the following fields:

Field	Description
<code>loglike</code>	Maximized log-likelihood value
<code>dfe</code>	Error degrees of freedom = $((d-m)^2 - (d+m))/2$
<code>chisq</code>	Approximate chi-squared statistic for the null hypothesis
<code>p</code>	Right-tail significance level for the null hypothesis

`factoran` does not compute the `chisq` and `p` fields unless `dfe` is positive and all the specific variance estimates in `psi` are positive (see “Heywood Case” on page 21-940 below). If  $X$  is a covariance matrix, then you must also specify the `'nobs'` parameter if you want `factoran` to compute the `chisq` and `p` fields.

`[lambda,psi,T,stats,F] = factoran(X,m)` also returns, in `F`, predictions of the common factors, known as factor scores. `F` is an  $n$ -by- $m$  matrix where each row is a prediction of  $m$  common factors. If  $X$  is a covariance matrix, `factoran` cannot compute `F`. `factoran` rotates `F` using the same criterion as for `lambda`.

`[...] = factoran(...,param1,val1,param2,val2,...)` enables you to specify optional parameter name/value pairs to control the model fit and the outputs. The following are the valid parameter/value pairs.

Parameter	Value	
<code>'xtype'</code>	Type of input in the matrix $X$ . <code>'xtype'</code> can be one of:	
	<code>'data'</code>	Raw data (default)
	<code>'covariance'</code>	Positive definite covariance or correlation matrix

<b>Parameter</b>	<b>Value</b>	
'scores'	Method for predicting factor scores. 'scores' is ignored if X is not raw data.	
	'wls' 'Bartlett'	Synonyms for a weighted least-squares estimate that treats F as fixed (default)
	'regression' 'Thomson'	Synonyms for a minimum mean squared error prediction that is equivalent to a ridge regression
'start'	Starting point for the specific variances psi in the maximum likelihood optimization. Can be specified as:	
	'random'	Chooses d uniformly distributed values on the interval [0,1].
	'Rsquared'	Chooses the starting vector as a scale factor times $\text{diag}(\text{inv}(\text{corrcoef}(X)))$ (default). For examples, see Jöreskog [2].
	Positive integer	Performs the given number of maximum likelihood fits, each initialized as with 'random'. factoran returns the fit with the highest likelihood.
	Matrix	Performs one maximum likelihood fit for each column of the specified matrix. The ith optimization is initialized with the values from the ith column. The matrix must have d rows.

Parameter	Value	
'rotate'	Method used to rotate factor loadings and scores. 'rotate' can have the same values as the 'Method' parameter of rotatefactors. See the reference page for rotatefactors for a full description of the available methods.	
	'none'	Performs no rotation.
	'equamax'	Special case of the orthomax rotation. Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'orthomax'	Orthogonal rotation that maximizes a criterion based on the variance of the loadings.  Use the 'coeff', 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'parsimax'	Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'pattern'	Performs either an oblique rotation (the default) or an orthogonal rotation to best match a specified pattern matrix. Use the 'type' parameter to choose the type of rotation. Use the 'target' parameter to specify the pattern matrix.

Parameter	Value	
	'procrustes'	<p>Performs either an oblique (the default) or an orthogonal rotation to best match a specified target matrix in the least squares sense.</p> <p>Use the 'type' parameter to choose the type of rotation. Use 'target' to specify the target matrix.</p>
	'promax'	<p>Performs an oblique procrustes rotation to a target matrix determined by factoran as a function of an orthomax solution.</p> <p>Use the 'power' parameter to specify the exponent for creating the target matrix. Because 'promax' uses 'orthomax' internally, you can also specify the parameters that apply to 'orthomax'.</p>
	'quartimax'	<p>Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</p>
	'varimax'	<p>Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.</p>

Parameter	Value
	<p>Function</p> <p>Function handle to rotation function of the form</p> $[B, T] = \text{myrotation}(A, \dots)$ <p>where A is a d-by-m matrix of unrotated factor loadings, B is a d-by-m matrix of rotated loadings, and T is the corresponding m-by-m rotation matrix.</p> <p>Use the <code>factoran</code> parameter <code>'userargs'</code> to pass additional arguments to this rotation function. See “User-Defined Rotation Function” on page 21-946.</p>
<code>'coeff'</code>	Coefficient, often denoted as $\gamma$ , defining the specific <code>'orthomax'</code> criterion. Must be from 0 to 1. The value 0 corresponds to <code>quartimax</code> , and 1 corresponds to <code>varimax</code> . Default is 1.
<code>'normalize'</code>	Flag indicating whether the loading matrix should be row-normalized (1) or left unnormalized (0) for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is 1.
<code>'reltol'</code>	Relative convergence tolerance for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is <code>sqrt(eps)</code> .
<code>'maxit'</code>	Iteration limit for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is 250.
<code>'target'</code>	Target factor loading matrix for <code>'procrustes'</code> rotation. Required for <code>'procrustes'</code> rotation. No default value.
<code>'type'</code>	Type of <code>'procrustes'</code> rotation. Can be <code>'oblique'</code> (default) or <code>'orthogonal'</code> .

Parameter	Value
'power'	Exponent for creating the target matrix in the 'promax' rotation. Must be $\geq 1$ . Default is 4.
'userargs'	Denotes the beginning of additional input values for a user-defined rotation function. <code>factoran</code> appends all subsequent values, in order and without processing, to the rotation function argument list, following the unrotated factor loadings matrix A. See “User-Defined Rotation Function” on page 21-946.
'nobs'	If X is a covariance or correlation matrix, indicates the number of observations that were used in its estimation. This allows calculation of significance for the null hypothesis even when the original data are not available. There is no default. 'nobs' is ignored if X is raw data.
'delta'	Lower bound for the specific variances $\psi_i$ during the maximum likelihood optimization. Default is 0.005.
'optimopts'	Structure that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. Create this structure with the function <code>statset</code> . Enter <code>statset('factoran')</code> to see the names and default values of the parameters that <code>factoran</code> accepts in the options structure. See the reference page for <code>statset</code> for more information about these options.

## Tips

### Observed Data Variables

The variables in the observed data matrix X must be linearly independent, i.e.,  $\text{cov}(X)$  must have full rank, for maximum likelihood

estimation to succeed. `factoran` reduces both raw data and a covariance matrix to a correlation matrix before performing the fit.

`factoran` standardizes the observed data  $X$  to zero mean and unit variance before estimating the loadings  $\lambda$ . This does not affect the model fit, because MLEs in this model are invariant to scale. However,  $\lambda$  and  $\psi$  are returned in terms of the standardized variables, i.e.,  $\lambda\lambda' + \text{diag}(\psi)$  is an estimate of the correlation matrix of the original data  $X$  (although not after an oblique rotation). See “Estimate and Plot Factor Loadings” on page 21-941 and “User-Defined Rotation Function” on page 21-946.

## Heywood Case

If elements of  $\psi$  are equal to the value of the `'delta'` parameter (i.e., they are essentially zero), the fit is known as a Heywood case, and interpretation of the resulting estimates is problematic. In particular, there can be multiple local maxima of the likelihood, each with different estimates of the loadings and the specific variances. Heywood cases can indicate overfitting (i.e.,  $m$  is too large), but can also be the result of underfitting.

## Rotation of Factor Loadings and Scores

Unless you explicitly specify no rotation using the `'rotate'` parameter, `factoran` rotates the estimated factor loadings,  $\lambda$ , and the factor scores,  $F$ . The output matrix  $T$  is used to rotate the loadings, i.e.,  $\lambda = \lambda_0 T$ , where  $\lambda_0$  is the initial (unrotated) MLE of the loadings.  $T$  is an orthogonal matrix for orthogonal rotations, and the identity matrix for no rotation. The inverse of  $T$  is known as the primary axis rotation matrix, while  $T$  itself is related to the reference axis rotation matrix. For orthogonal rotations, the two are identical.

`factoran` computes factor scores that have been rotated by  $\text{inv}(T')$ , i.e.,  $F = F_0 * \text{inv}(T')$ , where  $F_0$  contains the unrotated predictions. The estimated covariance of  $F$  is  $\text{inv}(T' * T)$ , which, for orthogonal or no rotation, is the identity matrix. Rotation of factor loadings and scores is an attempt to create a more easily interpretable structure in the loadings matrix after maximum likelihood estimation.

**Examples****Estimate and Plot Factor Loadings**

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [Acceleration Displacement Horsepower MPG Weight];  
X = X(all(~isnan(X),2),:);
```

Estimate the factor loadings using a minimum mean squared error prediction for a factor analysis with two common factors.

```
[Lambda,Psi,T,stats,F] = factoran(X,2,'scores','regression');  
inv(T'*T); % Estimated correlation matrix of F, == eye(2)  
Lambda*Lambda' + diag(Psi); % Estimated correlation matrix  
Lambda*inv(T); % Unrotate the loadings  
F*T'; % Unrotate the factor scores
```

Create biplot of two factors.

```
biplot(Lambda,'LineWidth',2,'MarkerSize',20)
```

# factoran

Estimate the factor loadings using the covariance (or correlation) matrix.

```
[Lambda,Psi,T] = factoran(cov(X),2,'xtype','cov')  
% [Lambda,Psi,T] = factoran(corrcoef(X),2,'xtype','cov')
```

Lambda =

```
-0.2432  -0.8500
```

```

0.8773    0.3871
0.7618    0.5930
-0.7978   -0.2786
0.9692    0.2129

```

Psi =

```

0.2184
0.0804
0.0680
0.2859
0.0152

```

T =

```

0.9476    0.3195
0.3195   -0.9476

```

Although the estimates are the same, the use of a covariance matrix rather than raw data doesn't let you request scores or significance level.

Use promax rotation.

```

[Lambda,Psi,T,stats,F] = factoran(X,2,'rotate','promax',...
'powerpm',4);
inv(T'*T)                % Estimated correlation of F,
                          % no longer eye(2)
Lambda*inv(T'*T)*Lambda'+diag(Psi) % Estimated correlation of X

```

ans =

```

1.0000    -0.6391
-0.6391    1.0000

```

```
ans =
```

```
    1.0000   -0.5424   -0.6893    0.4309   -0.4167  
   -0.5424    1.0000    0.8979   -0.8078    0.9328  
   -0.6893    0.8979    1.0000   -0.7730    0.8647  
    0.4309   -0.8078   -0.7730    1.0000   -0.8326  
   -0.4167    0.9328    0.8647   -0.8326    1.0000
```

Plot the unrotated variables with oblique axes superimposed.

```
invT = inv(T);  
Lambda0 = Lambda*invT;  
figure()  
line([-invT(1,1) invT(1,1) NaN -invT(2,1) invT(2,1)], ...  
      [-invT(1,2) invT(1,2) NaN -invT(2,2) invT(2,2)], ...  
      'Color','r','linewidth',2)  
grid on  
hold on  
biplot(Lambda0,'LineWidth',2,'MarkerSize',20)  
xlabel('Loadings for unrotated Factor 1')  
ylabel('Loadings for unrotated Factor 2')
```

Plot the rotated variables against the oblique axes.

```
figure()  
biplot(Lambda, 'LineWidth', 2, 'MarkerSize', 20)
```

## User-Defined Rotation Function

Syntax for passing additional arguments to a user-defined rotation function:

```
[Lambda,Psi,T] = ...  
    factoran(X,2,'rotate',@myrotation,'userargs',1,'two');
```

# TreeBagger.FBoot property

---

**Purpose** Fraction of in-bag observations

**Description** The FBoot property is the fraction of observations to be randomly selected with replacement for each bootstrap replica. The size of each replica is given by  $n \cdot \text{FBoot}$ , where  $n$  is the number of observations in the training set. The default value is 1.

**Purpose**

$F$  cumulative distribution function

**Syntax**

```
p = fcdf(x,v1,v2)
p = fcdf(x,v1,vv2,'upper')
```

**Description**

`p = fcdf(x,v1,v2)` computes the  $F$  cdf at each of the values in  $x$  using the corresponding numerator degrees of freedom  $v_1$  and denominator degrees of freedom  $v_2$ .  $x$ ,  $v_1$ , and  $v_2$  can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.  $v_1$  and  $v_2$  parameters must contain real positive values.

`p = fcdf(x,v1,vv2,'upper')` returns the complement of the  $F$  cdf at each value in  $x$ , using an algorithm that more accurately computes the extreme upper tail probabilities.

The  $F$  cdf is

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1+v_2}{2}}} dt$$

The result,  $p$ , is the probability that a single observation from an  $F$  distribution with parameters  $v_1$  and  $v_2$  will fall in the interval  $[0, x]$ .

**Examples****Compute  $F$  Distribution CDF**

The following illustrates a useful mathematical identity for the  $F$  distribution.

```
nu1 = 1:5;
nu2 = 6:10;
x = 2:6;
```

```
F1 = fcdf(x, nu1, nu2)
```

# fcdf

---

```
F1 =  
0.7930 0.8854 0.9481 0.9788 0.9919
```

```
F2 = 1 - fcdf(1./x,nu2,nu1)
```

```
F2 =  
0.7930 0.8854 0.9481 0.9788 0.9919
```

## How To

- “F Distribution” on page B-44

**Purpose**

Evaluate generalized linear regression model prediction

**Syntax**

```
ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn
```

**Description**

`ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew_2, ..., Xnewn]`.

**Tips**

- `feval` allows you to easily evaluate predictions of a model when the model was fitted using a table or dataset array. `predict` requires a table or dataset array with the same predictor names, but you can use simple arrays of scalars with `feval`.

**Input Arguments****mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

**Xnew1, Xnew2, ..., Xnewn**

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

**Output Arguments****ypred**

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

# GeneralizedLinearModel.feval

---

For binomial models, `feval` uses 1 as the `BinomialSize` parameter, so `ypred` is predicted probabilities.

For models with an offset, `feval` uses 0 as the offset value.

## Examples

### Predict Responses Using `feval`

Generate a generalized linear model, and plot its responses to a range of input data.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Generate a range of values for  $X(1)$  and  $X(2)$ , and plot the model predictions at those values.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Z = feval(mdl,Xtest1,Xtest2);
surf(Xtest1,Xtest2,Z)
```

## Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument.

`random` predicts with added noise.

# LinearModel.feval

---

**Purpose** Evaluate linear regression model prediction

**Syntax** `ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn`

**Description** `ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew2, ..., Xnewn]`.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **Xnew1, Xnew2, ..., Xnewn**

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

## Output Arguments

### **ypred**

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

For models with an offset, `feval` uses 0 as the offset value.

## Examples

### **Plot Different Categorical Levels**

Fit a mileage model to the `smallcar` data, including the `Year` categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data and fit a model.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a scatter plot of the mileage versus weight.

```
gscatter(tbl.Weight,tbl.MPG,tbl.Year);
```

Use feval to plot curves of the model predictions for the various years and weights.

```
w = linspace(min(tbl.Weight),max(tbl.Weight));
line(w,feval(mdl,w,'70'),'Color','r')
```

# LinearModel.feval

```
line(w, feval mdl, w, '76'), 'Color', 'g')  
line(w, feval mdl, w, '82'), 'Color', 'b')
```

## Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

## How To

- “Linear Regression Workflow” on page 9-45
- “Linear Regression” on page 9-12

# NonLinearModel.feval

---

**Purpose** Evaluate nonlinear regression model prediction

**Syntax** `ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn`

**Description** `ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew2, ..., Xnewn]`.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **Xnew1, Xnew2, ..., Xnewn**

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

## Output Arguments

### **ypred**

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

## Examples

### **Predict a Nonlinear Model from a Table**

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0);
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)
```

```
MPGnew =
```

```
21.8073
```

## Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

# ff2n

---

**Purpose** Two-level full factorial design

**Syntax** `dFF2 = ff2n(n)`

**Description** `dFF2 = ff2n(n)` gives factor settings `dFF2` for a two-level full factorial design with `n` factors. `dFF2` is  $m$ -by- $n$ , where  $m$  is the number of treatments in the full-factorial design. Each row of `dFF2` corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

**Examples**

```
dFF2 = ff2n(3)
dFF2 =
  0  0  0
  0  0  1
  0  1  0
  0  1  1
  1  0  0
  1  0  1
  1  1  0
  1  1  1
```

**See Also** `fullfact`

**Purpose**

Proximity matrix for training data

**Syntax**

```
B = fillProximities(B)
B = fillProximities(B, 'param1', val1, 'param2', val2, ...)
```

**Description**

`B = fillProximities(B)` computes a proximity matrix for the training data and stores it in the `Properties` field of `B`.

`B = fillProximities(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

- 'trees'        Either 'all' or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is 'all'.
- 'nprint'      Number of training cycles (grown trees) after which `TreeBagger` displays a diagnostic message showing training progress. Default is no diagnostic messages.

**See Also**

`CompactTreeBagger.outlierMeasure` |  
`CompactTreeBagger.proximity`

# grandstream.findobj

---

**Purpose** Find objects matching specified conditions

**Syntax** `hm = findobj(h, 'conditions')`

**Description** The `findobj` method of the `handle` class follows the same syntax as the MATLAB `findobj` command, except that the first argument must be an array of handles to objects.

`hm = findobj(h, 'conditions')` searches the handle object array `h` and returns an array of handle objects matching the specified conditions. Only the public members of the objects of `h` are considered when evaluating the conditions.

**See Also** `findobj` | `grandstream`

**Purpose** Find property of MATLAB handle object

**Syntax** `p = findprop(h,'propname')`

**Description** `p = findprop(h,'propname')` finds and returns the `meta.property` object associated with property name `propname` of scalar handle object `h`. `propname` must be a string. It can be the name of a property defined by the class of `h` or a dynamic property added to scalar object `h`.

If no property named `propname` exists for object `h`, an empty `meta.property` array is returned.

**See Also** `dynamicprops` | `findobj` | `meta.property` | `grandstream`

**Purpose**  $F$  inverse cumulative distribution function

**Syntax**  $X = \text{finv}(P, V1, V2)$

**Description**  $X = \text{finv}(P, V1, V2)$  computes the inverse of the  $F$  cdf with numerator degrees of freedom  $V1$  and denominator degrees of freedom  $V2$  for the corresponding probabilities in  $P$ .  $P$ ,  $V1$ , and  $V2$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

$V1$  and  $V2$  parameters must contain real positive values, and the values in  $P$  must lie on the interval  $[0\ 1]$ .

The  $F$  inverse function is defined in terms of the  $F$  cdf as

$$x = F^{-1}(p | v_1, v_2) = \{x : F(x | v_1, v_2) = p\}$$

where

$$p = F(x | v_1, v_2) = \int_0^x \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right]}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} \frac{t^{\frac{v_1-2}{2}}}{\left[1 + \left(\frac{v_1}{v_2}\right)t\right]^{\frac{v_1+v_2}{2}}} dt$$

## Examples

Find a value that should exceed 95% of the samples from an  $F$  distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.

```
x = finv(0.95,5,10)
x =
    3.3258
```

You would observe values greater than 3.3258 only 5% of the time by chance.

**How To**      • “F Distribution” on page B-44

# ClassificationDiscriminant.fit

---

<b>Purpose</b>	Fit discriminant analysis classifier (to be removed)
<b>Compatibility</b>	ClassificationDiscriminant.fit will be removed in a future release. Use fitcdiscr instead.
<b>Syntax</b>	<pre>obj = ClassificationDiscriminant.fit(x,y) obj = ClassificationDiscriminant.fit(x,y,Name,Value)</pre>
<b>Description</b>	<p>obj = ClassificationDiscriminant.fit(x,y) returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) x and output (response) y.</p> <p>obj = ClassificationDiscriminant.fit(x,y,Name,Value) fits a classifier with additional options specified by one or more Name, Value pair arguments. If you use one of the following five options, obj is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, obj is of class ClassificationDiscriminant.</p>
<b>Input Arguments</b>	<p><b>x - Predictor values</b> matrix of numeric values</p> <p>Predictor values, specified as a matrix of numeric values. Each column of x represents one variable, and each row represents one observation.</p> <p>ClassificationDiscriminant.fit considers NaN values in x as missing values. ClassificationDiscriminant.fit does not use observations with missing values for x in the fit.</p> <p><b>Example:</b></p> <p><b>Data Types</b> single   double</p> <p><b>y - Classification values</b> numeric vector   categorical vector   logical vector   character array   cell array of strings</p>

Classification values, specified as a numeric vector, categorical vector (nominal or ordinal), logical vector, character array, or cell array of strings. Each row of `y` represents the classification of the corresponding row of `x`.

`ClassificationDiscriminant.fit` considers NaN values in `y` to be missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `y` in the fit.

## Data Types

single | double | logical | char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'ClassNames' - Class names

array

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

## Data Types

single | double | logical | char

## 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

# ClassificationDiscriminant.fit

---

The default is  $\text{Cost}(i, j) = 1$  if  $i \neq j$ , and  $\text{Cost}(i, j) = 0$  if  $i = j$ .

## Data Types

single | double | struct

## 'CrossVal' - Flag to grow cross-validated decision tree

'off' (default) | 'on'

Flag to grow cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` creates a cross-validated classifier with 10 folds. You can use 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one of these options at a time for creating a cross-validated classifier.

Alternatively, cross validate `obj` later using the `crossval` method.

**Example:** 'CrossVal', 'on'

## 'CVPartition' - Cross-validated model partition

cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`. You can only use one option at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## 'Delta' - Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

## Data Types

single | double

### 'DiscrimType' - Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' | 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

**Example:** 'DiscrimType', 'quadratic'

### 'FillCoeffs' - Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and either 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

**Example:** 'FillCoeffs', 'off'

### 'Gamma' - Regularization parameter

scalar value in the range [0,1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0,1].

# ClassificationDiscriminant.fit

---

- Linear discriminant — Scalar value in the range [0, 1].
  - If you pass a value strictly between 0 and 1, `fitcdiscr` sets the discriminant type to 'Linear'.
  - If you pass 0 for `Gamma` and 'Linear' for `DiscrimType`, and if the correlation matrix is singular, `fitcdiscr` sets `Gamma` to the minimal value required for inverting the covariance matrix.
  - If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to 'DiagLinear'.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for `Gamma` and 'Quadratic' for `DiscrimType`, and if one of the classes has a singular covariance matrix, `fitcdiscr` errors.
  - If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to 'DiagQuadratic'.
  - If you set `Gamma` to a value between 0 and 1 for a quadratic discriminant, `fitcdiscr` errors.

**Example:** 'Gamma', 1

## Data Types

single | double

## 'Holdout' - Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can only use one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Holdout', 0.1

## Data Types

double | single

### 'KFold' - Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'KFold',8

## Data Types

single | double

### 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

## Data Types

char

### 'PredictorNames' - Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

# ClassificationDiscriminant.fit

---

## Data Types

cell

### 'Prior' - Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:
  - 'empirical' determines class probabilities from class frequencies in  $y$ . If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure  $S$  with two fields:
  - $S.ClassNames$  containing the class names as a variable of the same type as  $y$
  - $S.ClassProbs$  containing a vector of corresponding probabilities

**Example:** 'Prior','uniform'

## Data Types

single | double | struct

### 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable  $y$ .

**Example:** 'ResponseName', 'Response'

## Data Types

char

## 'SaveMemory' - Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.

**Example:** 'SaveMemory', 'on'

## 'ScoreTransform' - Score transform function

'none' (default) | valid score transform string | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and one of the following.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	$x$ (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$

# ClassificationDiscriminant.fit

---

String	Formula
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for

all other classes to -1.

Alternatively, you can use your own function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

**Example:** 'ScoreTransform', 'logit'

## Data Types

function\_handle

## 'Weights' - Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in x. fitcdiscr normalizes the weights to sum to 1.

## Data Types

single | double

## Output Arguments

### obj - Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, obj is of class ClassificationDiscriminant, and you can use the predict method to predict the response of new data.

## Definitions

### Discriminant Classification

The model for discriminant analysis is:

- Each class ( $Y$ ) generates data ( $X$ ) using a multivariate normal distribution. That is, the model assumes  $X$  has a Gaussian mixture distribution (`gmdistribution`).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k | x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y | k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

For details, see “How the predict Method Classifies” on page 15-6.

## Examples

### Construct a Discriminant Analysis Classifier

Load the sample data.

```
load fisheriris
```

# ClassificationDiscriminant.fit

---

Construct a discriminant analysis classifier using the sample data.

```
obj = ClassificationDiscriminant.fit(meas,species)
```

```
obj =
```

```
ClassificationDiscriminant
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  DiscrimType: 'linear'
  Mu: [3x4 double]
  Coeffs: [3x3 struct]
```

Properties, Methods

## Alternatives

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use:

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

`ClassificationDiscriminant` | `fitctree`

## How To

- “Discriminant Analysis” on page 15-3

<b>Purpose</b>	Fit $k$ -nearest neighbor classifier (to be removed)
<b>Compatibility</b>	ClassificationKNN.fit will be removed in a future release. Use fitcknn instead.
<b>Syntax</b>	<pre>mdl = ClassificationKNN.fit(x,y) mdl = ClassificationKNN.fit(x,y,Name,Value)</pre>
<b>Description</b>	<p>mdl = ClassificationKNN.fit(x,y) returns a classification model based on the input variables (also known as predictors, features, or attributes) x and output (response) y.</p> <p>mdl = ClassificationKNN.fit(x,y,Name,Value) fits a model with additional options specified by one or more Name,Value pair arguments.</p> <p>If you use one of these options, mdl is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, mdl is of class ClassificationKNN.</p>
<b>Input Arguments</b>	<p><b>x - Predictor values</b> matrix of scalar values</p> <p>Predictor values, specified as a matrix of scalar values. Each column of x represents one variable, and each row represents one observation.</p> <p><b>Data Types</b> single   double</p> <p><b>y - Classification values</b> numeric vector   categorical vector   logical vector   character array   cell array of strings</p> <p>Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings, with the same number of rows as x. Each row of y represents the classification of the corresponding row of x.</p>

# ClassificationKNN.fit

---

## Data Types

single | double | cell | logical | char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'BreakTies' - Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

**Example:** `'BreakTies','nearest'`

## 'BucketSize' - Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

**Example:** `'BucketSize',40`

## Data Types

single | double

### 'CategoricalPredictors' - Categorical predictor flag

[] (default) | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set CategoricalPredictors to 'all', the default Distance is 'hamming'.

**Example:** 'CategoricalPredictors', 'all'

### 'ClassNames' - Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in *y*.

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names in *y*.

## Data Types

single | double | char | logical | cell

### 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where  $\text{Cost}(i, j)$  is the cost of classifying a point into class *j* if its true class is *i*.

# ClassificationKNN.fit

---

- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is  $\text{Cost}(i, j) = 1$  if  $i \neq j$ , and  $\text{Cost}(i, j) = 0$  if  $i = j$ .

## Data Types

single | double | struct

### 'Cov' - Covariance matrix

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

## Data Types

single | double

### 'CrossVal' - Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If 'on', `fitcknn` creates a cross-validated model with 10 folds. Use the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one parameter at a time to create a cross-validated model.

Alternatively, cross validate `mdl` later using the `crossval` method.

**Example:** 'Crossval', 'on'

### 'CVPartition' - Cross-validated model partition

cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`. You can only use one of these four options at a

time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## 'Distance' - Distance metric

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric string or function handle. The allowable strings depend on the NSMethod parameter, which you set in fitcknn, and which exists as a field in ModelParameters. If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

For definitions, see “Distance Metrics” on page 16-9.

This table includes valid distance metrics of ExhaustiveSearcher.

Value	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.

## ClassificationKNN.fit

---

Value	Description
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix <b>C</b> . The default value of <b>C</b> is the sample covariance matrix of <b>x</b> , as computed by <code>nancov(x)</code> . To specify a different value for <b>C</b> , use the ' <b>Cov</b> ' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the ' <b>P</b> ' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between <b>x</b> and a query point is scaled, meaning divided by a scale value <b>S</b> . The default value of <b>S</b> is the standard deviation computed from <b>x</b> , <code>S = nanstd(X)</code> . To specify another value for <b>S</b> , use the <b>Scale</b> name-value pair argument.

Value	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Distance function handle. <i>distfun</i> has the form</p> <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> <li>• ZI is a 1-by-N vector containing one row of x or y.</li> <li>• ZJ is an M2-by-N matrix containing multiple rows of x or y.</li> <li>• D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J, :).</li> </ul>

**Example:** 'Distance', 'minkowski'

### Data Types

function\_handle

### 'DistanceWeight' - Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

# ClassificationKNN.fit

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance <sup>2</sup>
@fcn	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to $\ @(d)d.^{-2}$ .

**Example:** 'DistanceWeight','inverse'

## Data Types

function\_handle

## 'Exponent' - Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

**Example:** 'Exponent',3

## Data Types

single | double

## 'Holdout' - Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition','KFold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

## Data Types

single | double

## 'IncludeTies' - Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

**Example:** 'IncludeTies',true

## Data Types

logical

## 'KFold' - Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

## Data Types

single | double

## 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

# ClassificationKNN.fit

---

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

## 'NSMethod' - Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and either 'kdtree' or 'exhaustive'.

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
  - 'cityblock'
  - 'minkowski'
  - 'chebyshev'
- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in *x* to each point in *y* are computed to find nearest neighbors.

The default is 'kdtree' when *x* has 10 or fewer columns, *x* is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

**Example:** 'NSMethod', 'exhaustive'

## 'NumNeighbors' - Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in *x* to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

**Example:** 'NumNeighbors', 3

## Data Types

single | double

### 'PredictorNames' - Predictor variable names

{'x1', 'x2', ...} (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x`.

## Data Types

cell

### 'Prior' - Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:
  - 'empirical' determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class).
- A structure `S` with two fields:
  - `S.ClassNames` containing the class names as a variable of the same type as `y`
  - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

**Example:** 'Prior', 'uniform'

# ClassificationKNN.fit

---

## Data Types

single | double | struct

## 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable y.

**Example:** 'ResponseName', 'Response'

## Data Types

char

## 'Scale' - Distance scale

nanstd(x) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in x. Each coordinate difference between x and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

## Data Types

single | double

## 'Weights' - Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in x. fitcknn normalizes the weights in each class to add up to the value of the prior probability of the class.

## Data Types

single | double

## Output Arguments

### mdl - Classifier model

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, mdl is of class ClassificationKNN, and you can use the predict method to make predictions.

## Definitions

### Prediction

ClassificationKNN predicts the classification of a point  $X_{\text{new}}$  using a procedure equivalent to this:

- 1 Find the NumNeighbors points in the training set  $X$  that are nearest to  $X_{\text{new}}$ .
- 2 Find the NumNeighbors response values  $Y$  to those nearest points.
- 3 Assign the classification label  $Y_{\text{new}}$  that has the largest posterior probability among the values in  $Y$ .

For details, see “Posterior Probability” on page 21-2997 in the predict documentation.

## Examples

### Construct a KNN Classifier

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
```

# ClassificationKNN.fit

---

```
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',5)
```

```
mdl =
```

```
ClassificationKNN
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  Distance: 'euclidean'
  NumNeighbors: 5
```

Properties, Methods

## Construct a Classifier Using the Minkowski Metric

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 3-nearest neighbors with the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher.

```
mdl = ClassificationKNN.fit(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski');
```

To examine mdl properties, double-click mdl in the Workspace window to open the Variable Editor.

Name	Value	Min	Max
X	<150x4 dou...	0.1000	7.9000
Y	<150x1 cell>		
mdl	<1x1 Classi...		
meas	<150x4 dou...	0.1000	7.9000
species	<150x1 cell>		

Property	Value	Min	Max
NumNeighbors	3	3	3
Distance	'minkowski'		
DistParameter	2	2	2
IncludeTies	0

# ClassificationTree.fit

---

**Purpose** Fit classification tree (to be removed)

**Compatibility** ClassificationTree.fit will be removed in a future release. Use fitctree instead.

**Syntax**

```
tree = ClassificationTree.fit(x,y)
tree = ClassificationTree.fit(x,y,Name,Value)
```

**Description** tree = ClassificationTree.fit(x,y) returns a classification tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y. tree is a binary tree, where each branching node is split based on the values of a column of x.

tree = ClassificationTree.fit(x,y,Name,Value) fits a tree with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ,NameN,ValueN.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.

## Input Arguments

**x - Predictor values**  
matrix of floating point values

Predictor values, specified as a matrix of floating point values.

ClassificationTree.fit considers NaN values in x as missing values. ClassificationTree.fit does not use observations with all missing values for x in the fit. ClassificationTree.fit uses observations with some missing values for x to find splits on variables for which these observations have valid values.

**Data Types**  
single | double

## **y - predictor values**

numeric vector | categorical vector | logical vector | character array |  
cell array of strings

Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings.

Each row of **y** represents the classification of the corresponding row of **x**. For numeric **y**, consider using `fitrtree` instead. `ClassificationTree.fit` considers NaN values in **y** to be missing values.

`ClassificationTree.fit` does not use observations with missing values for **y** in the fit.

## **Data Types**

single | double | char | logical | cell

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **'AlgorithmForCategorical' - Algorithm for best split on categorical predictor**

'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with  $L$  levels for data with  $K \geq 3$  classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following.

'Exact'	Consider all $2^{L-1} - 1$ combinations
'PullLeft'	Pull left by purity

# ClassificationTree.fit

---

'PCA'	Principal component-based partition
'OVAbyClass'	One versus all by class

`ClassificationTree.fit` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For  $K = 2$  classes, `ClassificationTree.fit` always performs the exact search.

**Example:** `'AlgorithmForCategorical', 'PCA'`

## 'CategoricalPredictors' - Categorical predictors list

numeric or logical vector | cell array of strings | character matrix  
| 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to  $p$ , where  $p$  is the number of columns of  $x$ .
- A logical vector of length  $p$ , where a true entry means that the corresponding column of  $x$  is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

**Example:** `'CategoricalPredictors', 'all'`

## Data Types

single | double | char

## 'ClassNames' - Class names

numeric vector | categorical vector | logical vector | character array |  
cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in *y*.

Use *ClassNames* to order the classes or to select a subset of classes for training. The default is the class names that exist in *y*.

## Data Types

single | double | char | logical | cell

## 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification a point, specified as the comma-separated pair consisting of 'Cost' and one of the following.

- Square matrix, where  $\text{Cost}(i, j)$  is the cost of classifying a point into class *j* if its true class is *i*.
- Structure *S* having two fields: *S.ClassNames* containing the group names as a variable of the same type as *y*, and *S.ClassificationCosts* containing the cost matrix.

The default is  $\text{Cost}(i, j)=1$  if  $i \neq j$ , and  $\text{Cost}(i, j)=0$  if  $i=j$

## Data Types

single | double | struct

## 'CrossVal' - Flag to grow cross-validated tree

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `ClassificationTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you

# ClassificationTree.fit

---

can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

**Example:** 'CrossVal', 'on'

## **'CVPartition' - Partition for cross-validation tree**

cvpartition object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

## **'Holdout' - Fraction of data for holdout validation**

1 (default) | scalar value in the range (0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

## **Data Types**

single | double

## **'KFold' - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

## Data Types

single | double

## 'Leaveout' - Leave-one-out cross validation flag

'off' (default) | 'on'

Leave-one-out cross validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

## 'MaxCat' - Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `ClassificationTree.fit` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree.fit` finds the best categorical split using one of the inexact algorithms.

Note that passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

**Example:** 'MaxCat',8

## 'MergeLeaves' - Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on',

# ClassificationTree.fit

---

ClassificationTree.fit merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', ClassificationTree.fit does not merge leaves.

**Example:** 'MergeLeaves', 'off'

## 'MinLeaf' - Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, ClassificationTree.fit uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Example:** 'MinLeaf', 3

## Data Types

single | double

## 'MinParent' - Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, ClassificationTree.fit uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Example:** 'MinParent', 8

## Data Types

single | double

## 'NVarToSample' - Number of predictors for split

'all' | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and

a positive integer value. You can also specify 'all' to use all available predictors.

**Example:** 'NVarToSample',3

## Data Types

single | double

## 'PredictorNames' - Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in  $x$ .

## 'Prior' - Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:
  - 'empirical' determines class probabilities from class frequencies in  $y$ . If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure  $S$  with two fields:
  - $S.ClassNames$  containing the class names as a variable of the same type as  $y$
  - $S.ClassProbs$  containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

# ClassificationTree.fit

---

**Example:** 'Prior', 'uniform'

## **'Prune' - Pruning flag**

'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `ClassificationTree.fit` grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree.fit` grows the classification tree without pruning.

**Example:** 'Prune', 'off'

## **'PruneCriterion' - Pruning criterion**

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and either 'error' or 'impurity'.

**Example:** 'PruneCriterion', 'impurity'

## **'ResponseName' - Response variable name**

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string representing the name of the response variable  $y$ .

**Example:** 'ResponseName', 'Response'

## **'ScoreTransform' - Score transform function**

'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following strings representing a built-in transformation function.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	$x$ (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Example: 'ScoreTransform', 'logit'

### 'SplitCriterion' - Split criterion

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion', 'deviance'

### 'Surrogate' - Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

# ClassificationTree.fit

---

- When set to 'on', `ClassificationTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Example:** 'Surrogate', 'on'

## 'Weights' - Observation weights

`ones(size(x,1),1)` (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is equal to the number of rows in `x`. `ClassificationTree.fit` normalizes the weights in each class to add up to the value of the prior probability of the class.

## Data Types

single | double

## Output Arguments

### **tree** - Classification tree

classification tree object

Classification tree object, returned as a classification tree object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldpredict` to predict responses for observations not used for training.

Otherwise, tree is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

## Definitions

### Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*. Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes  $i$  at the node, and  $p(i)$  is the observed fraction of classes with class  $i$  that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With  $p(i)$  defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let  $L(i)$  denote the fraction of members of class  $i$  in the left child node after a split, and  $R(i)$  denote the fraction of members of class  $i$  in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left( \sum_i |L(i) - R(i)| \right)^2,$$

# ClassificationTree.fit

---

where  $P(L)$  and  $P(R)$  are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If  $j$  is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

## Examples

### Construct a Classification Tree

Construct a classification tree for the data in `ionosphere.mat`.

```
load ionosphere
tc = ClassificationTree.fit(X,Y)

tc =

ClassificationTree
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    CategoricalPredictors: []
    NumObservations: 351
```

# GeneralizedLinearModel.fit

---

<b>Purpose</b>	Create generalized linear regression model
<b>Compatibility</b>	GeneralizedLinearModel.fit will be removed in a future release. Use fitglm instead.
<b>Syntax</b>	<pre>mdl = GeneralizedLinearModel.fit(tbl) mdl = GeneralizedLinearModel.fit(X,y) mdl = GeneralizedLinearModel.fit(...,modelspec) mdl = GeneralizedLinearModel.fit(...,Name,Value) mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)</pre>
<b>Description</b>	<p><code>mdl = GeneralizedLinearModel.fit(tbl)</code> creates a generalized linear model of a table or dataset array <code>tbl</code>.</p> <p><code>mdl = GeneralizedLinearModel.fit(X,y)</code> creates a generalized linear model of the responses <code>y</code> to a data matrix <code>X</code>.</p> <p><code>mdl = GeneralizedLinearModel.fit(...,modelspec)</code> creates a generalized linear model as specified by <code>modelspec</code>.</p> <p><code>mdl = GeneralizedLinearModel.fit(...,Name,Value)</code> or <code>mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)</code> creates a generalized linear model with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• The generalized linear model <code>mdl</code> is a standard linear model unless you specify otherwise with the <code>Distribution</code> name-value pair.</li><li>• For other methods such as <code>devianceTest</code>, or properties of the <code>GeneralizedLinearModel</code> object, see <code>GeneralizedLinearModel</code>.</li></ul>
<b>Input Arguments</b>	<p><b>tbl - Input data</b> table   dataset array</p> <p>Input data, specified as a table or dataset array. When <code>modelspec</code> is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.</p>

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## modelspec - Model specification

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

# GeneralizedLinearModel.fit

---

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p+1)$  matrix, namely terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-1020.

**Example:** 'quadratic'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'BinomialSize' - Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is 'binomial'.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

## Data Types

single | double

## 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.

# GeneralizedLinearModel.fit

---

- If data is in matrix  $X$ , then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

## Data Types

`single` | `double` | `logical`

## 'DispersionFlag' - Indicator to compute dispersion parameter

`false` for 'binomial' and 'poisson' distributions (default) | `true`

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors
<code>false</code>	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

**Example:** `'DispersionFlag',true`

## 'Distribution' - Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

**Example:** 'Distribution', 'gamma'

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude', [2,3]

**Example:** 'Exclude', logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept', false

## 'Link' - Link function

# GeneralizedLinearModel.fit

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comprologlog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul>	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship  $f(\mu) = X*b$  between the mean response  $\mu$  and the linear combination of predictors  $X*b$ .

For more information on the canonical link functions, see [Definitions](#).

**Example:** 'Link', 'probit'

## 'Offset' - Offset variable

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

## Data Types

single | double | char

## 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

# GeneralizedLinearModel.fit

---

The default is all variables in X, or all variables in tbl except for ResponseVar.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in tbl (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array tbl, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

**Example:** 'ResponseVar','yield'

**Example:** 'ResponseVar',[4]

**Example:** 'ResponseVar',logical([0 0 0 1 0 0])

## Data Types

single | double | logical | char

### 'VarNames' - Names of variables in fit

{'x1','x2',...,'xn','y'} (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

```
'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

**Data Types**

cell

**'Weights' - Observation weights**

ones(n,1) (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

**Data Types**

single | double

**Output Arguments**

**mdl - Generalized linear model**

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

**Definitions**

**Terms Matrix**

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

# GeneralizedLinearModel.fit

---

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables  $A$ ,  $B$ , and  $C$ :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
0    0    0    0
1    0    0    0
0    0    1    0
0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
```

```
hospital.Smoker, 'VarNames', {'BloodPressure', 'Sex', 'Age', 'Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

T =

0	0	0	0
0	1	0	0
0	0	1	0
0	0	0	1

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall  
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

T =

0	0	0
1	0	0
0	1	0
1	1	0

# GeneralizedLinearModel.fit

```
0 2 0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable
  - $-$  means do not include the next variable
  - $:$  defines an interaction, a product of terms
  - $*$  defines an interaction **and all lower-order terms**
  - $^$  raises the predictor to a power, exactly as in  $*$  repeated, so  $^$  includes lower order terms as well
  - $()$  groups terms

# GeneralizedLinearModel.fit

---

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

---

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A\*B term.

'Y ~ A\*B + C' is the same as the previous example because  $A*B = A + B + A:B$ .

'Y ~ A\*B\*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A\*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k, where k is a positive integer	A, A <sup>2</sup> , ..., A <sup>k</sup>
A + B	A, B
A*B	A, B, A*B
A:B	A*B only

Wilkinson Notation	Factors in Standard Notation
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

## Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

## Examples

### Fit a Generalized Linear Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
```

# GeneralizedLinearModel.fit

---

```
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized Linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight  
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

The large  $p$ -value indicates the model might not differ statistically from a constant.

## Alternatives

You can also construct a generalized linear model using `fitglm`.

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

# gmdistribution.fit

---

**Purpose** Gaussian mixture parameter estimates

---

**Note** `fit` will be removed in a future release. Use `fitgmdist` instead.

---

**Syntax**

```
obj = gmdistribution.fit(X,k)
obj = gmdistribution.fit(...,param1,va11,param2,va12,...)
```

**Description** `obj = gmdistribution.fit(X,k)` uses an Expectation Maximization (EM) algorithm to construct an object `obj` of the `gmdistribution` class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with `k` components for data in the  $n$ -by- $d$  matrix `X`, where  $n$  is the number of observations and  $d$  is the dimension of the data.

`gmdistribution` treats NaN values as missing data. Rows of `X` with NaN values are excluded from the fit.

`obj = gmdistribution.fit(...,param1,va11,param2,va12,...)` provides control over the iterative EM algorithm. Parameters and values are listed below.

Parameter	Value
'Start'	Method used to choose initial component parameters. One of the following: <ul style="list-style-type: none"><li>'randSample' — To select <code>k</code> observations from <code>X</code> at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element <code>j</code> on the diagonal is the variance of <code>X(:,j)</code>. This is the default.</li><li><code>S</code> — A structure array with fields <code>mu</code>, <code>Sigma</code>, and <code>PComponents</code>. See <code>gmdistribution</code> for descriptions of values.</li></ul>

Parameter	Value
	<ul style="list-style-type: none"> <li><code>s</code> — A vector of length <math>n</math> containing an initial guess of the component index for each point.</li> </ul>
'Replicates'	A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.
'CovType'	'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.
'SharedCov'	Logical true if all the covariance matrices are restricted to be the same (pooled estimate); logical false otherwise.
'Regularize'	A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.
'Options'	Options structure for the iterative EM algorithm, as created by <code>statset.gmdistribution.fit</code> uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of $1e-6$ .

In some cases, `gmdistribution` may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:

- The number of dimension of your data is relatively high and there are not enough observations.
- Some of the features (variables) of your data are highly correlated.
- Some or all the features are discrete.

# gmdistribution.fit

---

- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Pre-process your data to remove correlated features.
- Set 'SharedCov' to true to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

In other cases `gmdistribution` may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

## Examples

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Next, fit a two-component Gaussian mixture model:

```
options = statset('Display','final');  
obj = gmdistribution.fit(X,2,'Options',options);  
10 iterations, log-likelihood = -7046.78  
  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

# gmdistribution.fit

Among the properties of the fit are the parameter estimates:

```
ComponentMeans = obj.mu
```

```
ComponentMeans =
```

```
    0.9391    2.0322
```

```
   -2.9823   -4.9737
```

```
ComponentCovariances = obj.Sigma
```

```
ComponentCovariances(:,:,1) =
```

```
    1.7786   -0.0528
```

```
   -0.0528    0.5312
```

```
ComponentCovariances(:,:,2) =  
    1.0491   -0.0150  
   -0.0150    0.9816  
  
MixtureProportions = obj.PComponents  
MixtureProportions =  
    0.5000    0.5000
```

The Akaike information is minimized by the two-component model:

```
AIC = zeros(1,4);  
obj = cell(1,4);  
for k = 1:4  
    obj{k} = gmdistribution.fit(X,k);  
    AIC(k) = obj{k}.AIC;  
end  
  
[minAIC,numComponents] = min(AIC);  
numComponents  
numComponents =  
    2  
  
model = obj{2}  
model =  
Gaussian mixture distribution  
with 2 components in 2 dimensions  
Component 1:  
Mixing proportion: 0.500000  
Mean:    0.9391    2.0322  
Component 2:  
Mixing proportion: 0.500000  
Mean:   -2.9823   -4.9737
```

Both the Akaike and Bayes information are negative log-likelihoods for the data with penalty terms for the number of estimated parameters. They are often used to determine an appropriate number of components for a model when the number of components is unspecified.

# LinearModel.fit

---

the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X.

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in y is the response for the corresponding row of X.

## Data Types

single | double

## modelspec - Model specification

string naming the model |  $t$ -by- $(p + 1)$  terms matrix | string of the form 'Y ~ terms'

Model specification, specified as one of the following. The choice is the starting model for `stepwiselm`.

- A string naming the model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p + 1)$  matrix, namely terms matrix, specifying terms to include in the model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formula in the form

```
'Y ~ terms',
```

where the terms are in “Wilkinson Notation” on page 21-1044.

**Example:** `'quadratic'`

**Example:** `'y ~ X1 + X2^2 + X1:X2'`

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'CategoricalVars' - Categorical variables**

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

## Data Types

single | double | logical

### 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

### 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array tbl, or a logical or numeric index vector indicating which columns are predictor variables.

# LinearModel.fit

---

The strings should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

**Example:** `'PredictorVars',logical([0 1 1 0 0 0])`

## Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

## Data Types

single | double | logical | char

### 'RobustOpts' - Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) \cdot \sin(r) \cdot r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) \cdot (1 - r^2)^2$	4.685
'cauchy'	$w = 1 \cdot (1 + r^2)$	2.385
'fair'	$w = 1 \cdot (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 \cdot \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) \cdot r$	1.205
'ols'	Ordinary least squares (no weighting function)	None

# LinearModel.fit

---

Weight Function	Equation	Default Tuning Constant
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(- (r.^2))$	2.985

The value  $r$  in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h}),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are  $p$  columns in  $X$ , the smallest  $p$  absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and

by an estimate of the error standard deviation before it calls the weight function.

**Example:** `'RobustOpts', 'andrews'`

## **'VarNames' - Names of variables in fit**

`{ 'x1', 'x2', ..., 'xn', 'y' }` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of  $X$  first, and the name for the response variable  $y$  last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

`'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

## **Data Types**

cell

## **'Weights' - Observation weights**

`ones(n,1)` (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

## **Data Types**

single | double

## **Output Arguments**

### **mdl - Linear model**

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

# LinearModel.fit

---

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex, hospital.BloodPressure(:,1), hospital.Age, ...
    hospital.Smoker, 'VarNames', {'Sex', 'BloodPressure', 'Age', 'Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    0    1    0    0
    0    0    1    0
    0    0    0    1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the

# LinearModel.fit

---

model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];  
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

```
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
```

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
```

```
Root Mean Squared Error: 4.13
```

```
R-squared: 0.738, Adjusted R-Squared 0.735
```

```
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable

# LinearModel.fit

---

- means do not include the next variable
- : defines an interaction, a product of terms
- \* defines an interaction **and all lower-order terms**
- ^ raises the predictor to a power, exactly as in \* repeated, so ^ includes lower order terms as well
- () groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

---

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A\*B term.

'Y ~ A\*B + C' is the same as the previous example because  $A*B = A + B + A:B$ .

'Y ~ A\*B\*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A\*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$
$A + B$	$A, B$
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include $B$
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

## Examples

### Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = LinearModel.fit(X,y)
```

```
mdl =
```

```
Linear regression model:
y ~ 1 + x1 + x2 + x3 + x4
```

# LinearModel.fit

---

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.45

R-squared: 0.982, Adjusted R-Squared 0.974

F-statistic vs. constant model: 111, p-value = 4.76e-07

## Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a table that contains a categorical predictor. Use a nonlinear response formula.

Load the carsmall data.

```
load carsmall
```

Construct a table containing continuous predictor variable Weight, nominal predictor variable Year, and response variable MPG.

```
tbl = table(MPG,Weight);  
tbl.Year = nominal(Model_Year);
```

Create a fitted model of MPG as a function of Year, Weight, and Weight<sup>2</sup>. (You don't have to include Weight explicitly in your formula because it is a lower-order term of Weight<sup>2</sup>. For details, see "Formula" on page 21-1043.)

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared 0.88

F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year (for more information on dummy variables see “Dummy Indicator Variables” on page 2-56). The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164Weight + 2.0887(Year\_76) + 8.1864(Year\_82) + 1.557e-06Weight^2$$

## Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the model using formula in linear regression.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data.

```
mdl = LinearModel.fit(hospital, 'Weight~1+Age*Sex*Smoker-Age:Sex:Smoker')
```

# LinearModel.fit

---

```
mdl =
```

```
Linear regression model:
```

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

```
Number of observations: 100, Error degrees of freedom: 93
```

```
Root Mean Squared Error: 8.75
```

```
R-squared: 0.898, Adjusted R-Squared 0.892
```

```
F-statistic vs. constant model: 137, p-value = 6.91e-44
```

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with gender at the 5% significance level.

## Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
```

```
X = ingredients; % predictor variables
```

```
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

$$y \sim 1 + x1 + x2 + x3 + x4$$

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8
```

```
Root Mean Squared Error: 2.65
```

```
R-squared: 0.979, Adjusted R-Squared 0.969
```

```
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

## Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

## Alternatives

You can also construct a linear model using `fitlm`.

You can construct a model in a range of possible models using `stepwiselm`. However, you cannot use robust regression and stepwise regression together.

## See Also

`LinearModel` | `predict` | `stepwiselm`

## How To

- “Linear Regression” on page 9-12

# LinearMixedModel.fit

---

<b>Purpose</b>	Fit linear mixed-effects model using tables
<b>Compatibility</b>	<code>LinearMixedModel.fit</code> will be removed in a future release. Use <code>fitlme</code> instead.
<b>Syntax</b>	<pre>lme = LinearMixedModel.fit(tbl,formula) lme = LinearMixedModel.fit(tbl,formula,Name,Value)</pre>
<b>Description</b>	<p><code>lme = LinearMixedModel.fit(tbl,formula)</code> returns a linear mixed-effects model, specified by <code>formula</code>, fitted to the variables in the table or dataset array <code>tbl</code>.</p> <p><code>lme = LinearMixedModel.fit(tbl,formula,Name,Value)</code> returns a linear mixed-effects model with additional options specified by one or more <code>Name, Value</code> pair arguments.</p> <p>For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using <code>fitlmematrix</code>.</li></ul>
<b>Input Arguments</b>	<p><b>tbl - Input data</b> table   dataset array</p> <p>Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using <code>formula</code>.</p> <p><b>Data Types</b> single   double   char   cell</p> <p><b>formula - Formula for model specification</b></p>

string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For full description, see “Formula” on page 21-1072.

**Example:** 'y ~ treatment +(1|block)'

## Data Types

char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'CovariancePattern' - Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of 'CovariancePattern' must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

# LinearMixedModel.fit

---

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where  $\sigma_b^2$  is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where  $\sigma_{b1}^2$  is the common variance of the random-effects terms and  $\sigma_{b1,b2}$  is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if PAT(a,b) = false, then the (a,b) element of

# LinearMixedModel.fit

---

the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

## 'FitMethod' - Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'	Default. Maximum likelihood estimation
'REML'	Restricted maximum likelihood estimation

**Example:** 'FitMethod', 'REML'

## 'Weights' - Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

## Data Types

single | double

## 'Exclude' - Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude', [13,67]

## Data Types

single | double | logical

## 'DummyVarCoding' - Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

## 'Optimizer' - Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If

# LinearMixedModel.fit

---

you don't specify the options, then `LinearMixedModel` uses the default options of `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.

**Example:** `'Optimizer','fminunc'`

## **'OptimizerOptions' - Options for optimization algorithm**

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

## **'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

## **'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

## **'MaxIter' - Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

## **'Display' - Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

## **'StartMethod' - Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'                      Default. An internally defined default value.

'random'                        A random initial value.

**Example:** 'StartMethod', 'random'

## **'Verbose' - Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

# LinearMixedModel.fit

---

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose',true

## 'CheckHessian' - Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian',true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples

### Random-Intercept Model

Load the sample data.

```
load flu
```

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns

corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with the nationwide a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date` and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

```
Model fit statistics:
```

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits for the standard deviation of the random-effects term,  $\sigma_b^2$ , do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILI_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where  $\hat{b}$  is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);  
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics  
STATS.Level1 = nominal(STATS.Level1);  
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level1=='
```

```
y_hat =  
    1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(28)  
  
ans =  
    1.4674
```

## Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `LinearMixedModel.fit` creates a matrix called a 'fixed effects design

# LinearMixedModel.fit

matrix' to describe the effect of Shift. This matrix has two columns, *Shift\_Evening* and *Shift\_Morning*, where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift} - \text{Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift} - \text{Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \varepsilon_{im},$$

where  $b \sim N(0, \sigma_b^2)$  and  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(shift, 'QCDev ~ Shift + (1|Operator)', ...  
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```

'Shift_Morning'	-0.91973	0.31206	-2.9473	12	0.0101

Random effects covariance parameters (95% CIs):

Group: Operator (5 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	2.0457

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.85462	0.52357	1.395

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```

0.5775
1.1757
-2.1715
2.3655
-1.9472

```

The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}
 \hat{y}_{Evening,Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\
 &= 3.6525 - 0.53293 - 2.1715 \\
 &= 0.94807.
 \end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
```

# LinearMixedModel.fit

---

```
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working in the morning shift is

$$\begin{aligned}\hat{y}_{Morning,Operator3} &= \hat{\beta}_0 + \hat{\beta}_2 Shift\_Morning + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value in the following way.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
```

```
0.5613
```

The operator tends to make a smaller magnitude of error in the morning shift.

## Split-Plot Experiment

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and

loamy. Each block is divided into five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S^* T)_{jk} + \varepsilon_{imjk},$$

where  $i = 1, 2, \dots, 60$ , the index  $m$  corresponds to the fertilizer types,  $j$  corresponds to the tomato types, and  $k = 1, 2, 3$  corresponds to the blocks (soil).  $S_k$  represents the  $k$ th soil type, and  $(S^* T)_{jk}$  represents the  $j$ th tomato type nested in the  $k$ th soil type.  $I[F]_{im}$  is the dummy variable representing level  $m$  of the fertilizer. Similarly,  $I[T]_{ij}$  is the dummy variable representing the level  $j$  of the tomato type.

The random effects and observation error have the following prior distributions:  $b_{0k} \sim N(0, \sigma^2_S)$ ,  $b_{0jk} \sim N(0, \sigma^2_{S^*T})$ , and  $\varepsilon_{imjk} \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil)
```

```
lme =
```

The  $p$ -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the anova method after refitting the model using 'effects' contrasts.

The confidence interval for the standard deviations of the random-effects terms ( $\sigma^2_{\epsilon}$ ), where the intercept is grouped by soil is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

## Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables  $I[\cdot]$ . Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$\begin{aligned} y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im}, \end{aligned}$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{0m}$  are random effects.  $IW$  stands for initial weight and  $I[\cdot]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have the

# LinearMixedModel.fit

---

following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
lme = LinearMixedModel.fit(tbl, 'y ~ InitialWeight + Program*Week + (Week |
```

'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different relative to the weight loss of subjects who are in Program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

# LinearMixedModel.fit

## Definitions

## Formula

In general, a formula for model specification is a string of the form 'y ~ terms'. For the linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where fixed and random contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable,  $y$
- Predictor variables,  $X_j$ , which can be continuous or grouping variables
- Grouping variables,  $g_1, g_2, \dots, g_R$ ,

where the grouping variables in  $X_j$  and  $g_r$  can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, 'y ~ fixed + (random<sub>1</sub>|g<sub>1</sub>) + ... + (random<sub>R</sub>|g<sub>R</sub>)', the term `fixed` corresponds to a specification of the fixed-effects design matrix  $X$ , `random1` is a specification of the random-effects design matrix  $Z_1$  corresponding to grouping variable  $g_1$ , and similarly `randomR` is a specification of the random-effects design matrix  $Z_R$  corresponding to grouping variable  $g_R$ . You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where $k$ is a positive integer	$X, X^2, \dots, X^k$
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$ )

Wilkinson Notation	Factors in Standard Notation
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

**Examples:**

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1   g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1   g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1   g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.

# LinearMixedModel.fit

Formula	Description
'y ~ X1 + (1   g1) + (-1 + X1   g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1   g1) + (1   g2) + (1   g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

## Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

## Alternatives

You can also construct a linear mixed-effects model using `fitlme`. If your data is in matrix format, then use `fitlmematrix`.

## See Also

# NaiveBayes.fit

---

## Purpose

Create Naive Bayes classifier object by fitting training data

## Syntax

```
nb = NaiveBayes.fit(training, class)
nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)
```

---

**Note** `fit` will be removed in a future release. Use `fitNaiveBayes` instead.

---

## Description

`nb = NaiveBayes.fit(training, class)` builds a `NaiveBayes` classifier object `nb`. `training` is an N-by-D numeric matrix of training data. Rows of `training` correspond to observations; columns correspond to features. `class` is a classing variable for `training` taking K distinct levels. Each element of `class` defines which class the corresponding row of `training` belongs to. `training` and `class` must have the same number of rows.

`nb = NaiveBayes.fit(..., 'param1',val1, 'param2',val2, ...)` specifies one or more of the following name/value pairs:

- `'Distribution'` – a string or a 1-by-D cell vector of strings, specifying which distributions `fit` uses to model the data. If the value is a string, `fit` models all the features using one type of distribution. `fit` can also model different features using different types of distributions. If the value is a cell vector, its *j*th element specifies the distribution `fit` uses for the *j*th feature. The available types of distributions are:

<code>'normal'</code> (default)	Normal (Gaussian) distribution.
<code>'kernel'</code>	Kernel smoothing density estimate.

'mvmn'	Multivariate multinomial distribution for discrete data. <code>fit</code> assumes each individual feature follows a multinomial model within a class. The parameters for a feature include the probabilities of all possible values that the corresponding feature can take.
'mn'	Multinomial distribution for classifying the count-based data such as the bag-of-tokens model. In the bag-of-tokens model, the value of the $j$ th feature is the number of occurrences of the $j$ th token in this observation, so it must be a non-negative integer. When 'mn' is used, <code>fit</code> considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial. The number of categories (bins) in this multinomial model is the number of distinct tokens, i.e., the number of columns of training.

- 'Prior' – The prior probabilities for the classes, specified as one of the following:

'empirical' (default)	<code>fit</code> estimates the prior probabilities from the relative frequencies of the classes in training.
'uniform'	The prior probabilities are equal for all classes.

# NaiveBayes.fit

---

vector	A numeric vector of length $K$ specifying the prior probabilities in the class order of <code>class</code> .
structure	A structure <code>S</code> containing class levels and their prior probabilities. <code>S</code> must have two fields: <ul style="list-style-type: none"><li>• <code>S.prob</code>: A numeric vector of prior probabilities.</li><li>▪ <code>S.class</code>: A vector of the same type as <code>class</code>, containing unique class levels indicating the class for the corresponding element of <code>prob</code>. <code>S.class</code> must contain all the <math>K</math> levels in <code>class</code>. It can also contain classes that do not appear in <code>class</code>. This can be useful if <code>training</code> is a subset of a larger training set. <code>fit</code> ignores any classes that appear in <code>S.class</code> but not in <code>class</code>.</li></ul>

If the prior probabilities don't sum to one, `fit` will normalize them.

- `'KSWidth'` – The bandwidth of the kernel smoothing window. The default is to select a default bandwidth automatically for each combination of feature and class, using a value that is optimal for a Gaussian distribution. You can specify the value as one of the following:

scalar	Width for all features in all classes.
row vector	1-by- $D$ vector where the $j$ th element is the bandwidth for the $j$ th feature in all classes.
column vector	$K$ -by-1 vector where the $i$ th element specifies the bandwidth for all features in the $i$ th class. $K$ represents the number of class levels.

**matrix** K-by-D matrix  $M$  where  $M(i, j)$  specifies the bandwidth for the  $j$ th feature in the  $i$ th class.

**structure** A structure  $S$  containing class levels and their bandwidths.  $S$  must have two fields:

- **S.width** – A numeric array of bandwidths specified as a row vector, or a matrix with  $D$  columns.
  - **S.class** – A vector of the same type as **class**, containing unique class levels indicating the class for the corresponding row of **width**.
- **'KSSupport'** – The regions where the density can be applied. It can be a string, a two-element vector as shown below, or a 1-by- $D$  cell array of these values:

**'unbounded'**  
(default)            The density can extend over the whole real line.

**'positive'**            The density is restricted to positive values.

**[L,U]**            A two-element vector specifying the finite lower bound  $L$  and upper bound  $U$  for the support of the density.

- **'KSType'** – The type of kernel smoother to use. It can be a string or a 1-by- $D$  cell array of strings. Each string can be **'normal'** (default), **'box'**, **'triangle'**, or **'epanechnikov'**.

## How To

- “Naive Bayes Classification” on page 15-38
- “Grouping Variables” on page 2-52

# NonLinearModel.fit

---

**Purpose** Fit nonlinear regression model

**Compatibility** `NonLinearModel.fit` will be removed in a future release. Use `fitnlm` instead.

**Syntax**

```
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)
```

**Description** `mdl = NonLinearModel.fit(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`. `NonLinearModel.fit` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = NonLinearModel.fit(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### **tbl - Input data**

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## modelfun - Functional form of the model

function handle | string of the form 'y ~ f(b1,b2,...,bj,x1,x2,...,xk)'

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - $b$  is a coefficient vector with the same number of elements as `beta0`.
  - $x$  is a matrix with the same number of columns as  $X$  or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as  $x$ . Each row of the vector is the result of

# NonLinearModel.fit

---

evaluating *modelfun* on the corresponding row of  $x$ . In other words, *modelfun* is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. *modelfun* should return real numbers to obtain meaningful coefficients.

- String of the form  $'y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)'$ , where  $f$  represents a scalar function of the scalar coefficient variables  $b_1, \dots, b_j$  and the scalar data variables  $x_1, \dots, x_k$ .

## **beta0 - Coefficients**

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

## **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

## **'CoefficientNames' - Names of the model coefficients**

{'b1', 'b2', ..., 'bk'} (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

## **Data Types**

char

## **'ErrorModel' - Form of the error variance model**

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero

and unit-variance variable  $e$  in combination with independent components: the function value  $f$ , and one or two parameters  $a$  and  $b$

'constant' (default)

$$y = f + ae$$

'proportional'

$$y = f + bfe$$

'combined'

$$y = f + (a + b|f|)e$$

The only allowed error model when using `Weights` is 'constant'.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

**Example:** `'ErrorModel', 'proportional'`

### 'ErrorParameters' - Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	$a$	1
'proportional'	$b$	1
'combined'	$a, b$	[1, 1]

You can only use the 'constant' error model when using `Weights`.

# NonLinearModel.fit

---

---

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

---

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for  $a$  and the starting value 2 for  $b$  as follows.

**Example:** 'ErrorParameters',[1,2]

## Data Types

char

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Options' - Options for controlling the iterative fitting procedure

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by statset. The relevant fields are the nonempty fields in the structure returned by the call statset('nlinfit').

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> <li>• 'off' — Displays no information.</li> <li>• 'final' — Displays the final output.</li> <li>• 'iter' — Displays iterative output to the Command Window.</li> </ul>	'off'
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 21-1362	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 21-1362 for the default, which depends on RobustWgtFun.

# NonLinearModel.fit

---

Option	Meaning	Default
ToIFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
ToIX	Termination tolerance for the parameters. Positive scalar.	1e-8

## Data Types

struct

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array `tbl`, or

a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say yield, as the response out of six variables, in one of the following ways.

**Example:** 'ResponseVar', 'yield'

**Example:** 'ResponseVar', [4]

**Example:** 'ResponseVar', logical([0 0 0 1 0 0])

## Data Types

single | double | logical | char

## 'VarNames' - Names of variables in fit

{ 'x1', 'x2', ..., 'xn', 'y' } (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

## Example:

'VarNames', {'Horsepower', 'Acceleration', 'Model\_Year', 'MPG'}

## Data Types

cell

## 'Weights' - Observation weights

ones(n,1) (default) | vector of nonnegative scalar values | function handle

# NonLinearModel.fit

---

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have  $n$  elements, where  $n$  is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by  $MSE * (1/W(i))$ , where `MSE` is the mean squared error.

## Data Types

`single` | `double` | `function_handle`

## Output Arguments

### `mdl` - Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

## Definitions

### Robust Options

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) \cdot \sin(r) \cdot r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) \cdot (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 \cdot (1 + r.^2)$	2.385
'fair'	$w = 1 \cdot (1 + \text{abs}(r))$	1.400

## Examples

### Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
```

```
mdl =
```

# NonLinearModel.fit

---

Nonlinear regression model:

$$\text{MPG} \sim b_1 + b_2 \cdot \text{Horsepower}^{b_3} + b_4 \cdot \text{Weight}^{b_5}$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

## Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)

mdl =
```

Nonlinear regression model:

$$y \sim b_1 + b_2 \cdot x_1^{b_3} + b_4 \cdot x_2^{b_5}$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

## Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);
```

```
Iteration          SSE          Norm of          Norm of
                  Gradient          Step
-----
```

# NonLinearModel.fit

---

```

123      6068.48      1.13809      0.432543
124      6068.48      0.295962      0.297511

Iterations terminated: relative change in SSE less than OPTIONS.TolFun
```

## Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753

b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the Hougén-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';  
mdl2 = NonLinearModel.fit(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

$$y \sim (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

# NonLinearModel.fit

---

## Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));  
  
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];  
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
```

```
mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)
```

```
mdl =
```

```
Nonlinear regression model (robust fit):  
y ~ b1 + b2*exp( - b3*x)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26

```
b3      2.9732      0.38496      7.7232      1.0346e-11
```

```
Number of observations: 100, Error degrees of freedom: 97  
Root Mean Squared Error: 0.501  
R-Squared: 0.807, Adjusted R-Squared 0.803  
F-statistic vs. constant model: 203, p-value = 2.34e-35
```

## Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	0.83085	0.58224	1.427	0.19142

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.037  
R-Squared: 0.998, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

## Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

Nonlinear regression model:  
y ~ hougen(b,X)

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 1.27  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

**Algorithms** NonLinearModel.fit uses the same fitting algorithm as nlinfit.

**Alternatives** You can also construct a nonlinear model using fitnlm.

# RegressionTree.fit

---

<b>Purpose</b>	Binary decision tree for regression (to be removed)
<b>Compatibility</b>	RegressionTree.fit will be removed in a future release. Use fitrtree instead.
<b>Syntax</b>	<pre>tree = RegressionTree.fit(x,y) tree = RegressionTree.fit(x,y,Name,Value)</pre>
<b>Description</b>	<p>tree = RegressionTree.fit(x,y) returns a regression tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y. tree is a binary tree where each branching node is split based on the values of a column of x.</p> <p>tree = RegressionTree.fit(x,y,Name,Value) fits a tree with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ,NameN,ValueN.</p> <p>Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.</p> <p>Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.</p>
<b>Input Arguments</b>	<p><b>x - Predictor values</b> matrix of scalar values</p> <p>Predictor values, specified as a matrix of scalar values. Each column of x represents one variable, and each row represents one observation.</p> <p>RegressionTree.fit considers NaN values in x as missing values. RegressionTree.fit does not use observations with all missing values for x the fit. RegressionTree.fit uses observations with some missing values for x to find splits on variables for which these observations have valid values.</p>

## Data Types

single | double

## **y** - Response values

vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as **x**. Each entry in **y** is the response to the data in the corresponding row of **x**.

`RegressionTree.fit` considers NaN values in **y** to be missing values. `RegressionTree.fit` does not use observations with missing values for **y** in the fit.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

## 'CategoricalPredictors' - Categorical predictors list

numeric or logical vector | cell array of strings | character matrix  
| 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to **p**, where **p** is the number of columns of **x**.
- A logical vector of length **p**, where a true entry means that the corresponding column of **x** is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.

# RegressionTree.fit

---

- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

**Example:**

## **Data Types**

single | double | logical | char | struct | cell

## **'CrossVal' - Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `RegressionTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

**Example:** 'CrossVal', 'on'

## **'CVPartition' - Partition for cross-validation tree**

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:**

## **'Holdout' - Fraction of data for holdout validation**

scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

### Data Types

single | double

### 'KFold' - Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

### Data Types

single | double

### 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

# RegressionTree.fit

---

**Example:** 'Leaveout', 'on'

## **'MergeLeaves' - Leaf merge flag**

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', RegressionTree.fit merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree.fit does not merge leaves.

**Example:** 'MergeLeaves', 'off'

## **'MinLeaf' - Minimum number of leaf node observations**

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Example:** 'MinLeaf', 3

## **Data Types**

single | double

## **'MinParent' - Minimum number of branch node observations**

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Example:** 'MinParent', 8

## Data Types

single | double

### 'NVarToSample' - Number of predictors for split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

**Example:** 'NVarToSample',3

## Data Types

single | double

### 'PredictorNames' - Predictor variable names

{'x1','x2',...} (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

**Example:**

## Data Types

cell

### 'Prune' - Pruning flag

'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `RegressionTree.fit` computes the full tree and the optimal sequence of pruned subtrees. When 'off', `RegressionTree.fit` computes the full tree without pruning.

**Example:** 'Prune','off'

### 'PruneCriterion' - Pruning criterion

'mse' (default)

# RegressionTree.fit

---

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

**Example:** 'PruneCriterion', 'mse'

## **'QEToler' - Quadratic error tolerance**

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below  $QEToler * QED$ , where QED is the quadratic error for the entire data computed before the decision tree is grown.

**Example:** 'QEToler', 1e4

## **'ResponseName' - Response variable name**

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable in  $y$ .

**Example:** 'ResponseName', 'Response'

## **Data Types**

char

## **'ResponseTransform' - Response transform function**

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

**Example:**

## Data Types

function\_handle

### 'SplitCriterion' - Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

**Example:** 'SplitCriterion','MSE'

### 'Surrogate' - Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', `RegressionTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Example:** 'Surrogate','on'

## Data Types

single | double

### 'Weights' - Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

# RegressionTree.fit

---

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in x.

**Example:**

## Data Types

single | double

## Output Arguments

### tree - Regression tree

regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.

## Examples

### Predict Values Using a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree to predict the mileage of cars based on their weights and numbers of cylinders.

```
tree = RegressionTree.fit([Weight, Cylinders],MPG,...  
    'MinParent',20,...  
    'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree  
    PredictorNames: {'W' 'C'}  
    ResponseName: 'Y'  
    ResponseTransform: 'none'
```

```
CategoricalPredictors: []  
NumObservations: 94
```

Predict the mileage of a car that weighs 2200 lbs and has four cylinders.

```
predict(tree,[2200,4])
```

```
ans =  
29.6111
```

## How To

- “Splitting Categorical Predictors” on page 16-61

# fitcdiscr

---

**Purpose** Fit discriminant analysis classifier

**Syntax**  
`obj = fitcdiscr(x,y)`  
`obj = fitcdiscr(x,y,Name,Value)`

**Description** `obj = fitcdiscr(x,y)` returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`.

`obj = fitcdiscr(x,y,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification, prior probabilities for each class, or observation weights.

## Input Arguments

### **x - Predictor values**

matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of `x` represents one variable, and each row represents one observation.

`fitcdiscr` considers NaN values in `x` as missing values. `fitcdiscr` does not use observations with missing values for `x` in the fit.

### **Data Types**

single | double

### **y - Classification values**

numeric vector | categorical vector | logical vector | character array | cell array of strings

Classification values, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Each row of `y` represents the classification of the corresponding row of `x`.

`fitcdiscr` considers NaN values in `y` to be missing values. `fitcdiscr` does not use observations with missing values for `y` in the fit.

### **Data Types**

single | double | logical | char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'DiscrimType', 'quadratic', 'SaveMemory', 'on'` specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.

## 'ClassNames' - Class names

array

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

## Data Types

single | double | logical | char

## 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i≠j`, and `Cost(i, j)=0` if `i=j`.

## Data Types

single | double | struct

## 'CrossVal' - Flag to grow cross-validated decision tree

'off' (default) | 'on'

Flag to grow cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If you specify 'on', then fitcdiscr creates a cross-validated classifier with 10 folds. You can use 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one of these options at a time for creating a cross-validated classifier.

Alternatively, cross validate `obj` later using the `crossval` method.

**Example:** 'CrossVal', 'on'

## 'CVPartition' - Cross-validated model partition

cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`. You can only use one option at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## 'Delta' - Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

## Data Types

single | double

## 'DiscrimType' - Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic' | 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

**Example:** 'DiscrimType', 'quadratic'

### 'FillCoeffs' - Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and either 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

**Example:** 'FillCoeffs', 'off'

### 'Gamma' - Regularization parameter

scalar value in the range [0,1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0,1].

- Linear discriminant — Scalar value in the range [0,1].
  - If you pass a value strictly between 0 and 1, fitcdiscr sets the discriminant type to 'Linear'.
  - If you pass 0 for Gamma and 'Linear' for DiscrimType, and if the correlation matrix is singular, fitcdiscr sets Gamma to the minimal value required for inverting the covariance matrix.

- If you set Gamma to 1, fitcdiscr sets the discriminant type to 'DiagLinear'.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for Gamma and 'Quadratic' for DiscrimType, and if one of the classes has a singular covariance matrix, fitcdiscr errors.
  - If you set Gamma to 1, fitcdiscr sets the discriminant type to 'DiagQuadratic'.
  - If you set Gamma to a value between 0 and 1 for a quadratic discriminant, fitcdiscr errors.

**Example:** 'Gamma',1

### **Data Types**

single | double

### **'Holdout' - Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Holdout',0.1

### **Data Types**

double | single

### **'KFold' - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'KFold',8

### Data Types

single | double

### 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

### Data Types

char

### 'PredictorNames' - Predictor variable names

{'x1','x2',...} (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in  $x$ .

### Data Types

cell

### 'Prior' - Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:
  - 'empirical' determines class probabilities from class frequencies in *y*. If you pass observation weights, they are used to compute the class probabilities.
  - 'uniform' sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure *S* with two fields:
  - *S.ClassNames* containing the class names as a variable of the same type as *y*
  - *S.ClassProbs* containing a vector of corresponding probabilities

**Example:** 'Prior','uniform'

## Data Types

single | double | struct

## 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable *y*.

**Example:** 'ResponseName', 'Response'

## Data Types

char

## 'SaveMemory' - Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but

instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

**Example:** `'SaveMemory', 'on'`

**'ScoreTransform' - Score transform function**

`'none'` (default) | valid score transform string | function handle

Score transform function, specified as the comma-separated pair consisting of `'ScoreTransform'` and one of the following.

String	Formula
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1-x))$
<code>'ismax'</code>	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
<code>'logit'</code>	$1/(1 + e^{-x})$
<code>'none'</code>	$x$ (no transformation)
<code>'sign'</code>	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
<code>'symmetric'</code>	$2x - 1$
<code>'symmetriclogit'</code>	$2/(1 + e^{-x}) - 1$
<code>'symmetricismax'</code>	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

Alternatively, you can use your own function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

**Example:** 'ScoreTransform', 'logit'

### Data Types

function\_handle

### 'Weights' - Observation weights

ones(size(X,1),1) (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of **Weights** is the number of rows in **x**. `fitcdiscr` normalizes the weights to sum to 1.

### Data Types

single | double

## Output Arguments

### **obj** - Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `obj` is of class `ClassificationDiscriminant`, and you can use the `predict` method to predict the response of new data.

## Examples

### **Construct a Discriminant Analysis Classifier**

Construct a discriminant analysis classifier for the Fisher iris data.

```
load fisheriris
obj = fitcdiscr(meas,species)
```

```
obj =
```

```

ClassificationDiscriminant
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  DiscrimType: 'linear'
  Mu: [3x4 double]
  Coeffs: [3x3 struct]

```

Properties, Methods

## Definitions

### Discriminant Classification

The model for discriminant analysis is:

- Each class ( $Y$ ) generates data ( $X$ ) using a multivariate normal distribution. That is, the model assumes  $X$  has a Gaussian mixture distribution (`gmdistribution`).
  - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
  - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.

- $\hat{P}(k|x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y|k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

For details, see “How the predict Method Classifies” on page 15-6.

## Alternative Functionality

### Functions

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use.

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

<b>Purpose</b>	Fit $k$ -nearest neighbor classifier
<b>Syntax</b>	<pre>mdl = fitcknn(x,y) mdl = fitcknn(x,y,Name,Value)</pre>
<b>Description</b>	<p><code>mdl = fitcknn(x,y)</code> returns a classification model based on the input variables (also known as predictors, features, or attributes) <math>x</math> and output (response) <math>y</math>.</p> <p><code>mdl = fitcknn(x,y,Name,Value)</code> fits a model with additional options specified by one or more name-value pair arguments. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.</p>
<b>Input Arguments</b>	<p><b>x - Predictor values</b> matrix of scalar values</p> <p>Predictor values, specified as a matrix of scalar values. Each column of <math>x</math> represents one variable, and each row represents one observation.</p> <p><b>Data Types</b> single   double</p> <p><b>y - Classification values</b> numeric vector   categorical vector   logical vector   character array   cell array of strings</p> <p>Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings, with the same number of rows as <math>x</math>. Each row of <math>y</math> represents the classification of the corresponding row of <math>x</math>.</p> <p><b>Data Types</b> single   double   cell   logical   char</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding</p>

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:**

'NumNeighbors',3,'NSMethod','exhaustive','Distance','minkowski' specifies a classifier for 3-nearest neighbors using the nearest neighbor search method and the Minkowski metric.

**'BreakTies' - Tie-breaking algorithm**

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the predict method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of 'BreakTies' and one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

**Example:** 'BreakTies','nearest'

**'BucketSize' - Maximum data points in node**

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when NSMethod is 'kdtree'.

**Example:** 'BucketSize',40

**Data Types**

single | double

**'CategoricalPredictors' - Categorical predictor flag**

[] (default) | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set CategoricalPredictors to 'all', the default Distance is 'hamming'.

**Example:** 'CategoricalPredictors','all'

### 'ClassNames' - Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in *y*.

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names in *y*.

### Data Types

single | double | char | logical | cell

### 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where  $Cost(i, j)$  is the cost of classifying a point into class *j* if its true class is *i*.
- Structure *S* having two fields: *S.ClassNames* containing the group names as a variable of the same type as *y*, and *S.ClassificationCosts* containing the cost matrix.

The default is  $Cost(i, j)=1$  if  $i \neq j$ , and  $Cost(i, j)=0$  if  $i=j$ .

## Data Types

single | double | struct

## 'Cov' - Covariance matrix

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

## Data Types

single | double

## 'CrossVal' - Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'. If 'on', fitcknn creates a cross-validated model with 10 folds. Use the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one parameter at a time to create a cross-validated model.

Alternatively, cross validate mdl later using the crossval method.

**Example:** 'Crossval', 'on'

## 'CVPartition' - Cross-validated model partition

cvpartition object

Cross-validated model partition, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition. You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## 'Distance' - Distance metric

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric string or function handle. The allowable strings depend on the NSMethod parameter, which you set in fitcknn, and which exists as a field in ModelParameters. If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

For definitions, see “Distance Metrics” on page 16-9.

This table includes valid distance metrics of ExhaustiveSearcher.

Value	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.

Value	Description
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix $C$ . The default value of $C$ is the sample covariance matrix of $x$ , as computed by <code>nancov(x)</code> . To specify a different value for $C$ , use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between $x$ and a query point is scaled, meaning divided by a scale value $S$ . The default value of $S$ is the standard deviation computed from $x$ , $S = \text{nanstd}(X)$ . To specify another value for $S$ , use the Scale name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form  <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> <li>• ZI is a 1-by-N vector containing one row of <math>x</math> or <math>y</math>.</li> <li>• ZJ is an M2-by-N matrix containing multiple rows of <math>x</math> or <math>y</math>.</li> </ul>

Value	Description
	<ul style="list-style-type: none"> <li>D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(J, :).</li> </ul>

**Example:** 'Distance', 'minkowski'

**Data Types**

function\_handle

**'DistanceWeight' - Distance weighting function**

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance <sup>2</sup>
@fcn	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

**Example:** 'DistanceWeight', 'inverse'

**Data Types**

function\_handle

**'Exponent' - Minkowski distance exponent**

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

**Example:** 'Exponent',3

### **Data Types**

single | double

### **'Holdout' - Fraction of data for holdout validation**

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition' 'Kfold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

### **Data Types**

single | double

### **'IncludeTies' - Tie inclusion flag**

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

**Example:** 'IncludeTies',true

### **Data Types**

logical

### **'Kfold' - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

### Data Types

single | double

### 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

### 'NSMethod' - Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and either 'kdtree' or 'exhaustive'.

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
  - 'cityblock'
  - 'minkowski'
  - 'chebyshev'

- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in  $x$  to each point in  $y$  are computed to find nearest neighbors.

The default is 'kdtree' when  $x$  has 10 or fewer columns,  $x$  is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

**Example:** 'NSMethod', 'exhaustive'

### **'NumNeighbors' - Number of nearest neighbors to find**

1 (default) | positive integer value

Number of nearest neighbors in  $x$  to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

**Example:** 'NumNeighbors', 3

### **Data Types**

single | double

### **'PredictorNames' - Predictor variable names**

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in  $x$ .

### **Data Types**

cell

### **'Prior' - Prior probabilities**

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A string:

- 'empirical' determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
- 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class).
- A structure `S` with two fields:
  - `S.ClassNames` containing the class names as a variable of the same type as `y`
  - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

**Example:** 'Prior', 'uniform'

### Data Types

single | double | struct

### 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable `y`.

**Example:** 'ResponseName', 'Response'

### Data Types

char

### 'Scale' - Distance scale

`nanstd(x)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in `x`. Each coordinate difference

between  $x$  and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when `'Distance'` is `'seuclidean'`.

## Data Types

single | double

## 'Weights' - Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The length of `Weights` is the number of rows in  $x$ . `fitcknn` normalizes the weights in each class to add up to the value of the prior probability of the class.

## Data Types

single | double

## Output Arguments

### mdl - Classifier model

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the `'CrossVal'`, `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

## Examples

### Construct a 5-Nearest Neighbor Classifier

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the sample data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5)
```

```
mdl =
```

```
ClassificationKNN
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 150
  Distance: 'euclidean'
  NumNeighbors: 5
```

Properties, Methods

## Construct a Classifier Using the Minkowski Metric

Load the data.

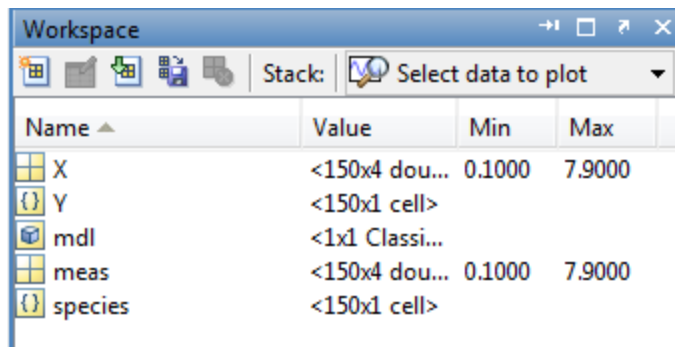

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 3-nearest neighbors with the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher.

```
mdl = fitcknn(X,Y,'NumNeighbors',3,...
  'NSMethod','exhaustive','Distance','minkowski');
```

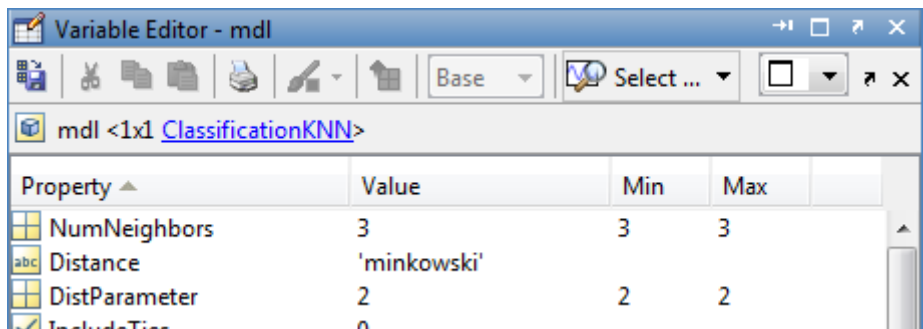

To examine mdl properties, double-click mdl in the Workspace window to open the Variable Editor.

# fitknn

Workspace

Name	Value	Min	Max
X	<150x4 dou...>	0.1000	7.9000
Y	<150x1 cell>

meas	<150x4 dou...>	0.1000	7.9000
species	<150x1 cell>		

Variable Editor - mdl

mdl <1x1 ClassificationKNN>

Property	Value	Min	Max
NumNeighbors	3	3	3
Distance	'minkowski'		
DistParameter	2	2	2
IncludeTies	0		

## Definitions

### Prediction

ClassificationKNN predicts the classification of a point  $X_{new}$  using a procedure equivalent to this:

- 1 Find the NumNeighbors points in the training set  $X$  that are nearest to  $X_{new}$ .
- 2 Find the NumNeighbors response values  $Y$  to those nearest points.
- 3 Assign the classification label  $Y_{new}$  that has the largest posterior probability among the values in  $Y$ .

For details, see “Posterior Probability” on page 21-2997 in the predict documentation.

# fitcsvm

---

**Purpose** Train binary support vector machine classifier

**Syntax**  
SVMModel = fitcsvm(X,Y)  
SVMModel = fitcsvm(X,Y,Name,Value)

**Description** SVMModel = fitcsvm(X,Y) returns a support vector machine classifier SVMModel, trained by predictors X and class labels Y for one- or two-class classification.

SVMModel = fitcsvm(X,Y,Name,Value) returns a support vector machine classifier with additional options specified by one or more Name,Value pair arguments.

For example, you can specify the type of cross validation, the cost for misclassification, or the type of score transformation function.

## Input Arguments

### **X - Predictor data**

matrix of numeric values

Predictor data to which the SVM classifier is trained, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor.

The length of Y and the number of rows of X must be equal.

It is good practice to:

- Cross validate using the KFold name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.
- Standardize the predictor variables using the Standardize name-value pair argument.

To specify the names of the predictors in the order of their appearance in X, use the PredictorNames name-value pair argument.

## Data Types

double | single

## Y - Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the SVM classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If Y is a character array, then each element must correspond to one row of the array.

The length of Y and the number of rows of X must be equal.

It is good practice to specify the order of the classes using the `ClassNames` name-value pair argument.

To specify the response variable name, use the `ResponseName` name-value pair argument.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

**Example:** `'Kfold',10,'Cost',[0 2;1 0], 'ScoreTransform','sign'` specifies to perform 10-fold cross validation, apply double the penalty to false positives compared to false negatives, and transform the scores using the sign function.

## 'Alpha' - Initial estimates of alpha coefficients

vector of nonnegative real values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a vector of nonnegative real values. The length of Alpha must be equal to the number of rows of X.

- Each element of Alpha corresponds to an observation in X.
- Alpha cannot contain any NaNs.
- If you specify Alpha and any of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'Kfold', or 'Leaveout'), then the software returns an error.

The defaults are:

- `0.5*ones(size(X,1),1)` for one-class learning
- `zeros(size(X,1),1)` for two-class learning

**Example:** `'Alpha',0.1*ones(size(X,1))`

### Data Types

double | single

### 'BoxConstraint' - Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

**Example:** `'BoxConstraint',100`

### Data Types

double | single

### 'CacheSize' - Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and a positive scalar or a string.

If CacheSize is a positive scalar, then the software reserves CacheSize megabytes of disk space for training the classifier.

If CacheSize is 'maximal', then the software reserves enough disk space to hold the entire  $n$ -by- $n$  Gram matrix.

**Example:** 'CacheSize','maximal'

**Data Types**

double | char | single

**'ClassNames' - Class names**

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and categorical or character array, logical or numeric vector, or cell array of strings. You must set ClassNames using the data type of Y.

The default is the distinct class names of Y.

If Y is a character array, then each element must correspond to one row of the array.

Use ClassNames to order the classes or to select a subset of classes for training.

**Example:** 'ClassNames',logical([0,1])

**'Cost' - Misclassification cost**

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

- The square matrix Cost, then Cost(i, j) is the cost of classifying a point into class j if its true class is i
- The structure S, then it must have two fields:
  - S.ClassNames, which contains the class names as a variable of the same data type as Y
  - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described

in the cost matrix. Subsequently, the cost matrix resets to the default. For more details, see “Algorithms” on page 21-1162.

The defaults are:

- For one-class learning, `Cost = 0`.
- For two-class learning, `Cost(i,j) = 1` if  $i \neq j$ , and `Cost(i,j) = 0` if  $i = j$ .

**Example:** `'Cost',[0,1;2,0]`

### Data Types

double | single | struct

### 'CrossVal' - Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and a string.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments.

You can only use one of these four options at a time for creating a cross-validated model: `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Alternatively, cross-validate `SVMModel` later by passing it to `crossval`.

**Example:** `'Crossval','on'`

### Data Types

char

### 'CVPartition' - Cross-validation partition

`cvpartition partition` | `[]` (default)

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition as created

by `cvpartition`. You can only use one of these four options at a time for creating a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

`crossval` splits the data into subsets using `cvpartition`.

### **'DeltaGradientTolerance' - Tolerance for gradient difference**

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

If `DeltaGradientTolerance` is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The defaults are:

- `1e-3` if the solver is SMO (for example, you set `'Solver','SMO'`)
- `0` if the solver is ISDA (for example, you set `'Solver','ISDA'`)

**Example:** `'DeltaGapTolerance',1e-2`

### **Data Types**

double | single

### **'GapTolerance' - Feasibility gap tolerance**

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of `'GapTolerance'` and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

**Example:** `'GapTolerance',1e-2`

### **Data Types**

double | single

## **'Holdout' - Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can only use one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Holdout',0.1

### **Data Types**

double | single

## **'IterationLimit' - Maximal number of numerical optimization iterations**

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained classifier regardless of whether the optimization routine successfully converges.

**Example:** 'IterationLimit',1e8

### **Data Types**

double | single

## **'KernelFunction' - Kernel function**

string

Kernel function used to compute the Gram matrix, specified as the comma-separated pair consisting of 'KernelFunction' and a string.

This table summarizes the available options for setting a kernel function.

Value	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_1, x_2) = \exp\left(-\frac{\ x_1 - x_2\ ^2}{2\sigma^2}\right)$
'linear'	Linear kernel, default for two-class learning	$G(x_1, x_2) = x_1'x_2$
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', polyOrder to specify a polynomial kernel of order polyOrder.	$G(x_1, x_2) = (1 + x_1'x_2)^p$

You can set your own kernel function, for example, kernel, by setting 'KernelFunction', 'kernel'. kernel must have the following form:

```
function G = kernel(U,V)
```

where:

- U is an *m*-by-*p* matrix.
- V is an *n*-by-*p* matrix.
- G is an *m*-by-*n* Gram matrix of the rows of U and V.

And kernel.m must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

**Example:** 'KernelFunction', 'gaussian'

### Data Types

char

### 'KernelOffset' - Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 0.1 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

**Example:** 'KernelOffset',0

### Data Types

double | single

### 'KernelScale' - Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar.

- If KernelFunction is 'gaussian' ('rbf'), 'linear', or 'polynomial', then the software divides all elements of the predictor matrix X by the value of KernelScale. Then, the software applies the appropriate kernel norm to compute the Gram matrix.
- If you specify 'auto', then the software uses a heuristic procedure to select the scale value. The heuristic procedure uses subsampling. Therefore, to reproduce results, set a random number seed using rng before training the classifier.
- If you specify KernelScale and your own kernel function, for example, kernel, using 'KernelFunction', 'kernel', then the software displays an error. You must apply scaling within kernel.

**Example:** 'KernelScale','auto'

### Data Types

double | single | char

**'KFold' - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

You can only use one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'KFold',8

**Data Types**

single | double

**'KKTolerance' - Karush-Kuhn-Tucker complementarity conditions violation tolerance**

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions violation tolerance, specified as the comma-separated pair consisting of 'KKTolerance' and a nonnegative scalar.

If KKTolerance is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The defaults are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 1e-3 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

**Example:** 'KKTolerance',1e-2

**Data Types**

double | single

**'Leaveout' - Leave-one-out cross-validation flag**

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'Kfold' name-value pair arguments.

**Example:** 'Leaveout','on'

## Data Types

char

## 'Nu' - parameter for one-class learning

0.5 (default) | positive scalar

$\nu$  parameter for one-class learning, specified as the comma-separated pair consisting of 'Nu' and a positive scalar. Nu must be greater than 0 and at most 1.

Set Nu to control the tradeoff between ensuring most training examples are in the positive class and minimizing the weights in the score function.

**Example:** 'Nu',0.25

## Data Types

double | single

## 'NumPrint' - Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you use 'Verbose',1 and 'NumPrint',numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

**Example:** 'NumPrint',500

**Data Types**

double | single

**'OutlierFraction' - Expected proportion of outliers in training data**

0 (default) | nonnegative scalar

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a nonnegative scalar. OutlierFraction must be at least 0 and less than 1.

If you set 'OutlierFraction', outlierfraction, where outlierfraction is a value greater than 0, then:

- For two-class learning, the software implements *robust learning*. In other words, the software attempts to remove  $100 \times \text{outlierfraction}\%$  of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that outlierfraction of the observations in the training set have negative scores.

**Example:** 'OutlierFraction',0.01

**Data Types**

double | single

**'PolynomialOrder' - Polynomial kernel function order**

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.

If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software displays an error.

**Example:** 'PolynomialOrder',2

**Data Types**

double | single

## 'PredictorNames' - Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in X.

**Example:** 'PredictorNames', {'PedalWidth', 'PedalLength'}

## Data Types

cell

## 'Prior' - Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a string, numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y.
'uniform'	All class prior probabilities are equal to $1/K$ , where $K$ is the number of classes.

Value	Description
numeric vector	Each element is a class prior probability. Order the elements according to <code>SVMModel.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure <code>S</code> with two fields: <ul style="list-style-type: none"> <li>• <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>.</li> <li>• <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.</li> </ul>

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details, see “Algorithms” on page 21-1162.

**Example:**

```
struct('ClassNames',{{'setosa','versicolor'}},'ClassProbs',[1,2])
```

**Data Types**

char | double | single | struct

**'ResponseName' - Response variable name**

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable `Y`.

**Example:** 'ResponseName', 'IrisType'

## Data Types

char

### 'ScoreTransform' - Score transform function

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' (default) | 'sign' | 'symmetric' | 'symmetriclogit' | 'symmetricismax' | function handle

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a string or function handle.

- If the value is a string, then it must correspond to a built-in function. This table summarizes the available, built-in functions.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	$x$ (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

- For a MATLAB function, or a function that you define, enter its function handle.

```
SVMModel.ScoreTransform = @function;
```

function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

**Example:** 'ScoreTransform','sign'

**Data Types**

char | function\_handle

**'ShrinkagePeriod' - Number of iterations between movement of observations from active to inactive set**

0 (default) | nonnegative integer

Number of iterations between the movement of observations from the active to inactive set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod',0, then the software does not shrink the active set.

**Example:** 'ShrinkagePeriod',1000

**Data Types**

double | single

**'Solver' - Optimization routine**

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as a string.

This table summarizes the available optimization routine options.

Value	Description
'ISDA'	Iterative Single Data Algorithm
'L1QP'	L1 soft-margin minimization by quadratic programming (requires an Optimization Toolbox license).
'SMO'	Sequential Minimal Optimization

The defaults are:

- 'ISDA' if you set 'OutlierFraction' to a positive value and for two-class learning
- 'SMO' otherwise

**Example:** 'Solver', 'ISDA'

## **Data Types**

char

## **'Standardize' - Flag to standardize predictors**

false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively. It is good practice to standardize the predictor data.

**Example:** 'Standardize', true

## **Data Types**

logical

## **'Verbose' - Verbosity level**

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0, 1, or 2. Verbose controls the amount of optimization information that the software displays in the Command Window and saves as a structure to SVMModel.ConvergenceInfo.History.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every numprint iterations, where numprint is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

**Example:** 'Verbose',1

**Data Types**

double | single

**'Weights' - Observation weights**

ones(size(X,1),1) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector.

The size of Weights must be equal to the number of rows of X. The software weighs the observations in each row of X with the corresponding weight in Weights.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

**Data Types**

double | single

**Output Arguments**

**SVMModel - Trained SVM classifier**

ClassificationSVM classifier | ClassificationPartitionedModel cross-validated classifier

Trained SVM classifier, returned as a `ClassificationSVM` classifier or `ClassificationPartitionedModel` cross-validated classifier.

If you set any of the name-value pair arguments 'KFold', 'Holdout', 'Leaveout', 'CrossVal', or 'CVPartition', then `SVMMModel` is a `ClassificationPartitionedModel`. Otherwise, `SVMMModel` is a `ClassificationSVM` classifier.

To reference properties of `SVMMModel`, use dot notation. For example, enter `SVMMModel.Alpha` in the Command Window to display the trained Lagrange multipliers.

## Examples

### Train a Support Vector Machine Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths, and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species,'setosa');
X = meas(inds,3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVMMModel = fitcsvm(X,y)
```

```
SVMMModel =
```

```
ClassificationSVM
  PredictorNames: {'x1' 'x2'}
  ResponseName: 'Y'
  ClassNames: {'versicolor' 'virginica'}
  ScoreTransform: 'none'
  NumObservations: 100
  Alpha: [24x1 double]
  Bias: -14.4149
  KernelParameters: [1x1 struct]
  BoxConstraints: [100x1 double]
```

```

ConvergenceInfo: [1x1 struct]
IsSupportVector: [100x1 logical]
Solver: 'SMO'

```

The Command Window shows that `SVModel` is a trained `ClassificationSVM` classifier and a property list. Display the properties of `SVModel`, for example, to determine the class order, by using dot notation.

```
classOrder = SVModel.ClassNames
```

```

classOrder =

    'versicolor'
    'virginica'

```

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```

sv = SVModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off

```

The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and therefore the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

## Train and Cross Validate an SVM Classifier

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. It is good practice to standardize the predictors.

```
SVMModel = fitsvm(X,Y,'Standardize',true,'KernelFunction','RBF',...
    'KernelScale','auto');
```

SVMModel is a trained `ClassificationSVM` classifier.

Cross validate the SVM classifier. By default, the software uses 10-fold cross validation.

```
CVSVMModel = crossval(SVMModel);
```

CVSVMModel is a `ClassificationPartitionedModel` cross-validated classifier.

Estimate the out-of-sample misclassification rate.

```
classLoss = kfoldLoss(CVSVMModel)
```

```
classLoss =
```

```
    0.0484
```

The generalization rate is approximately 5%.

## **Detect Outliers Using SVM and One-Class Learning**

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```
load fisheriris
X = meas(:,1:2);
```

```
y = ones(size(X,1),1);
```

Train an SVM classifier using the processed data set. Assume that 5% of the observations are outliers. It is good practice to standardize the predictors.

```
rng(1);  
SVMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,...  
    'OutlierFraction',0.05);
```

SVMModel is a trained ClassificationSVM classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```
svInd = SVMModel.IsSupportVector;  
h = 0.02; % Mesh grid step size  
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...  
    min(X(:,2)):h:max(X(:,2)));  
[~,score] = predict(SVMModel,[X1(:),X2(:)]);  
scoreGrid = reshape(score,size(X1,1),size(X2,2));  
  
figure  
plot(X(:,1),X(:,2),'k. ')  
hold on  
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)  
contour(X1,X2,scoreGrid)  
colorbar;  
title('{\bf Iris Outlier Detection via One-Class SVM}')  
xlabel('Sepal Length (cm)')  
ylabel('Sepal Width (cm)')  
legend('Observation','Support Vector')  
hold off
```

The boundary separating the outliers from the rest of the data occurs where the contour value is 0.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```
CVSVMModel = crossval(SVMModel);
[~,scorePred] = kfoldPredict(CVSVMModel);
outlierRate = mean(scorePred<0)
```

```
outlierRate =  
  
    0.0467
```

## Find Multiple Class Boundaries Using Binary SVM

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris  
X = meas(:,3:4);  
Y = species;
```

Examine a scatter plot of the data.

```
figure  
gscatter(X(:,1),X(:,2),Y);  
title('\bf Scatter Diagram of Iris Measurements');  
xlabel('Petal Length (cm)');  
ylabel('Petal Width (cm)');  
legend('Location','Northwest');  
lims = get(gca,{'XLim','YLim'}); % Extract the _x_ and _y_ axis limits
```

There are three classes, one of which is linearly separable from the others.

For each class:

- 1** Create a logical vector (`indx`) indicating whether an observation is a member of the class.
- 2** Train an SVM classifier using the predictor data and `indx`.

**3** Store the classifier in a cell of a cell array.

```
% It is good practice to define the class order and standardize the
% predictors.
SVMModels = cell(3,1);
classes = unique(Y);
rng(1); % For reproducibility

for j = 1:numel(classes);
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMModels{j} = fitcsvm(X,indx,'ClassNames',[false true],'Standardize'
        'KernelFunction','rbf','BoxConstraint',1);
end
```

SVMModels is a 3-by-1 cell array, with each cell containing a ClassificationSVM classifier. For each cell, the positive class is setosa, versicolor, and virginica, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier.

```
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
N = size(xGrid,1);
Scores = zeros(N,numel(classes));

for j = 1:numel(classes);
    [~,score] = predict(SVMModels{j},xGrid);
    Scores(:,j) = score(:,2); % Second column contains positive-class scores
end
```

Each row of Scores contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

```
[~,maxScore] = max(Scores,[],2);
```

Color in the regions of the plot based on which class the corresponding new observation belongs.

```
figure
h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...
    [0.1 0.5 0.5; 0.5 0.1 0.5; 0.5 0.5 0.1]);
hold on
h(4:6) = gscatter(X(:,1),X(:,2),Y);
title('\bf Iris Classification Regions');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend(h,{'setosa region','versicolor region','virginica region',...
    'observed setosa','observed versicolor','observed virginica'},...
    'Location','Northwest');
axis tight
hold off
```

## Algorithms

- All solvers implement  $L1$  soft-margin minimization.
- `fitcsvm` and `svmtrain` use, among other algorithms, SMO for optimization. The software implements SMO differently between the two functions, but numerical studies show that there is sensible agreement in the results.
- For one-class learning, the software estimates the Lagrange multipliers,  $a_1, \dots, a_n$ , such that

$$\sum_{j=1}^n \alpha_j = nv.$$

- For two-class learning, if you specify a cost matrix  $C$ , then the software updates the class prior probabilities ( $p$ ) to  $p_c$  by incorporating the penalties described in  $C$ . The formula for the updated prior probability vector is

$$p_c = \frac{p'C}{\sum p'C}.$$

Subsequently, the software resets the cost matrix to the default:

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

- If you set 'Standardize', true when you train the SVM classifier using `fitcsvm`, then the software trains the classifier using the standardized predictor matrix, but stores the unstandardized data in the classifier property  $X$ . However, if you standardize the data, then the data size in memory doubles until optimization ends.
- Let  $p$  be the proportion of outliers you expect in the training data. If you use 'OutlierFraction',  $p$  when you train the SVM classifier using `fitcsvm`, then:
  - For one-class learning, the software trains the bias term such that 100 $p$ % of the observations in the training data have negative scores.
  - The software implements *robust learning* for two-class learning. In other words, the software attempts to remove 100 $p$ % of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

## Definitions

### Box Constraint

A parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

### Gram Matrix

The Gram matrix of a set of  $n$  vectors  $\{x_1, \dots, x_n; x_j \in R^p\}$  is an  $n$ -by- $n$  matrix with element  $(j, k)$  defined as  $G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle$ , an inner product of the transformed predictors using the kernel function  $\phi$ .

For nonlinear SVM, the algorithm forms a Gram matrix using the predictor matrix columns. The dual formalization replaces the inner product of the predictors with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Subsequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

### Karush-Kuhn-Tucker Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j [y_j (w' \phi(x_j) + b) - 1 + \xi_j] = 0 \\ \xi_j (C - \alpha_j) = 0 \end{cases}$$

for all  $j = 1, \dots, n$ , where  $w_j$  is a weight,  $\phi$  is a kernel function (see Gram matrix), and  $\xi_j$  is a slack variable. If the classes are perfectly separable, then  $\xi_j = 0$  for all  $j = 1, \dots, n$ .

## One-Class Learning

One-class learning, or unsupervised SVM, aims at separating data from the origin in the high-dimensional, predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification. The objective is to minimize dual expression

$$0.5 \sum_{jk} \alpha_j \alpha_k G(x_j, x_k)$$

with respect to  $\alpha_1, \dots, \alpha_n$ , subject to

$$\sum \alpha_j = nv$$

and  $0 \leq \alpha_j \leq 1$  for all  $j = 1, \dots, n$ .  $G(x_j, x_k)$  is element  $(j, k)$  of the Gram matrix.

A small value of  $v$  leads to fewer support vectors, and, therefore, a smooth, crude decision boundary. A large value of  $v$  leads to more support vectors, and therefore, a curvy, flexible decision boundary. The optimal value of  $v$  should be large enough to capture the data complexity and small enough to avoid overtraining. Also,  $0 < v \leq 1$ .

For more details, see [3].

## Support Vector

Support vectors are observations corresponding to strictly positive estimates of  $\alpha_1, \dots, \alpha_n$ .

SVM classifiers that yield fewer support vectors for a given training set are more desirable.

## Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a *margin* (space that does not contain any observations) surrounding itself, which creates

boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + \beta_0,$$

where:

- $x$  is an observation (corresponding to a row of  $X$ ).
- The vector  $\beta$  contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `SVMMODEL.BETA`). For separable data, the optimal margin length is  $2/\|\beta\|$ .
- $\beta_0$  is the bias term (corresponding to `SVMMODEL.BIAS`).

The root of  $f(x)$  for particular coefficients defines a hyperplane. For a particular hyperplane,  $f(z)$  is the distance from point  $z$  to the hyperplane.

An SVM classifier searches for the maximum margin length, while keeping observations in the positive ( $y = 1$ ) and negative ( $y = -1$ ) classes separate. Therefore:

- For separable classes, the objective is to minimize  $\|\beta\|$  with respect to the  $\beta$  and  $\beta_0$  subject to  $y_j f(x_j) \geq 1$ , for all  $j = 1, \dots, n$ . This is the *primal* formalization for separable classes.
- For inseparable classes, SVM uses slack variables ( $\xi_j$ ) to penalize the objective function for observations that cross the margin boundary for their class.  $\xi_j = 0$  for observations that do not cross the margin boundary for their class, otherwise  $\xi_j \geq 0$ .

The objective is to minimize  $0.5\|\beta\|^2 + C\sum \xi_j$  with respect to the  $\beta$ ,  $\beta_0$ , and  $\xi_j$  subject to  $y_j f(x_j) \geq 1 - \xi_j$  and  $\xi_j \geq 0$  for all  $j = 1, \dots, n$ , and for a positive scalar box constraint  $C$ . This is the primal formalization for inseparable classes.

SVM uses the Lagrange multipliers method to optimize the objective. This introduces  $n$  coefficients  $\alpha_1, \dots, \alpha_n$  (corresponding to `SVMModel.Alpha`). The dual formalizations for linear SVM are:

- For separable classes, minimize

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^n \alpha_j$$

with respect to  $\alpha_1, \dots, \alpha_n$ , subject to  $\sum \alpha_j y_j = 0$ ,  $\alpha_j \geq 0$  for all  $j = 1, \dots, n$ , and Karush-Kuhn-Tucker (KKT) complementarity conditions.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition  $0 \leq \alpha_j \leq C$  for all  $j = 1, \dots, n$ .

The resulting score function is

$$f(x) = \sum_{j=1}^n \alpha_j y_j x' x_j + b.$$

The score function is free of the estimate of  $\beta$  as a result of the primal formalization.

In some cases, there is a nonlinear boundary separating the classes. *Nonlinear SVM* works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^n \alpha_j$$

with respect to  $\alpha_1, \dots, \alpha_n$ , subject to  $\sum \alpha_j y_j = 0$ ,  $0 \leq \alpha_j \leq C$  for all  $j = 1, \dots, n$ , and the KKT complementarity conditions.  $G(x_k, x_j)$  are elements of the Gram matrix. The resulting score function is

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x, x_j) + b.$$

For more details, see Understanding Support Vector Machines, [1], and [2].

## Limitations

- The software trains SVM classifiers for one- or two-class learning applications.

## Tips

- For one-class learning:
  - The default setting for the name-value pair argument 'Alpha' can lead to long training times. To speed up training, set Alpha to a vector mostly composed of 0s.
  - Set the name-value pair argument Nu to a value closer to 0 to yield fewer support vectors, and, therefore, a smoother, but crude decision boundary
- Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set BoxConstraint to a large value. This also increases the training time.
- For large data sets, try optimizing the cache size. This can have a significant impact on the training speed.
- If the support vector set is much less than the number of observations in the training set, then you might significantly speed up convergence by shrinking the active-set using the name-value pair argument 'ShrinkagePeriod'. It is good practice to use 'ShrinkagePeriod', 1000.

# fitctree

---

## Purpose

Fit classification tree

## Syntax

```
tree = fitctree(x,y)
tree = fitctree(x,y,Name,Value)
```

## Description

`tree = fitctree(x,y)` returns a classification tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. The returned tree is a binary tree, where each branching node is split based on the values of a column of `x`.

`tree = fitctree(x,y,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.

## Input Arguments

### **x** - Predictor values

matrix of floating-point values

Predictor values, specified as a matrix of floating-point values.

`fitctree` considers NaN values in `x` as missing values. `fitctree` does not use observations with all missing values for `x` in the fit. `fitctree` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

### Data Types

single | double

### **y** - predictor values

numeric vector | categorical vector | logical vector | character array | cell array of strings

Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of strings.

Each row of  $y$  represents the classification of the corresponding row of  $x$ . For numeric  $y$ , consider using `fitctree` instead. `fitctree` considers NaN values in  $y$  to be missing values.

`fitctree` does not use observations with missing values for  $y$  in the fit.

### Data Types

`single` | `double` | `char` | `logical` | `cell`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'CrossVal','on','MinLeaf',40` specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

### 'AlgorithmForCategorical' - Algorithm for best categorical predictor split

`'Exact'` | `'PullLeft'` | `'PCA'` | `'OVAbyClass'`

Algorithm to find the best split on a categorical predictor with  $C$  categories for data and  $K \geq 3$  classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following.

<code>'Exact'</code>	Consider all $2^{C-1} - 1$ combinations.
<code>'PullLeft'</code>	Start with all $C$ categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the $K$ classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.

'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVAByClass'	Start with all $C$ categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`fitctree` automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For  $K = 2$  classes, `fitctree` always performs the exact search. Use the 'AlgorithmForCategorical' name-value pair argument to specify a particular algorithm.

**Example:** 'AlgorithmForCategorical', 'PCA'

### 'CategoricalPredictors' - Categorical predictors list

numeric or logical vector | cell array of strings | character matrix  
| 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through  $p$ , where  $p$  is the number of columns of  $x$ .
- A logical vector of length  $p$ , where a true entry means that the corresponding column of  $x$  is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in PredictorNames values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in PredictorNames values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

**Example:** 'CategoricalPredictors', 'all'

#### **Data Types**

single | double | char

#### **'ClassNames' - Class names**

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in  $y$ .

Use ClassNames to order the classes or to select a subset of classes for training. The default is the class names that exist in  $y$ .

#### **Data Types**

single | double | char | logical | cell

#### **'Cost' - Cost of misclassification**

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where  $\text{Cost}(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ .
- Structure  $S$  having two fields:  $S.\text{ClassNames}$  containing the group names as a variable of the same data type as  $y$ , and  $S.\text{ClassificationCosts}$  containing the cost matrix.

The default is  $\text{Cost}(i, j)=1$  if  $i \neq j$ , and  $\text{Cost}(i, j)=0$  if  $i=j$ .

### Data Types

single | double | struct

### 'CrossVal' - Flag to grow cross-validated decision tree

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `fitctree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross validate `tree` later using the `crossval` method.

**Example:** 'CrossVal', 'on'

### 'CVPartition' - Partition for cross-validated tree

cvpartition object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

### 'Holdout' - Fraction of data for holdout validation

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0, 1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

### Data Types

single | double

### 'KFold' - Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

### Data Types

single | double

### 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross-validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

### 'MaxCat' - Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `fitctree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `fitctree` finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

**Example:** 'MaxCat',8

### **'MergeLeaves' - Leaf merge flag**

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. If you specify 'on', `fitctree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. If you specify 'off', `fitctree` does not merge leaves.

**Example:** 'MergeLeaves', 'off'

### **'MinLeaf' - Minimum number of leaf node observations**

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `fitctree` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

**Example:** 'MinLeaf',3

### **Data Types**

single | double

### **'MinParent' - Minimum number of branch node observations**

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer

value. Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `fitctree` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

**Example:** `'MinParent',8`

### Data Types

single | double

### 'NVarToSample' - Number of predictors for split

`'all'` | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

**Example:** `'NVarToSample',3`

### Data Types

single | double

### 'PredictorNames' - Predictor variable names

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing the names for the predictor variables, in the order in which they appear in `x`.

### 'Prior' - Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- A string:
  - `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, `fitctree` uses the weights to compute the class probabilities.
  - `'uniform'` sets all class probabilities equal.

- A vector (one scalar value for each class)
- A structure `S` with two fields:
  - `S.ClassNames` containing the class names as a variable of the same type as `y`
  - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

**Example:** `'Prior', 'uniform'`

### **'Prune' - Pruning flag**

`'on'` (default) | `'off'`

Pruning flag, specified as the comma-separated pair consisting of `'Prune'` and either `'on'` or `'off'`. When `'on'`, `fitctree` grows the classification tree, and computes the optimal sequence of pruned subtrees. When `'off'` `fitctree` grows the classification tree without pruning.

**Example:** `'Prune', 'off'`

### **'PruneCriterion' - Pruning criterion**

`'error'` (default) | `'impurity'`

Pruning criterion, specified as the comma-separated pair consisting of `'PruneCriterion'` and either `'error'` or `'impurity'`.

**Example:** `'PruneCriterion', 'impurity'`

### **'ResponseName' - Response variable name**

`'Y'` (default) | string

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a string representing the name of the response variable `y`.

**Example:** `'ResponseName', 'Response'`

**'ScoreTransform' - Score transform function**

'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following strings representing a built-in transformation function.

String	Formula
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Set the score for the class with the largest score to 1, and scores for all other classes to 0.
'logit'	$1/(1 + e^{-x})$
'none'	$x$ (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetriclogit'	$2/(1 + e^{-x}) - 1$
'symmetricismax'	Set the score for the class with the largest score to 1, and scores for all other classes to -1.

**Example:** 'ScoreTransform', 'logit'

**'SplitCriterion' - Split criterion**

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for

the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

**Example:** 'SplitCriterion', 'deviance'

## 'Surrogate' - Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `fitctree` finds at most 10 surrogate splits at each branch node.
- When set to 'all', `fitctree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, `fitctree` finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors.

**Example:** 'Surrogate', 'on'

## 'Weights' - Observation weights

`ones(size(x,1),1)` (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` equals the number of rows in `x`. `fitctree` normalizes the weights in each class to add up to the value of the prior probability of the class.

## Data Types

single | double

## Output Arguments

### **tree - Classification tree**

classification tree object

Classification tree, returned as a classification tree object.

Using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldpredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

## Examples

### **Construct a Classification Tree**

Construct a classification tree using sample data.

Construct a classification tree using the data in `ionosphere.mat`.

```
load ionosphere
tc = fitctree(X,Y)

tc =

ClassificationTree
    PredictorNames: {1x34 cell}
    ResponseName: 'Y'
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    CategoricalPredictors: []
    NumObservations: 351
```

Properties, Methods

## Definitions      Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*. Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes  $i$  at the node, and  $p(i)$  is the observed fraction of classes with class  $i$  that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With  $p(i)$  defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('`twoing`') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let  $L(i)$  denote the fraction of members of class  $i$  in the left child node after a split, and  $R(i)$  denote the fraction of members of class  $i$  in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left( \sum_i |L(i) - R(i)| \right)^2,$$

where  $P(L)$  and  $P(R)$  are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If  $j$  is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

## Concepts

- “Splitting Categorical Predictors” on page 16-61

# fitglm

---

**Purpose** Create generalized linear regression model

**Syntax**

```
mdl = fitglm(tbl)
mdl = fitglm(X,y)
mdl = fitglm(___,modelspec)
mdl = fitglm(___,Name,Value)
```

**Description** `mdl = fitglm(tbl)` returns a generalized linear model fit to variables in the table or dataset array `tbl`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm(___,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm(___,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

## Input Arguments

**tbl - Input data**  
table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52).

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### modelspec - Model specification

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p+1)$  matrix, namely “Terms Matrix” on page 21-1196, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a “Formula” on page 21-1199 in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-1200.

**Example:** `'quadratic'`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### Example:

```
'Distribution', 'normal', 'link', 'probit', 'Exclude', [23,59]
```

specifies that the distribution of the response is normal, and instructs `fitglm` to use the probit link function and exclude the 23rd and 59th observations from the fit.

### 'BinomialSize' - Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

### Data Types

single | double

### 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array

tbl, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array tbl, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix X, then the default value of this name-value pair argument is an empty matrix []. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** 'CategoricalVars',[2,3]

**Example:** 'CategoricalVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'DispersionFlag' - Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

**Example:** 'DispersionFlag',true

## 'Distribution' - Distribution of the response variable

```
'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse
gaussian'
```

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

**Example:** 'Distribution','gamma'

### 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

### Data Types

single | double | logical

### 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

## 'Link' - Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comprologlog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul>	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship  $f(\mu) = X*b$  between the mean response  $\mu$  and the linear combination of predictors  $X*b$ .

For more information on the canonical link functions, see [Definitions](#).

**Example:** 'Link', 'probit'

### 'Offset' - Offset variable

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`fitglm` and `stepwiseglm` use `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

### Data Types

single | double | char

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

**Example:** `'PredictorVars',logical([0 1 1 0 0 0])`

### **Data Types**

single | double | logical | cell

### **'ResponseVar' - Response variable**

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### **Data Types**

single | double | logical | char

### **'VarNames' - Names of variables in fit**

{`'x1'`,`'x2'`,...,`'xn'`,`'y'`} (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

```
'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

**Data Types**

cell

**'Weights' - Observation weights**

ones(n,1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

**Data Types**

single | double

**Output Arguments**

**mdl - Generalized linear model**

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

**Examples**

**Fit a Logistic Regression Model**

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized Linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight  
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 5.07, p-value = 0.535

All of the  $p$ -values (under pValue) are large. This means none of the coefficients are significant. The large  $p$ -value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

## GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:,[1 3 6])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = fitglm(X,y,'linear','Distribution','poisson')
```

```
mdl =
```

```
Generalized Linear regression model:
```

```
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	0.88723	0.070969	12.502	7.3149e-36
x1	0.44413	0.052337	8.4858	2.1416e-17
x2	0.0083388	0.056527	0.14752	0.88272
x3	0.21518	0.063416	3.3932	0.00069087
x4	-0.058386	0.065503	-0.89135	0.37274
x5	-0.060824	0.073441	-0.8282	0.40756
x6	0.34267	0.056778	6.0352	1.5878e-09
x7	0.04316	0.06146	0.70225	0.48252

```
100 observations, 92 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 119, p-value = 1.55e-22
```

The  $p$ -values of  $2.14e-17$ ,  $0.00069$ , and  $1.58e-09$  indicate that the coefficients of the variables  $x_1$ ,  $x_3$ , and  $x_6$  are statistically significant.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0    0    0    0
1    0    0    0
0    0    1    0
0    0    0    1

```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

T =

```

0    0    0    0
0    1    0    0
0    0    1    0
0    0    0    1

```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

T =

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

$y \sim 1 + x1*x2 + x2^2$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable
  - $-$  means do not include the next variable
  - $:$  defines an interaction, a product of terms
  - $*$  defines an interaction **and all lower-order terms**

- $\wedge$  raises the predictor to a power, exactly as in \* repeated, so  $\wedge$  includes lower order terms as well
- ( ) groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include - 1 in the formula.

---

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A\*B term.

'Y ~ A\*B + C' is the same as the previous example because  $A*B = A + B + A:B$ .

'Y ~ A\*B\*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A\*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k, where k is a positive integer	A, A <sup>2</sup> , ..., A <sup>k</sup>

Wilkinson Notation	Factors in Standard Notation
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

### Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

### Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

### Tips

- The generalized linear model mdl is a standard linear model unless you specify otherwise with the Distribution name-value pair.

- For methods such as `plotResiduals` or `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

## Alternative Functionality

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

<b>Purpose</b>	Fit Gaussian mixture distribution to data
<b>Syntax</b>	<code>GMMModel = fitgmdist(X,k)</code> <code>GMMModel = fitgmdist(X,k,Name,Value)</code>
<b>Description</b>	<p><code>GMMModel = fitgmdist(X,k)</code> returns a Gaussian mixture distribution model (<code>GMMModel</code>) with <code>k</code> components fitted to data (<code>X</code>).</p> <p><code>GMMModel = fitgmdist(X,k,Name,Value)</code> returns a Gaussian mixture distribution model with additional options specified by one or more <code>Name,Value</code> pair arguments.</p> <p>For example, you can specify a regularization value or the covariance type.</p>
<b>Input Arguments</b>	<p><b>X - Data</b> numeric matrix</p> <p>Data to which the Gaussian mixture model is fit, specified as a numeric matrix.</p> <p>The rows of <code>X</code> correspond to observations, and columns correspond to variables.</p> <p>NaNs indicate missing values. The software removes rows of <code>X</code> containing at least one NaN before fitting, which decreases the effective sample size.</p> <p><b>Data Types</b> double</p> <p><b>k - Number of components</b> positive integer</p> <p>Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify <code>k = 3</code>, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (<code>X</code>).</p>

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Regularize', 0.1, 'CovType', 'diagonal'` specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.

### **'CovType' - Type of covariance matrix**

`'diagonal' | 'full' (default)`

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of `'CovType'` and either `'diagonal'` or `'full'`.

If you set `'diagonal'`, then the software fits diagonal covariance matrices. In this case, the software estimates  $k \times d$  covariance parameters, where  $d$  is the number of columns in  $X$  (i.e.,  $d = \text{size}(X, 2)$ ).

Otherwise, the software fits full covariance matrices. In this case, the software estimates  $k \times d \times (d+1) / 2$  covariance parameters.

**Example:** `'CovType', 'diagonal'`

### **Data Types**

char

### **'Options' - Iterative EM algorithm optimization options**

`statset options structure`

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of `'Options'` and a `statset options structure`.

This table describes the available name-value pair arguments.

Name	Value
'Display'	'final': Display the final output.  'iter': Display iterative output to the Command Window for some functions; otherwise display the final output.  'off': Do not display optimization information.
'MaxIter'	Positive integer indicating the maximum number of iterations allowed. The default is 100
'TolFun'	Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is $1e-6$ .

**Example:**

```
'Options',statset('Display','final','MaxIter',1500,'TolFun',1e-5)
```

**'Regularize' - Regularization parameter value**

nonnegative scalar | 0 (default)

Regularization parameter value, specified as the comma-separated pair consisting of 'Regularize' and a nonnegative scalar.

Set `regularize` to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

**Example:** 'Regularize',0.01

**Data Types**

double

**'Replicates' - Number of times to repeat EM algorithm**

positive integer | 1 (default)

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of 'Replicates' and a positive integer.

If `Replicates` is greater than 1, then:

- The name-value pair argument `Start` must be `randSample` (it is by default).
- `GMMModel` is the fit with the largest loglikelihood.

**Example:** 'Replicates',10

## Data Types

double

## 'SharedCov' - Flag indicating whether all covariance matrices are identical

logical false (default) | logical true

Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of 'SharedCov' and either logical value `false` or `true`.

If `SharedCov` is `true`, then all  $k$  covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of  $k$ .

## 'Start' - Initial value setting method

'randSample' (default) | vector of integers | structure array

Initial value setting method, specified as the comma-separated pair consisting of 'Start' and 'randSample', a vector of integers, or a structure array.

The value of `Start` determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

Value	Description
'randSample'	The software selects $k$ observations from $X$ at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element $j$ on the diagonal is the variance of $X(:, j)$ .
Vector of integers	A vector of length $n$ (the number of observations) containing an initial guess of the component index for each point. That is, each element is an integer from 1 to $k$ , which corresponds to a component. The software collects all observations corresponding to the same component, computes means, covariances, and mixing proportions for each, and sets the initial values to these statistics.
Structure array	<p>Suppose that there are <math>d</math> variables (i.e., <math>d = \text{size}(X, 2)</math>). The structure array, e.g., <math>S</math>, must have three fields:</p> <ul style="list-style-type: none"> <li>• <b>S.mu</b>: A <math>k</math>-by-<math>d</math> matrix specifying the initial mean of each component</li> <li>• <b>S.Sigma</b>: A numeric array specifying the covariance matrix of each component. <b>Sigma</b> is one of the following: <ul style="list-style-type: none"> <li>▪ A <math>d</math>-by-<math>d</math>-by-<math>k</math> array. <math>\text{Sigma}(:, :, j)</math> is the initial covariance matrix of component <math>j</math>.</li> <li>▪ A 1-by-<math>d</math>-by-<math>k</math> array. <math>\text{diag}(\text{Sigma}(:, :, j))</math> is the initial covariance matrix of component <math>j</math>.</li> <li>▪ A <math>d</math>-by-<math>d</math> matrix. <b>Sigma</b> is the initial covariance matrix for all components.</li> <li>▪ A 1-by-<math>d</math> vector. <math>\text{diag}(\text{Sigma})</math> is the initial covariance matrix for all components.</li> </ul> </li> <li>• <b>S.PComponents</b>: A 1-by-<math>k</math> vector of scalars specifying the initial mixing proportions of each component. The default is uniform.</li> </ul>

**Example:** 'Start',ones(n,1))

## Data Types

char | double | struct

## Output Arguments

### **GMMModel - Fitted Gaussian mixture model**

gmdistribution model

Fitted Gaussian mixture model, returned as a gmdistribution model.

Access properties of GMMModel using dot notation. For example, display the AIC by entering GMMModel.AIC.

## Examples

### **Cluster Data Using a Gaussian Mixture Model**

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 2];  
Sigma1 = [2 0; 0 0.5];  
mu2 = [-3 -5];  
Sigma2 = [1 0; 0 1];  
rng(1); % For reproducibility  
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];
```

Fit a Gaussian mixture model. Specify that there are two components.

```
GMMModel = fitgmdist(X,2);
```

Plot the data over the fitted Gaussian mixture model contours.

```
figure  
y = [zeros(1000,1);ones(1000,1)];  
h = gscatter(X(:,1),X(:,2),y);  
hold on  
ezcontour(@(x1,x2)pdf(GMMModel,[x1 x2]),get(gca,{'XLim','YLim'}))  
title('\bf Scatter Plot and Fitted Gaussian Mixture Contours')  
legend(h,'Model 0','Model1')  
hold off
```

### Regularize Gaussian Mixture Model Estimation

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

```
mu1 = [1 2];  
Sigma1 = [1 0; 0 1];  
mu2 = [3 4];  
Sigma2 = [0.5 0; 0 0.5];
```

# fitgmdist

---

```
rng(1); % For reproducibility
X1 = [mvnrnd(mu1,Sigma1,100);mvnrnd(mu2,Sigma2,100)];
X = [X1,X1(:,1)+X1(:,2)];
```

The columns of X are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use try / catch statements to help manage error messages.

```
rng(1); % Reset seed for common start values
try
    GMMModel = fitgmdist(X,2)
catch exception
    disp('There was an error fitting the Gaussian mixture model')
    error = exception.message
end
```

```
There was an error fitting the Gaussian mixture model
```

```
error =
```

```
Ill-conditioned covariance created at iteration 2.
```

The covariance estimates are ill-conditioned. Subsequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization.

```
rng(1); % Reset seed for common start values
GMMModel = fitgmdist(X,2,'Regularize',0.1)
```

```
GMMModel =
```

```
Gaussian mixture distribution with 2 components in 3 dimensions
Component 1:
```

```
Mixing proportion: 0.507057
Mean:      0.9767      2.0130      2.9897

Component 2:
Mixing proportion: 0.492943
Mean:      3.1030      3.9544      7.0574
```

In this case, the algorithm converges to a solution due to regularization.

### Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set.

```
load fisheriris
classes = unique(species)
```

```
classes =

    'setosa'
    'versicolor'
    'virginica'
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization.

# fitgmdist

---

```
[~,score] = pca(meas,'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to 1000. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```
GMModels = cell(3,1); % Preallocation
options = statset('MaxIter',1000);
rng(1); % For reproducibility

for j = 1:3
    GMModels{j} = fitgmdist(score,j,'Options',options);
    fprintf('\n GM Mean for %i Component(s)\n',j)
    Mu = GMModels{j}.mu
end
```

```
GM Mean for 1 Component(s)
```

```
Mu =
```

```
1.0e-14 *
-0.3082  -0.0896
```

```
GM Mean for 2 Component(s)
```

```
Mu =
```

```
1.3212  -0.0954
-2.6424  0.1909
```

```
GM Mean for 3 Component(s)
```

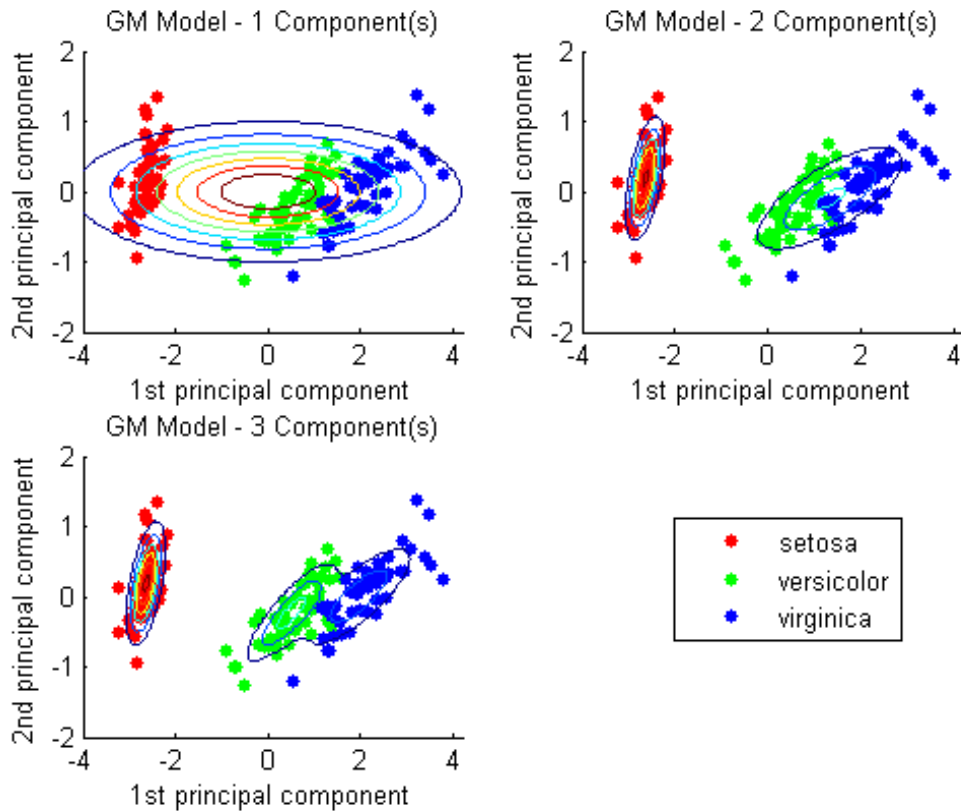

```
Mu =  
  
    1.9642    0.0062  
   -2.6424    0.1909  
    0.4750   -0.2292
```

GMModels is a cell array containing three, fitted gmdistribution models. The means in the three component models are different, suggesting that the model distinguishes among the three iris species.

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels, use gscatter to distinguish between the true number of components.

```
figure  
for j = 1:3  
    subplot(2,2,j)  
    gscatter(score(:,1),score(:,2),species)  
    hold on  
    ezcontour(@(x1,x2)pdf(GMModels{j},[x1 x2]),...  
        cell2mat(get(gca,{'XLim','YLim'})),100)  
    title(sprintf('GM Model - %i Component(s)',j));  
    xlabel('1st principal component');  
    ylabel('2nd principal component');  
    if(j ~= 3)  
        legend off;  
    end  
    hold off  
end  
g = legend;  
set(g,'Position',[0.7,0.25,0.1,0.1])
```

# fitgmdist

The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.

- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

### Determine the Best Gaussian Mixture Fit Using AIC

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
Sigma2 = [0.2 0; 0 0.2];
rng(1);
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];

plot(X(:,1),X(:,2),'ko')
title('Scatter Plot')
xlim([min(X(:)) max(X(:))]) % Make axes have the same scale
ylim([min(X(:)) max(X(:))])
```

# fitgmdist

---

Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a `statset` structure as the value of the `Options` name-value pair argument.

```
options = statset('Display','final');  
GMMModel = fitgmdist(X,2,'CovType','diagonal','Options',options);
```

```
10 iterations, log-likelihood = -4787.38
```

GMMModel is a fitted `gmdistribution` model.

Examine the AIC over varying numbers of components.

```
AIC = zeros(1,4);  
GMMModels = cell(1,4);  
options = statset('MaxIter',500);  
for k = 1:4  
    GMMModels{k} = fitgmdist(X,k,'Options',options,'CovType','diagonal');  
    AIC(k) = GMMModels{k}.AIC;  
end  
  
[minAIC,numComponents] = min(AIC);  
numComponents
```

```
BestModel = GMMModels{numComponents}
```

```
numComponents =
```

```
2
```

```
BestModel =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions  
Component 1:
```

```
Mixing proportion: 0.501736  
Mean:      1.9824      4.0013
```

```
Component 2:  
Mixing proportion: 0.498264  
Mean:      0.9879      1.0511
```

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.

## Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using `fitgmdist`.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris  
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify  $k = 3$  components.

```
rng(10); % For reproducibility  
GMMModel1 = fitgmdist(X,3);
```

By default, the software:

- 1** Randomly chooses  $k = 3$  data points
- 2** Treats the chosen data points as initial means for each component
- 3** Sets the initial covariance matrices as diagonal, where element  $(j, j)$  is the variance of  $X(:, j)$

**4** Treats the initial mixing proportions as uniform

Fit a Gaussian mixture model by connecting each observation to its label.

```
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;
```

```
GMMModel2 = fitgmdist(X,3,'Start',y);
```

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

```
Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'PComponents',PComponents);
```

```
GMMModel3 = fitgmdist(X,3,'Start',S);
```

Use `gscatter` to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

```
figure
subplot(2,2,1)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
xlim = get(gca,'XLim');
ylim = get(gca,'YLim');
d = (max([xlim ylim]) - min([xlim ylim]))/1000;
[X1Grid,X2Grid] = meshgrid(xlim(1):d:xlim(2),ylim(1):d:ylim(2));
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel1,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
```

```
title('\bf Random Initial Values');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,2)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel2,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('\bf Initial Values from Labels');
xlabel('Sepal length');
ylabel('Sepal width');
legend off
hold off
subplot(2,2,3)
h = gscatter(X(:,1),X(:,2),species,[],'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMMModel3,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('\bf Initial Values from the Structure');
xlabel('Sepal length');
ylabel('Sepal width');
g = legend;
set(g,'Position',[0.7,0.25,0.1,0.1])
hold off
```

According to the counters, GMMode12 seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```
table(GMMode11.mu,GMMode12.mu,GMMode13.mu,'VariableNames',...
      {'Model11','Model12','Model13'})
```

ans =

Model1		Model2		Model3	
5.0241	1.8658	4.2857	1.3339	1.4604	0.2429
4.7471	1.4616	1.462	0.246	4.7509	1.4629
1.4605	0.24306	5.5507	2.0316	5.0158	1.8592

GMMModel2 seems to distinguish between the iris species the best.

## Tips

gmdistribution might:

- Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues might result in an ill-conditioned covariance matrix:

- The number of dimensions of your data is relatively high and there are not enough observations.
- Some of the predictors (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Preprocess your data to remove correlated features.
- Set 'SharedCov' to true to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

- Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

## Algorithms

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

# fitlm

---

**Purpose** Create linear regression model

**Syntax**

```
mdl = fitlm(tbl)
mdl = fitlm(tbl,modelspec)
```

```
mdl = fitlm(X,y)
mdl = fitlm(X,y,modelspec)
```

```
mdl = fitlm( __ ,Name,Value)
```

**Description** `mdl = fitlm(tbl)` returns a linear model fit to variables in the table or dataset array `tbl`. By default, `fitlm` takes the last variable as the response variable.

`mdl = fitlm(tbl,modelspec)` returns a linear model of the type you specify in `modelspec` fit to variables in the table or dataset array `tbl`.

`mdl = fitlm(X,y)` returns a linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(X,y,modelspec)` returns a linear model of the type you specify in `modelspec` for the responses `y`, fit to the data matrix `X`.

`mdl = fitlm( __ ,Name,Value)` returns a linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

## Input Arguments

**tbl - Input data**  
table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response

variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### Data Types

single | double

### modelspec - Model specification

'linear' (default) | string naming the model |  $t$ -by- $(p + 1)$  terms  
matrix | string of the form 'Y ~ terms'

Model specification, specified as one of the following. The choice is the starting model for `stepwiselm`. Default is `'linear'`.

- A string naming the model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, <code>'poly2111'</code> has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p + 1)$  matrix, namely terms matrix, specifying terms to include in the model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus 1 is for the response variable.
- A string representing a formula in the form

`'Y ~ terms'`,

where the `terms` are in Wilkinson Notation.

**Example:** `'quadratic'`

**Example:** `'y ~ X1 + X2^2 + X1:X2'`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### **Example:**

`'Intercept',false,'PredictorVars',[1,3],'ResponseVar',5,'RobustOpts'`, specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

### **'CategoricalVars' - Categorical variables**

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

## Data Types

single | double | logical

### 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

### 'Intercept' - Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

**Example:** `'PredictorVars',logical([0 1 1 0 0 0])`

### Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### Data Types

single | double | logical | char

### 'RobustOpts' - Indicator of robust fitting type

'off' (default) | 'on' | string | structure with string or function handle

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of `'RobustOpts'` and one of the following.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting. When you use robust fitting, 'bisquare' weight function is the default.
- String — Name of the robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant in the table.
- Structure with the string `RobustWgtFun` containing the name of the robust fitting weight function from the following table and optional scalar `Tune` fields — `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. You can choose the name of the robust fitting weight function from this table. If you do not supply a `Tune` field, the fitting function uses the corresponding default tuning constant.

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

The value  $r$  in the weight functions is

$$r = \text{resid}/(\text{tune}*s*\text{sqrt}(1-h)),$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD}/0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are  $p$  columns in `X`, the smallest  $p$  absolute deviations are excluded when computing the median.

Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

- Structure with the function handle `RobustWgtFun` and optional scalar `Tune` fields — You can specify a custom weight function. `fitlm` uses the `RobustWgtFun` weight function and `Tune` tuning constant from the structure. Specify `RobustWgtFun` as a function handle that accepts a vector of residuals, and returns a vector of weights the same size. The fitting function scales the residuals, dividing by the tuning constant (default 1) and by an estimate of the error standard deviation before it calls the weight function.

**Example:** `'RobustOpts', 'andrews'`

### **'VarNames' - Names of variables in fit**

`{ 'x1', 'x2', ..., 'xn', 'y' }` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

```
'VarNames',{ 'Horsepower','Acceleration','Model_Year','MPG'}
```

**Data Types**

cell

**'Weights' - Observation weights**

ones(n,1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

**Data Types**

single | double

## Output Arguments

**mdl - Linear model**

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, mdl, see the LinearModel class page.

## Examples

**Linear Regression with Categorical Predictor and Quadratic Term**

Fit a quadratic linear regression model to variables in a table. The data includes continuous and categorical predictor variables.

Load the sample data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight` and response variable `MPG`. Add the nominal predictor variable `Year`.

```
tbl = table(MPG,Weight);
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`. For details, see “Formula” on page 21-1239.

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

Linear regression model:

```
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat
(Intercept)	54.206	4.7117	11.505
Weight	-0.016404	0.0031249	-5.2493
Year_76	2.0887	0.71491	2.9215
Year_82	8.1864	0.81531	10.041
Weight^2	1.5573e-06	4.9454e-07	3.149

pValue

(Intercept)	2.6648e-19
Weight	1.0283e-06
Year_76	0.0044137
Year_82	2.6364e-16
Weight^2	0.0022303

Number of observations: 94, Error degrees of freedom: 89  
Root Mean Squared Error: 2.78  
R-squared: 0.885, Adjusted R-Squared 0.88  
F-statistic vs. constant model: 172, p-value = 5.52e-41

`fitlm` creates two dummy (indicator) variables for the nominal variables, `Year`. The dummy variable `Year_76` takes the value 1 if the model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. 1970 is the reference year (for details on dummy variables, see “Dummy Indicator Variables” on page 2-56). The fitted model is

$$\hat{MPG} = 54.206 - 0.0164Weight + 2.0887(Year\_76) + 8.1864(Year\_82) + 1.557e - 06Weight^2$$

## Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the model using a formula in linear regression.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Indicate which variable is the response variable and identify the continuous and categorical predictors using name-value pair arguments.

```
mdl = fitlm(hospital, 'Weight~1+Age*Sex*Smoker - Age:Sex:Smoker', 'ResponseVariable')
```

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

Estimate	SE	tStat	pValue
----------	----	-------	--------

(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.09699
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.05037
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.7821

Number of observations: 100, Error degrees of freedom: 93

Root Mean Squared Error: 8.75

R-squared: 0.898, Adjusted R-Squared 0.892

F-statistic vs. constant model: 137, p-value = 6.91e-44

The  $t$ -statistics in `tStat` and corresponding  $p$ -values in `pValue` indicate that patient weights do not seem to differ significantly according to age, or the status of smoking, or the interaction of these factors with gender at the 5% significance level.

### Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % Predictor variables
y = heat; % Response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

```
y ~ 1 + x1 + x2 + x3 + x4
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8  
 Root Mean Squared Error: 2.65  
 R-squared: 0.979, Adjusted R-Squared 0.969  
 F-statistic vs. constant model: 94.6, p-value = 9.03e-07

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
1     0     0     0
0     0     1     0
0     0     0     1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
```

```
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739  
 F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$y \sim 1 + x2$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of fitlm in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.

- *terms* contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - \* defines an interaction **and all lower-order terms**
  - ^ raises the predictor to a power, exactly as in \* repeated, so ^ includes lower order terms as well
  - () groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

---

For example,

'Y ~ A + B + C' means a three-variable linear model with intercept.

'Y ~ A + B + C - 1' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A\*B term.

'Y ~ A\*B + C' is the same as the previous example because  $A*B = A + B + A:B$ .

'Y ~ A\*B\*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A\*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$
$A + B$	$A, B$
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include $B$
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

# fitlme

---

**Purpose** Fit linear mixed-effects model

**Syntax**  
`lme = fitlme(tbl,formula)`  
`lme = fitlme(tbl,formula,Name,Value)`

**Description** `lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

## Input Arguments

**tbl - Input data**  
`table` | `dataset array`

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using `formula`.

**Data Types**  
`single` | `double` | `char` | `cell`

### **formula - Formula for model specification**

string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a string of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The string is case sensitive. For a full description, see “Formula” on page 21-1267.

**Example:** `'y ~ treatment + (1|block)'`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

#### **Example:**

`'CovariancePattern', 'Diagonal', 'Optimizer', 'fminunc', 'OptimizerOptions'` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

### **'CovariancePattern' - Pattern of covariance matrix**

`'FullCholesky'` (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of `'CovariancePattern'` must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

'CompSymm'

where  $\sigma^2_{b_1}$  is the common variance of the random-effects terms.

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma^2_{b_1} & \sigma_{b_1,b_2} & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma^2_{b_1} & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma_{b_1,b_2} & \sigma^2_{b_1} \end{pmatrix}$$

where  $\sigma^2_{b_1}$  is the common variance of the random-effects terms and  $\sigma_{b_1,b_2}$  is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $\text{PAT}(a,b) = \text{false}$ , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

### 'FitMethod' - Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'	Default. Maximum likelihood estimation
'REML'	Restricted maximum likelihood estimation

**Example:** 'FitMethod','REML'

### **'Weights' - Observation weights**

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

#### **Data Types**

single | double

### **'Exclude' - Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude',[13,67]

#### **Data Types**

single | double | logical

### **'DummyVarCoding' - Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

### 'Optimizer' - Optimization algorithm

'quasnewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasnewton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> .

with 'Algorithm' set to  
'quasi-newton'.

**Example:** 'Optimizer','fminunc'

## **'OptimizerOptions' - Options for optimization algorithm**

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinewton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinewton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

## **'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

## **'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

**'MaxIter' - Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

**'Display' - Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

**'StartMethod' - Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'                                      Default. An internally defined default value.

'random'                                        A random initial value.

**Example:** 'StartMethod','random'

**'Verbose' - Indicator to display optimization process on screen**

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose',true

**'CheckHessian' - Indicator to check positive definiteness of Hessian**

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian',true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples

### Fit Linear Mixed-Effects Model

Load the sample data.

```
load imports-85
```

Store the variables in a table.

```
tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{'Horsepower','CityMPG'})
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans =
```

Horsepower	CityMPG	EngineType
111	21	13
111	21	13
154	19	37

102	24	35
115	18	35

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```
lme = fitlme(tbl, 'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|Eng
```

In this model, CityMPG is the response variable, horsepower is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to  $1 + \text{Horsepower}$ , because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a `1` to eliminate the intercept from the second random-effect term.

Display the model.

```
lme
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	203
Fixed effects coefficients	2
Random effects coefficients	14
Covariance parameters	3

```
Formula:
```

```
CityMPG ~ 1 + Horsepower + (1 | EngineType) + (Horsepower | Engine
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
1099.5	1116	-544.73	1089.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	37.276	2.8556	13.054	201	1.3147e-
'Horsepower'	-0.12631	0.02284	-5.53	201	9.8848e-

Random effects covariance parameters (95% CIs):

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'(Intercept)'	'(Intercept)'	'std'	5.7338	2.9078	8.5600

Group: EngineType (7 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Horsepower'	'Horsepower'	'std'	0.050357	0.02284	0.07787

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.226	2.9078	3.5789

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```
lme2 = fitlme(tbl, 'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to (1 + Horsepower|EngineType).

Display the model.

```
lme2
```

```
lme2 =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	203
Fixed effects coefficients	2
Random effects coefficients	14
Covariance parameters	4

```
Formula:
```

```
CityMPG ~ 1 + Horsepower + (1 + Horsepower | EngineType)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
1089	1108.9	-538.52	1077

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pVa
'(Intercept)'	33.824	4.0181	8.4178	201	7.1
'Horsepower'	-0.1087	0.032912	-3.3029	201	0

```
Random effects covariance parameters (95% CIs):
```

```
Group: EngineType (7 Levels)
```

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	9.4952
'Horsepower'	'(Intercept)'	'corr'	-0.96843
'Horsepower'	'Horsepower'	'std'	0.078874

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	3.1845	2.8774	3.5243

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

## Random Intercept Model

Load the sample data.

```
load flu
```

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into a tall array. The new dataset array, flu2, must have the new response variable FluRate, the nominal variable Region that shows which region each estimate is from, the nationwide estimate WtdILI, and the grouping variable Date.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Display the first six rows of flu2.

```
flu2(1:6,:)
```

```
ans =
```

Date	WtdILI	Region	FluRate
10/9/2005	1.182	NE	0.97
10/9/2005	1.182	MidAtl	1.025
10/9/2005	1.182	ENCentral	1.232
10/9/2005	1.182	WNCentral	1.286
10/9/2005	1.182	SAtl	1.082
10/9/2005	1.182	ESCentral	1.457

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, WtdILI, and a random intercept that varies by Date. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable Date.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable Date and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = fitlme(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	0.16385	0.057525	2.8484	466	0.0045
'WtdILI'	0.7236	0.032219	22.459	466	3.05e-46

```
Random effects covariance parameters (95% CIs):
```

```

Group: Date (52 Levels)
      Name1          Name2          Type          Estimate    Lower    Upper
      '(Intercept)'  '(Intercept)'  'std'       0.17146     0.13227  0.22226
Group: Error
      Name          Estimate    Lower    Upper
      'Res Std'     0.30201    0.28217  0.32324

```

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of  $\sigma_b$  is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}
 \hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\
 &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\
 &= 1.46749,
 \end{aligned}$$

where  $\hat{b}$  is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```

beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005');

y_hat =

    1.4674

```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);

1.4674
```

## Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and fitlme creates a matrix called a “fixed effects design matrix” to describe the effect of shift. This matrix has two columns, *Shift\_Evening* and *Shift\_Morning*, where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\begin{aligned} \text{Morning Shift: } QCDev_{im} &= \beta_0 + \beta_2 \text{Shift} - \text{Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5, \\ \text{Evening Shift: } QCDev_{im} &= \beta_0 + \beta_1 \text{Shift} - \text{Evening}_i + b_{0m} + \varepsilon_{im}, \\ \text{Night Shift: } QCDev_{im} &= \beta_0 - \beta_1 \text{Shift} - \text{Evening}_i - \beta_2 \text{Shift} - \text{Morning}_i + b_{0m} + \varepsilon_{im}, \end{aligned}$$

where  $b \sim N(0, \sigma_b^2)$  and  $\varepsilon \sim N(0, \sigma^2)$ .

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B =
```

```
    0.5775
    1.1757
   -2.1715
    2.3655
   -1.9472
```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{y}_{Evening,Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

0.9481

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{y}_{Morning,Operator3} &= \hat{\beta}_0 + \hat{\beta}_2 Shift\_Morning + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
```

```
ans =
```

```
0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

## Split-Plot Experiment

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided

into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S^* T)_{jk} + \varepsilon_{imjk},$$

where  $i = 1, 2, \dots, 60$ , index  $m$  corresponds to the fertilizer types,  $j$  corresponds to the tomato types, and  $k = 1, 2, 3$  corresponds to the blocks (soil).  $S_k$  represents the  $k$ th soil type, and  $(S^* T)_{jk}$  represents the  $j$ th tomato type nested in the  $k$ th soil type.  $I[F]_{im}$  is the dummy variable representing level  $m$  of the fertilizer. Similarly,  $I[T]_{ij}$  is the dummy variable representing level  $j$  of the tomato type.

The random effects and observation error have these prior distributions:  $b_{0k} \sim N(0, \sigma_S^2)$ ,  $b_{0jk} \sim N(0, \sigma_{S^*T}^2)$ , and  $\varepsilon_{imjk} \sim N(0, \sigma^2)$ .

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

```
lme =

The  $p$ -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the anova method after refitting the model using 'effects' contrasts.

The confidence interval for the standard deviations of the random-effects terms ( $\sigma^2_{\epsilon}$ ), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

```
lme = fitlme(ds, 'Yield ~ Fertilizer + Tomato + (1|Soil:Tomato)')
```

```
lme =
```

Name1	Name2	Type	Estimate	Lo
'(Intercept)'	'(Intercept)'	'std'	10.02	6.

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	12.325	10.024	15.153

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

## Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables  $I[.]$ . Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables. This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{0m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program B. The random effects and observation error have these prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

lme =

Linear mixed-effects model fit by ML

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

$y \sim 1 + \text{InitialWeight} + \text{Program} * \text{Week} + (1 + \text{Week} \mid \text{Subject})$

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'(Intercept)'	0.66105	0.25892	2.5531	111
'InitialWeight'	0.0031879	0.0013814	2.3078	111
'Program_B'	0.36079	0.13139	2.746	111
'Program_C'	-0.033263	0.13117	-0.25358	111
'Program_D'	0.11317	0.13132	0.86175	111

'Program_B:Week'	0.038771	0.095394	0.40644	111
'Program_C:Week'	0.030543	0.095394	0.32018	111
'Program_D:Week'	0.033114	0.095394	0.34713	111

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	
'(Intercept)'	'(Intercept)'	'std'	0.18407	C
'Week'	'(Intercept)'	'corr'	0.66841	C
'Week'	'Week'	'std'	0.15033	C

Group: Error			
Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

## Definitions

### Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable,  $y$
- Predictor variables,  $X_j$ , which can be continuous or grouping variables
- Grouping variables,  $g_1, g_2, \dots, g_R$ ,

where the grouping variables in  $X_j$  and  $g_r$  can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix  $X$ , `random1` is a specification of the random-effects design matrix  $Z_1$  corresponding to grouping variable  $g_1$ , and similarly `randomR` is a specification of the random-effects design matrix  $Z_R$  corresponding to grouping variable  $g_R$ . You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where $k$ is a positive integer	$X, X^2, \dots, X^k$
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$ )
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`. Here are some examples for linear mixed-effects model specification.

### Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, $X1$ and $X2$ . This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for $X1$ and $X2$ . The implicit intercept term is suppressed by including <code>-1</code> .

Formula	Description
'y ~ 1 + (1   g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1   g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1   g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1   g1)'.
'y ~ X1 + (1   g1) + (-1 + X1   g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1   g1) + (1   g2) + (1   g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

### Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N\left(0, \sigma^2 D(\theta)\right),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

**Alternatives**

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

**See Also**

`LinearMixedModel` | `fitlmematrix`

# fitlmematrix

---

**Purpose** Fit linear mixed-effects model

**Syntax**

```
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix(___,Name,Value)
```

**Description** `lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where  $n$  is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(___,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

## **Input Arguments**

### **X - Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where  $n$  is the number of observations, and  $p$  is the number of fixed-effects

predictor variables. Each row of  $X$  corresponds to one observation, and each column of  $X$  corresponds to one variable.

**Data Types**

single | double

**y - Response values**

$n$ -by-1 vector

Response values, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations.

**Data Types**

single | double

**Z - Random-effects design**

$n$ -by- $q$  matrix | cell array of  $R$   $n$ -by- $q(r)$  matrices,  $r = 1, 2, \dots, R$

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then  $Z$  must be an  $n$ -by- $q$  matrix, where  $n$  is the number of observations and  $q$  is the number of variables in the random-effects term.
- If there are  $R$  random-effects terms, then  $Z$  must be a cell array of length  $R$ . Each cell of  $Z$  contains an  $n$ -by- $q(r)$  design matrix  $Z\{r\}$ ,  $r = 1, 2, \dots, R$ , corresponding to each random-effects term. Here,  $q(r)$  is the number of random effects term in the  $r$ th random effects design matrix,  $Z\{r\}$ .

**Data Types**

single | double | cell

**G - Grouping variable or variables**

$n$ -by-1 vector | cell array of  $R$   $n$ -by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then  $G$  must be an  $n$ -by-1 vector corresponding to a single grouping variable with  $M$  levels or groups.

G can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then G must be a cell array of length  $R$ . Each cell of G contains a grouping variable  $G\{r\}$ ,  $r = 1, 2, \dots, R$ , with  $M(r)$  levels.

$G\{r\}$  can be a categorical vector, numeric vector, character array, or cell array of strings.

## Data Types

single | double | char | cell

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### Example:

`'CovariancePattern', 'Diagonal', 'DummyVarCoding', 'full', 'Optimizer', 'fminunc` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

## 'FixedEffectPredictors' - Names of columns in fixed-effects design matrix

`{'x1', 'x2', ..., 'xP'}` (default) | cell array of length  $p$

Names of columns in the fixed-effects design matrix  $X$ , specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a cell array of length  $p$ .

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

**Example:**

```
'FixedEffectPredictors', {'Intercept', 'TimeSpent', 'Gender_Male'},
```

**Data Types**

cell

**'RandomEffectPredictors' - Names of columns in random-effects design matrix or cell array**

cell array of length  $q$  | cell array of length  $R$  with elements of length  $q(r)$ ,  $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array  $Z$ , specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

- A cell array of length  $q$  when  $Z$  is an  $n$ -by- $q$  design matrix. In this case, the default is {'z1', 'z2', ..., 'zQ'}.
- A cell array of length  $R$ , when  $Z$  is a cell array of length  $R$  with each element  $Z\{r\}$  of length  $q(r)$ ,  $r = 1, 2, \dots, R$ . In this case, the default is {'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}

For example, suppose you have correlated random effects for intercept and a variable named Acceleration. Then, you can specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors', {'Intercept', 'Acceleration'}
```

If you have two random effects terms, one for the intercept and the variable Acceleration grouped by variable g1, and the second for the intercept, grouped by the variable g2, then you specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors', {'Intercept', 'Acceleration'}, {'Intercept'}}
```

**Data Types**

cell

**'ResponseVarName' - Name of response variable**

'y' (default) | string

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

**Example:** 'ResponseVarName', 'score'

## Data Types

char

## 'RandomEffectGroups' - Names of random effects grouping variables

'g' or {'g1', 'g2', ..., 'gR'} (default) | string | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if  $G$  is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable  $G$ . The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if  $G$  is a cell array of length  $R$ , then the value of 'RandomEffectGroups' is a cell array of length  $R$ , where each cell contains the name for the grouping variable  $G\{r\}$ . The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, `z1` and `z2`, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

**Example:** 'RandomEffectGroups', {'sex', 'subject'}

## Data Types

char | cell

## 'CovariancePattern' - Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of 'CovariancePattern' must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

'FullCholesky'	Default. Full covariance matrix using the Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
'Full'	Full covariance matrix, using the log-Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
'Diagonal'	Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where  $\sigma_b^2$  is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where  $\sigma_{b1}^2$  is the common variance of the random-effects terms and  $\sigma_{b1,b2}$  is the common covariance

between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $PAT(a,b) = \text{false}$ , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

### 'FitMethod' - Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

**Example:** 'FitMethod', 'REML'

### 'Weights' - Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

#### Data Types

single | double

## **'Exclude' - Indices for rows to exclude**

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude',[13,67]

## **Data Types**

single | double | logical

## **'DummyVarCoding' - Coding to use for dummy variables**

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

## **'Optimizer' - Optimization algorithm**

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinewton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

**Example:** 'Optimizer','fminunc'

### 'OptimizerOptions' - Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasinewton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinewton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

### **'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

### **'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

### **'MaxIter' - Maximum number of iterations allowed**

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

### **'Display' - Level of display**

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

### **'StartMethod' - Method to start iterative optimization**

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'	Default. An internally defined default value.
'random'	A random initial value.

**Example:** 'StartMethod', 'random'

### 'Verbose' - Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose', true

### 'CheckHessian' - Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian', true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples      No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = fitlmematrix(X,y,Z,Model_Year)
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	94
Fixed effects coefficients	2

## Longitudinal Study with a Covariate

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned} y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ & + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ & + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im}, \end{aligned}$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{0m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[\cdot]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have these prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;
```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC',...
'RandomEffectPredictors',{'Intercept','Week'}},'RandomEffectGroups',G);

lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

# fitlmematrix

Linear Mixed Formula with 10 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	0.66105	0.25892	2.5531	111	0.0115
'InitWeight'	0.0031879	0.0013814	2.3078	111	0.0228
'PrgB'	0.36079	0.13139	2.746	111	0.0071
'PrgC'	-0.033263	0.13117	-0.25358	111	0.8000
'PrgD'	0.11317	0.13132	0.86175	111	0.3880
'Week'	0.1732	0.067454	2.5677	111	0.0115
'Week_PrgB'	0.038771	0.095394	0.40644	111	0.6870
'Week_PrgC'	0.030543	0.095394	0.32018	111	0.7470
'Week_PrgD'	0.033114	0.095394	0.34713	111	0.7310

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.18407	0.1220
'Week'	'Intercept'	'corr'	0.66841	0.2100
'Week'	'Week'	'std'	0.15033	0.1100

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the compare method.

## Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 WtdILI_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date` and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b_{0m} \sim N(0, \sigma_{FR}^2)$  and the error term has the distribution,  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

# fitlmematrix

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept','NationalRate'},  
'RandomEffectPredictors',{'Intercept'},'RandomEffectGroups',{'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue
'Intercept'	0.16385	0.057525	2.8484	466	0.0046
'NationalRate'	0.7236	0.032219	22.459	466	3.0502e-46

```
Random effects covariance parameters (95% CIs):
```

```
Group: Date (52 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	0.17146	0.13227	0.22226

```
Group: Error
```

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term  $\sigma_{b_{0m}}^2$ , do not include zero (0.13227, 0.22226), which indicates that

the random-effects term is significant. You can also test the significance of the random-effects using compare method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILLI_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where  $\hat{b}$  is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level);

y_hat =

    1.4674
```

You can simply display the fitted value using the fitted(lme) method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

## Randomized Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix,  $X1$  and  $X2$ , where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift} - \text{Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift} - \text{Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift} - \text{Evening}_i - \beta_2 \text{Shift} - \text{Morning}_i + b_{0m} + \varepsilon_{im},$$

where  $i$  represents the observations, and  $m$  represents the operators,  $i = 1, 2, \dots, 15$ , and  $m = 1, 2, \dots, 5$ . The random effects and the observation error have these distributions:  $b_{0m} \sim N(0, \sigma_{b_{0m}}^2)$  and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{Y}_{Evening, Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
```

```
ans =
```

```
  0.9481
```

## Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having these distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ , and  $b_{1m} \sim N(0, \sigma_1^2)$ .  $m$  represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{'Intercept'}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year'}, 'M
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3

# fitlmematrix

---

Random effects coefficients            26  
Covariance parameters                 3

Formula:

`y ~ Intercept + Acceleration + Horsepower + (Intercept | Model_Year)`

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	49.839	2.0518	24.291	389	5.61
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.16
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.97

Random effects covariance parameters (95% CIs):

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate	Lower	Upper
'Intercept'	'Intercept'	'std'	8.0669e-07	NaN	NaN

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate
'Acceleration'	'Acceleration'	'std'	0.18783

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.7258	3.4698	4.0007

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where  $m$  represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```
Z = [ones(406,1) Acceleration];
G = Model_Year;
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'Intercept'	50.133	2.2652	22.132	389
'Acceleration'	-0.58327	0.13394	-4.3545	389
'Horsepower'	-0.16954	0.0072609	-23.35	389

Random effects covariance parameters (95% CIs):

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate
'Intercept'	'Intercept'	'std'	3.3475
'Acceleration'	'Intercept'	'corr'	-0.87971
'Acceleration'	'Acceleration'	'std'	0.33789

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the `compare` method.

## Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .

$\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have these prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

# fitlmematrix

---

## Model information:

Number of observations	120
Fixed effects coefficients	6
Random effects coefficients	40
Covariance parameters	2

## Formula:

`y ~ Intercept + InitWeight + PrgB + PrgC + PrgD + Week + (Intercept +`

## Model fit statistics:

'PrgD'	0.121	0.12111	0.99911	114	0.321
'Week'	0.19881	0.037134	5.3538	114	4.51e-08

## Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.16561	0.1289

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10272	0.088014	0.11987

## Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response `y`, the predictor variables `X`, and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

**Definitions****Cholesky Parameterization**

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

[fitlme](#) | [LinearMixedModel](#) | [compare](#)

**Purpose**

Fit repeated measures model

**Syntax**

```
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

**Description**

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

**Input Arguments****t - Input data**

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

**Data Types**

table

**modelspec - Formula for model specification**

string of the form 'y1-yk ~ terms'

Formula for model specification, specified as a string of the form 'y1-yk ~ terms'. The responses and terms are specified using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, char arrays, or a cell arrays of strings.

For example, if you have four repeated measures as responses and the factors `x1`, `x2`, and `x3` as the predictor variables, then you can define a repeated measures model as follows.

**Example:** `'y1-y4 ~ x1 + x2 * x3'`

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'WithinDesign', 'W', 'WithinModel', 'w1+w2'` specifies the matrix `w` as the design matrix for within-subject factors, and the model for within-subject factors `w1` and `w2` is `'w1+w2'`.

### **'WithinDesign' - Design for within-subject factors**

numeric vector of length  $r$  (default) |  $r$ -by- $k$  numeric matrix |  $r$ -by- $k$  table

Design for within-subject factors, specified as the comma-separated pair consisting of `'WithinDesign'` and one of the following:

- Numeric vector of length  $r$ , where  $r$  is the number of repeated measures.

In this case, `fitrm` treats the values in the vector as continuous, and these are typically time values.

- $r$ -by- $k$  numeric matrix of the values of the  $k$  within-subject factors,  $w_1, w_2, \dots, w_k$ .

In this case, `fitrm` treats all  $k$  variables as continuous.

- $r$ -by- $k$  table that contains the values of the  $k$  within-subject factors.

In this case, `fitrm` treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

**Example:** `'WithinDesign', weeks`

**Data Types**

single | double | table

**'WithinModel' - Model specifying within-subject hypothesis test**

'separatemeans' (default) | 'orthogonalcontrasts' | string that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of 'WithinModel' and one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- 'orthogonalcontrasts' — This is valid only when the within-subject model has a single numeric factor  $T$ . Responses are the average, the slope of centered  $T$ , and, in general, all orthogonal contrasts for a polynomial up to  $T^{(p-1)}$ , where  $p$  is the number of rows in the within-subject model.
- A string that defines a model specification in the within-subject factors. You can define the model based on the rules for the terms in `modelspec`.

For example, if there are three within-subject factors  $w_1$ ,  $w_2$ , and  $w_3$ , then you can specify a model for the within-subject factors as follows.

**Example:** 'WithinModel', 'w1+w2+w2\*w3'

**Data Types**

single | double

**Output Arguments****rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

## Examples

### Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas)
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```
BetweenDesign: [150x5 table]
```

```
ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
```

```
BetweenFactorNames: {'species'}
```

```
BetweenModel: '1 + species'
```

```
Within Subjects:
```

```
WithinDesign: [4x1 table]
```

```
WithinFactorNames: {'Measurements'}
```

```
WithinModel: 'separatemeans'
```

```
Estimates:
```

```
Coefficients: [3x4 table]
```

Covariance: [4x4 table]

Display the coefficients.

rm.Coefficients

ans =

	meas1	meas2	meas3	meas4
	-----	-----	-----	-----
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

fitrm uses the 'effects' contrasts which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species\_setosa} = \begin{cases} 1, & \text{if } setosa \\ 0, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases} \quad \text{and} \quad \text{species\_versicolor} = \begin{cases} 0, & \text{if } setosa \\ 1, & \text{if } versicolor \\ -1, & \text{if } virginica \end{cases}$$

Display the covariance matrix.

rm.Covariance

ans =

	meas1	meas2	meas3	meas4
	-----	-----	-----	-----
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

## Specify the Within-Subject Hypothesis

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix  $Y$  contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of  $Y$  corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']
```

Store the data in a proper table array format to conduct repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...
'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time, 'WithinModel', 'orthogonal
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```
  BetweenDesign: [16x6 table]
```

```
  ResponseNames: {'t0' 't2' 't4' 't6' 't8'}
```

```
  BetweenFactorNames: {'Gender'}
```

```
  BetweenModel: '1 + Gender'
```

```
Within Subjects:
```

```
  WithinDesign: [5x1 table]
```

```
  WithinFactorNames: {'Time'}
```

```
  WithinModel: 'orthogonalcontrasts'
```

```
Estimates:
```

```
  Coefficients: [2x5 table]
```

```
  Covariance: [5x5 table]
```

### Fit a Model with Covariates

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the eight repeated measurements `y1–y8` as responses and the between-subject factors `Group`, `Gender`, `IQ`, and `Age`. `IQ` and `Age` as continuous variables. The table `within` includes the within-subject factors `w1` and `w2`.

Fit a repeated measures model, where `age`, `IQ`, and `group`, `gender` are the predictor variables, and the model includes the interaction effect of `group` and `gender`. Also define the within-subject factors.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender+Age+IQ','WithinDesign',within
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```

    BetweenDesign: [30x12 table]
    ResponseNames: {'y1' 'y2' 'y3' 'y4' 'y5' 'y6' 'y7' 'y8'}
    BetweenFactorNames: {'Age' 'IQ' 'Group' 'Gender'}
    BetweenModel: '1 + Age + IQ + Group*Gender'

```

```

Within Subjects:
    WithinDesign: [8x2 table]
    WithinFactorNames: {'w1' 'w2'}
    WithinModel: 'separatemeans'

```

```

Estimates:
    Coefficients: [8x8 table]
    Covariance: [8x8 table]

```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

	y1	y2	y3	y4
	-----	-----	-----	-----
(Intercept)	141.38	195.25	9.8663	-49.154
Age	0.32042	-4.7672	-1.2748	0.6216
IQ	-1.2671	-1.1653	0.05862	0.4288
Group_A	-1.2195	-9.6186	22.532	15.303
Group_B	2.5186	1.417	-2.2501	0.50181
Gender_Female	5.3957	-3.9719	8.5225	9.3403
Group_A:Gender_Female	4.1046	10.064	-7.3053	-3.3085
Group_B:Gender_Female	-0.48486	-2.9202	1.1222	0.69715

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

**Definitions****Model Specification Using Wilkinson Notation**

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in `modelspec`.

Wilkinson Notation	Meaning
Y1,Y2,Y3	Specific list of variables
Y1-Y5	All table variables from Y1 through Y5

The following rules specify terms in `modelspec`.

Wilkinson notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where k is a positive integer	$X, X^2, \dots, X^k$
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

# fitdist

---

## Purpose

Fit probability distribution object to data

## Syntax

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

## Description

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

## Input Arguments

### **x** - Input data

column vector

Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector causes `fitdist` to ignore the corresponding values in `x`.

**Data Types**

single | double

**distname - Distribution name**

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbaumSaunders'	Birnbaum-Saunders distribution	prob.BirnbaumSaundersDistribution
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Kernel'	Kernel distribution	prob.KernelDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution

Distribution Name	Description	Distribution Class
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	$t$ Location-Scale distribution	prob.tLocationScaleDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

## groupvar - Grouping variable

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender, Smoker}`

divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

**Example:** {Gender,Smoker}

### Data Types

single | double | logical | cell | char

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `fitdist(x,'Kernel','Kernel','triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

### 'Censoring' - Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of 'Censoring' and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding elements is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector causes `fitdist` to ignore the corresponding values in the censoring vector.

### Data Types

logical

### 'Frequency' - Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of 'Frequency' and a vector of nonnegative integer values

that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector are ignored by the fitting calculations. Additionally, any NaN values in `x` or the censoring vector causes `fitdist` to ignore the corresponding values in the frequency vector.

### **Data Types**

logical

### **'Options' - Control parameters**

structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of 'Options' and a structure you create using `statset`.

### **Data Types**

struct

### **'NTrials' - Number of trials**

positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of 'NTrials' and a positive integer value. You must specify `distname` as 'Binomial' to use this option.

### **Data Types**

single | double

### **'Theta' - Threshold parameter**

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of 'Theta' and a scalar value. You must specify `distname` as 'GeneralizedPareto' to use this option.

**Data Types**

single | double

**'Kernel' - Kernel smoother type**

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following:

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

You must specify `distname` as 'Kernel' to use this option.

**'Support' - Kernel density support**

'unbounded' (default) | 'positive' | two-element vector

Kernel density support, specified as the comma-separated pair consisting of 'Support' and a string or two-element vector. The string must be one of the following.

'unbounded'	Density can extend over the whole real line.
'positive'	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as 'Kernel' to use this option.

**Data Types**

single | double

**'Width' - Bandwidth of kernel smoothing window**

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify `distname` as 'Kernel' to use this option.

## Data Types

single | double

## Output Arguments

### **pd** - Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object.

### **pdca** - Probability distribution objects

cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array.

### **gn** - Group labels

cell array of strings

Group labels, returned as a cell array of strings.

### **gl** - Grouping variable levels

cell array of strings

Grouping variable levels, returned as a cell array of strings containing one column for each grouping variable.

## Examples

### **Fit a Normal Distribution to Data**

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 154 [148.728, 159.272]
sigma = 26.5714 [23.3299, 30.8674]
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;
pdf = pdf(pd,x_values);
plot(x_values,pdf,'LineWidth',2)
```

# fitdist

---

## Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;  
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```
pd = fitdist(x,'Kernel','Kernel','epanechnikov')
```

```
pd =
```

```
KernelDistribution
```

```
Kernel = epanechnikov
```

```
Bandwidth = 14.3792
```

```
Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
pdf = pdf(pd,x_values);  
plot(x_values,pdf)
```

# fitdist

---

## Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;  
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)

pdca =

    Column 1

    [1x1 prob.NormalDistribution]

    Column 2

    [1x1 prob.NormalDistribution]

gn =

    'Female'
    'Male'

gl =

    'Female'
    'Male'
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two strings of the group labels. The cell array `gl` contains two strings of the group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1} % distribution for females

female =

    NormalDistribution
```

# fitdist

---

```
Normal distribution
    mu = 130.472    [128.183, 132.76]
    sigma = 8.30339    [6.96947, 10.2736]
```

```
male = pdca{2} % distribution for males
```

```
male =
```

```
NormalDistribution
```

```
Normal distribution
    mu = 180.532    [177.833, 183.231]
    sigma = 9.19322    [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;
femalepdf = pdf(female,x_values);
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure;
plot(x_values,femalepdf,'LineWidth',2)
hold on;
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
legend(gn,'Location','NorthEast');
hold off;
```

### Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital;  
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;  
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array pdca to see the kernel distributions for each gender.

```
female = pdca{1} % distribution for females
```

```
female =
```

```
KernelDistribution  
  
Kernel = triangle  
Bandwidth = 4.25894  
Support = unbounded
```

```
male = pdca{2} % distribution for males
```

```
male =
```

```
KernelDistribution  
  
Kernel = triangle  
Bandwidth = 5.08961  
Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure;  
plot(x_values,femalepdf,'LineWidth',2)  
hold on;  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)
```

```
legend(gn, 'Location', 'NorthEast');  
hold off;
```

## Algorithms

The `fitdist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.

- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

## Alternative Functionality

### App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

- 'GentleBoost'
- 'RobustBoost' (requires an Optimization Toolbox license)
- 'LPBoost' (requires an Optimization Toolbox license)
- 'TotalBoost' (requires an Optimization Toolbox license)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For classification with three or more classes:
  - 'AdaBoostM2'
  - 'LPBoost' (requires an Optimization Toolbox license)
  - 'TotalBoost' (requires an Optimization Toolbox license)
  - 'RUSBoost'
  - 'Subspace'
  - 'Bag'
- For regression:
  - 'LSBoost'
  - 'Bag'

'Bag' applies to all methods. So when you use 'Bag', indicate whether you want a classifier or regressor with the type name-value pair set to 'classification' or 'regression'.

## **NLearn**

Number of ensemble learning cycles, a positive integer (or the string 'AllPredictorCombinations', see the next paragraph). At every training cycle, fitensemble loops over all learner templates in Learners and trains one weak learner for every template. The total number of trained learners in Ensemble is NLearn\*numel(Learners).

If you set `Method` to `'Subspace'`, you can set `NLearn` to `'AllPredictorCombinations'`. With this setting, `fitensemble` constructs learners for all possible combinations of predictors taken `NPredToSample` at a time. This gives a total of `nchoosek(size(X,2),NPredToSample)` learners in the ensemble. You can use only one learner template for this setting.

`NLearn` for ensembles can vary from a few dozen to a few thousand. Usually, an ensemble with a good predictive power needs from a few hundred to a few thousand weak learners. You do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and, if necessary, train more weak learners using the `resume` method of the ensemble.

### Learners

One of the following:

- A string with the name of a weak learner:
  - `'Discriminant'` (applies only to `'Subspace'`)
  - `'KNN'` (applies only to `'Subspace'`)
  - `'Tree'` (applies to all methods except `'Subspace'`)
- A single weak learner template you create with `templateTree`, `templateKNN`, or `templateDiscriminant`.
- A cell array of weak learner templates. Usually you should supply only one weak learner template.

Ensemble performance depends on the parameters of the weak learners, and you can get poor performance using weak learners with default parameters. Specify the parameters for the weak learners in the template. Specify parameters for the ensemble in the `fitensemble` name-value pairs.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## All Ensembles:

### 'CategoricalPredictors'

List of categorical predictors. Pass CategoricalPredictors as one of:

- A numeric vector with indices from 1 to p, where p is the number of columns of X.
- A logical vector of length p, where a true entry means that the corresponding column of X is a categorical variable.
- 'All', meaning all predictors are categorical.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the PredictorNames property.
- A character matrix, where each row of the matrix is the name of a predictor variable. The names must match entries in the PredictorNames property. Pad the names with extra blanks so each row of the character matrix has the same length.

You can set CategoricalPredictors for these learners:

- 'Tree'
- 'KNN', when all predictors are categorical

**Default:** [ ]

### 'CrossVal'

If 'On', grows a cross-validated learner with 10 folds. You can use 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' parameters to override this cross-validation setting. You can only use one of these four parameters ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated learner.

**Default:** 'Off'

**'CVPartition'**

Partition created with `cvpartition` to use in a cross-validated learner. You can only use one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**'FResample'**

Fraction of the training set to be selected by resampling for every weak learner. A numeric scalar from 0 to 1. This parameter has no effect unless you grow an ensemble by bagging or set 'resample' to 'on'. The default setting is the one used most often for an ensemble grown by resampling.

**Default:** 1

**'Holdout'**

Holdout validation tests the specified fraction of the data, and uses the remaining data for training. Specify a numeric scalar from 0 to 1. You can only use one of these four options at a time for creating a cross-validated learner: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**'KFold'**

Number of folds to use in a cross-validated learner, a positive integer. You can only use one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Default:** 10

**'Leaveout'**

Use leave-one-out cross validation by setting to 'on'. You can only use one of these four options at a time: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

## **'NPredToSample'**

Number of predictors in each random subspace learner, a positive integer from 1 to `size(X,2)`.

**Default:** 1

## **'NPrint'**

Printout frequency, a positive integer scalar. Set to 'Off' for no printout. Use this parameter to track how many weak learners have been trained so far. This is useful when you train ensembles with many learners on large datasets. If you use one of the cross-validation options, this parameter defines the printout frequency per number of cross-validation folds.

**Default:** 'Off'

## **'PredictorNames'**

Cell array of names for the predictor variables, in the order in which they appear in `X`.

**Default:** {'x1', 'x2', ...}

## **'Replace'**

'On' or 'Off'. If 'On', sample with replacement. If 'Off', sample without replacement. This parameter has no effect unless you grow an ensemble by bagging or set `Resample` to 'On'. If you set `Resample` to 'On' and `Replace` to 'Off', `fitensemble` samples training observations assuming uniform weights, and boosts by reweighting observations.

**Default:** 'On'

## **'Resample'**

'On' or 'Off'. If 'On', grow an ensemble by resampling, with the resampling fraction given by `FResample`, and sampling with or without replacement given by `Replace`.

- Boosting — When 'Off', the boosting algorithm reweights observations at every learning iteration. When 'On', the algorithm samples training observations using updated weights as the multinomial sampling probabilities.
- Bagging — You can use only the default value of this parameter ('On').

**Default:** 'Off' for boosting, 'On' for bagging

#### **'ResponseName'**

Name of the response variable  $Y$ , a string.

**Default:** 'Y'

#### **'Type'**

String, either 'Classification' or 'Regression'. Specify Type when the Method is 'Bag'.

#### **'Weights'**

Vector of observation weights. The length of Weights is the number of rows in  $X$ .

**Default:** `ones(size(X,1),1)`

#### **Classification Ensembles:**

##### **'ClassNames'**

Array of class names. Specify a data type the same as exists in  $Y$ .

**Default:** Class names that exist in  $Y$

## 'Cost'

Square matrix  $C$ , where  $C(i, j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ . Alternatively, `cost` can be a structure  $S$  having two fields:

- `S.ClassNames` containing the group names as a categorical variable, character array, or cell array of strings
- `S.ClassificationCosts` containing the cost matrix  $C$

If `Method` is `Bag`, `Type` is `Classification`, and `Cost` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

**Default:**  $C(i, j) = 1$  if  $i \neq j$ , and  $C(i, j) = 0$  if  $i = j$

## 'Prior'

Prior probabilities for each class. Specify as one of:

- A string:
  - `'Empirical'` determines class probabilities from class frequencies in  $Y$ . If you pass observation weights, they are used to compute the class probabilities.
  - `'Uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure  $S$  with two fields:
  - `S.ClassNames` containing the class names as a categorical variable, character array, or cell array of strings
  - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

If `Method` is `Bag`, `Type` is `Classification`, and `Prior` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

**Default:** 'Empirical'

**AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, RUSBoost, and LSBoost:**

**'LearnRate'**

Learning rate for shrinkage, a numeric scalar from 0 to 1. If you set the learning rate to less than 1, the ensemble requires more learning iterations but often achieves a better accuracy. 0.1 is a popular choice for an ensemble grown with shrinkage.

**Default:** 1

**RUSBoost:**

**'RatioToSmallest'**

Either a numeric scalar or vector with `K` elements when there are `K` classes. Every element of this vector is the sampling proportion for this class with respect to the class with fewest observations in `Y`. If you pass a scalar, `fitensemble` uses this sampling proportion for all classes. For example, suppose you have class A with 100 observations and class B with 10 observations. If you pass `[2 1]` for 'RatioToSmallest', every learner in the ensemble is trained on 20 observations of class A and 10 observations of class B. If you pass 2 or `[2 2]`, every learner is trained

on 20 observations of class A and 20 observations of class B. If you pass 'ClassNames', fitensemble matches elements in the array of class names to elements in this vector.

**Default:** ones(K,1)

**LPBoost and TotalBoost:**

**'MarginPrecision'**

Margin precision, a numeric scalar between 0 and 1. MarginPrecision affects the number of boosting iterations required for conversion. Use a small value to grow an ensemble with many learners, and use a large value to grow an ensemble with few learners.

**Default:** 0.01

**RobustBoost:**

**'RobustErrorGoal'**

Target classification error for RobustBoost, a numeric scalar from 0 to 1. Usually there is an optimal range for this parameter for your training data. If you set the error goal too low or too high, RobustBoost can produce a model with poor classification accuracy.

**Default:** 0.1

**'RobustMarginSigma'**

Spread of the distribution of classification margins over the training set for RobustBoost, a numeric positive scalar. You should consult literature on RobustBoost before setting this parameter

**Default:** 0.1

**'RobustMaxMargin'**

Maximal classification margin for `RobustBoost` in the training set, a nonnegative numeric scalar. `RobustBoost` minimizes the number of observations in the training set with classification margins below `RobustMaxMargin`.

**Default:** 0

## Output Arguments

### Ensemble

Ensemble object for predicting characteristics. The class of `Ensemble` depends on settings. In the following table, cross-validation names are `CrossVal`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Settings	Class
Resample name-value pair is 'Off', and you don't set a cross-validation name-value pair argument.	<code>ClassificationEnsemble</code>
Resample name-value pair is 'Off', and you don't set a cross-validation name-value pair argument.	<code>RegressionEnsemble</code>
Resample name-value pair is 'On', type is 'classification', and you don't set a cross-validation name-value pair argument.	<code>ClassificationBaggedEnsemble</code>
Resample name-value pair is 'On', type is 'regression', and you don't set a cross-validation name-value pair argument.	<code>RegressionBaggedEnsemble</code>
Method is a classification method, and you set a cross-validation name-value pair argument.	<code>ClassificationPartitionedEnsemble</code>
Method is a regression method, and you set a cross-validation name-value pair argument.	<code>RegressionPartitionedEnsemble</code>

## Examples

### Estimate the Resubstitution Loss of a Boosting Ensemble

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the ionosphere data set.

```
load ionosphere;
```

Train a decision tree ensemble using AdaBoost, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

ClassTreeEns is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns,'Mode','Cumulative');
```

rsLoss is a 100-by-1 vector, where element  $k$  contains the resubstitution loss after the first  $k$  learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);  
xlabel('Number of Learning Cycles');  
ylabel('Resubstitution Loss');
```

In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

- 1 Randomly partitioning the data into training and cross-validation sets. Do this by specifying 'holdout', holdoutProportion when you train the ensemble using fitensemble.
- 2 Passing the trained ensemble to kfoldLoss, which estimates the generalization error.

## Train a Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors.

Load the carsmall data set. Set the predictors to X.

```
load carsmall
X = [Cylinders,Displacement,Horsepower,Weight];
xnames = {'Cylinders','Displacement','Horsepower','Weight'};
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```
RegTreeTemp = templateTree('Surrogate','On');
```

Train the regression tree ensemble using LSBoost and 100 learning cycles.

```
RegTreeEns = fitensemble(X,MPG,'LSBoost',100,RegTreeTemp,...
    'PredictorNames',xnames);
```

RegTreeEns is a trained RegressionEnsemble regression ensemble.

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(RegTreeEns,[4 200 150 3000])
```

```
predMPG =
```

21.7781

The average fuel economy of a car with the specifications is 21.78 mpg.

### **Estimate the Generalization Error of a Boosting Ensemble**

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the ionosphere data set.

```
load ionosphere;
```

Train a decision tree ensemble using AdaBoostM1, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

ClassTreeEns is a trained ClassificationEnsemble ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

genError is a 100-by-1 vector, where element  $k$  contains the generalization error after the first  $k$  learning cycles.

Plot the generalization error over the number of learning cycles.

```
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```

# fitensemble

---

The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

## Algorithms

- For details of boosting and bagging algorithms, see “Ensemble Algorithms” on page 16-164.
- `fitensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more

observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

## Tips

Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector. This is particularly important if you train using a small sample size.

## How To

- “Supervised Learning (Machine Learning) Workflow and Algorithms” on page 16-2
- “Ensemble Methods” on page 16-64

# fitnlm

---

**Purpose** Fit nonlinear regression model

**Syntax**

```
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm( ___,modelfun,beta0,Name,Value)
```

**Description** `mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm( ___,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**tbl - Input data**  
table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model string. If you do not provide a model string, you can set a different column as the response variable by using the `ResponseVar` name-value pair argument. You can select a subset of the columns as predictors by using the `PredictorVars` name-value pair argument.

**Data Types**  
single | double | logical

## **X - Predictor variables**

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

### **Data Types**

single | double | logical

## **y - Response variable**

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### **Data Types**

single | double

## **modelfun - Functional form of the model**

function handle | string of the form 'y ~  
 $f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - $b$  is a coefficient vector with the same number of elements as `beta0`.
  - $x$  is a matrix with the same number of columns as  $X$  or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as  $x$ . Each row of the vector is the result of evaluating `modelfun` on the corresponding row of  $x$ . In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- String of the form  $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ , where  $f$  represents a scalar function of the scalar coefficient variables  $b_1, \dots, b_j$  and the scalar data variables  $x_1, \dots, x_k$ .

## **beta0 - Coefficients**

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

## **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

**Example:** 'ErrorModel', 'combined', 'Exclude', 2, 'Options', opt specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure opt to control the iterative fitting procedure.

## **'CoefficientNames' - Names of the model coefficients**

{'b1', 'b2', ..., 'bk'} (default) | cell array of strings

Names of the model coefficients, specified as a cell array of strings.

## **Data Types**

char

## **'ErrorModel' - Form of the error variance model**

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable  $e$  in combination with independent components: the function value  $f$ , and one or two parameters  $a$  and  $b$

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f )e$

The only allowed error model when using `Weights` is 'constant'.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

**Example:** `'ErrorModel','proportional'`

### 'ErrorParameters' - Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	$a$	1
'proportional'	$b$	1
'combined'	$a, b$	[1,1]

You can only use the 'constant' error model when using `Weights`.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

---

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for  $a$  and the starting value 2 for  $b$  as follows.

**Example:** 'ErrorParameters',[1,2]

### **Data Types**

single | double

### **'Exclude' - Observations to exclude**

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

### **Data Types**

single | double | logical

### **'Options' - Options for controlling the iterative fitting procedure**

[] (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> <li>• 'off' — Displays no information.</li> <li>• 'final' — Displays the final output.</li> <li>• 'iter' — Displays iterative output to the Command Window.</li> </ul>	'off'
FunValCheck	String indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 21-1362	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 21-1362 for the default, which depends on RobustWgtFun.

Option	Meaning	Default
ToIFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
ToIX	Termination tolerance for the parameters. Positive scalar.	1e-8

## Data Types

struct

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical | cell

### 'ResponseVar' - Response variable

last column of `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable

name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable.

If you supply a model string, it specifies the response variable. Otherwise, when fitting a table or dataset array, `'ResponseVar'` indicates which variable `fitnlm` should use as the response.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### Data Types

`single` | `double` | `logical` | `char`

### 'VarNames' - Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

#### Example:

`'VarNames',{ 'Horsepower','Acceleration','Model_Year','MPG' }`

### Data Types

`cell`

### 'Weights' - Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have  $n$  elements, where  $n$  is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `NonLinearModel` estimates the error variance at observation `i` by  $\text{MSE} * (1/W(i))$ , where `MSE` is the mean squared error.

### Data Types

single | double | function\_handle

## Output Arguments

### `mdl` - Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

## Examples

### Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
```

```
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```
Number of observations: 392, Error degrees of freedom: 387
```

```
Root Mean Squared Error: 3.96
```

```
R-Squared: 0.745, Adjusted R-Squared 0.743
```

```
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

### Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

Nonlinear regression model:

$$y \sim b_1 + b_2 * x_1^{b_3} + b_4 * x_2^{b_5}$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387

Root Mean Squared Error: 3.96

R-Squared: 0.745, Adjusted R-Squared 0.743

F-statistic vs. constant model: 283, p-value = 1.79e-113

## Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step
0	1.82248e+06		
1	678600	788810	1691.07
2	616716	6.12739e+06	45.4738
-----			
122	6068.48	1.56393	0.629325
123	6068.48	1.13809	0.432543
124	6068.48	0.295962	0.297511

%%% Many iterations deleted %%%

Iterations terminated: relative change in SSE less than OPTIONS.TolFun

## Specify Nonlinear Regression Using Model String Syntax

Specify a nonlinear regression model for estimation using a function handle or model string syntax.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998  
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use a string expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';  
mdl2 = fitnlm(X,y,myfun,beta0)
```

```
mdl2 =
```

Nonlinear regression model:

$$y \sim (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 0.193  
R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

## Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));

rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a string expression to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';

mdl = fitnlm(x,y,modelstr,b0,'Options',opts)

mdl =
```

```
Nonlinear regression model (robust fit):
    y ~ b1 + b2*exp( - b3*x)
```

```
Estimated Coefficients:
              Estimate      SE          tStat      pValue
```

b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

Number of observations: 100, Error degrees of freedom: 97  
Root Mean Squared Error: 0.501  
R-Squared: 0.807, Adjusted R-Squared 0.803  
F-statistic vs. constant model: 203, p-value = 2.34e-35

## Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =
```

```
Nonlinear regression model:  
y ~ hougen(b,X)
```

```
Estimated Coefficients:  
Estimate SE tStat pValue
```

b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8  
 Root Mean Squared Error: 0.037  
 R-Squared: 0.998, Adjusted R-Squared 0.998  
 F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

### Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
```

```
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue

# LinearMixedModel.fitmatrix

---

**Purpose** Fit linear mixed-effects model using design matrices

**Compatibility** `LinearMixedModel.fitmatrix` will be removed in a future release. Use `fitlmematrix` instead.

**Syntax**

```
lme = LinearMixedModel.fitmatrix(X,y,Z,[])  
lme = LinearMixedModel.fitmatrix(X,y,Z,G)  
lme = LinearMixedModel.fitmatrix(__,Name,Value)
```

**Description** `lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(__,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

## Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

## Input Arguments

### **X - Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of X corresponds to one observation, and each column of X corresponds to one variable.

### **Data Types**

single | double

### **y - Response values**

*n*-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

### **Data Types**

single | double

### **Z - Random-effects design**

*n*-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then Z must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then Z must be a cell array of length *R*. Each cell of Z contains an *n*-by-*q*(*r*) design matrix  $Z\{r\}$ ,  $r = 1, 2, \dots, R$ , corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix,  $Z\{r\}$ .

### **Data Types**

single | double | cell

# LinearMixedModel.fitmatrix

---

## **G - Grouping variable or variables**

$n$ -by-1 vector | cell array of  $R$   $n$ -by-1 vectors

Grouping variable or variables, specified as either of the following.

- If there is one random-effects term, then **G** must be an  $n$ -by-1 vector corresponding to a single grouping variable with  $M$  levels or groups.

**G** can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then **G** must be a cell array of length  $R$ . Each cell of **G** contains a grouping variable  $G\{r\}$ ,  $r = 1, 2, \dots, R$ , with  $M(r)$  levels.

$G\{r\}$  can be a categorical vector, numeric vector, character array, or cell array of strings.

## **Data Types**

single | double | char | cell

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

## **'FixedEffectPredictors' - Names of columns in fixed-effects design matrix**

{'x1', 'x2', ..., 'xP'} (default) | cell array of length  $p$

Names of columns in the fixed-effects design matrix **X**, specified as the comma-separated pair consisting of **'FixedEffectPredictors'** and a cell array of length  $p$ .

For example, if you have a constant term and two predictors, say **TimeSpent** and **Gender**, where **Female** is the reference level for **Gender**, as the fixed effects, then you can specify the names of

your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

**Example:**

```
'FixedEffectPredictors',{ 'Intercept', 'TimeSpent', 'Gender_Male' },
```

**Data Types**

cell

**'RandomEffectPredictors' - Names of columns in random-effects design matrix or cell array**

cell array of length  $q$  | cell array of length  $R$  with elements of length  $q(r)$ ,  $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array  $Z$ , specified as the comma-separated pair consisting of `'RandomEffectPredictors'` and either of the following:

- A cell array of length  $q$  when  $Z$  is an  $n$ -by- $q$  design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length  $R$ , when  $Z$  is a cell array of length  $R$  with each element  $Z\{r\}$  of length  $q(r)$ ,  $r = 1, 2, \dots, R$ . In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)', ..., {'zr1', 'zr2', ..., 'zrQ(r)'}}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors',{ 'Intercept', 'Acceleration' }
```

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

**Example:**

```
'RandomEffectPredictors',{ {'Intercept', 'Acceleration'}, {'Intercept'}}
```

## Data Types

cell

### 'ResponseVarName' - Name of response variable

'y' (default) | string

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a string.

For example, if your response variable name is `score`, then you can specify it as follows.

**Example:** 'ResponseVarName', 'score'

## Data Types

char

### 'RandomEffectGroups' - Names of random effects grouping variables

'g' or {'g1', 'g2', ..., 'gR'} (default) | string | cell array of strings

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- String — If there is only one random-effects term, that is, if **G** is a vector, then the value of 'RandomEffectGroups' is a string containing the name for the grouping variable **G**. The default is 'g'.
- Cell array of strings — If there are multiple random-effects terms, that is, if **G** is a cell array of length *R*, then the value of 'RandomEffectGroups' is a cell array of length *R*, where each cell contains the name for the grouping variable  $G\{r\}$ . The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, `z1` and `z2`, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

**Example:** 'RandomEffectGroups', {'sex', 'subject'}

## Data Types

char | cell

### 'CovariancePattern' - Pattern of covariance matrix

'FullCholesky' (default) | string | square symmetric logical matrix | cell array of strings or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a string, a square symmetric logical matrix, or a cell array of strings or logical matrices.

If there are  $R$  random-effects terms, then the value of 'CovariancePattern' must be a cell array of length  $R$ , where each element  $r$  of this cell array specifies the pattern of the covariance matrix of the random-effects vector associated with the  $r$ th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

# LinearMixedModel.fitmatrix

---

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where  $\sigma_b^2$  is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where  $\sigma_{b1}^2$  is the common variance of the random-effects terms and  $\sigma_{b1,b2}$  is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if  $PAT(a,b) = \text{false}$ , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

**Example:** 'CovariancePattern', 'Diagonal'

**Example:** 'CovariancePattern', {'Full', 'Diagonal'}

**'FitMethod' - Method for estimating parameters**

'ML' (default) | 'REML'

# LinearMixedModel.fitmatrix

---

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'	Default. Maximum likelihood estimation
'REML'	Restricted maximum likelihood estimation

**Example:** 'FitMethod','REML'

## 'Weights' - Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$ , where  $n$  is the number of observations.

## Data Types

single | double

## 'Exclude' - Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

**Example:** 'Exclude',[13,67]

## Data Types

single | double | logical

## 'DummyVarCoding' - Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

**Example:** 'DummyVarCoding','effects'

## 'Optimizer' - Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> .

# LinearMixedModel.fitmatrix

---

with 'Algorithm' set to  
'quasi-newton'.

**Example:** 'Optimizer','fminunc'

## **'OptimizerOptions' - Options for optimization algorithm**

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinewton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinewton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

## **'TolFun' - Relative tolerance on gradient of objective function**

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

## **'TolX' - Absolute tolerance on step size**

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

## 'MaxIter' - Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

## 'Display' - Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

## 'StartMethod' - Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

'default'                      Default. An internally defined default value.

'random'                        A random initial value.

**Example:** 'StartMethod','random'

## 'Verbose' - Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

**Example:** 'Verbose',true

# LinearMixedModel.fitmatrix

---

## 'CheckHessian' - Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

**Example:** 'CheckHessian',true

## Output Arguments

### lme - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

## Examples

### No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =
```

# LinearMixedModel.fitmatrix

Linear mixed-effects model fit by ML

Model information:

Number of observations	94
Fixed effects coefficients	2
Random effects coefficients	3
Covariance parameters	2

Formula:

$y \sim x1 + x2 + (z11 | g1)$

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance

## Longitudinal Study with Covariate

Navigate to a folder containing sample data.

`cd(matlabroot)`

```
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + \beta_6 (Week_i * I[PB]_i) + \beta_7 (Week_i * I[PC]_i) + \beta_8 (Week_i * I[PD]_i) \\ + b_{0m} + b_{1m} Week_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .  $\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{0m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
Subject = nominal(Subject);  
Program = nominal(Program);  
D = dummyvar(Program); % Create dummy variables for Program  
X = [ones(120,1), InitialWeight, D(:,2:4), Week,...  
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];  
Z = [ones(120,1), Week];  
G = Subject;
```

# LinearMixedModel.fitmatrix

---

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...  
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC',  
'RandomEffectPredictors',{ 'Intercept','Week'}},'RandomEffectGroups',{ 'Su
```

```
lme =
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	120
Fixed effects coefficients	9
Random effects coefficients	40
Covariance parameters	4

Formula:

Linear Mixed Formula with 10 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
-22.981	13.257	24.49	-48.981

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	0.66105	0.25892	2.5531	111	0.0116
'InitWeight'	0.0031879	0.0013814	2.3078	111	0.0224
'PrgB'	0.36079	0.13139	2.746	111	0.0074
'PrgC'	-0.033263	0.13117	-0.25358	111	0.8001
'PrgD'	0.11317	0.13132	0.86175	111	0.3891
'Week'	0.1732	0.067454	2.5677	111	0.0116

'Week_PrgB'	0.038771	0.095394	0.40644	111
'Week_PrgC'	0.030543	0.095394	0.32018	111
'Week_PrgD'	0.033114	0.095394	0.34713	111

Random effects covariance parameters (95% CIs):

Group: Subject (20 Levels)

Name1	Name2	Type	Estimate	LC
'Intercept'	'Intercept'	'std'	0.18407	0
'Week'	'Intercept'	'corr'	0.66841	0
'Week'	'Week'	'std'	0.15033	0

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The  $p$ -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

## Random-Intercept Model

Load the sample data.

```
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into a tall array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

# LinearMixedModel.fitmatrix

---

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by Date. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \text{WtdILLI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable Date.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable Date and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b_{0m} \sim N(0, \sigma^2_{FR})$  and the error term has the distribution,  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILLI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',{'Intercept'},
'RandomEffectPredictors',{'Intercept'}),'RandomEffectGroups',{'Date'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + NationalRate + (Intercept | Date)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVa
'Intercept'	0.16385	0.057525	2.8484	466	0
'NationalRate'	0.7236	0.032219	22.459	466	3.0

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Low
'Intercept'	'Intercept'	'std'	0.17146	0.1

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term  $\sigma^2_{b_{om}}$ , do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 WtdILLI_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where  $\hat{b}$  is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
```

# LinearMixedModel.fitmatrix

---

```
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='1');

y_hat =

    1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)

ans =

    1.4674
```

## Randomized-Block Design

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the

coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix,  $X1$  and  $X2$ , where

$$\text{Shift\_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases} \quad \text{and} \quad \text{Shift\_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}.$$

The model corresponds to

$$\text{Morning Shift: } QCDev_{im} = \beta_0 + \beta_2 \text{Shift\_Morning}_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 5,$$

$$\text{Evening Shift: } QCDev_{im} = \beta_0 + \beta_1 \text{Shift\_Evening}_i + b_{0m} + \varepsilon_{im},$$

$$\text{Night Shift: } QCDev_{im} = \beta_0 - \beta_1 \text{Shift\_Evening}_i - \beta_2 \text{Shift\_Morning}_i + b_{0m} + \varepsilon_{im}.$$

where  $i$  represents the observations, and  $m$  represents the operators,  $i = 1, 2, \dots, 15$ , and  $m = 1, 2, \dots, 5$ . The random effects and the observation error have the following distributions:  $b_{0m} \sim N(0, \sigma^2_{b_{0m}})$  and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FitMethod','REML','FixedEffects',{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{'Intercept','RandomEffectGroups','Operator'},'DummyVarCoding','effects')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

1.1757

```
-2.1715  
2.3655  
-1.9472
```

The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{Evening,Operator3} &= \hat{\beta}_0 + \hat{\beta}_1 Shift\_Evening + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value in the following way.

```
F = fitted(lme);  
F(shift.Shift=='Evening' & shift.Operator=='3')  
  
ans =  
  
0.9481
```

## Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ , and  $b_{1m} \sim N(0, \sigma_1^2)$ .  $m$  represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

# LinearMixedModel.fitmatrix

---

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'})
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

```
Formula:
```

```
y ~ Intercept + Acceleration + Horsepower + (Intercept | Model_Year)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	49.839	2.0518	24.291	389	5.61e-50
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.16e-08
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.97e-47

```
Random effects covariance parameters (95% CIs):
```

```

Group: Model_Year (13 Levels)
      Name1          Name2          Type          Estimate
      'Intercept'    'Intercept'    'std'       8.0669e-07
Group: Model_Year (13 Levels)
      Name1          Name2          Type          Estimate
      'Acceleration' 'Acceleration' 'std'       0.18783
Group: Error
      Name          Estimate    Lower    Upper
      'Res Std'    3.7258    3.4698    4.0007

```

The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case the random-effects terms have the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( 0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where  $m$  represents the model year.

First prepare the random-effects design matrix and grouping variable.

```

Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = LinearMixedModel.fitmatrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept','Acceleration'},'RandomEffectGroups',{'Model_Year'})

lme =

```

Linear mixed-effects model fit by ML

# LinearMixedModel.fitmatrix

---

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2193.5	2221.3	-1089.7	2179.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	50.133	2.2652	22.132	389	7.77
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.70
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.1

Random effects covariance parameters (95% CIs):

Group: Model\_Year (13 Levels)

Name1	Name2	Type	Estimate
'Intercept'	'Intercept'	'std'	3.3475
'Acceleration'	'Intercept'	'corr'	-0.87971
'Acceleration'	'Acceleration'	'std'	0.33789

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the compare method.

## Specify the Covariance Pattern

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 Week_i + \beta_3 I[PB]_i + \beta_4 I[PC]_i + \beta_5 I[PD]_i \\ + b_{0m} + b_{1m} Week2_{im} + b_{2m} Week4_{im} + b_{3m} Week6_{im} + b_{4m} Week8_{im} \\ + b_{5m} Week10_{im} + b_{6m} Week12_{im} + \varepsilon_{im},$$

where  $i = 1, 2, \dots, 120$ , and  $m = 1, 2, \dots, 20$ .

$\beta_j$  are the fixed-effects coefficients,  $j = 0, 1, \dots, 8$ , and  $b_{1m}$  and  $b_{1m}$  are random effects.  $IW$  stands for initial weight and  $I[.]$  is a dummy

# LinearMixedModel.fitmatrix

---

variable representing a type of program. For example,  $I[PB]_i$  is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:  $b_{0m} \sim N(0, \sigma_0^2)$ ,  $b_{1m} \sim N(0, \sigma_1^2)$ , and  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

```
lme =
```

```
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	120
Fixed effects coefficients	6
Random effects coefficients	40
Covariance parameters	2

```
Formula:
```

```
y ~ Intercept + InitWeight + PrgB + PrgC + PrgD + Week + (Intercept +
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
-24.783	-2.483	20.391	-40.783

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pVal
'Intercept'	0.4208	0.28169	1.4938	114	0.138
'InitWeight'	0.0045552	0.0015338	2.9699	114	0.0033

'PrgB'	0.36993	0.12119	3.0525	114

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.10272	0.088014	0.11987

## Definitions

### Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where  $D$  is a  $q$ -by- $q$  symmetric and positive semidefinite matrix, parameterized by a variance component vector  $\theta$ ,  $q$  is the number of variables in the random-effects term, and  $\sigma^2$  is the observation error variance. Since the covariance matrix of the random effects,  $D$ , is symmetric, it has  $q(q+1)/2$  free parameters. Suppose  $L$  is the lower triangular Cholesky factor of  $D(\theta)$  such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the  $q^*(q+1)/2$ -by-1 unconstrained parameter vector  $\theta$  is formed from elements in the lower triangular part of  $L$ .

For example, if

# LinearMixedModel.fitmatrix

---

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

## Log-Cholesky Parameterization

When the diagonal elements of  $L$  in Cholesky parameterization are constrained to be positive, then the solution for  $L$  is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of  $L$  are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing  $L_{ii} \geq 0$ ,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

## Alternatives

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response  $y$ , the predictor variables  $X$ , and the grouping

variables, and formula is of the form 'y ~ fixed + (random<sub>1</sub>|g<sub>1</sub>) + ... + (random<sub>R</sub>|g<sub>R</sub>)'.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

## See Also

`fitlme` | `LinearMixedModel`

# fitNaiveBayes

---

**Purpose** Train naive Bayes classifier

**Syntax** NBModel = fitNaiveBayes(X,Y)  
NBModel = fitNaiveBayes(X,Y,Name,Value)

**Description** NBModel = fitNaiveBayes(X,Y) returns a naive Bayes classifier NBModel, trained by predictors X and class labels Y for *K*-level classification.

Predict labels for new data by passing the data and NBModel to predict.

NBModel = fitNaiveBayes(X,Y,Name,Value) returns a naive Bayes classifier with additional options specified by one or more Name, Value pair arguments.

For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

## Input Arguments

### **X - Predictor data**

matrix of numeric values

Predictor data to which the naive Bayes classifier is trained, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equivalent.

### **Data Types**

double

### **Y - Class labels**

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels to which the naive Bayes classifier is trained, specified as a categorical or character array, logical or numeric vector, or cell

array of strings. Each element of `Y` defines the class membership of the corresponding row of `X`. `Y` supports  $K$  class levels.

If `Y` is a character array, then each element must correspond to one class label.

The length of `Y` and the number of rows of `X` must be equivalent.

### Data Types

`cell` | `char` | `double` | `logical`

---

**Note:** The software treats NaNs, empty strings (' '), or undefined values as missing values.

- If `Y` contains missing values, then the software removes the corresponding rows of `X`.
  - If `X` contains missing values and you set `'Distribution','mn'`, then the software removes the corresponding rows of `X`. Otherwise, the software removes the missing values, and uses the values of other features in the corresponding rows of `X`.
- 

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### Example:

`'Distribution','mn','Prior','uniform','KSWidth',0.5` specifies the following: the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

### 'Distribution' - Data distributions

`'kernel'` | `'mn'` | `'mvmn'` | `'normal'` (default) | cell array of strings

# fitNaiveBayes

---

Data distributions `fitNaiveBayes` uses to model the data, specified as the comma-separated pair consisting of 'Distribution' and a string or cell array of strings.

This table summarizes the available distributions.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial distribution. For details, see “Algorithms” on page 21-1411.
'mvmn'	Multivariate multinomial distribution. For details, see “Algorithms” on page 21-1411.
'normal'	Normal (Gaussian) distribution.

If you specify a string, then the software models all the features using that distribution. If you specify a 1-by- $D$  cell array of strings, then the software models feature  $j$  using the distribution in element  $j$  of the cell array.

**Example:** 'Distribution',{ 'kernel', 'mn' }

## Data Types

cell | char

## 'KSSupport' - Kernel smoothing density support

'positive' | 'unbounded' (default) | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'KSSupport' and a numeric row vector, a string, or a cell array. The software applies the kernel smoothing density to this region.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- $D$  cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel support in cell  $j$  for feature  $j$  in  $X$ .

**Example:** 'KSSupport',{[-10,20],'unbounded'}

### Data Types

cell | char | double

### 'KSType' - Kernel smoother type

'box' | 'epanechnikov' | 'normal' (default) | 'triangle' | cell array of strings

Kernel smoother type, specified as the comma-separated pair consisting of 'KSType' and a string or cell array of strings.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

This table summarizes the available options for setting the kernel smoothing density region. Let  $I\{u\}$  denote the indicator function.

# fitNaiveBayes

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x  \leq 1\}$
'epanechnikov'	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x  \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 -  x )I\{ x  \leq 1\}$

If you specify a 1-by- $D$  cell array, with each cell containing any value in the table, then the software trains the classifier using the kernel smoother type in cell  $j$  for feature  $j$  in  $X$ .

**Example:** 'KSType', {'epanechnikov', 'normal'}

## Data Types

cell | char

## 'KSWidth' - Kernel smoothing window bandwidth

matrix of numeric values (default) | numeric column vector | numeric row vector | scalar | structure array

Kernel smoothing window bandwidth, specified as the comma-separated pair consisting of 'KSWidth' and a matrix of numeric values, numeric row vector, numeric column vector, scalar, or structure array.

If you do not specify 'Distribution', 'kernel', then the software ignores the values of 'KSSupport', 'KSType', and 'KSWidth'.

Suppose there are  $K$  class levels and  $D$  predictors. This table summarizes the available options for setting the kernel smoothing window bandwidth.

Value	Description
$K$ -by- $D$ matrix of numeric values	Element $(k,d)$ specifies the bandwidth for predictor $d$ in class $k$ .
$K$ -by-1 numeric column vector	Element $k$ specifies the bandwidth for all predictors in class $k$ .
1-by- $D$ numeric row vector	Element $d$ specifies the bandwidth in all class levels for predictor $d$ .
scalar	Specifies the bandwidth for all features in all classes.
structure array	<p>A structure array <math>S</math> containing class levels and their bandwidths. <math>S</math> must have two fields:</p> <ul style="list-style-type: none"> <li>• <math>S.width</math>: A numeric row vector of bandwidths, or a matrix of numeric values with <math>D</math> columns.</li> <li>• <math>S.group</math>: A vector of the same type as <math>Y</math>, containing unique class levels indicating the class for the corresponding element of <math>S.width</math>.</li> </ul>

By default, the software selects a default bandwidth automatically for each combination of feature and class by using a value that is optimal for a Gaussian distribution.

**Example:**

```
'KSWidth',struct('width',[0.5,0.25],'group',{'b';'g'})
```

**Data Types**

double | struct

# fitNaiveBayes

---

## 'Prior' - Class prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Class prior probabilities, specified as the comma-separated pair consisting of 'Prior' and a numeric vector, structure array, or string.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The software uses the class relative frequencies distribution for the prior probabilities.
numeric vector	<p>A numeric vector of length <math>K</math> specifying the prior probabilities for each class. The order of the elements of <code>Prior</code> should correspond to the order of the class levels. For details on the order of the classes, see “Algorithms” on page 21-1411.</p> <p>The software normalizes prior probabilities to sum to 1.</p>
structure array	<p>A structure array <code>S</code> containing class levels and their prior probabilities. <code>S</code> must have two fields:</p> <ul style="list-style-type: none"><li>• <code>S.prob</code>: A numeric vector of prior probabilities. The software normalizes prior probabilities to sum to 1.</li><li>• <code>S.group</code>: A vector of the same type as <code>Y</code> containing unique class levels indicating the class for the corresponding element of <code>S.prob</code>. <code>S.class</code> must contain all the <math>K</math> levels in <code>Y</code>. It can also contain classes that do not appear in <code>Y</code>. This can be useful if <code>X</code> is a subset of a larger training set. The software ignores any classes that appear in <code>S.group</code> but not in <code>Y</code>.</li></ul>
'uniform'	The prior probabilities are equal for all classes.

**Example:** `'Prior',struct('prob',[1,2],'group',{{'b';'g'}})`

## Data Types

`char | double | struct`

## Output Arguments

### NBModel - Trained naive Bayes classifier

NaiveBayes classifier

Trained naive Bayes classifier, returned as a NaiveBayes classifier.

## Examples

### Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
y = species;
tabulate(y)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier using the data.

```
NBModel = fitNaiveBayes(X,y)
```

```
NBModel =
```

```
Naive Bayes classifier with 3 classes for 2 dimensions.
Feature Distribution(s):normal
Classes:setosa, versicolor, virginica
```

# fitNaiveBayes

---

NBModel is a trained NaiveBayes classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within setosa.

```
setosaIndex = strcmp(NBModel.ClassLevels,'setosa');
estimates = NBModel.Params{setosaIndex,1}
```

```
estimates =
```

```
    1.4620
    0.1737
```

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

```
figure
gscatter(X(:,1),X(:,2),y);
xlim = cell2mat(get(gca,{'Xlim','Ylim'})); % Gets current axis limits
hold on
Params = cell2mat(NBModel.Params);
Mu = Params(2*(1:3)-1,1:2); % Extracts the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)); % Extracts the standard deviation
    ezcontour(@(x1,x2)mvnpdf([x1,x2],Mu(j,:),Sigma(:,:,j)),...
        xlim+0.5*[-1,1,-1,1]) ...
        % Draws contours for the multivariate normal distributions
end
title('Naive Bayes Classifier -- Fisher''s Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
```

You can change the default distribution using the name-value pair argument 'Distribution'. For example, If some predictors are count based, then you can specify that they are multinomial random variables using 'Distribution','mn'.

### Specify Predictor Distributions for Navie Bayes Classifiers

Load Fisher's iris data set.

# fitNaiveBayes

---

```
load fisheriris
X = meas;
y = species;
```

Train a naive Bayes classifier using every predictor.

```
NBModel1 = fitNaiveBayes(X,y);
NBModel1.ClassLevels % Display the class order
NBModel1.Params
NBModel1.Params{1,2}
```

```
ans =
```

```
'setosa'
'versicolor'
'virginica'
```

```
ans =
```

```
[2x1 double] [2x1 double] [2x1 double] [2x1 double]
[2x1 double] [2x1 double] [2x1 double] [2x1 double]
[2x1 double] [2x1 double] [2x1 double] [2x1 double]
```

```
ans =
```

```
3.4280
0.3791
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `NBModel1.Params` corresponds to a numeric vector containing the mean and standard

deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for NBModel1.

```
predictLabels1 = predict(NBModel1,X);  
[ConfusionMat1,labels] = confusionmat(y,predictLabels1)
```

```
ConfusionMat1 =
```

```
    50     0     0  
     0    47     3  
     0     3    47
```

```
labels =
```

```
    'setosa'  
    'versicolor'  
    'virginica'
```

Element ( $j$ ,  $k$ ) of `ConfusionMat1` represents the number of observations that the software classifies as  $k$ , but the data show as being in class  $j$ .

Retrain the classifier using the Gaussian distribution for predictors 1 and 3 (the sepal and petal widths), and the default normal kernel density for predictors 2 and 4 (the sepal and petal lengths).

```
NBModel2 = fitNaiveBayes(X,y,...  
    'Distribution',{'normal','kernel','normal','kernel'});  
NBModel2.Params{1,2}
```

```
ans =
```

```
KernelDistribution
```

# fitNaiveBayes

---

```
Kernel = normal  
Bandwidth = 0.179536  
Support = unbounded
```

The software does not train parameters to the kernel density. The software chooses an optimal bandwidth. However, you can specify a bandwidth using the 'KSWidth' name-value pair argument.

Estimate the confusion matrix for NBModel2.

```
predictLabels2 = predict(NBModel2,X);  
ConfusionMat2 = confusionmat(y,predictLabels2)
```

```
ConfusionMat2 =  
  
    50     0     0  
     0    47     3  
     0     3    47
```

The two classifiers perform similarly.

## **Train Naive Bayes Classifiers Using Multinomial Predictors**

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, if you assume that the predictors are independent, then they are multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to y for each email.

```
n = 1000; % Sample size
rng(1); % For reproducibility
y = randsample([-1 1],n,true); % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```
tokenProbs = [0.2 0.3 0.1 0.15 0.25;...
              0.4 0.1 0.3 0.05 0.15]; % Token relative frequencies
tokensPerEmail = 20;
X = zeros(n,5);
X(y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(y == 1));
X(y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(y == -1));
```

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
NBModel = fitNaiveBayes(X,y,'Distribution','mn');
```

NBModel is a trained NaiveBayes classifier.

Assess the in-sample performance of NBModel by estimating the misclassification rate.

```
predSpam = predict(NBModel,X);
misclass = sum(y'~=predSpam)/n
```

```
misclass =
0.0200
```

The in-sample misclassification rate is 2%.

# fitNaiveBayes

---

Randomly generate deviates that represent a new batch of emails.

```
nOut = 500;
yOut = randsample([-1 1],nOut,true);
XOut = zeros(nOut,5);
XOut(yOut == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),...
    sum(yOut == 1));
XOut(yOut == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),...
    sum(yOut == -1));
```

Classify the new emails using the trained naive Bayes classifier NBMModel, and determine whether the algorithm generalizes.

```
predSpamOut = predict(NBMModel,XOut);
genRate = sum(yOut' ~= predSpamOut)/nOut
```

```
genRate =
    0.0260
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

## Tips

- For classifying count-based data, such as the bag-of-tokens model, use the multinomial distribution (e.g., set 'Distribution','mn').
- This list defines the order of the classes. It is useful when you specify prior probabilities by setting 'Prior',prior, where prior is a numeric vector.
  - If Y is a categorical array, then the order of the class levels matches the output of categories(Y).
  - If Y is a numeric or logical vector, then the order of the class levels matches the output of sort(unique(Y)).

- For cell arrays of string and character arrays, the order of the class labels is the order which each label appears in  $Y$ .

## Definitions

### Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor  $j$  is the nonnegative number of occurrences of token  $j$  in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, i.e., the number of predictors.

## Algorithms

- If you specify 'Distribution', 'mn', then the software considers each observation as multiple trials of a multinomial distribution, and considers each occurrence of a token as one trial (see “Bag-of-Tokens Model” on page 21-1411).
- If you specify 'Distribution', 'mvmn', then the software assumes each individual predictor follows a multinomial model within a class. The parameters for a predictor include the probabilities of all possible values that the corresponding feature can take.

# ClassificationSVM.fitPosterior

---

**Purpose** Fit posterior probabilities

**Syntax**

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] =
fitPosterior(SVMModel,Name,Value)
```

**Description** `ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function.
- If the classes are perfectly separable, then the transformation function is the step function.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score transformation function in `ScoreSVMModel.ScoreTransform`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`).

[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value) returns the optimal score-to-posterior-probability transformation function and its parameters with additional options specified by one or more Name,Value pair arguments.

## Tips

Here is one way to predict positive class posterior probabilities.

- 1** Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as, `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to none.
- 2** Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMModel`, is the same, trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3** Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

## Input Arguments

### **SVMModel - Trained SVM classifier**

ClassificationSVM classifier

Trained SVM classifier, specified as a `ClassificationSVM`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# ClassificationSVM.fitPosterior

---

specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## 'CVPartition' - Cross-validation partition

cvpartition partition | [] (default)

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a cvpartition partition as created by cvpartition. You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

crossval splits the data into subsets using cvpartition.

## 'Holdout' - Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Holdout',0.1

## Data Types

double | single

## 'Kfold' - Number of folds

10 (default) | positive integer value

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'KFold',8

## Data Types

single | double

## 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Leaveout', 'on'

## Output Arguments

### ScoreSVMModel - Trained SVM classifier

ClassificationSVM classifier

Trained SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a ClassificationSVM classifier.

To estimate posterior probabilities for the training set observations, pass ScoreSVMModel to resubPredict.

To estimate posterior probabilities for new observations, then pass them and ScoreSVMModel to predict. If you set 'Standardize', true in fitsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

### ScoreTransform - Optimal score transformation function parameters

# ClassificationSVM.fitPosterior

---

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field `Type` is `sigmoid`, then `ScoreTransform` has the following other fields:
  - `Slope`: The value of  $A$  in the sigmoid function
  - `Intercept`: The value of  $B$  in the sigmoid function
- If field `Type` is `step`, then `ScoreTransform` has the following other fields:
  - `PositiveClassProbability`: The value of  $\pi$  in the step function. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval  $(\text{LowerBound}, \text{UpperBound})$ .
  - `LowerBound`: The value  $\max s_n$  in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class 0.
  - `UpperBound`: The value  $\min s_n$  in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class 1.

- If field `Type` is constant, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`.  
The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

## Definitions

### Sigmoid Function

The sigmoid function that maps score  $s_j$  corresponding to observation  $j$  to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters  $A$  and  $B$  correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

### Step Function

The step function that maps score  $s_j$  corresponding to observation  $j$  to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- $s_j$  the score of observation  $j$ .
- $+1$  and  $-1$  denote the positive and negative classes, respectively.
- $\pi$  is the prior probability that an observation is in the positive class.

# ClassificationSVM.fitPosterior

---

If the output argument `ScoreTransform.Type` is `step`, then the

quantities  $\max_k s_k$  and  $\min_k s_k$  correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

## Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

## Examples

### Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVModel` is a `ClassificationSVM` classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility  
ScoreSVModel = fitPosterior(SVModel)
```

```
ScoreSVModel =
```

```
ClassificationSVM  
PredictorNames: {1x34 cell}  
ResponseName: 'Y'
```

# ClassificationSVM.fitPosterior

```
ClassNames: {'b' 'g'}
ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
NumObservations: 351
Alpha: [90x1 double]
Bias: -0.1343
KernelParameters: [1x1 struct]
Mu: [1x34 double]
Sigma: [1x34 double]
BoxConstraints: [351x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [351x1 logical]
Solver: 'SMO'
```

Since the classes are inseparable, the score transformation function (`ScoreSVMModel.ScoreTransform`) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
      {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

ans =

TrueLabel	PredictedLabel	Score	PosteriorProbability
'g'	'g'	1.4861	0.82215
'b'	'b'	-1.0004	0.30436
'g'	'g'	1.8685	0.86916
'b'	'b'	-2.6458	0.084183
'g'	'g'	1.2805	0.79184
'b'	'b'	-1.4617	0.22028

# ClassificationSVM.fitPosterior

---

'g'	'g'	2.1672	0.89814
'b'	'b'	-5.7085	0.0050122
'g'	'g'	2.4797	0.92223
'b'	'b'	-2.7811	0.074805

## Plot Posterior Probability Contours for Multiple Classes Using SVM

This example uses one-versus-all (OVA) classification to train a multi-class SVM classifier, and plots probability contours for each class.

Load Fisher's iris data set. Use the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal length');
ylabel('Petal width');
legend('Location','Northwest');
axis tight
```

Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. It is good practice to define the class order and standardize the predictors.

```
classNames = {'setosa'; 'virginica'; 'versicolor'};  
numClasses = size(classNames,1);  
inds = cell(3,1); % Preallocation  
SVMModel = cell(3,1);
```

# ClassificationSVM.fitPosterior

---

```
rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j}); % OVA classification
    SVMModel{j} = fitsvm(X,inds{j},'ClassNames',[false true],...
        'Standardize',true,'KernelFunction','rbf','KernelScale','auto');
end
```

`fitsvm` uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```
for j = 1:numClasses
    SVMModel{j} = fitPosterior(SVMModel{j});
end
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```
d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
```

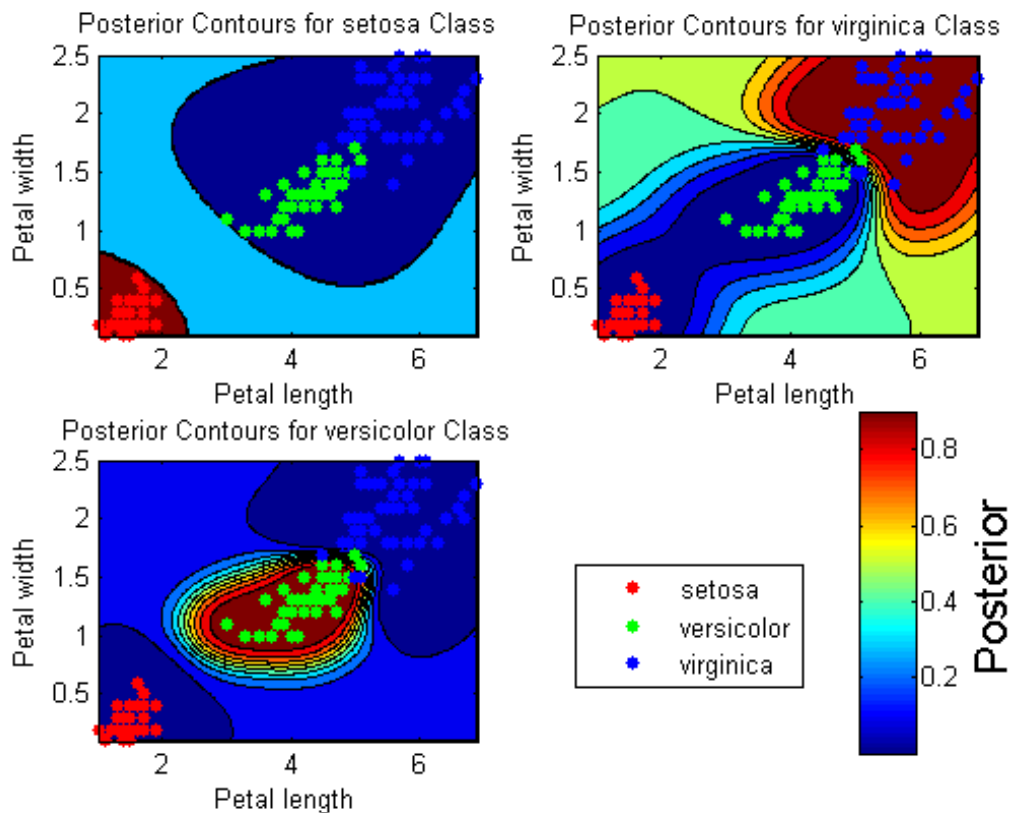

```
posterior = cell(3,1);
for j = 1:numClasses
    [~,posterior{j}] = predict(SVMModel{j},xGrid);
end
```

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```
figure
h = zeros(numClasses + 1,1); % Preallocation for graphics handles
```

```
for j = 1:numClasses
    subplot(2,2,j)
    contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x2Grid,1)))
    hold on
    h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);
    title(sprintf('Posterior Contours for %s Class',classNames{j}));
    xlabel('Petal length');
    ylabel('Petal width');
    legend off
    axis tight
    hold off
end
h(numClasses + 1) = colorbar('Location','EastOutside',...
    'Position',[0.8,0.1,0.05,0.4]);
set(get(h(numClasses + 1),'YLabel'),'String','Posterior','FontSize',10);
legend(h(1:numClasses),'Location',[0.6,0.2,0.1,0.1]);
```

# ClassificationSVM.fitPosterior

## Fit Optimal Posterior Probability Function Using Holdout Cross Validation

Platt (2000) outlines a bias-reducing method of estimating the score-to-posterior-probability transformation function. This method estimates the transformation function after the SVM classifier is trained, and uses cross validation to reduce bias. By default, `fitPosterior` and `fitSVMPosterior` use 10-fold cross validation when they estimate the transformation function. To reduce run time for larger data sets, you can specify to use holdout cross validation instead.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVModel is a ClassificationSVM classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function. For comparison, use 10-fold cross validation (default) and specify a 10% holdout test sample.

```
rng(1); % For reproducibility

tic; % Start the stopwatch
SVModel_10FCV = fitPosterior(SVModel);
toc % Stop the stopwatch and display the run time

tic;
SVModel_HO = fitPosterior(SVModel,'Holdout',0.10);
toc
```

```
Elapsed time is 1.037328 seconds.
```

```
Elapsed time is 0.203447 seconds.
```

Though both runtimes are short because the data set is relatively small, SVModel\_HO fitted the score transformation function much faster than SVModel\_10FCV.

## Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not none, then the software:

- Displays a warning

# ClassificationSVM.fitPosterior

---

- Resets the original transformation function to 'none' before estimating the new one

## Alternatives

You can also fit the posterior probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

# CompactClassificationSVM.fitposterior

---

## Purpose

Fit posterior probabilities

## Syntax

```
ScoreSVMModel = fitPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,X,Y)
```

## Description

`ScoreSVMModel = fitPosterior(SVMModel,X,Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMModel`, and by conducting 10-fold cross validation using the stored predictor data (`SVMModel.X`) and the class labels (`SVMModel.Y`) as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function.
- If the classes are perfectly separable, the transformation function is the step function.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function. `fitPosterior` is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

```
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,X,Y)
```

additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`)

# CompactClassificationSVM.fitposterior

---

## Tips

Here is one way to predict positive class posterior probabilities.

- 1** Train an SVM classifier by passing the data to `fitsvm`. The result is a trained SVM classifier, such as, `SVModel`, that stores the data. The software sets the score transformation function property (`SVModel.ScoreTransformation`) to `none`.
- 2** Pass the trained SVM classifier `SVModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVModel`, is the same, trained SVM classifier as `SVModel`, except the software sets `ScoreSVModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3** Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

## Input Arguments

### **SVModel - Trained, compact SVM classifier**

`CompactClassificationSVM` classifier

Trained, compact SVM classifier, specified as a `CompactClassificationSVM`.

### **X - Predictor data**

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows of X must be equal.

If you set 'Standardize', true in fitcsvm to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

## Data Types

double | single

## Y - Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If Y is a character array, then each element must correspond to one class label.

The length of Y and the number of rows of X must be equal.

## Output Arguments

### ScoreSVMModel - Trained, compact SVM classifier

CompactClassificationSVM classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a CompactClassificationSVM classifier.

To estimate posterior probabilities, pass ScoreSVMModel and predictor data to predict. If you set 'Standardize', true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

### ScoreTransform - Optimal score transformation function parameters

structure array

# CompactClassificationSVM.fitposterior

---

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If field `Type` is `sigmoid`, then `ScoreTransform` has the following other fields:
  - `Slope`: The value of  $A$  in the sigmoid function
  - `Intercept`: The value of  $B$  in the sigmoid function
- If field `Type` is `step`, then `ScoreTransform` has the following other fields:
  - `PositiveClassProbability`: The value of  $\pi$  in the step function. It represents the probability that an observation is in the positive class. Also, the posterior probability that an observation is in the positive class given that its score is in the interval `(LowerBound,UpperBound)`.
  - `LowerBound`: The value  $\max s_n$  in the step function. It represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being the positive class 0.
  - `UpperBound`: The value  $\min s_n$  in the step function. It represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being the positive class 1.
- If field `Type` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`.  
The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

## Definitions

### Sigmoid Function

The sigmoid function that maps score  $s_j$  corresponding to observation  $j$  to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters  $A$  and  $B$  correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

### Step Function

The step function that maps score  $s_j$  corresponding to observation  $j$  to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- $s_j$  the score of observation  $j$ .
- $+1$  and  $-1$  denote the positive and negative classes, respectively.
- $\pi$  is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the

quantities  $\max_{y_k=-1} s_k$  and  $\min_{y_k=+1} s_k$  correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

# CompactClassificationSVM.fitposterior

---

## Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

## Examples

### Estimate Posterior Probabilities for New Data When Classes Are Inseparable

Load the ionosphere data set. Reserve 20 random observations of the data, and consider this set new data.

```
load ionosphere
n = size(X,1);
rng(1); % For reproducibility
```

```
indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
```

The classes of this data set are inseparable.

Train an SVM classifier using the training data. It is good practice to specify the class order and standardize the data.

```
SVMMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
    'Standardize',true);
```

SVMMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as g. For efficiency, make a compact version of the SVM classifier SVMMModel, and pass it and the new data to fitPosterior.

```
CompactSVMMModel = compact(SVMMModel);
```

# CompactClassificationSVM.fitposterior

```
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...  
X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMModel.ScoreTransform  
ScoreParameters
```

```
ScoreTransform =
```

```
@(S)sigmoid(S,-1.098922e+00,4.519963e-01)
```

```
ScoreParameters =
```

```
    Type: 'sigmoid'  
    Slope: -1.0989  
    Intercept: 0.4520
```

ScoreTransform is the optimal score transform function.  
ScoreParameters is a structure array having three fields: the score transformation function name (Type), the sigmoid slope (Slope) and sigmoid intercept (Intercept) estimates.

Alternatively, you can pass SVMModel and the new data to fitSVMPosterior, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are in class g.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));  
table(Y(~indx),labels,postProbs(:,2),...  
    'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans =
```

```
    TrueLabel    PredictedLabel    PosteriorProbability
```

# CompactClassificationSVM.fitposterior

## Estimate Posterior Probabilities for New Data When Classes Are Separable

Load Fisher's iris data set. Use the petal lengths and widths, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);
```

```
rng(1); % For reproducibility
```

# CompactClassificationSVM.fitposterior

```
indx1 = 1:numel(species);  
indx2 = indx1(classKeep);  
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the train  
  
gscatter(X(indx,1),X(indx,2),Y(indx));  
title('Scatter Diagram of Iris Measurements')  
xlabel('Petal length')  
ylabel('Petal width')  
legend('Setosa','Versicolor')
```

# CompactClassificationSVM.fitposterior

---

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMMModel = fitcsvm(X(indx,:),Y(indx),...  
    'ClassNames',{'setosa','versicolor'],'Standardize',true);
```

SVMMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as versicolor. For efficiency, make a compact version of the SVM classifier SVMMModel, and pass it and the new data to fitPosterior.

```
CompactSVMMModel = compact(SVMMModel);  
[ScoreCSVMMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...  
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMMModel.ScoreTransform
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior  
transformation is a step function.
```

```
ScoreTransform =
```

```
@(S) step(S, -1.338450e+00, 2.012495e+00, 5.333333e-01)
```

fitPosterior displays a warning whenever the classes are separable, and stores the step function in ScoreSVMMModel.ScoreTransform.

Display the score function type and its estimated values.

```
ScoreParameters
```

# CompactClassificationSVM.fitposterior

```
ScoreParameters =  
  
                Type: 'step'  
            LowerBound: -1.3385  
            UpperBound: 2.0125  
    PositiveClassProbability: 0.5333
```

ScoreParameters is a structure array having four fields:

- The score transformation function type (Type)
- The score corresponding to negative class boundary (LowerBound)
- The score corresponding to positive class boundary (UpperBound)
- The positive class probability (PositiveClassProbability)

Alternatively, you can pass SVMModel and the new data to fitSVMPosterior, but this does not have the benefit of efficiency.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));  
table(Y(~indx),labels,postProbs(:,2),...  
      'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans =
```

TrueLabel	PredictedLabel	PosteriorProbability
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0
'setosa'	'setosa'	0

# CompactClassificationSVM.fitposterior

---

```
'setosa'      'setosa'      0
'setosa'      'setosa'      0
'setosa'      'setosa'      0
'setosa'      'setosa'      0
'versicolor'  'versicolor'  1
'versicolor'  'versicolor'  1
```

Since the classes are separable, the step function transforms the positive-class score to:

- 0, if the score is less than `ScoreParameters.LowerBound`
- 1, if the score is greater than `ScoreParameters.UpperBound`
- `ScoreParameters.PositiveClassProbability`, if the score is in the interval `[ ScoreParameters.LowerBound , ScoreParameters.LowerBound]`

## Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to `'none'` before estimating the new one

## Alternatives

You can also estimate the optimal score-to-posterior-probability function using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad since it accepts a wider range of SVM classifier types.

`CompactClassificationSVM` | `predict` | `fitSVMPosterior` | `fitsvm`

# fitrtree

---

**Purpose** Binary decision tree for regression

**Syntax**  
`tree = fitrtree(x,y)`  
`tree = fitrtree(x,y,Name,Value)`

**Description** `tree = fitrtree(x,y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. The returned tree is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = fitrtree(x,y,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments. For example, you can grow a cross-validated tree, hold out a fraction of data for validation, or specify observation weights.

## Input Arguments

**x - Predictor values**  
matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of `x` represents one variable, and each row represents one observation.

`fitrtree` considers NaN values in `x` as missing values. `fitrtree` does not use observations with all missing values for `x` in the fit. `fitrtree` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

**Data Types**  
single | double

**y - Response values**  
vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

`fitrtree` considers NaN values in `y` to be missing values. `fitrtree` does not use observations with missing values for `y` in the fit.

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

**Example:** `'CrossVal','on','MinParent',30` specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

**'CategoricalPredictors' - Categorical predictors list**numeric or logical vector | cell array of strings | character matrix  
| 'all'

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of `x`.
- A logical vector of length `p`, where a true entry means that the corresponding column of `x` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

**Data Types**

single | double | logical | char | cell

**'CrossVal' - Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', fitrtree grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these arguments at a time when creating a cross-validated tree.

Alternatively, cross validate tree later using the crossval method.

**Example:** 'CrossVal','on'

## **'CVPartition' - Partition for cross-validated tree**

cvpartition object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using cvpartition.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

## **'Holdout' - Fraction of data for holdout validation**

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

## **Data Types**

single | double

## **'KFold' - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

### Data Types

single | double

### 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Specify 'on' to use leave-one-out cross validation.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

### 'MergeLeaves' - Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. If you specify 'on', then fitrtree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. If you specify 'off', then fitrtree does not merge leaves.

**Example:** 'MergeLeaves', 'off'

### 'MinLeaf' - Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer

value. Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `fitrtree` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

**Example:** `'MinLeaf',3`

### **Data Types**

`single` | `double`

### **'MinParent' - Minimum number of branch node observations**

`10` (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of `'MinParent'` and a positive integer value. Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `fitrtree` uses the setting that gives larger leaves: `MinParent=max(MinParent,2*MinLeaf)`.

**Example:** `'MinParent',8`

### **Data Types**

`single` | `double`

### **'NVarToSample' - Number of predictors for split**

`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

**Example:** `'NVarToSample',3`

### **Data Types**

`single` | `double`

### **'PredictorNames' - Predictor variable names**

`{'x1','x2',...}` (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of strings containing

the names for the predictor variables, in the order in which they appear in  $x$ .

### Data Types

cell

#### 'Prune' - Pruning flag

'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', fitrtree computes the full tree and the optimal sequence of pruned subtrees. When 'off' fitrtree computes the full tree without pruning.

**Example:** 'Prune', 'off'

#### 'PruneCriterion' - Pruning criterion

'mse'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

**Example:** 'PruneCriterion', 'mse'

#### 'QEToler' - Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when the quadratic error per node drops below  $QEToler * QED$ , where QED is the quadratic error for all data computed before the decision tree is grown.

**Example:** 'QEToler', 1e-4

#### 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable in  $y$ .

**Example:** 'ResponseName', 'Response'

## Data Types

char

## 'ResponseTransform' - Response transform function

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

## Data Types

function\_handle

## 'SplitCriterion' - Split criterion

'MSE'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

**Example:** 'SplitCriterion', 'MSE'

## 'Surrogate' - Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and one of 'on', 'off', 'all', or a positive integer value.

- When 'on', fitrtree finds at most 10 surrogate splits at each branch node.

- When set to a positive integer value, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `fitrtree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors.

**Example:** 'Surrogate', 'on'

#### Data Types

single | double

#### 'Weights' - Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of Weights is the number of rows in `x`.

#### Data Types

single | double

## Output Arguments

#### **tree** - Regression tree

regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

## Examples

### Construct a Regression Tree

Load the sample data.

# fitrtree

---

```
load carsmall
```

Construct a regression tree using the sample data.

```
tree = fitrtree([Weight,Cylinders],MPG,'MinParent',20,...  
               'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree  
    PredictorNames: {'W' 'C'}  
    ResponseName: 'Y'  
    ResponseTransform: 'none'  
    CategoricalPredictors: []  
    NumObservations: 94
```

Properties, Methods

Use the regression tree to predict the mileage of a car that weighs 2200 lbs and has four cylinders.

```
predict(tree,[2200,4])
```

```
ans =  
    29.6111
```

## Concepts

- “Splitting Categorical Predictors” on page 16-61

## Purpose

Fit posterior probabilities

## Syntax

```
ScoreSVMMModel = fitSVMPosterior(SVMMModel)
ScoreSVMMModel = fitSVMPosterior(SVMMModel,Name,Value)
ScoreSVMMModel = fitSVMPosterior(SVMMModel,X,Y)
[ScoreSVMMModel,ScoreTransform] = fitSVMPosterior( ___ )
```

## Description

`ScoreSVMMModel = fitSVMPosterior(SVMMModel)` returns `ScoreSVMMModel`, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMMModel`, and by cross validation using the stored predictor data (`SVMMModel.X`) and the class labels (`SVMMModel.Y`). The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMMModel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function.
- If the classes are perfectly separable, the transformation function is the step function.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function. `fitSVMPosterior` is not appropriate for one-class learning.
- If `SVMMModel` is a `ClassificationSVM` classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, `SVMMModel` must be a `ClassificationPartitionedModel` classifier. `SVMMModel` specifies the cross-validation method.
- The software stores the optimal transformation function in `ScoreSVMMModel.ScoreTransform`.

# fitSVMPosterior

---

`ScoreSVMModel = fitSVMPosterior(SVMModel,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments provided `SVMModel` is a `ClassificationSVM` classifier.

For example, you can specify the number of folds to use in *k*-fold cross validation.

`ScoreSVMModel = fitSVMPosterior(SVMModel,X,Y)` returns a trained, support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMModel`. The software estimates the score transformation function using predictor data `X` and class labels `Y`.

`[ScoreSVMModel,ScoreTransform] = fitSVMPosterior( ___ )` additionally returns the transformation function parameters (`ScoreTransform`) using any of the input arguments in the previous syntaxes.

## Input Arguments

### **SVMModel - Trained SVM classifier**

`ClassificationSVM` classifier | `CompactClassificationSVM` classifier  
| `ClassificationPartitionedModel` classifier

Trained SVM classifier, specified as a `ClassificationSVM`, `CompactClassificationSVM`, or `ClassificationPartitionedModel` classifier.

If `SVMModel` is a `ClassificationSVM` classifier, then you can set optional name-value pair arguments.

If `SVMModel` is a `CompactClassificationSVM` classifier, then you must input predictor data `X` and class labels `Y`.

### **X - Predictor data**

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of  $X$  corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of  $Y$  and the number of rows of  $X$  must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of  $X$  using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`. If the software fits the transformation-function parameter estimates using standardized data, then the estimates might differ from estimation without standardized data.

## Data Types

double | single

## Y - Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical or character array, logical or numeric vector, or cell array of strings.

If  $Y$  is a character array, then each element must correspond to one class label.

The length of  $Y$  and the number of rows of  $X$  must be equal.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'KFold', 8` performs 8-fold cross validation when `SVMModel` is a `ClassificationSVM` classifier.

## 'CVPartition' - Cross-validation partition

`cvpartition partition | []` (default)

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

`crossval` splits the data into subsets using `cvpartition`.

### **'Holdout' - Fraction of data for holdout validation**

scalar value in the range (0,1)

Fraction of data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Holdout',0.1

### **Data Types**

double | single

### **'Kfold' - Number of folds**

10 (default) | positive integer value

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Kfold',8

## Data Types

single | double

## 'Leaveout' - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross validation by using 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

**Example:** 'Leaveout', 'on'

## Output Arguments

### ScoreSVMModel - Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier  
| ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

The ScoreSVMModel classifier type is the same as the SVMModel classifier type.

To estimate posterior probabilities, pass ScoreSVMModel and predictor data to predict. If you set 'Standardize', true in fitcsvm to train SVMModel, then predict standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

### ScoreTransform - Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field `Type` is:

- `sigmoid`, then `ScoreTransform` has these fields:
  - `Slope` — The value of  $A$  in the sigmoid function
  - `Intercept` — The value of  $B$  in the sigmoid function
- `step`, then `ScoreTransform` has these fields:
  - `PositiveClassProbability`: the value of  $\pi$  in the step function.  $\pi$  represents:
    - The probability that an observation is in the positive class.
    - The posterior probability that a score is in the interval `(LowerBound,UpperBound)`.
  - `LowerBound`: the value  $\max_{y=+1} s_n$  in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability` to scores. Any observation with a score less than `LowerBound` has posterior probability of being the positive class 0.
  - `UpperBound`: the value  $\min_{y=+1} s_n$  in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has posterior probability of being the positive class 1.
- `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`.  
The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

## Examples

### Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
y = species(classKeep);

gscatter(X(:,1),X(:,2),y);
title('Scatter Diagram of Iris Measurements')
xlabel('Petal length')
ylabel('Petal width')
legend('Setosa','Versicolor')
```

# fitSVMPosterior

The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```
rng(1);  
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior transformation is a step function.
```

fitSVMPosterior does the following:

- Uses the data that the software stored in CVSVMModel to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in ScoreCVSVMModel.ScoreTransform

Display the score function type and its parameter values.

ScoreParameters

```
ScoreParameters =  
  
                Type: 'step'  
            LowerBound: -0.8431  
            UpperBound: 0.6897  
    PositiveClassProbability: 0.5000
```

ScoreParameters is a structure array with four fields:

- The score transformation function type (Type)
- The score corresponding to the negative class boundary (LowerBound)
- The score corresponding to the positive class boundary (UpperBound)
- The positive class probability (PositiveClassProbability)

# fitSVMPosterior

---

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.

## Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the ionosphere data set.

```
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true,...
    'CrossVal','on');
ScoreTransform = CVSVMModel.ScoreTransform
```

```
ScoreTransform =
```

```
none
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
ScoreParameters
```

```
ScoreTransform =  
  
@(S) sigmoid(S, -9.481576e-01, -1.218300e-01)  
  
ScoreParameters =  
  
    Type: 'sigmoid'  
    Slope: -0.9482  
    Intercept: -0.1218
```

`ScoreTransform` is the optimal score transform function. `ScoreParameters` contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing `ScoreCVSVMModel` to `kfoldPredict`.

## Estimate Posterior Probabilities for Test Samples

Determine positive class posterior probabilities for the test set of an SVM algorithm.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility  
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...  
    'ClassNames',{'b','g'});
```

`CVSVMModel` is a trained `ClassificationPartitionedModel` cross-validated classifier.

# fitSVMPosterior

---

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

ScoreSVMModel is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);  
indx = ~isnan(OOSPostProbs(:,2));  
hoObs = find(indx); % Holdout observation numbers  
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];  
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...  
      'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

ans =

ObservationIndex	PosteriorProbability
6	0.17378
7	0.89637
8	0.0076609
9	0.91602
16	0.026718
22	4.6081e-06
23	0.9024
24	2.4129e-06
38	0.00042697
41	0.86427

## Tips

Here is one way to predict positive class posterior probabilities.

- 1 Train an SVM classifier by passing the data to `fitsvm`. The result is a trained SVM classifier, such as, `SVMMModel`, that stores the data. The software sets the score transformation function property (`SVMMModel.ScoreTransformation`) to `none`.
- 2 Pass the trained SVM classifier `SVMMModel` to `fitSVMPosterior` or `fitPosterior`. The result, for example, `ScoreSVMMModel`, is the same, trained SVM classifier as `SVMMModel`, except the software sets `ScoreSVMMModel.ScoreTransformation` to the optimal score transformation function.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- 3 Pass the trained SVM classifier containing the optimal score transformation function (`ScoreSVMMModel`) and predictor data matrix to `predict`. The second column of the second output argument stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

## Algorithms

If you reestimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

## Definitions

### Sigmoid Function

The sigmoid function that maps score  $s_j$ , corresponding to observation  $j$  to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the output argument `ScoreTransform.Type` is `sigmoid`, then parameters  $A$  and  $B$  correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

## Step Function

The step function that maps score  $s_j$  corresponding to observation  $j$  to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- $s_j$  the score of observation  $j$ .
- $+1$  and  $-1$  denote the positive and negative classes, respectively.
- $\pi$  is the prior probability that an observation is in the positive class.

If the output argument `ScoreTransform.Type` is `step`, then the

quantities  $\max_{y_k=-1} s_k$  and  $\min_{y_k=+1} s_k$  correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

## Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

# LinearMixedModel.fitted

---

**Purpose** Fitted responses from a linear mixed-effects model

**Syntax**  
`yfit = fitted(lme)`  
`yfit = fitted(lme,Name,Value)`

**Description** `yfit = fitted(lme)` returns the fitted conditional response from the linear mixed-effects model `lme`.

`yfit = fitted(lme,Name,Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Conditional' - Indicator for conditional response**

`True` (default) | `False`

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

**Example:** 'Conditional','False'

## Output Arguments

### **yfit - Fitted response values**

*n*-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

## Examples

### **Compute Fitted Conditional and Marginal Responses**

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

# LinearMixedModel.fitted

---

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by Date.

Region is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example,  $I[MidAtl]$  is the dummy variable representing the region MidAtl. For details, see “Dummy Indicator Variables” on page 2-56.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SAtl]_i + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable Date,  $\beta_j$ ,  $j = 0, 1, \dots, 8$ , are the fixed-effects coefficients, with  $\beta_0$  being the coefficient for region NE.  $b_{0m}$  is the random effect for level  $m$  of the grouping variable Date, and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b_{0m} \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon_{im} \sim N(0, \sigma^2)$ .

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

```
FluRate ~ 1 + Region + (1|Date)
```

Model fit statistics:

# LinearMixedModel.fitted

AIC	BIC	LogLikelihood	Deviance
318.71	364.35	-148.36	296.71

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'(Intercept)'	1.2233	0.096678	12.654	459
'Region_MidAtl'	0.010192	0.052221	0.19518	459
'Region_ENCentral'	0.051923	0.052221	0.9943	459
'Region_WNCentral'	0.23687	0.052221	4.5359	459
'Region_SAtl'	0.075481	0.052221	1.4454	459
'Region_ESCentral'	0.33917	0.052221	6.495	459
'Region_WSCentral'	0.069	0.052221	1.3213	459
'Region_Mtn'	0.046673	0.052221	0.89377	459
'Region_Pac'	-0.16013	0.052221	-3.0665	459

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.6443

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The  $p$ -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term,  $\sigma^2_b$ , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

# LinearMixedModel.fitted

---

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

y_hat =

    1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for  $\beta_0$  and `beta(4)` corresponds to the estimate for  $\beta_3$ . You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')

ans =

    1.2884
```

The estimated marginal response for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005}^{(\text{marginal})} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme, 'Conditional', false);
```

```
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

```
1.4602
```

## Plot Residuals vs. Fitted Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);
R = residuals(lme);
```

Plot the residuals versus the fitted values.

# LinearMixedModel.fitted

---

```
plot(F,R,'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();  
gscatter(F,R,Program)
```

## Definitions

### Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model,  $lme$ , has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also, suppose the  $p$ -by-1 estimated fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1

# LinearMixedModel.fitted

---

estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

# LinearMixedModel.fixedEffects

---

**Purpose** Estimates of fixed effects and related statistics

**Syntax**

```
beta = fixedEffects(lme)
[beta,betanames] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme)
[beta,betanames,stats] = fixedEffects(lme,Name,Value)
```

**Description** `beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betanames] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betanames`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betanames,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betanames,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

## 'Alpha' - Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value  $\alpha$ , the confidence level is  $100*(1-\alpha)\%$ .

For example, for 99% confidence intervals, you can specify the confidence level as follows.

**Example:** `'Alpha', 0.01`

## Data Types

single | double

## 'DFMethod' - Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom for the  $t$ -statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'Residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$ , where $n$ is the number of observations and $p$ is the number of fixed effects.
'Satterthwaite'	Satterthwaite approximation.
'None'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

# LinearMixedModel.fixedEffects

---

Example: 'DFMethod', 'Satterthwaite'

## Output Arguments

### **beta - Fixed-effects coefficients estimates**

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

### **betanames - Names of fixed-effects coefficients**

table

Names of fixed-effects coefficients in `beta`, returned as a table.

### **stats - Fixed-effects estimates and related statistics**

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed effect coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effect coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effect coefficient

## Examples

### Display Fixed-Effects Coefficient Estimates and Names

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = tbl(InitWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```
[beta,betaname] = fixedEffects(lme);
```

```
beta =
    0.6610
    0.0032
    0.3608
   -0.0333
```

# LinearMixedModel.fixedEffects

---

```
0.1132
0.1732
0.0388
0.0305
0.0331
```

```
betanames =
```

```
Name
'(Intercept) '
'InitWeight '
'Program_B '
'Program_C '
'Program_D '
'Week '
'Program_B:Week '
'Program_C:Week '
'Program_D:Week '
```

## Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF
'(Intercept)'	50.133	2.2652	22.132	389
'Acceleration'	-0.58327	0.13394	-4.3545	389
'Horsepower'	-0.16954	0.0072609	-23.35	389

The small  $p$ -values (under `pValue`) indicate that all fixed-effects coefficients are significant.

## Compute Confidence Intervals with Specified Options

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load shift
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

# LinearMixedModel.fixedEffects

---

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift,'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme,'alpha',0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	12	0.004
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0.4
'Shift_Night'	1.9856	0.48344	4.1072	12	0.001

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme,'DFMethod','Satterthwaite','alpha',0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	6.123	0.
'Shift_Morning'	-0.3868	0.48344	-0.80009	10	0.
'Shift_Night'	1.9856	0.48344	4.1072	10	0.

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger  $p$ -values (pValue) and larger confidence intervals (see Lower and Upper).

**Purpose** *F* probability density function

**Syntax** `Y = fpdf(X,V1,V2)`

**Description** `Y = fpdf(X,V1,V2)` computes the *F* pdf at each of the values in *X* using the corresponding numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *X*, *V1*, and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. *V1* and *V2* parameters must contain real positive values, and the values in *X* must lie on the interval  $[0 \infty)$ .

The probability density function for the *F* distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right] \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} x^{\frac{v_1 - 2}{2}}}{\Gamma\left(\frac{v_1}{2}\right) \Gamma\left(\frac{v_2}{2}\right) \left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1 + v_2}{2}}}$$

## Examples

```
y = fpdf(1:6,2,2)
y =
    0.2500    0.1111    0.0625    0.0400    0.0278    0.0204
```

```
z = fpdf(3,5:10,5:10)
z =
    0.0689    0.0659    0.0620    0.0577    0.0532    0.0487

**Default:** {'X1', 'X2', ...}

## 'MaxInt'

Positive integer setting the maximum level of interaction to include in the confounding output.

**Default:** 2

## Output Arguments

### X

The two-level fractional factorial design. X is a matrix of size N-by-P, where

- $N = 2^K$ , where K is the number of letters of the alphabet in gen.
- P is the number of words in gen.

Because X is a two-level design, the components of X are  $-1$ . For the meaning of X, see “Fractional Factorial Designs” on page 18-5.

### conf

Cell array of strings containing the confounding pattern for the design.

## Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')
```

```
x =  
    -1    -1    -1    -1  
    -1    -1     1     1  
    -1     1    -1     1  
    -1     1     1    -1  
     1    -1    -1     1  
     1    -1     1    -1  
     1     1    -1    -1  
     1     1     1     1
```

---

Find generators for a six-factor design that uses four factors and achieves resolution IV using fracfactgen. Use the result to specify the design:

```
generators = fracfactgen('a b c d e f',4, ... % 4 factors
    4) % resolution 4
```

```
generators =
    'a'
    'b'
    'c'
    'd'
    'bcd'
    'acd'
```

```
x = fracfact(generators)
```

```
x =
    -1    -1    -1    -1    -1    -1
    -1    -1    -1     1     1     1
    -1    -1     1    -1     1     1
    -1    -1     1     1    -1    -1
    -1     1    -1    -1     1    -1
    -1     1    -1     1    -1     1
    -1     1     1     1     1    -1
     1    -1    -1    -1    -1     1
     1    -1    -1     1     1    -1
     1    -1     1    -1     1    -1
     1    -1     1     1    -1     1
     1     1    -1    -1     1     1
     1     1    -1     1    -1    -1
     1     1     1    -1    -1    -1
     1     1     1     1     1     1
```

# fracfact

## How To

- “Fractional Factorial Designs” on page 18-5

**Purpose**

Fractional factorial design generators

**Syntax**

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

**Description**

`generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a string consisting of words formed from the 52 case-sensitive letters a-z, separated by spaces. Use 'a' - 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-character words indicate main effects to be estimated; multiple-character words indicate interactions. Alternatively, `terms` is an  $m$ -by- $n$  matrix of 0s and 1s where  $m$  is the number of model terms to be estimated and  $n$  is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of strings with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with  $2^k$ -runs, if possible. If `k` is `[]`, `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is 3.

A design of *resolution R* is one in which no  $n$ -factor interaction is confounded with any other effect containing less than  $R - n$  factors. Thus a resolution III design does not confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model.

# fracfactgen

---

If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

## Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require  $2^4 = 16$  runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only  $2^3 = 8$  runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
  'a'
  'b'
  'c'
  'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
  -1  -1  -1  -1
  -1  -1   1   1
  -1   1  -1   1
  -1   1   1  -1
   1  -1  -1   1
   1  -1   1  -1
   1   1  -1  -1
   1   1   1   1
confounding =
  'Term'      'Generator'    'Confounding'
  'X1'        'a'             'X1'
  'X2'        'b'             'X2'
```

'X3'	'c'	'X3'
'X4'	'abc'	'X4'
'X1*X2'	'ab'	'X1*X2 + X3*X4'
'X1*X3'	'ac'	'X1*X3 + X2*X4'
'X1*X4'	'bc'	'X1*X4 + X2*X3'
'X2*X3'	'bc'	'X1*X4 + X2*X3'
'X2*X4'	'ac'	'X1*X3 + X2*X4'
'X3*X4'	'ab'	'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

## How To

- “Fractional Factorial Designs” on page 18-5

# friedman

---

**Purpose** Friedman's test

**Syntax**

```
p = friedman(X, reps)
p = friedman(X, reps, displayopt)
[p, table] = friedman(...)
[p, table, stats] = friedman(...)
```

**Description** `p = friedman(X, reps)` performs the nonparametric Friedman's test to compare column effects in a two-way layout. Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of  $X$  represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each "cell," which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where  $\mu$  is an overall location parameter,  $\alpha_i$  represents the column effect,  $\beta_j$  represents the row effect, and  $\varepsilon_{ijk}$  represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The  $p$  that `friedman` returns is the  $p$  value for the null hypothesis that  $\alpha_i = 0$ . If the  $p$  value is near zero, this casts doubt on the null hypothesis. A sufficiently small  $p$  value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical  $p$  value to determine whether a result is “statistically significant” is left to the researcher. It is common to declare a result significant if the  $p$  value is less than 0.05 or 0.01.

`friedman` also displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman’s chi-square statistic.
- The sixth shows the  $p$  value for the chi-square statistic.

`p = friedman(X, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p,table] = friedman(...)` returns the ANOVA table (including column and row labels) in cell array `table`. (You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the **Edit** menu.

`[p,table,stats] = friedman(...)` returns a `stats` structure that you can use to perform a follow-up multiple comparison test. The `friedman` test evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. Sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying the `stats` structure as input.

## Assumptions

Friedman's test makes the following assumptions about the data in `X`:

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

## Examples

### Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn  
popcorn
```

```
popcorn =  
  
    5.5000    4.5000    3.5000
```

5.5000	4.5000	4.0000
6.0000	4.0000	3.0000
6.5000	5.0000	4.0000
7.0000	5.5000	5.0000
7.0000	5.0000	4.5000

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```

```
p =
```

```
0.0010
```

Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	99.75	2	49.875	13.76	0.001
Interaction	0.0833	2	0.0417		
Error	16.1667	12	1.3472		
Total	116	17			

Test for column effects after row effects are removed

The small value of  $p = 0.001$  indicates the popcorn brand affects the yield of popcorn.

# frnd

---

**Purpose**  $F$  random numbers

**Syntax**  
R = frnd(V1,V2)  
R = frnd(V1,V2,m,n,...)  
R = frnd(V1,V2,[m,n,...])

**Description** R = frnd(V1,V2) generates random numbers from the  $F$  distribution with numerator degrees of freedom V1 and denominator degrees of freedom V2. V1 and V2 can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for V1 or V2 is expanded to a constant array with the same dimensions as the other input.

R = frnd(V1,V2,m,n,...) or R = frnd(V1,V2,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the  $F$  distribution with parameters V1 and V2. V1 and V2 can each be scalars or arrays of the same size as R.

**Examples**

```
n1 = frnd(1:6,1:6)
n1 =
    0.0022    0.3121    3.0528    0.3189    0.2715    0.9539

n2 = frnd(2,2,[2 3])
n2 =
    0.3186    0.9727    3.0268
    0.2052   148.5816    0.2191

n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
    0.6233    0.2322   31.5458
    2.5848    0.2121    4.4955
```

**See Also** random | fpdf | fcdf | finv | fstat

**How To** • “F Distribution” on page B-44

**Purpose***F* mean and variance**Syntax**`[M,V] = fstat(V1,V2)`**Description**

`[M,V] = fstat(V1,V2)` returns the mean of and variance for the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of *M* and *V*. A scalar input for *V1* or *V2* is expanded to a constant arrays with the same dimensions as the other input.

The mean of the *F* distribution for values of  $\nu_2$  greater than 2 is

$$\frac{\nu_2}{\nu_2 - 2}$$

The variance of the *F* distribution for values of  $\nu_2$  greater than 4 is

$$\frac{2\nu_2^2(\nu_1 + \nu_2 - 2)}{\nu_1(\nu_2 - 2)^2(\nu_2 - 4)}$$

The mean of the *F* distribution is undefined if  $\nu_2$  is less than 3. The variance is undefined for  $\nu_2$  less than 5.

**Examples**

`fstat` returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)
m =
    NaN    NaN    3.0000    2.0000    1.6667
v =
    NaN    NaN    NaN    NaN    8.8889
```

**How To**

- “F Distribution” on page B-44

# fsurfht

---

**Purpose** Interactive contour plot

**Syntax** `fsurfht(fun,xlims,ylims)`  
`fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)`

**Description** `fsurfht(fun,xlims,ylims)` is an interactive contour plot of the function specified by the text variable `fun`. The  $x$ -axis limits are specified by `xlims` in the form `[xmin xmax]`, and the  $y$ -axis limits are specified by `ylims` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylims,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current  $x$  value and  $y$  value. You can drag these reference lines and watch the calculated  $z$ -values (at the top of the plot) update simultaneously. Alternatively, you can type the  $x$  value and  $y$  value into editable text fields on the  $x$ -axis and  $y$ -axis.

**Examples** Plot the Gaussian likelihood function for the `gas.mat` data.

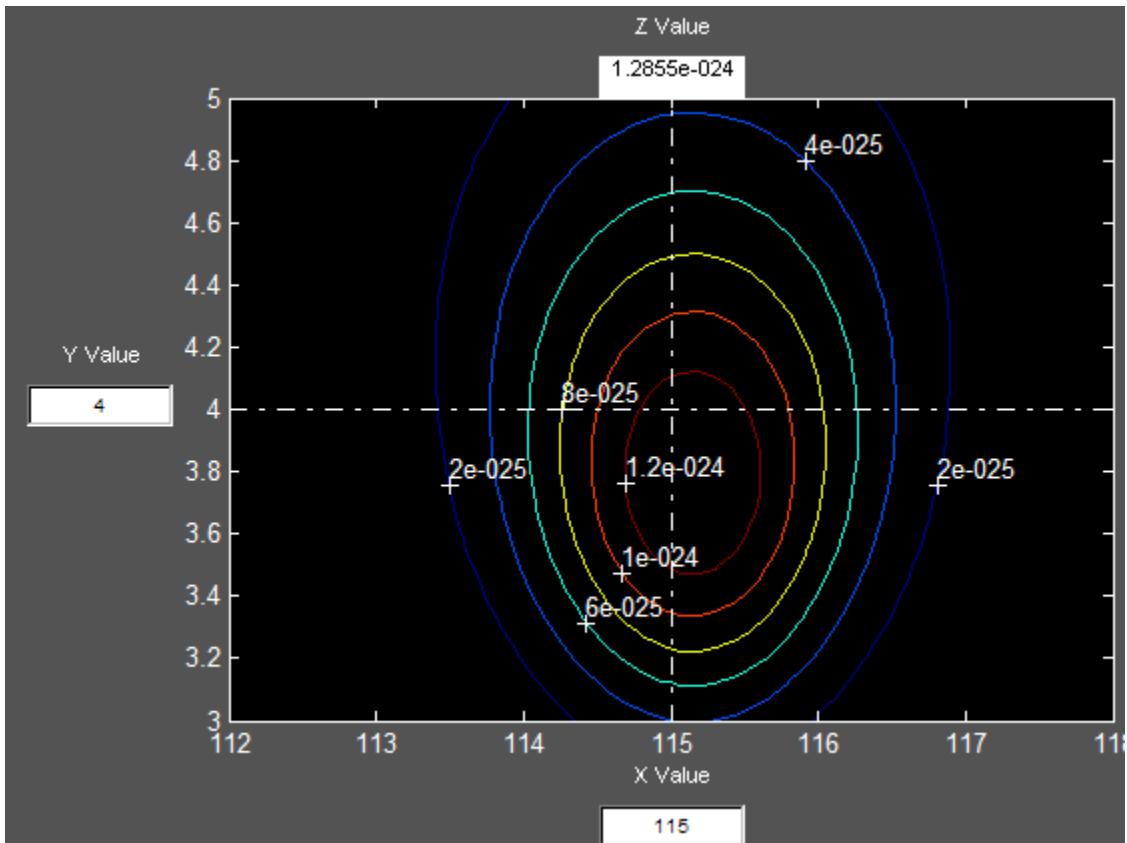

```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)
n = length(p1);
z = ones(size(mu));
for i = 1:n
z = z .* (normpdf(p1(i),mu,sigma));
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters  $\mu$  and  $\sigma$  as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],price1)
```

The sample mean is the x value at the maximum, but the sample standard deviation is *not* the y value at the maximum.

```

mumax = mean(price1)
mumax =
    115.1500
sigmax = std(price1)*sqrt(19/20)
sigmax =
    3.7719

```

**Purpose** Full factorial design

**Syntax** `dFF = fullfact(levels)`

**Description** `dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with  $n$  factors, where the number of levels for each factor is given by the vector `levels` of length  $n$ . `dFF` is  $m$ -by- $n$ , where  $m$  is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

**Examples** The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
     1     1
     2     1
     1     2
     2     2
     1     3
     2     3
     1     4
     2     4
```

**See Also** `ff2n`

# gagerr

---

**Purpose** Gage repeatability and reproducibility study

**Syntax**  
`gagerr(y, {part, operator})`  
`gagerr(y, GROUP)`  
`gagerr(y, part)`  
`gagerr(..., param1, val1, param2, val2, ...)`  
`[TABLE, stats] = gagerr(...)`

**Description** `gagerr(y, {part, operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, or cell arrays of strings. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 x standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If  $NDC > 5$ , the measurement system is capable.
- If  $NDC < 2$ , the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If  $PRR < 10\%$ , the measurement system is capable.

- If  $PRR > 30\%$ , the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y, GROUP)` performs a gage R&R study on measurements in `y` with part and operator represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y, part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(..., param1, val1, param2, val2, ...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If  $PTR < 0.1$ , the measurement system is capable.
- If  $PTR > 0.3$ , the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- `'printtable'` — A string with a value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A string with a value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of operator is random or not. The default value is `true`.

- 'model' — The model to use, specified by one of:
  - 'linear' — Main effects only (default)
  - 'interaction' — Main effects plus two-factor interactions
  - 'nested' — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

- ndc — Number of distinct categories
- prr — Percentage of gage R&R of total variations
- ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

## Examples

### Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, `y`, operators do on the parts.

```
rng(1234, 'twister')           % for reproducibility
y = randn(100,1);              % measurements
part = ceil(3*rand(100,1));     % parts
operator = ceil(4*rand(100,1)); % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y, {part, operator}, 'randomoperator', true)
```

Columns 1 through 4

% of Gage R&R of total variations (PRR): 99.63

Note: The last column of the above table does not have to sum to 100%

## How To

- “Grouping Variables” on page 2-52

**Purpose**

Gamma cumulative distribution function

**Syntax**

```
gamcdf(x,a,b)
[p,plo,pup] = gamcdf(x,a,b,pcov,alpha)
[p,plo,pup] = gamcdf( __ , 'upper' )
```

**Description**

`gamcdf(x,a,b)` returns the gamma cdf at each of the values in `x` using the corresponding shape parameters in `a` and scale parameters in `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must be positive.

`[p,plo,pup] = gamcdf(x,a,b,pcov,alpha)` produces confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1-alpha)% confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = gamcdf( __ , 'upper' )` returns the complement of the gamma cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The gamma cdf is

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

The result,  $p$ , is the probability that a single observation from a gamma distribution with parameters  $a$  and  $b$  will fall in the interval  $[0, x]$ .

`gammainc` is the gamma distribution with  $b$  fixed at 1.

## Examples

### Compute Gamma Distribution CDF

The mean of the gamma distribution is the product of the parameters,  $ab$ . In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```
a = 1:6;  
b = 5:10;  
prob = gamcdf(a.*b,a,b)
```

```
prob =  
    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

## See Also

## How To

- “Gamma Distribution” on page B-47

**Purpose**

Gamma parameter estimates

**Syntax**

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

**Description**

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns  $100(1 - \alpha)\%$  confidence intervals. For example,  $\alpha = 0.01$  yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

**Examples**

Fit a gamma distribution to random data generated from a specified gamma distribution:

# gamfit

---

```
a = 2; b = 4;  
data = gamrnd(a,b,100,1);
```

```
[p,ci] = gamfit(data)  
p =  
    2.1990    3.7426  
ci =  
    1.6840    2.8298  
    2.7141    4.6554
```

## How To

• “Gamma Distribution” on page B-47

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Gamma probability distribution object

**Description** `prob.GammaDistribution` is an object consisting of parameters, a model description, and sample data for a gamma probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Gamma')` creates a gamma probability distribution object using the default parameter values.

`pd = makedist('Gamma','a',a,'b',b)` creates a gamma probability distribution object using the specified parameter values.

## Input Arguments

### **a** - Shape parameter

1 (default) | positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

### Data Types

single | double

### **b** - Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

### Data Types

single | double

**Properties** **a** - Shape parameter

positive scalar value

# prob.GammaDistribution

---

Shape parameter for the gamma distribution, stored as a positive scalar value.

## Data Types

single | double

## **b - Scale parameter**

nonnegative scalar value

Scale parameter for the gamma distribution, stored as a nonnegative scalar value.

## Data Types

single | double

## **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

# prob.GammaDistribution

---

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

### **Data Types**

char

## **ParameterValues - Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

### **Data Types**

single | double

## **Truncation - Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

### **Data Types**

single | double

## Definitions

### Gamma Distribution

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b \geq 0$

The probability density function (pdf) is

$$f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}} ; \quad x > 0,$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a Gamma Distribution Object Using Default Parameters

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 1
```

```
  b = 1
```

## Create a Gamma Distribution Object Using Specified Parameters

Create a gamma distribution object by specifying the parameter values.

```
pd = makedist('Gamma', 'a',2,'b',4)
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
  a = 2
```

```
  b = 4
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
  8
```

## Concepts

- “Gamma Distribution” on page B-47
- Class Attributes
- Property Attributes

# gaminv

---

**Purpose** Gamma inverse cumulative distribution function

**Syntax**  
`X = gaminv(P,A,B)`  
`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)`

**Description** `X = gaminv(P,A,B)` computes the inverse of the gamma cdf with shape parameters in `A` and scale parameters in `B` for the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `P` must lie on the interval `[0 1]`.

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p | a, b) = \{x : F(x | a, b) = p\}$$

where

$$p = F(x | a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

`[X,XLO,XUP] = gamcdf(P,A,B,pcov,alpha)` produces confidence bounds for `P` when the input parameters `A` and `B` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1-alpha)% confidence bounds. `PLO` and `PUP` are arrays of the same size as `P` containing the lower and upper confidence bounds.

**Algorithms** There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

**Examples** This example shows the relationship between the gamma cdf and its inverse function.

```
a = 1:5;
b = 6:10;
x = gaminv(gamcdf(1:5,a,b),a,b)
x =
    1.0000    2.0000    3.0000    4.0000    5.0000
```

**See Also**

[icdf](#) | [gamcdf](#) | [gampdf](#) | [gamstat](#) | [gamfit](#) | [gamlike](#) | [gamrnd](#)

**How To**

- “Gamma Distribution” on page B-47

# gamlike

---

## Purpose

Gamma negative log-likelihood

## Syntax

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

## Description

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters.

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

## Examples

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;
r = gamrnd(a,b,100,1);

[nlogL,AVAR] = gamlike(gamfit(r),r)
nlogL =
    267.5648
AVAR =
```

0.0788 -0.1104  
-0.1104 0.1955

**How To**

- “Gamma Distribution” on page B-47

# gampdf

---

**Purpose** Gamma probability density function

**Syntax** `Y = gampdf(X,A,B)`

**Description** `Y = gampdf(X,A,B)` computes the gamma pdf at each of the values in `X` using the corresponding shape parameters in `A` and scale parameters in `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval  $[0 \infty)$ .

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and  $\chi^2$  functions are special cases of the gamma function.

**Examples** The exponential distribution is a special case of the gamma distribution.

```
mu = 1:5;
```

```
y = gampdf(1,1,mu)
```

```
y =  
0.3679 0.3033 0.2388 0.1947 0.1637
```

```
y1 = exppdf(1,mu)
```

```
y1 =  
0.3679 0.3033 0.2388 0.1947 0.1637
```

**How To**

- “Gamma Distribution” on page B-47

# gamrnd

---

**Purpose** Gamma random numbers

**Syntax**  
R = gamrnd(A,B)  
R = gamrnd(A,B,m,n,...)  
R = gamrnd(A,B,[m,n,...])

**Description** R = gamrnd(A,B) generates random numbers from the gamma distribution with shape parameters in A and scale parameters in B. A and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for A or B is expanded to a constant array with the same dimensions as the other input.

R = gamrnd(A,B,m,n,...) or R = gamrnd(A,B,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the gamma distribution with parameters A and B. A and B can each be scalars or arrays of the same size as R.

**Examples**

```
n1 = gamrnd(1:5,6:10)
n1 =
    9.1132  12.8431  24.8025  38.5960 106.4164

n2 = gamrnd(5,10,[1 5])
n2 =
    30.9486  33.5667  33.6837  55.2014  46.8265

n3 = gamrnd(2:6,3,1,5)
n3 =
    12.8715  11.3068  3.0982  15.6012  21.6739
```

**See Also** randg | random | gampdf | gamcdf | gaminv | gamstat | gamfit | gamlike

**How To** • “Gamma Distribution” on page B-47

**Purpose** Gamma mean and variance

**Syntax** `[M,V] = gamstat(A,B)`

**Description** `[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in *A* and scale parameters in *B*. *A* and *B* can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of *M* and *V*. A scalar input for *A* or *B* is expanded to a constant array with the same dimensions as the other input.

The mean of the gamma distribution with parameters *a* and *b* is  $ab$ . The variance is  $ab^2$ .

**Examples** `[m,v] = gamstat(1:5,1:5)`

```
m =  
    1    4    9   16   25
```

```
v =  
    1    8   27   64  125
```

```
[m,v] = gamstat(1:5,1./(1:5))
```

```
m =  
    1    1    1    1    1
```

```
v =  
  1.0000  0.5000  0.3333  0.2500  0.2000
```

**See Also** `gampdf` | `gamcdf` | `gaminv` | `gamfit` | `gamlike` | `gamrnd`

**How To** • “Gamma Distribution” on page B-47

**Purpose** Greater than or equal relation for handles

**Syntax** `h1 >= h2`

**Description** `h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

# prob.GeneralizedExtremeValueDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Generalized extreme value probability distribution object

**Description** `prob.GeneralizedExtremeValueDistribution` is an object consisting of parameters, a model description, and sample data for a generalized extreme value probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('GeneralizedExtremeValue')` creates a generalized extreme value probability distribution object using the default parameter values.

`pd = makedist('GeneralizedExtremeValue','k',k,'sigma',sigma,'mu',mu)` creates a generalized extreme value probability distribution object using the specified parameter values.

## Input Arguments

### **k** - Shape parameter

0 (default) | scalar value

Shape parameter for the generalized extreme value distribution, specified as a scalar value.

### Data Types

single | double

### **sigma** - Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized extreme value distribution, specified as a nonnegative scalar value.

### Data Types

single | double

# prob.GeneralizedExtremeValueDistribution

---

## **mu - Location parameter**

0 (default) | scalar value

Location parameter for the generalized extreme value distribution, specified as a scalar value.

## **Data Types**

single | double

## **Properties**

## **k - Shape parameter**

scalar value

Shape parameter of the generalized extreme value distribution, stored as a scalar value.

## **Data Types**

single | double

## **sigma - Scale parameter**

nonnegative scalar value

Scale parameter of the generalized extreme value distribution, stored as a nonnegative scalar value.

## **Data Types**

single | double

## **mu - Location parameter**

scalar value

Location parameter of the generalized extreme value distribution, stored as a scalar value.

## **Data Types**

single | double

## **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

### **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

### **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

### **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

### **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

# prob.GeneralizedExtremeValueDistribution

---

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParametersIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

# prob.GeneralizedExtremeValueDistribution

---

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

# prob.GeneralizedExtremeValueDistribution

---

mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Generalized Extreme Value Distribution

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's  $t$  distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

# prob.GeneralizedExtremeValueDistribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
k	Shape parameter	$-\infty \leq k \leq \infty$
sigma	Scale parameter	$\sigma \geq 0$
mu	Location parameter	$-\infty \leq \mu \leq \infty$

The probability density function (pdf) for a Type 1 distribution, where shape parameter  $k = 0$ , is

$$f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x-\mu)}{\sigma}\right) - \frac{(x-\mu)}{\sigma}\right) ; \quad -\infty < x < \infty.$$

When  $k \neq 0$ , the pdf is

$$f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\left(1+k\frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right) \left(1+k\frac{(x-\mu)}{\sigma}\right)^{-1-\frac{1}{k}}$$

for

$$1+k\frac{(x-\mu)}{\sigma} > 0.$$

For the Type 2 case,  $k > 0$  and  $x \geq \mu - \frac{\sigma}{k}$ . For the Type 3 case,  $k < 0$

and  $x < \mu - \frac{\sigma}{k}$ .

# prob.GeneralizedExtremeValueDistribution

---

## Examples

### Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
```

```
    k = 0
```

```
    sigma = 1
```

```
    mu = 0
```

### Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue','k',0,'sigma',2,'mu',1)
```

```
pd =
```

```
GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
```

```
    k = 0
```

```
    sigma = 2
```

```
    mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

## Concepts

- “Generalized Extreme Value Distribution” on page B-53
- Class Attributes
- Property Attributes

# GeneralizedLinearModel

---

**Purpose** Generalized linear regression model class

**Description** An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the `predict` or `feval` methods.

**Construction** `mdl = fitglm(tbl)` or `mdl = fitglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitglm`.

`mdl = stepwiseglm(tbl)` or `mdl = stepwiseglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiseglm`.

## Input Arguments

### **tbl** - Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### **Data Types**

single | double | logical

### **X** - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## Properties

### CoefficientCovariance

Covariance matrix of coefficient estimates.

### CoefficientNames

Cell array of strings containing a label for each coefficient.

### Coefficients

Coefficient values stored as a table. `Coefficients` has one row for each coefficient and these columns:

- Estimate — Estimated coefficient value
- SE — Standard error of the estimate
- tStat —  $t$  statistic for a test that the coefficient is zero
- pValue —  $p$ -value for the  $t$  statistic

# GeneralizedLinearModel

---

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

## Deviance

Deviance of the fit. It is useful for comparing two models when one is a special case of the other. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 21-1554.

## DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

## Diagnostics

Table with diagnostics helpful in finding outliers and influential observations. The table contains the following fields:

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with $p$ coefficients and $n$ observations, the average value of Leverage is $p/n$ . An observation

Field	Meaning	Utility
		with Leverage larger than $2*p/n$ can be an outlier.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an $n$ -by- $n$ matrix such that $\text{Fitted} = \text{HatMatrix} * Y$ , where $Y$ is the response vector and $\text{Fitted}$ is the vector of fitted response values.

All of these quantities are computed on the scale of the linear predictor. So, for example, in the equation that defines the hat matrix,

```
Yfit = glm.Fitted.LinearPredictor  
Y = glm.Fitted.LinearPredictor + glm.Residuals.LinearPredictor
```

## Dispersion

Scale factor of the variance of the response. Dispersion multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is  $p(1-p)/n$ , where  $p$  is the probability parameter and  $n$  is the sample size parameter. If Dispersion is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If Dispersion is larger than 1, the data are "overdispersed" relative to the binomial distribution.

## DispersionEstimated

Logical value indicating whether fitglm used the Dispersion property to compute standard errors for the coefficients in Coefficients.SE. If DispersionEstimated is false, fitglm used the theoretical value of the variance.

# GeneralizedLinearModel

---

- DispersionEstimated can be false only for 'binomial' or 'poisson' distributions.
- Set DispersionEstimated by setting the DispersionFlag name-value pair in fitglm.

## Distribution

Structure with the following fields relating to the generalized distribution:

Field	Description
Name	Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gamma'.
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When DispersionEstimated is true, Dispersion multiplies the variance function in the computation of the coefficient standard errors.

## Fitted

Table of predicted (fitted) values based on the training data, a table with one row for each observation and the following columns.

Field	Description
Response	Predicted values on the scale of the response.
LinearPredictor	Predicted values on the scale of the linear predictor. These are the same as the link function applied to the Response fitted values.
Probability	Fitted probabilities (this column is included only with the binomial distribution).

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector `f` of fitted values on the response scale is

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

## Formula

Object containing information about the model.

## Link

Structure with fields relating to the link function. The link is a function  $f$  that links the distribution parameter  $\mu$  to the fitted linear combination  $Xb$  of the predictors:

$$f(\mu) = Xb.$$

The structure has the following fields.

Field	Description
Name	Name of the link function, or '' if you specified the link as a function handle rather than a string.
LinkFunction	The function that defines $f$ , a function handle.
DevianceFunction	Derivative of $f$ , a function handle.
VarianceFunction	Inverse of $f$ , a function handle.

## LogLikelihood

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

## ModelCriterion

# GeneralizedLinearModel

---

AIC and other information criteria for comparing models. A structure with fields:

- AIC — Akaike information criterion
- AICc — Akaike information criterion corrected for sample size
- BIC — Bayesian information criterion
- CAIC — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

## **NumCoefficients**

Number of coefficients in the model, a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

## **NumEstimatedCoefficients**

Number of estimated coefficients in the model, a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

## **NumObservations**

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

## **NumPredictors**

Number of variables `fitlm` used as predictors for fitting.

## **NumVariables**

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

## ObservationInfo

Table with the same number of rows as the input data (`tbl` or `X`).

Field	Description
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

## ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

## Offset

Vector with the same length as the number of rows in the data, passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly 1. In other words, the formula for fitting was

# GeneralizedLinearModel

---

$\mu \sim \text{Offset} + (\text{terms involving real predictors})$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying  $\log(A)$  as an offset, you can force the model to satisfy this theoretical constraint.

## PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

## Residuals

Table containing residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
LinearPredictor	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.
Pearson	Raw residuals divided by the estimated standard deviation of the response.
Anscombe	Residuals defined on transformed data with the transformation chosen to remove skewness.
Deviance	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

## **ResponseName**

String giving naming the response variable.

## **Rsquared**

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$Rsquared = SSR/SST = 1 - SSE/SST.$$

`Rsquared` is a structure with two fields:

- `Ordinary` — Ordinary (unadjusted) R-squared
- `Adjusted` — R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

# GeneralizedLinearModel

---

## SSE

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## SST

Total sum of squares, the sum of squared deviations of  $y$  from  $\text{mean}(y)$ .

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## Steps

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'

Field	Description
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The History table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> <li>'Start' — First step</li> <li>'Add' — A term is added</li> <li>'Remove' — A term is removed</li> </ul>
TermName	<ul style="list-style-type: none"> <li>'Start' step: The starting model specification</li> <li>'Add' or 'Remove' steps: The term moved in that step</li> </ul>
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code> )
DF	Regression degrees of freedom after this step
de1DF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	$F$ statistic that led to this step
PValue	$p$ -value of the $F$ statistic

## VariableInfo

Table containing metadata about Variables. There is one row for each term in the model, and the following columns.

# GeneralizedLinearModel

---

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"><li>• Continuous variable — Two-element vector <math>[min, max]</math>, the minimum and maximum values</li><li>• Categorical variable — Cell array of distinct variable values</li></ul>
InModel	Logical vector, where true indicates the variable is in the model
IsCategorical	Logical vector, where true indicates a categorical variable

## VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

## Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix  $X$  and response vector  $y$ .

## Methods

<code>addTerms</code>	Add terms to generalized linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of generalized linear model
<code>coefTest</code>	Linear hypothesis test on generalized linear regression model coefficients
<code>devianceTest</code>	Analysis of deviance
<code>disp</code>	Display generalized linear regression model
<code>feval</code>	Evaluate generalized linear regression model prediction
<code>fit</code>	Create generalized linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of generalized linear regression model
<code>plotResiduals</code>	Plot residuals of generalized linear regression model
<code>plotSlice</code>	Plot of slices through fitted generalized linear regression surface
<code>predict</code>	Predict response of generalized linear regression model
<code>random</code>	Simulate responses for generalized linear regression model
<code>removeTerms</code>	Remove terms from generalized linear model

# Generalized Linear Model

step	Improve generalized linear regression model by adding or removing terms
stepwise	Create generalized linear regression model by stepwise regression

## Definitions Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

## Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

## Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and a diagonal weight matrix  $W$ :

$$H = X(X^T W X)^{-1} X^T W^T.$$

$W$  has diagonal elements  $w_i$ :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- $g$  is the link function mapping  $y_i$  to  $x_i b$ .
- $g'$  is the derivative of the link function  $g$ .
- $V$  is the variance function.
- $\mu_i$  is the  $i$ th mean.

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

## Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = w_i \frac{e_i^2}{p\hat{\sigma}^2} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

# Generalized Linear Model

---

- $\hat{\phi}$  is the dispersion parameter (estimated or theoretical).
- $e_i$  is the linear predictor residual,  $g(y_i) - x_i\hat{\beta}$ , where
  - $g$  is the link function.
  - $y_i$  is the observed response.
  - $x_i$  is the observation.
  - $\hat{\beta}$  is the estimated coefficient vector.
- $p$  is the number of coefficients in the regression model.
- $h_{ii}$  is the  $i$ th diagonal element of the Hat Matrix  $H$ .

## Deviance

Deviance of a model  $M_1$  is twice the difference between the loglikelihood of that model and the saturated model,  $M_S$ . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are  $n$  observations  $y_i$ ,  $i = 1, 2, \dots, n$ , with potentially different values for  $X_i^T\beta$ , then you can define a saturated model with  $n$  parameters. Let  $L(b, y)$  denote the maximum value of the likelihood function for a model. Then the deviance of model  $M_1$  is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where  $b_1$  are the estimated parameters for model  $M_1$  and  $b_S$  are the estimated parameters for the saturated model. The deviance has a chi-square distribution with  $n - p$  degrees of freedom, where  $n$  is the number of parameters in the saturated model and  $p$  is the number of parameters in model  $M_1$ .

If  $M_1$  and  $M_2$  are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances  $D_1$  and  $D_2$  of these models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom  $\nu$  equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. That is, it is equal to the difference in the number of parameters estimated in  $M_1$  and  $M_2$ . You can get the  $p$ -value for this test using `1 - chi2cdf(D, V)`, where  $D = D_2 - D_1$ .

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds, modelspec, 'Distribution', 'binomial')
```

```
mdl =
```

Generalized Linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
```

# GeneralizedLinearModel

---

```
Distribution = Binomial

Estimated Coefficients:

```

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

```
100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

The large  $p$ -value indicates the model might not differ statistically from a constant.

## Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

mdl =

Generalized Linear regression model:

$\log(y) \sim 1 + x5 + x10 + x15$   
Distribution = Poisson

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

# prob.GeneralizedParetoDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Generalized Pareto probability distribution object

**Description** prob.GeneralizedParetoDistribution is an object consisting of parameters, a model description, and sample data for a generalized Pareto probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('GeneralizedParetoDistribution')` creates a generalized Pareto probability distribution object using default parameter values.

`pd = makedist('GeneralizedParetoDistribution','k',k,'sigma',sigma,'theta',theta)` creates a generalized Pareto probability distribution object using the specified parameter values.

## Input Arguments

### **k** - Shape parameter

1 (default) | scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma** - Scale parameter

1 (default) | nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

## **theta - Location parameter**

1 (default) | scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

## **Data Types**

single | double

## **Properties**

## **k - Shape parameter**

scalar value

Shape parameter for the generalized Pareto distribution, stored as a scalar value.

## **Data Types**

single | double

## **sigma - Scale parameter**

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, stored as a nonnegative scalar value.

## **Data Types**

single | double

## **theta - Location parameter**

scalar value

Location parameter for the generalized Pareto distribution, stored as a scalar value.

## **Data Types**

single | double

## **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

# prob.GeneralizedParetoDistribution

---

## Data Types

char

## InputData - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance - Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

### Data Types

single | double

### ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

### Data Types

char

### ParameterIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

### Data Types

logical

### ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

### Data Types

char

# prob.GeneralizedParetoDistribution

---

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Definitions

### Generalized Pareto Distribution

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's  $t$ , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

# prob.GeneralizedParetoDistribution

Parameter	Description	Support
k	Shape parameter	$-\infty < k < \infty$
sigma	Scale parameter	$\sigma \geq 0$
theta	Location parameter	$-\infty < \theta < \infty$

The probability density function (pdf) of the generalized Pareto distribution with shape parameter  $k \neq 0$  is

$$f(x | k, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \left(1 + k \frac{(x - \theta)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for  $x > \theta$ , when  $k > 0$ , or for  $\theta < x < -\frac{\sigma}{k}$ , when  $k < 0$ .

For  $k = 0$ , the pdf is

$$y = f(x | 0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \exp\left(-\frac{(x - \theta)}{\sigma}\right)$$

for  $x > \theta$ .

If  $k = 0$  and  $\theta = 0$ , the generalized Pareto distribution is equivalent

to the exponential distribution. If  $k > 0$  and  $\theta = \frac{\sigma}{k}$ , the generalized Pareto distribution is equivalent to the Pareto distribution.

## Examples

### Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')
```

```
pd =  
  
GeneralizedParetoDistribution  
  
Generalized Pareto distribution  
    k = 1  
    sigma = 1  
    theta = 1
```

## Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)
```

```
pd =  
  
GeneralizedParetoDistribution  
  
Generalized Pareto distribution  
    k = 0  
    sigma = 2  
    theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =  
  
    2.1544
```

## Concepts

- “Generalized Pareto Distribution” on page B-60
- Class Attributes

# prob.GeneralizedParetoDistribution

---

- Property Attributes

**Purpose** Geometric cumulative distribution function

**Syntax**  
`y = geocdf(x,P)`  
`y = geocdf(x,P, 'upper')`

**Description** `y = geocdf(x,P)` computes the geometric cdf at each of the values in `x` using the corresponding probabilities in `P`. `x` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `P` must lie on the interval `[0 1]`.

`y = geocdf(x,P, 'upper')` returns the complement of the geometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The geometric cdf is

$$y = F(x | p) = \sum_{i=0}^{\text{floor}(x)} pq^i$$

where  $q = 1 - p$ .

The result, `y`, is the probability of observing up to `x` trials before a success, when the probability of success in any given trial is `p`.

## Examples **Compute Geometric Distribution CDF**

Suppose you toss a fair coin repeatedly. If the coin lands face up (heads), that is a success. What is the probability of observing three or fewer tails before getting a heads?

```
p = geocdf(3,0.5)
```

```
p =  
0.9375
```

# geomean

---

**Purpose** Geometric mean

**Syntax** `m = geomean(x)`  
`geomean(X,dim)`

**Description** `m = geomean(x)` calculates the geometric mean of a sample. For vectors, `geomean(x)` is the geometric mean of the elements in `x`. For matrices, `geomean(X)` is a row vector containing the geometric means of each column. For N-dimensional arrays, `geomean` operates along the first nonsingleton dimension of `X`.

`geomean(X,dim)` takes the geometric mean along the dimension `dim` of `X`.

The geometric mean is

$$m = \left[ \prod_{i=1}^n x_i \right]^{\frac{1}{n}}$$

**Examples** The arithmetic mean is greater than or equal to the geometric mean.

```
x = exprnd(1,10,6);
```

```
geometric = geomean(x)
```

```
geometric =  
    0.7466    0.6061    0.6038    0.2569    0.7539    0.3478
```

```
average = mean(x)
```

```
average =  
    1.3509    1.1583    0.9741    0.5319    1.0088    0.8122
```

**See Also** `mean` | `median` | `harmmean` | `trimmean`

**How To** • “Geometric Distribution” on page B-65

**Purpose** Geometric probability density function

**Syntax** `Y = geopdf(X,P)`

**Description** `Y = geopdf(X,P)` computes the geometric pdf at each of the values in `X` using the corresponding probabilities in `P`. `X` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `P` must lie on the interval `[0 1]`.

The geometric pdf is

$$y = f(x | p) = pq^x I_{(0,1,\dots)}(x)$$

where  $q = 1 - p$ .

**Examples** Suppose you toss a fair coin repeatedly. If the coin lands face up (heads), that is a success. What is the probability of observing exactly three tails before getting a heads?

```
p = geopdf(3,0.5)
p =
    0.0625
```

**See Also** `pdf` | `geocdf` | `geoinv` | `geostat` | `geornd`

**How To** • “Geometric Distribution” on page B-65

# geornd

---

**Purpose** Geometric random numbers

**Syntax**  
R = geornd(P)  
R = geornd(P,m,n,...)  
R = geornd(P,[m,n,...])

**Description** R = geornd(P) generates geometric random numbers with probability parameter P. P can be a vector, a matrix, or a multidimensional array. The size of R is the size of P. The geometric distribution is useful when you want to model the number of successive failures preceding a success, where the probability of success in any given trial is the constant P. The parameters in P must lie in the interval [0 1].

R = geornd(P,m,n,...) or R = geornd(P,[m,n,...]) generates an m-by-n-by-... array containing random numbers from the geometric distribution with probability parameter P. P can be a scalar or an array of the same size as R.

**Examples**  
r1 = geornd(1 ./ 2.^(1:6))  
r1 =  
2 10 2 5 2 60

r2 = geornd(0.01,[1 5])  
r2 =  
65 18 334 291 63

r3 = geornd(0.5,1,6)  
r3 =  
0 7 1 3 1 0

**See Also** random | geopdf | geocdf | geoinv | geostat

**How To** • “Geometric Distribution” on page B-65

**Purpose** Geometric mean and variance

**Syntax** `[M,V] = geostat(P)`

**Description** `[M,V] = geostat(P)` returns the mean of and variance for the geometric distribution with corresponding probabilities in P.

The mean of the geometric distribution with parameter  $p$  is  $q/p$ , where  $q = 1-p$ . The variance is  $q/p^2$ .

**Examples** `[m,v] = geostat(1./(1:6))`

```
m =  
    0  1.0000  2.0000  3.0000  4.0000  5.0000  
v =  
    0  2.0000  6.0000 12.0000 20.0000 30.0000
```

**See Also** `geopdf` | `geocdf` | `geoinv` | `geornd`

**How To** • “Geometric Distribution” on page B-65

# clustering.evaluation.GapEvaluation

---

**Superclasses** ClusterCriterion

**Purpose** Gap criterion clustering evaluation object

**Description** clustering.evaluation.GapEvaluation is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using evalclusters.

**Construction** `eva = evalclusters(x,clust,'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Gap',Name,Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

## Input Arguments

### **x - Input data**

matrix

Input data, specified as an  $N$ -by- $P$  matrix.  $N$  is the number of observations, and  $P$  is the number of variables.

### **Data Types**

single | double

### **clust - Clustering algorithm**

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the <code>kmeans</code> clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the <code>clusterdata</code> agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the <code>gmdistribution</code> Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using the `function_handle` (@) operator. The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric  $n$ -by- $K$  matrix of score for  $n$  observations and  $K$  classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a  $n$ -by- $K$  matrix containing the proposed clustering solutions.  $n$  is the number of observations in the sample data, and  $K$  is the number of proposed clustering solutions. Column  $j$  contains the cluster indices for each of the  $N$  points in the  $j$ th clustering solution.

# clustering.evaluation.GapEvaluation

---

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

## **B - Number of reference data sets**

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of `'B'` and a positive integer value.

**Example:** `'B',150`

## **Distance - Distance metric**

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of `'Distance'` and one of the following.

<code>'sqEuclidean'</code>	Squared Euclidean distance
<code>'Euclidean'</code>	Euclidean distance
<code>'cityblock'</code>	Sum of absolute differences
<code>'cosine'</code>	One minus the cosine of the included angle between points (treated as vectors)
<code>'correlation'</code>	One minus the sample correlation between points (treated as sequences of values)

'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (`@`) operator. The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- $n$  vector corresponding to a single row of the input matrix `X`, and `XJ` is an  $m_2$ -by- $n$  matrix corresponding to multiple rows of `X`. `distfun` must return an  $m_2$ -by-1 vector of distances `d2`, whose  $k$ th element is the distance between `XI` and `XJ(k, :)`.

If `Criterion` is 'silhouette', you can also specify `Distance` as the output vector `output` created by the function `pdist`.

When `Clust` is a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses Euclidean distance and Ward linkage.
- If `Clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

**Example:** 'Distance', 'Euclidean'

**KList - List of number of clusters to evaluate**

# clustering.evaluation.GapEvaluation

---

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when `clust` is a clustering algorithm name string or a function handle. When `criterion` is 'gap', `clust` must be a string or a function handle, and you must specify KList.

**Example:** 'KList',[1:6]

## **ReferenceDistribution - Reference data generation method**

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix <code>x</code> .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix <code>x</code> .

**Example:** 'ReferenceDistribution','uniform'

## **SearchMethod - Method for selecting optimal number of clusters**

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

'globalMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters,  $\text{GAPMAX}$  is the largest gap value, and  $\text{SE}(\text{GAPMAX})$  is the standard error corresponding to the largest gap value.

'firstMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where  $K$  is the number of clusters,  $\text{Gap}(K)$  is the gap value for the clustering solution with  $K$  clusters, and  $\text{SE}(K + 1)$  is the standard error of the clustering solution with  $K + 1$  clusters.

**Example:** 'SearchMethod', 'globalMaxSE'

## Properties

### **B**

Number of data sets generated from the reference distribution, stored as a positive integer value.

### **ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

### **CriterionName**

# clustering.evaluation.GapEvaluation

---

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

## **CriterionValues**

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

## **Distance**

Distance measure used for clustering data, stored as a valid distance measure name string.

## **ExpectedLogW**

Expectation of the natural logarithm of  $W$  based on the generated reference data, stored as a vector of scalar values.  $W$  is the within-cluster dispersion computed using the distance measurement `Distance`.

## **InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

## **LogW**

Natural logarithm of  $W$  based on the input data, stored as a vector of scalar values.  $W$  is the within-cluster dispersion computed using the distance measurement `Distance`.

## **Missing**

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

## **NumObservations**

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

## **OptimalK**

Optimal number of clusters, stored as a positive integer value.

## **OptimalY**

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

## **ReferenceDistribution**

Reference data generation method, stored as a valid reference distribution name string.

## **SE**

Standard error of the natural logarithm of  $W$  with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values.  $W$  is the within-cluster dispersion computed using the distance measurement `Distance`.

## **SearchMethod**

Method for determining the optimal number of clusters, stored as a valid search method name string.

## **StdLogW**

Standard deviation of the natural logarithm of  $W$  with respect to the reference data for each number of clusters in `InspectedK`.  $W$  is the within-cluster dispersion computed using the distance measurement `Distance`.

## **X**

Data used for clustering, stored as a matrix of numerical values.

## **Methods**

`increaseB`

Increase reference data sets

# clustering.evaluation.GapEvaluation

---

## Inherited Methods

addK	Evaluate additional numbers of clusters
compact	Compact clustering evaluation object
plot	Plot clustering evaluation object criterion values

## Definitions

### Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$Gap_n(k) = E_n^* \{ \log(W_k) \} - \log(W_k),$$

where  $n$  is the sample size,  $k$  is the number of clusters being evaluated, and  $W_k$  is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r,$$

where  $n_r$  is the number of data points in cluster  $r$ , and  $D_r$  is the sum of the pairwise distances for all points in cluster  $r$ .

The expected value  $E_n^* \{ \log(W_k) \}$  is determined by Monte Carlo sampling from a reference distribution, and  $\log(W_k)$  is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

## Examples

### Evaluate the Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using kmeans.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
```

```
eva =
```

```
    GapEvaluation with properties:
```

```
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [1x6 double]
    OptimalK: 4
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is four.

Plot the gap criterion values for each number of clusters tested.

```
figure;
```

# clustering.evaluation.GapEvaluation

---

```
plot(eva);
```

Based on the plot, the maximum value of the gap criterion occurs at five clusters. However, the value at four clusters is within one standard error of the maximum, so the suggested optimal number of clusters is four.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure;  
PetalLength = meas(:,3);  
PetalWidth = meas(:,4);  
ClusterGroup = eva.OptimalY;  
figure;  
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgk','xod^');
```

The plot shows cluster 1 in the lower-left corner, completely separated from the other three clusters. Cluster 1 contains flowers with the smallest petal widths and lengths. Cluster 4 is in the upper-right

# clustering.evaluation.GapEvaluation

---

corner, and contains flowers with the largest petal widths and lengths. Clusters 2 and 3 are near the center of the plot, and contain flowers with measurements between the two extremes.

## Concepts

- [Class Attributes](#)
- [Property Attributes](#)

**Purpose**

Access dataset array properties

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

**Description**

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by the string `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

**Examples**

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'},...
              {meas, 'SL', 'SW', 'PL', 'PW'},...
              'ObsNames', NameObs);

get(iris)
Description: ''
Units: {}
DimNames: {'Observations' 'Variables'}
UserData: []
ObsNames: {150x1 cell}
VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

# dataset.get

---

```
ON = get(iris, 'ObsNames');  
ON(1:3)  
ans =  
    'Obs1'  
    'Obs2'  
    'Obs3'
```

[set](#) | [summary](#)

## Purpose

Access categorical array labels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
labels = getlabels(A)
```

## Description

`labels = getlabels(A)` returns the labels of the levels in the categorical array `A` as a cell array of strings `labels`. For ordinal `A`, the labels are returned in the order of the levels.

## Examples

### Example 1

Display levels in a nominal and an ordinal array:

```
standings = nominal({'Leafs','Canadiens','Bruins'});  
getlabels(standings)
```

```
ans =  
    'Bruins'    'Canadiens'    'Leafs'
```

```
standings = ordinal(1:3,{'Leafs','Canadiens','Bruins'});  
getlabels(standings)
```

```
ans =  
    'Leafs'    'Canadiens'    'Bruins'
```

### Example 2

Display age groups containing data in `hospital.mat`:

```
load hospital  
edges = 0:10:100;  
labels = strcat(num2str((0:10:90)','%d'),{'s'});  
AgeGroup = ordinal(hospital.Age,labels,[],edges);  
AgeGroup = droplevels(AgeGroup);  
getlabels(AgeGroup)
```

```
ans =  
    '20s'    '30s'    '40s'    '50s'
```

# categorical.getlabels

## See Also

`getlevels` | `setlabels`

**Purpose**

Get categorical array levels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

`S = getlevels(A)`

**Description**

`S = getlevels(A)` returns the levels for the categorical array `A`. `S` is a vector with the same type as `A`.

<b>Purpose</b>	Generalized extreme value cumulative distribution function
<b>Syntax</b>	<pre>p = gevcdf(x,k,sigma,mu) p = gevcdf(x,k,sigma,mu,'upper')</pre>
<b>Description</b>	<p><code>p = gevcdf(x,k,sigma,mu)</code> returns the cdf of the generalized extreme value (GEV) distribution with shape parameter <code>k</code>, scale parameter <code>sigma</code>, and location parameter, <code>mu</code>, evaluated at the values in <code>x</code>. The size of <code>p</code> is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.</p> <p><code>p = gevcdf(x,k,sigma,mu,'upper')</code> returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.</p> <p>Default values for <code>k</code>, <code>sigma</code>, and <code>mu</code> are 0, 1, and 0, respectively.</p> <p>When <math>k &lt; 0</math>, the GEV is the type III extreme value distribution. When <math>k &gt; 0</math>, the GEV distribution is the type II, or Frechet, extreme value distribution. If <math>w</math> has a Weibull distribution as computed by the <code>wblcdf</code> function, then <math>-w</math> has a type III extreme value distribution and <math>1/w</math> has a type II extreme value distribution. In the limit as <math>k</math> approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the <code>evcdf</code> function.</p> <p>The mean of the GEV distribution is not finite when <math>k \geq 1</math>, and the variance is not finite when <math>k \geq 1/2</math>. The GEV distribution has positive density only for values of <math>X</math> such that <math>k*(X-mu)/sigma &gt; -1</math>.</p>
<b>References</b>	<p>[1] Embrechts, P., C. Klüppelberg, and T. Mikosch. <i>Modelling Extremal Events for Insurance and Finance</i>. New York: Springer, 1997.</p> <p>[2] Kotz, S., and S. Nadarajah. <i>Extreme Value Distributions: Theory and Applications</i>. London: Imperial College Press, 2000.</p>
<b>See Also</b>	<code>cdf</code>   <code>gevpdf</code>   <code>gevinv</code>   <code>gevstat</code>   <code>gevfit</code>   <code>gevlike</code>   <code>gevrnd</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Generalized Extreme Value Distribution” on page B-53</li></ul>

**Purpose**

Generalized extreme value parameter estimates

**Syntax**

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

**Description**

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in X. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns  $100(1-\alpha)\%$  confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When  $k < 0$ , the GEV is the type III extreme value distribution. When  $k > 0$ , the GEV distribution is the type II, or Frechet, extreme value distribution. If  $w$  has a Weibull distribution as computed by the `wblfit` function, then  $-w$  has a type III extreme value distribution and  $1/w$  has a type II extreme value distribution. In the limit as  $k$  approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when  $k \geq 1$ , and the variance is not finite when  $k \geq 1/2$ . The GEV distribution is defined for  $k*(X-\mu)/\sigma > -1$ .

# gevrnd

---

**Purpose** Generalized extreme value random numbers

**Syntax**  
R = gevrnd(k, sigma, mu)  
R = gevrnd(k, sigma, mu, m, n, ...)  
R = gevrnd(k, sigma, mu, [m, n, ...])

**Description** R = gevrnd(k, sigma, mu) returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter k, scale parameter sigma, and location parameter, mu. The size of R is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of R is the size of the other parameters.

R = gevrnd(k, sigma, mu, m, n, ...) or R = gevrnd(k, sigma, mu, [m, n, ...]) generates an m-by-n-by-... array containing random numbers from the GEV distribution with parameters k, sigma, and mu. The k, sigma, mu parameters can each be scalars or arrays of the same size as R.

When  $k < 0$ , the GEV is the type III extreme value distribution. When  $k > 0$ , the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the wblrnd function, then -w has a type III extreme value distribution and 1/w has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the evrnd function.

The mean of the GEV distribution is not finite when  $k \geq 1$ , and the variance is not finite when  $k \geq 1/2$ . The GEV distribution has positive density only for values of X such that  $k*(X-mu)/sigma > -1$ .

<b>How To</b>	• “Generalized Extreme Value Distribution” on page B-53

**Purpose**

Interactively add line to plot

**Syntax**

```
gline(h)
gline
hline = gline(...)
```

**Description**

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

**Examples**

Use `gline` to connect two points in a plot:

```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

# gline

---

## See Also

`refline` | `refcurve` | `lsline`

**Purpose**

Generalized linear model regression

**Syntax**

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

**Description**

`b = glmfit(X,y,distr)` returns a  $(p + 1)$ -by-1 vector `b` of coefficient estimates for a generalized linear regression of the responses in `y` on the predictors in `X`, using the distribution `distr`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `distr` can be any of the following strings: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, `y` is an  $n$ -by-1 vector of observed responses. For the binomial distribution, `y` can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

---

**Note** By default, `glmfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmfit` using the 'constant' parameter, below.

---

`glmfit` treats NaNs in either `X` or `y` as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
'link'	'identity', default for the distribution 'normal'	$\mu = Xb$
	'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
	'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
	'probit'	$\text{norminv}(\mu) = Xb$
	'comploglog'	$\log(-\log(1 - \mu)) = Xb$
	'reciprocal', default for the distribution 'gamma'	$1/\mu = Xb$
	'loglog'	$\log(-\log(\mu)) = Xb$
	p (a number), default for the distribution 'inverse gaussian' (with $p = -2$ )	$\mu^p = Xb$
'link'	cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).	Custom-defined link function. You must provide <ul style="list-style-type: none"> <li>• FL(mu)</li> <li>• FD = dFL(mu) / dmu</li> <li>• FI = FL^(-1)</li> </ul>

Parameter	Value	Description
'estdisp'	'on'	Estimates a dispersion parameter for the binomial or Poisson distribution.
	'off' (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
'offset'	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
'weights'	Vector of prior weights, such as the inverses of the relative variance of each observation	
'constant'	'on' (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of b.
	'off'	Omit the constant term.

`[b,dev] = glmfit(...)` returns `dev`, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `s` — Theoretical or estimated dispersion parameter

- `sfit` — Estimated dispersion parameter
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `covb` — Estimated covariance matrix for `B`
- `t` —  $t$  statistics for `b`
- `p` —  $p$ -values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

## Examples

### Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...  
     3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';  
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each `y` value is the number of successes in corresponding number of trials `inn`, and `x` contains the predictor variable values.

Fit a probit regression model for `y` on `x`.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes and plot the percent observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,'probit','size',n);  
plot(x, y./n, 'o',x,yfit./n, '-','LineWidth',2)
```

### Use Custom-defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists

of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);  
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using @, that define the link, the derivative of the link, and the inverse link for a logit link function, and store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));  
derlink = @(mu) 1 ./ (mu .* (1-mu));  
invlink = @(resp) 1 ./ (1 + exp(-resp));  
F = {link, derlink, invlink};
```

Fit a logistic regression using glmfit with the link function you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b =  
  
    42.6378  
     2.4652  
     6.6809  
    -9.4294  
   -18.2861
```

Now, fit a generalized linear model using the logit link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b =  
  
    42.6378  
     2.4652  
     6.6809
```

-9.4294  
-18.2861

`glmval` | `regress` | `regstats` | `GeneralizedLinearModel` | `fitglm`  
| `stepwiseglm`

# glmval

---

**Purpose** Generalized linear model values

**Syntax**  
`yhat = glmval(b,X,link)`  
`[yhat,dylo,dyhi] = glmval(b,X,link,stats)`  
`[...] = glmval(...,param1,val1,param2,val2,...)`

**Description** `yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the strings or the custom-defined link functions used as values for the 'link' name-value pair argument in the `glmfit` function.

---

**Note** By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the 'constant' parameter, below.

---

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are:

Parameter	Value
'confidence' — the confidence level for the confidence bounds	A scalar between 0 and 1
'size' — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
'constant'	<ul style="list-style-type: none"> <li>'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b.</li> <li>'off' — Omit the constant term</li> </ul>
'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)	true or false

## Examples

### Fit Generalized Linear Model with Probit Link

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials inn, and x contains the predictor variable values.

Fit a generalized linear model for y on x using a probit link function.

```
b = glmfit(x,[y n],'binomial','link','probit');
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,'probit','size',n);  
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```

## Use Custom-defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...  
     3300 3500 3700 3900 4100 4300]';  
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
```

```
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each  $y$  value is the number of successes in corresponding number of trials in  $n$ , and  $x$  contains the predictor variable values.

Now define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function, and store them in a cell array.

```
link = @(mu) norminv(mu);  
derlink = @(mu) 1 ./ normpdf(norminv(mu));  
invlink = @(resp) normcdf(resp);  
F = {link, derlink, invlink};
```

Fit a generalized linear model for  $y$  on  $x$  using the link function you defined.

```
b = glmfit(x,[y n],'binomial','link',F);
```

Compute the estimated number of successes and plot the observed and estimated percent success versus the  $x$  values.

```
yfit = glmval(b,x,F,'size',n);  
plot(x, y./n,'o',x,yfit./n,'-','LineWidth',2)
```

## Purpose

Glyph plot

## Syntax

```
glyphplot(X)
glyphplot(X, 'glyph', 'face')
glyphplot(X, 'glyph', 'face', 'features', f)
glyphplot(X, ..., 'grid', [rows, cols])
glyphplot(X, ..., 'grid', [rows, cols], 'page', p)
glyphplot(X, ..., 'centers', C)
glyphplot(X, ..., 'centers', C, 'radius', r)
glyphplot(X, ..., 'obslabels', labels)
glyphplot(X, ..., 'standardize', method)
glyphplot(X, ..., prop1, val1, ...)
h = glyphplot(X, ...)
```

## Description

`glyphplot(X)` creates a star plot from the multivariate data in the  $n$ -by- $p$  matrix  $X$ . Rows of  $X$  correspond to observations, columns to variables. A star plot represents each observation as a “star” whose  $i$ th spoke is proportional in length to the  $i$ th coordinate of that observation. `glyphplot` standardizes  $X$  by shifting and scaling each column separately onto the interval  $[0, 1]$  before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in  $X$  as missing values, and does not plot the corresponding rows of  $X$ . `glyphplot(X, 'glyph', 'star')` is a synonym for `glyphplot(X)`.

`glyphplot(X, 'glyph', 'face')` creates a face plot from  $X$ . A face plot represents each observation as a “face,” whose  $i$ th facial feature is drawn with a characteristic proportional to the  $i$ th coordinate of that observation. The features are described in “Face Features” on page 21-1617 Face Features.

`glyphplot(X, 'glyph', 'face', 'features', f)` creates a face plot where the  $i$ th element of the index vector  $f$  defines which facial feature will represent the  $i$ th column of  $X$ .  $f$  must contain integers from 0 to 17, where 0 indicate that the corresponding column of  $X$  should not be plotted. See “Face Features” on page 21-1617 for more information.

# glyphplot

---

`glyphplot(X, ..., 'grid', [rows, cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X, ..., 'grid', [rows, cols], 'page', p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page `p`. If `p` is a vector, `glyphplot` displays multiple pages in succession. If `p` is 'all', `glyphplot` displays all pages. If `p` is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X, ..., 'centers', C)` creates a plot with each glyph centered at the locations in the  $n$ -by-2 matrix `C`.

`glyphplot(X, ..., 'centers', C, 'radius', r)` creates a plot with glyphs positioned using `C`, and scale the glyphs so the largest has radius `r`.

`glyphplot(X, ..., 'obslabels', labels)` labels each glyph with the text in the character array or cell array of strings `labels`. By default, the glyphs are labelled 1:N. Use '' for blank labels.

`glyphplot(X, ..., 'standardize', method)` standardizes `X` before making the plot. Choices for `method` are

- 'column' — Maps each column of `X` separately onto the interval  $[0, 1]$ . This is the default.
- 'matrix' — Maps the entire matrix `X` onto the interval  $[0, 1]$ .
- 'PCA' — Transforms `X` to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval  $[0, 1]$ .
- 'off' — No standardization. Negative values in `X` may make a star plot uninterpretable.

`glyphplot(X, ..., prop1, val1, ...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X, ...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:, 1)` and `h(:, 2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:, 1)` and `h(:, 2)` contain object handles

to the lines making up each face and to the pupils, respectively. `h(:,3)` contains handles to the text objects for the labels, if present.

### Face Features

The following table describes the correspondence between the columns of the vector `f`, the value of the 'Features' input parameter, and the facial features of the glyph plot. If `X` has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

# glyphplot

---

## Examples

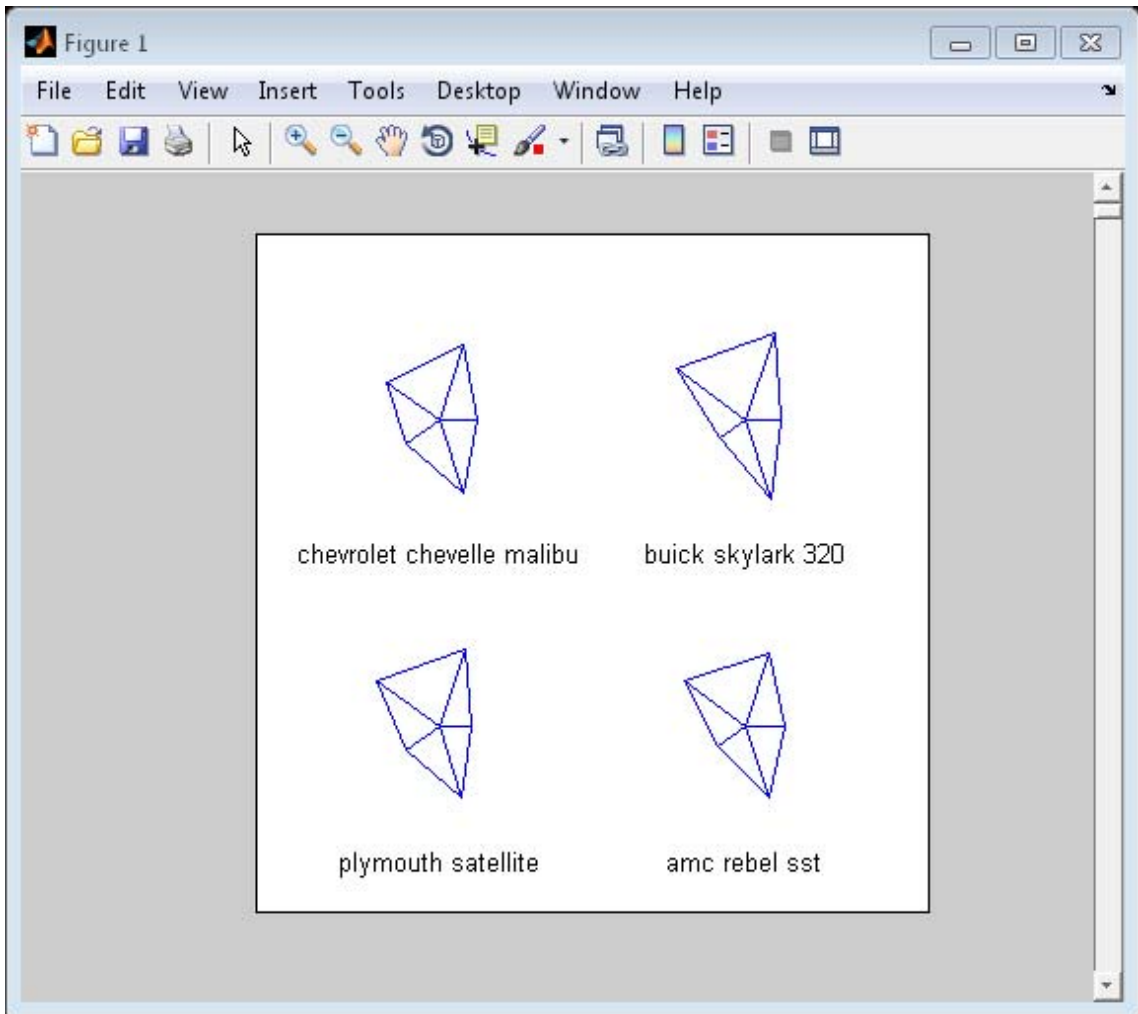

### Star and Face Plots of Multivariate Data

Load the sample data.

```
load carsmall  
X = [Acceleration Displacement Horsepower MPG Weight];
```

Create a star plot of the data in  $X$ . Standardize the data before plotting.

```
glyphplot(X, 'standardize', 'column', 'obslabels', Model, 'grid', [2 2], ...  
          'page', 'scroll');
```

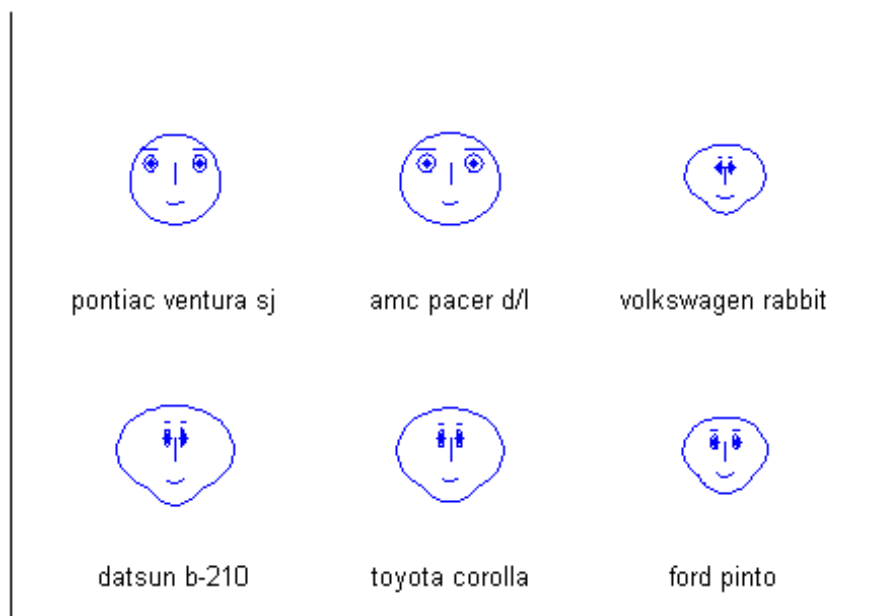

Create a faceplot of the data in  $X$  .

```
glyphplot(X,'glyph','face','obslabels',Model,'grid',[2 3],'page',9);
```

# glyphplot

**Purpose** Gaussian mixture models

**Description** An object of the `gmdistribution` class defines a Gaussian mixture distribution, which is a multivariate distribution that consists of a mixture of one or more multivariate Gaussian distribution components. The number of components for a given `gmdistribution` object is fixed. Each multivariate Gaussian component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

**Construction** To create a Gaussian mixture distribution by specifying the distribution parameters, use the `gmdistribution` constructor. To fit a Gaussian mixture distribution model to data, use `fitgmdist`.

<code>fit</code>	Gaussian mixture parameter estimates
<code>gmdistribution</code>	Construct Gaussian mixture distribution

**Properties** All objects of the class have the properties listed in the following table.

<code>CovType</code>	Type of covariance matrices
<code>DistName</code>	Type of distribution
<code>mu</code>	Input matrix of means $\mu$
<code>NComponents</code>	Number $k$ of mixture components
<code>NDimensions</code>	Dimension $d$ of multivariate Gaussian distributions
<code>PComponents</code>	Input vector of mixing proportions
<code>SharedCov</code>	true if all covariance matrices are restricted to be the same
<code>Sigma</code>	Input array of covariances

# gmdistribution

---

Objects constructed with `fitgmdist` have the additional properties listed in the following table.

AIC	Akaike Information Criterion
BIC	Bayes Information Criterion
Converged	Determine if algorithm converged
Iters	Number of iterations
NlogL	Negative of log-likelihood
RegV	Value of 'Regularize' parameter

## Methods

<code>cdf</code>	Cumulative distribution function for Gaussian mixture distribution
<code>cluster</code>	Construct clusters from Gaussian mixture distribution
<code>disp</code>	Display Gaussian mixture distribution object
<code>display</code>	Display Gaussian mixture distribution object
<code>fit</code>	Gaussian mixture parameter estimates
<code>mahal</code>	Mahalanobis distance to component means
<code>pdf</code>	Probability density function for Gaussian mixture distribution
<code>posterior</code>	Posterior probabilities of components
<code>random</code>	Random numbers from Gaussian mixture distribution

subsasgn	Subscripted reference for Gaussian mixture distribution object
suboref	Subscripted reference for Gaussian mixture distribution object

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Fit a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function. Fit the resulting data.

Generate the data using 1000 points from each distribution.

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];
```

```
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

# gmdistribution

---

Fit a two-component Gaussian mixture model.

```
options = statset('Display','final');  
obj = fitgmdist(X,2,'Options',options);
```

18 iterations, log-likelihood = -7058.35

Plot the fit.

```
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

# gmdistribution

---

## Concepts

**Purpose** Construct Gaussian mixture distribution

**Syntax** `obj = gmdistribution(mu,sigma,p)`

**Description** `obj = gmdistribution(mu,sigma,p)` constructs an object `obj` of the `gmdistribution` class defining a Gaussian mixture distribution.

`mu` is a  $k$ -by- $d$  matrix specifying the  $d$ -dimensional mean of each of the  $k$  components.

`sigma` specifies the covariance of each component. The size of `sigma` is:

- $d$ -by- $d$ -by- $k$  if there are no restrictions on the form of the covariance. In this case, `sigma(:, :, I)` is the covariance of component  $I$ .
- 1-by- $d$ -by- $k$  if the covariance matrices are restricted to be diagonal, but not restricted to be same across components. In this case, `sigma(:, :, I)` contains the diagonal elements of the covariance of component  $I$ .
- $d$ -by- $d$  matrix if the covariance matrices are restricted to be the same across components, but not restricted to be diagonal. In this case, `sigma` is the pooled estimate of covariance.
- 1-by- $d$  if the covariance matrices are restricted to be diagonal and the same across components. In this case, `sigma` contains the diagonal elements of the pooled estimate of covariance.

`p` is an optional 1-by- $k$  vector specifying the mixing proportions of each component. If `p` does not sum to 1, `gmdistribution` normalizes it. The default is equal proportions.

## Examples **Construct a Gaussian Mixture Distribution**

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2; -3 -5];  
sigma = cat(3, [2 0; 0 .5], [1 0; 0 1]);
```

# gmdistribution

---

```
p = ones(1,2)/2;  
obj = gmdistribution(mu,sigma,p);  
  
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

**Purpose** Add case names to plot

**Syntax**

```
gname(cases)
gname
h = gname(cases,line_handle)
```

**Description** `gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array or a cell array of strings, in which each row of the character array or each element of the cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a cell array of strings or a character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases,line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

**Examples** This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
```

# gname

---

```
plot(education, arts, '+' )  
gname(names)
```

Click the point at the top of the graph to display its label, “New York.”

<b>How To</b>	<ul style="list-style-type: none"> <li>“Generalized Pareto Distribution” on page B-60</li> </ul>

**Purpose** Generalized Pareto parameter estimates

**Syntax**

```
parmhat = gpfif(X)  
[parmhat,parmci] = gpfif(X)  
[parmhat,parmci] = gpfif(X,alpha)  
[...] = gpfif(X,alpha,options)
```

**Description** `parmhat = gpfif(X)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `X`. `parmhat(1)` is the tail index (shape) parameter, `K` and `parmhat(2)` is the scale parameter, `sigma`. `gpfif` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfif(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfif(X,alpha)` returns  $100(1-\text{alpha})\%$  confidence intervals for the parameter estimates.

`[...] = gpfif(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfif')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfif` does not estimate `theta`. It is assumed to be known, and subtracted from `X` before calling `gpfif`.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for

`X > theta`, or, when  $K < 0$ , for

$$0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}$$

**How To**

- “Generalized Pareto Distribution” on page B-60

**Purpose** Generalized Pareto inverse cumulative distribution function

**Syntax** `X = gpinv(P,K,sigma,theta)`

**Description** `X = gpinv(P,K,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `K`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for

`X > theta`, or, when

$$K < 0, 0 \leq \frac{x-\theta}{\sigma} \leq -\frac{1}{k}.$$

**How To** • “Generalized Pareto Distribution” on page B-60

**Purpose** Matrix of scatter plots by group

**Syntax**

```
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)
gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,ynam)
[h,ax,bigax] = gplotmatrix(...)
```

**Description** `gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has  $p$  columns and `y` has  $q$  columns, the figure contains a  $p$ -by- $q$  matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, string array, or cell array of strings. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. The default for `clr` is `'bgrcmyk'`. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `DefaultLineMarkerSize` property. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt)` controls what appears along the diagonal of a plot matrix of *y* versus *x*. Allowable values are 'none', to leave the diagonals blank, 'hist', to plot histograms, or 'variable', to write the variable names. `gplotmatrix` displays histograms along the diagonal only when there is only one variable (i.e., `gplotmatrix(x,[],[],[],[],[],[], 'hist')`).

`gplotmatrix(x,y,group,clr,sym,siz,doleg,dispopt,xnam,yname)` specifies the names of the columns in the *x* and *y* arrays. These names are used to label the *x*- and *y*-axes. *xname* and *yname* must be character arrays or cell arrays of strings, with one name for each column of *x* and *y*, respectively.

`[h,ax,bigax] = gplotmatrix(...)` returns three arrays of handles. *h* is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in *G*. *ax* is a matrix of handles to the axes of the individual plots. If *dispopt* is 'hist', *ax* contains one extra row of handles to invisible axes in which the histograms are plotted. *bigax* is a handle to big (invisible) axes framing the entire plot matrix. *bigax* is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

## Examples

### Create Grouped Data Scatter Plot Matrix

Load the sample data.

```
load discrim;
```

The ratings array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The group array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, climate and housing, with categories 4 (crime) and 7 (arts). Specify group as the grouping variable to visually distinguish the data for large and small cities.

```
figure;  
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```

The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

# gplotmatrix

```
figure;  
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...  
    'br','.o',[],'on',' ',categories(1:2,:),...  
    categories([4 7],:));
```

## How To

- “Grouping Variables” on page 2-52

**Purpose**

Generalized Pareto random numbers

**Syntax**

```
R = gprnd(K,sigma,theta)
R = gprnd(K,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

**Description**

`R = gprnd(K,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gprnd(K,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `K`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `R`.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for

$X > \text{theta}$ , or, when

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

**Purpose** Generalized Pareto mean and variance

**Syntax** `[M,V] = gpstat(K,sigma,theta)`

**Description** `[M,V] = gpstat(K,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `K`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `K = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `K > 0` and `theta = sigma/K`, the GP is equivalent to the Pareto distribution. The mean of the GP is not finite when  $K \geq 1$ , and the variance is not finite when  $K \geq 1/2$ . When  $K \geq 0$ , the GP has positive density for  $X > \theta$ , or when

$$K < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

## Purpose

Train additional trees and add to ensemble

## Syntax

```
B = growTrees(B,ntrees)
B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)
```

## Description

`B = growTrees(B,ntrees)` grows `ntrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B,ntrees,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

- |           |   |
|-----------|---|
| 'nprint'  | Specifies that a diagnostic message showing training progress should display after every value training cycles (grown trees). Default is no diagnostic messages.  |
| 'options' | A struct that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to <code>statset</code> . You can retrieve values of the individual fields with a call to <code>statget</code> . Applicable <code>statset</code> parameters are: <ul style="list-style-type: none"><li>'UseParallel' — If true and if a parpool of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, or serial computation.</li></ul> |

# TreeBagger.growTrees

---

- **UseSubstreams** — Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set Streams to a type allowing substreams: 'mlfg6331\_64' or 'mrg32k3a'.
- **Streams** — A RandStream object or cell array of such objects. If you do not specify Streams, growTrees uses the default stream or streams. If you choose to specify Streams, use a single object except in the case
  - You have an open Parallel pool
  - UseParallel is true
  - UseSubstreams is falseIn that case, use a cell array the same size as the Parallel pool.

**Purpose**

Create index vector from grouping variable

**Syntax**

```
[G,GN]=grp2idx(S)
[G,GN,GL] = grp2idx(S)
```

**Description**

`[G,GN]=grp2idx(S)` creates an index vector `G` from the grouping variable `S`. `S` can be a categorical, numeric, or logical vector; a cell vector of strings; or a character matrix with each row representing a group label. The result `G` is a vector taking integer values from 1 up to the number `K` of distinct groups. `GN` is a cell array of strings representing group labels. `GN(G)` reproduces `S` (aside from any differences in type).

The order of `GN` depends on the grouping variable:

- For numeric and logical grouping variables, the order is the sorted order of `S`.
- For categorical grouping variables, the order is the order of `getlabels(S)`.
- For string grouping variables, the order is the order of first appearance in `S`.

`[G,GN,GL] = grp2idx(S)` returns a column vector `GL` representing the group levels. The set of groups and their order in `GL` and `GN` are the same, except that `GL` has the same type as `S`. If `S` is a character matrix, `GL(G,:)` reproduces `S`, otherwise `GL(G)` reproduces `S`.

`grp2idx` treats NaNs (numeric or logical), empty strings (char or cell array of strings), or `<undefined>` values (categorical) in `S` as missing values and returns NaNs in the corresponding rows of `G`. `GN` and `GL` don't include entries for missing values.

**Examples**

Load the data in `hospital.mat` and create a categorical grouping variable:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);
```

```
ages = hospital.Age(1:5)
ages =
    38
    43
    38
    40
    49

group = AgeGroup(1:5)
group =
    30s
    40s
    30s
    40s
    40s

indices = grp2idx(group)
indices =
    4
    5
    4
    5
    5
```

## How To

- “Grouping Variables” on page 2-52

**Purpose**

Summary statistics organized by group

**Syntax**

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)
```

```
means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] =
grpstats(X,group,whichstats,'Alpha',alpha)
```

```
grpstats(X,group,alpha)
```

**Description**

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a cell array of strings containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character array), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If `X` is a matrix, then `means` is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in `whichstats`.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix `X` determined by the values of the grouping variable, `group`. The grouping variable values are on the horizontal plot axis. Each group mean has  $100 \times (1 - \alpha)\%$  confidence intervals.

- If `X` is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If `group` is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

## **Input Arguments**

### **tbl - Input data**

table | dataset array

Input data, specified as a table or dataset array. `tbl` must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in `tbl` (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument `DataVars` to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

### **groupvar - Identifiers for the grouping variables**

cell array of strings | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input data, `tbl`, specified as one of the following:

String or cell array of strings	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables

Vector of logical values with number of elements equal to the number of variables in `tbl`      Logical indicator with value `true` for grouping variables and `false` otherwise

`[]`      No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, or cell array of strings.

For example, consider an input table, `tbl`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a cell array of strings or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl, 'Gender')`
- `statarray = grpstats(tbl,4)`
- `statarray = grpstats(tbl,logical([0 0 0 1 0 0]))`

## Data Types

`double` | `logical` | `cell` | `char`

## whichstats - Types of summary statistics

`string` | `function handle`

Types of summary statistics to compute, specified as a string or function handle, or a cell array of strings and function handles. Use a cell array to specify multiple types of summary statistics.

Possible string values are:

<code>'mean'</code>	Mean
<code>'sem'</code>	Standard error of the mean
<code>'numel'</code>	Count, or number, of non-NaN elements

'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Range
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

**Example:** `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, Alpha.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

**Example:** `[stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})`

### Data Types

char | function\_handle

### alpha - Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in `whichstats`, you can use `alpha` to specify the significance level for the confidence or prediction intervals. If you specify `alpha`, then `grpstats` returns  $100 \times (1 - \alpha)\%$  confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals ( $\alpha = 0.05$ ).
- Use `alpha` with the `grpstats(X,group,alpha)` syntax to plot group means and corresponding  $100 \times (1 - \alpha)\%$  confidence intervals.

### Data Types

double

### X - Input data

vector | matrix

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

### Data Types

double | single

### group - Grouping variable

categorical array | logical or numeric vector | cell array of strings | []

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use [] to compute summary statistics for all data, without using groups.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'DataVars',[1,3,4],'Alpha',0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

### 'Alpha' - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value  $\alpha$ , then `grpstats` returns  $100 \times (1 - \alpha)\%$  confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ( $\alpha = 0.05$ ).

**Example:** `'Alpha',0.1`

### Data Types

double

### 'DataVars' - Variable names or columns

cell array of strings | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data `tbl` you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a cell array of strings, vector of positive integers, or a logical vector. Use a string to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in `tbl` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

**Example:** `'DataVars',{ 'Height', 'Weight' }`

### Data Types

`double` | `cell` | `char`

### 'VarNames' - Variable names for output

cell array of strings

Variable names for the output `statarray`, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

**Example:** `'VarNames',{ 'MaleMean', 'FemaleMean' }`

### Data Types

`cell`

## Output Arguments

### `statarray` - Group summary statistics

`table` | `dataset array`

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `statarray` as a table. If `tbl` is a dataset array, `grpstats` returns `statarray` as a dataset array.

`statarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by

`groupvar`. There is a row in `statarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `statarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `statarray` is  $n_{groupvars} + 1 + n_{datavars} \times n_{stats}$ , where  $n_{groupvars}$  is the number of variables in `groupvar`,  $n_{datavars}$  is the number of variables for which summary statistics are computed, and  $n_{stats}$  is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `statarray`, unless you specify variable names using the name-value pair argument `VarNames`.

### **means - Group means**

column vector | array

Group means for the groups of data in the vector or matrix `X` determined by the levels of `group`, returned as an  $n_{groups}$ -by- $n_{cols}$  array. Here,  $n_{groups}$  is the number of unique values in the grouping variable, and  $n_{cols}$  is the number of columns in `X`. If `X` is a vector, then `means` is a column vector.

### **stats1,...,statsN - Group summary statistics**

column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix `X` determined by the levels of `group`, returned as  $n_{groups}$ -by- $n_{cols}$  arrays. Here,  $n_{groups}$  is the number of unique values in the grouping variable, and  $n_{cols}$  is the number of columns in `X`. You must specify an output argument for each type of summary statistic specified in `whichstats`.

If a summary statistic type in which `stats` returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups-by-ncols-by-nvals* array.

## Examples

### Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Sex', 'Age', 'Weight', 'Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(ds, 'Sex')
```

```
statarray =
```

	Sex	GroupCount	mean_Age	mean_Weight	mean_Smoker
Female	Female	53	37.717	130.47	0.24528
Male	Male	47	38.915	180.53	0.44681

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`. `GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
statarray = grpstats(ds, 'Smoker', 'mean', 'DataVars', {'Age', 'Weight'})
```

```
statarray =
```

	Smoker	GroupCount	mean_Age	mean_Weight
0	false	66	37.97	149.91
1	true	34	38.882	161.94

In this case, not all variables in `ds` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(ds, {'Sex', 'Smoker'}, {'min', 'max'}, ...
                    'DataVars', 'Weight')
```

```
statarray =
```

	Sex	Smoker	GroupCount	min_Weight	max_Weight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

### Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
ds = hospital(:, {'Age', 'Weight', 'Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(ds, [], {'mean', 'min', 'max'})
```

```
statarray =
```

	GroupCount	mean_Age	min_Age	max_Age	mean_Weight	
All	100	38.28	25	50	154	
	min_Weight	max_Weight	mean_Smoker	min_Smoker	max_Smoker	
All	111	202	0.34	false	true	

The observation name `All` indicates that all observations in `ds` were used to compute the summary statistics.

## Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration,Origin)
```

```
means =  
    18.0500  
    16.3778  
    15.5000  
    15.8867  
    16.6000  
    14.4377
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means =  
    18.0500  
    16.3375  
    16.7000  
    15.5000  
    15.9143  
    15.5000  
    16.6000  
    17.0818  
    16.5267  
    11.6406
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

# grpstats

---

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},...  
                        {'mean','gname'})
```

```
means =
```

```
17.0818  
16.5267  
11.6406  
18.0500  
15.9143  
15.5000  
16.3375  
16.7000  
16.6000  
15.5000
```

```
grps =
```

```
'USA'      '4'  
'USA'      '6'  
'USA'      '8'  
'France'   '4'  
'Japan'    '4'  
'Japan'    '6'  
'Germany'  '4'  
'Germany'  '6'  
'Sweden'   '4'  
'Italy'    '4'
```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

## Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load('carsmall')
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum, median, and maximum acceleration, grouped by country of origin.

```
[grpMin,grpMed,grpMax,grp] = grpstats(Acceleration,Origin,...  
                                     {'min','median','max','gname'})
```

```
grpMin =
```

```
8.0000  
15.3000  
13.9000  
12.2000  
15.7000  
15.5000
```

```
grpMed =
```

```
14.7000  
17.5000  
15.7000  
15.3000  
16.6000  
15.5000
```

```
grpMax =
```

```
22.2000
21.9000
18.2000
24.6000
17.5000
15.5000
```

```
grp =
    'USA'
    'France'
    'Japan'
    'Germany'
    'Sweden'
    'Italy'
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

## Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups

figure()
errorbar((1:ngrps)', means, pred(:,2) - means)
set(gca, 'xtick', 1:ngrps, 'xticklabel', grp)
title('90% Prediction Intervals for Weight by Year')
```

### Plot Group Means and Confidence Intervals

Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

```
grpstats(Acceleration,Cylinders,0.05)
```

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by Cylinders, and 95% confidence intervals. Scale the Weight values by 1000 so the means of Weight and Acceleration are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both Cylinders and Model\_Year. Specify 95% confidence intervals.

```
grpstats(Acceleration,{Cylinders,Model_Year},0.05)
```

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

## Algorithms

- `grpstats` treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

# RepeatedMeasuresModel.grpstats

---

**Purpose** Compute descriptive statistics of repeated measures data by group

**Syntax**  
`statstbl = grpstats(rm,g)`  
`statstbl = grpstats(rm,g,stats)`

**Description** `statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

**Tips**

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain NaNs.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **g - Name of grouping factor or factors**

string | cell array of strings

Name of grouping factor or factors, specified as a string or cell array of strings.

**Example:** 'Drug'

**Example:** {'Drug', 'Sex'}

### **Data Types**

char

## stats - Statistics to compute

string | function handle | cell array of multiple strings and function handles

Statistics to compute, specified as one of the following:

- String specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count or number of elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Maximum minus minimum
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A cell array of strings and function handles.

**Example:** @median

# RepeatedMeasuresModel.grpstats

---

**Example:** @skewness

**Example:** 'gname'

**Example:** {'gname','range','predci'}

## Data Types

char | function\_handle | cell

## Output Arguments

### **statstbl** - Statistics values for each group

table

Statistics values for each group, returned as a table.

## Examples

### **Compute Group Statistics**

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to species.

```
grpstats(rm,'species')
```

# RepeatedMeasuresModel.grpstats

```
ans =
```

species	GroupCount	mean	std
'setosa'	200	2.5355	1.8483
'versicolor'	200	3.573	1.7624
'virginica'	200	4.285	1.9154

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm, 'species', {'gname', 'range', 'predci'})
```

```
ans =
```

species	gname	GroupCount	range	predci
'setosa'	'setosa'	200	5.7	-1.1185
'versicolor'	'versicolor'	200	6	0.088976
'virginica'	'virginica'	200	6.5	0.4985

## Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

# RepeatedMeasuresModel.grpstats

---

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',withi
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors Group and Gender.

```
GS = grpstats(rm,{'Group','Gender'},{'mean','std',@skewness,@kurtosis})
```

```
GS =
```

Group	Gender	GroupCount	mean	std	skewness	kurtosis
A	Female	40	16.554	21.498	0.35324	3.7
A	Male	40	9.8335	20.602	-0.38722	2.7
B	Female	40	11.261	25.779	-0.49177	4.1
B	Male	40	3.6078	24.646	0.55447	2.7
C	Female	40	-11.335	27.186	1.7499	6.1
C	Male	40	-14.028	31.984	1.7362	5.

## See Also

[plot](#) | [fitrm](#)

**Purpose**

Scatter plot by group

**Syntax**

```
gscatter(x,y,group)
gscatter(x,y,group,clr,sym,siz)
gscatter(x,y,group,clr,sym,siz,doleg)
gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)
h = gscatter(...)
```

**Description**

`gscatter(x,y,group)` creates a scatter plot of `x` and `y`, grouped by `group`. `x` and `y` are vectors of the same size. `group` is a grouping variable in the form of a categorical variable, vector, string array, or cell array of strings. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group and appear on the graph with the same marker and color.

`gscatter(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a string array of colors recognized by the `plot` function. The default for `clr` is `'bgrcmyk'`. `sym` is a string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default determined by the `'DefaultLineMarkerSize'` property. If you do not specify enough values for all groups, `gscatter` cycles through the specified values as needed.

`gscatter(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gscatter(x,y,group,clr,sym,siz,doleg,xnam,ynam)` specifies the name to use for the `x`-axis and `y`-axis labels. If the `x` and `y` inputs are simple variable names and `xnam` and `ynam` are omitted, `gscatter` labels the axes with the variable names.

`h = gscatter(...)` returns an array of handles to the lines on the graph.

## Examples

### Scatter Plot of Climate and Housing Ratings

Load the sample data.

```
load discrim
```

The sample data contains ratings of cities according to nine factors such as climate, housing, education, and health in the matrix `ratings` .

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
figure;  
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')  
xlabel('climate');  
ylabel('housing');
```

**See Also** [gplotmatrix](#) | [grpstats](#) | [scatter](#)

**How To** • “Grouping Variables” on page 2-52

# grandstream.gt

---

**Purpose** Greater than relation for handles

**Syntax** `h1 > h2`

**Description** `h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

**See Also** `grandstream` | `eq` | `ge` | `le` | `lt` | `ne`

**Superclasses** grandset

**Purpose** Halton quasi-random point sets

**Description** haltonset is a quasi-random point set class that produces points from the Halton sequence.

**Construction** haltonset Construct Halton quasi-random point set

## Methods **Inherited Methods**

Methods in the following table are inherited from grandset.

disp	Display grandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set
size	Number of dimensions in matrix
suboref	Subscripted reference for grandset

## Properties **Inherited Properties**

Properties in the following table are inherited from grandset.

Dimensions	Number of dimensions
Leap	Interval between points

# haltonset

---

ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

## Copy Semantics

Handle. To learn how this affects your use of the class, see Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation.

## How To

- “Quasi-Random Point Sets” on page 6-16

## Purpose

Construct Halton quasi-random point set

## Syntax

```
p = haltonset(d)
p = haltonset(d,prop1,val1,prop2,val2,...)
```

## Description

`p = haltonset(d)` constructs a  $d$ -dimensional point set `p` of the `haltonset` class, with default property settings.

`p = haltonset(d,prop1,val1,prop2,val2,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `haltonset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of  $2^{53}$ ). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

## Examples

Generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : RR2
```

# haltonset

---

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

**Purpose** Harmonic mean

**Syntax** `m = harmmean(X)`  
`harmmean(X,dim)`

**Description** `m = harmmean(X)` calculates the harmonic mean of a sample. For vectors, `harmmean(x)` is the harmonic mean of the elements in `x`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For  $N$ -dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`harmmean(X,dim)` takes the harmonic mean along dimension `dim` of `X`.

The harmonic mean is

$$m = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

**Examples** The arithmetic mean is greater than or equal to the harmonic mean.

```
x = exprnd(1,10,6);
```

```
harmonic = harmmean(x)
```

```
harmonic =  
    0.3382    0.3200    0.3710    0.0540    0.4936    0.0907
```

```
average = mean(x)
```

```
average =  
    1.3509    1.1583    0.9741    0.5319    1.0088    0.8122
```

**See Also** `mean` | `median` | `geomean` | `trimmean`

# hist3

---

**Purpose** Bivariate histogram

**Syntax**

```
hist3(X)
hist3(X,nbins)
hist3(X,ctrs)
hist3(X,'Edges',edges)
N = hist3(X,...)
[N,C] = hist3(X,...)
hist3(...,param1,val1,param2,val2,...)
```

**Description** `hist3(X)` bins the elements of the  $m$ -by-2 matrix  $X$  into a 10-by-10 grid of equally spaced containers, and plots a histogram. Each column of  $X$  corresponds to one dimension in the bin grid.

`hist3(X,nbins)` plots a histogram using an `nbins(1)`-by-`nbins(2)` grid of bins. `hist3(X,'Nbins',nbins)` is equivalent to `hist3(X,nbins)`.

`hist3(X,ctrs)`, where `ctrs` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins centered on `ctrs{1}` in the first dimension and on `ctrs{2}` in the second. `hist3` assigns rows of  $X$  falling outside the range of that grid to the bins along the outer edges of the grid, and ignores rows of  $X$  containing NaNs. `hist3(X,'Ctrs',ctrs)` is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)`, where `edges` is a two-element cell array of numeric vectors with monotonically non-decreasing values, uses a 2-D grid of bins with edges at `edges{1}` in the first dimension and at `edges{2}` in the second. The  $(i,j)$ th bin includes the value  $X(k,:)$  if

$$\begin{aligned} \text{edges}\{1\}(i) &\leq X(k,1) < \text{edges}\{1\}(i+1) \\ \text{edges}\{2\}(j) &\leq X(k,2) < \text{edges}\{2\}(j+1) \end{aligned}$$

Rows of  $X$  that fall on the upper edges of the grid, `edges{1}(end)` or `edges{2}(end)`, are counted in the  $(I,j)$ th or  $(i,J)$ th bins, where  $I$  and  $J$  are the lengths of `edges{1}` and `edges{2}`. `hist3` does not count rows of  $X$  falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-NaN values.

`N = hist3(X, ...)` returns a matrix containing the number of elements of `X` that fall in each bin of the grid, and does not plot the histogram.

`[N,C] = hist3(X, ...)` returns the positions of the bin centers in a 1-by-2 cell array of numeric vectors, and does not plot the histogram. `hist3(ax,X, ...)` plots onto an axes with handle `ax` instead of the current axes. See the axes reference page for more information about handles to plots.

`hist3(...,param1,val1,param2,val2,...)` allows you to specify graphics parameter name/value pairs to fine-tune the plot.

## Examples

### Plot Density Histogram with Intensity Map

Load the sample data.

```
load seamount
```

Correct grid for negative y-values and draw histogram in 2D.

```
hold on  
dat = [-y,x];  
hist3(dat)
```

# hist3

Extract histogram data.

```
n = hist3(dat); % default is to 10x10 bins  
n1 = n';  
n1(size(n,1) + 1, size(n,2) + 1) = 0;
```

Generate grid for 2-D projected view of intensities.

```
xb = linspace(min(dat(:,1)),max(dat(:,1)),size(n,1)+1);  
yb = linspace(min(dat(:,2)),max(dat(:,2)),size(n,1)+1);
```

Make a pseudocolor plot.

```
h = pcolor(xb,yb,n1);
```

Set the z-level and colormap of the displayed grid, and display the default 3-D perspective view.

```
set(h, 'zdata', ones(size(n1)) * -max(max(n)))
colormap(hot) % heat map
```

# hist3

```
title('Seamount:Data Point Density Histogram and Intensity Map');  
grid on  
view(3);
```

Seamount:Data Point Density Histogram and Intensity Map

## Histogram with Semi-Transparent Bars

Load the sample data.

```
load carbig
```

Use the data to make histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];  
hist3(X,[7 7]);  
xlabel('MPG'); ylabel('Weight');
```

Make a histogram with semi-transparent bars.

```
hist3(X,[7 7],'FaceAlpha',.65);  
xlabel('MPG'); ylabel('Weight');
```

# hist3

```
set(gcf, 'renderer', 'opengl');
```

Specify bin centers, different in each direction; get back counts, but don't make the plot.

```
cnt = hist3(X, {0:10:50 2000:500:5000});
```

### **Histogram Bars Colored According to Height**

Load the sample data.

```
load carbig
```

Make a histogram on a 7-by-7 grid of bins.

```
X = [MPG,Weight];  
hist3(X,[7 7]);  
xlabel('MPG'); ylabel('Weight');  
set(gcf,'renderer','opengl');
```

# hist3

Color the bars based on the frequency of the observations, i.e. according to the height of the bars.

```
set(get(gca,'child'),'FaceColor','interp','CDataMode','auto');
```

## See Also

[accumarray](#) | [bar](#) | [bar3](#) | [hist](#) | [histc](#)

# categorical.hist

---

## Purpose

Plot histogram of categorical data

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
hist(Y)
hist(Y,X)
hist(ax,...)
N = hist(...)
[N,X] = hist(...)
```

## Description

`hist(Y)` plots a histogram bar plot of the counts for each level of the categorical vector `Y`. If `Y` is an  $m$ -by- $n$  categorical matrix, `hist` computes counts for each column of `Y`, and plots a group of  $n$  bars for each categorical level.

`hist(Y,X)` plots bars only for the levels specified in `X`. `X` is a categorical vector or a cell array of level names as strings.

`hist(ax,...)` plots into the axes with handle `ax` instead of `gca`.

`N = hist(...)` returns the counts for each categorical level. If `Y` is a matrix, `hist` works down the columns of `Y` and returns a matrix of counts with one column for each column of `Y` and one row for each categorical level.

`[N,X] = hist(...)` returns the categorical levels corresponding to each count in `N`, or corresponding to each column of `N` if `Y` is a matrix.

## Examples

Create a histogram of age groups from the `hospital.mat` dataset:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);
AgeGroup = droplevels(AgeGroup);
hist(AgeGroup)
```

**See Also**

`hist` | `categorical.levelcounts` | `categorical.getlevels`

# histfit

---

**Purpose** Histogram with a distribution fit

**Syntax**

```
histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)

h = histfit( __ )
```

**Description** `histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit( __ )` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

## Input Arguments

### **data - Input data**

vector

Input data, specified as a vector.

**Example:** `data = [1.5 2.5 4.6 1.2 3.4]`

**Example:** `data = [1.5 2.5 4.6 1.2 3.4]'`

### **Data Types**

double | single

### **nbins - Number of bins**

positive integer | []

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use `[]` for the default number of bins when fitting a distribution.

**Example:** `y = histfit(x,8)`

**Example:** `y = histfit(x,10,'gamma')`

**Example:** `y = histfit(x,[],'weibull')`

### Data Types

double | single

### dist - Distribution to fit

'normal' (default) | string

Distribution to fit to the histogram, specified as a string. The following table shows the supported distributions.

dist	Description
'beta'	Beta
'birnbaumsaunders'	Birnbaum-Saunders
'burr'	Burr Type XII
'exponential'	Exponential
'extreme value' or 'ev'	Extreme value
'gamma'	Gamma
'generalized extreme value' or 'gev'	Generalized extreme value
'generalized pareto' or 'gp'	Generalized Pareto (threshold 0)
'inversegaussian'	Inverse Gaussian
'logistic'	Logistic
'loglogistic'	Loglogistic
'lognormal'	Lognormal

# histfit

---

<b>dist</b>	<b>Description</b>
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocationscale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in data. It works best with continuously distributed samples.

## Data Types

char

## Output Arguments

### **h** - Handles for the plot

plot handle

Handles for the plot, returned as a vector, where  $h(1)$  is the handle to the histogram, and  $h(2)$  is the handle to the density curve.

## Examples

### **Histogram with a Normal Distribution Fit**

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng('default'); % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```

### Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng('default'); % For reproducibility
```

# histfit

---

```
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```

## Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng('default') % For reproducibility  
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```

## **Histogram with a Kernel Smoothing Function Fit**

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng('default') % For reproducibility  
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```

### Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng('default'); % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

# histfit

---

```
h = histfit(r,10,'normal')
```

```
h =
```

```
175.0723  
176.0718
```

Change the bar colors of the histogram.

```
set(h(1), 'FaceColor', [.8 .8 1])
```

Change the color of the density curve.

```
set(h(2), 'Color', [.2 .2 .2])
```

# histfit

---

**See Also**     `hist` | `normfit` | `dffitool`

**Purpose**

Hidden Markov model posterior state probabilities

**Syntax**

```
PSTATES = hmmdecode(seq,TRANS,EMIS)
[PSTATES,logpseq] = hmmdecode(...)
[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...)
hmmdecode(...,'Symbols',SYMBOLS)
```

**Description**

PSTATES = hmmdecode(seq,TRANS,EMIS) calculates the posterior state probabilities, PSTATES, of the sequence seq, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state  $k$  at step  $i$ , given the observed sequence of symbols, sym. You specify the model by a transition probability matrix, TRANS, and an emissions probability matrix, EMIS. TRANS( $i$ ,  $j$ ) is the probability of transition from state  $i$  to state  $j$ . EMIS( $k$ , seq) is the probability that symbol seq is emitted from state  $k$ .

PSTATES is an array with the same length as seq and one row for each state in the model. The ( $i$ ,  $j$ )th element of PSTATES gives the probability that the model is in state  $i$  at the  $j$ th step, given the sequence seq.

---

**Note** The function hmmdecode begins with the model in state 1 at step 0, prior to the first emission. hmmdecode computes the probabilities in PSTATES based on the fact that the model begins in state 1.

---

[PSTATES,logpseq] = hmmdecode(...) returns logpseq, the logarithm of the probability of sequence seq, given transition matrix TRANS and emission matrix EMIS.

[PSTATES,logpseq,FORWARD,BACKWARD,S] = hmmdecode(...) returns the forward and backward probabilities of the sequence scaled by S.

hmmdecode(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

# hmmdecode

---

## Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
pStates = hmmdecode(seq,trans,emis);
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'})
pStates = hmmdecode(seq,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'});
```

## See Also

[hmmgenerate](#) | [hmmestimate](#) | [hmmviterbi](#) | [hmmtrain](#)

**Purpose**

Hidden Markov model parameter estimates from emissions and states

**Syntax**

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

**Description**

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, TRANS, and emission, EMIS, probabilities of a hidden Markov model for sequence, seq, with known states, states.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix PSEUDO. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size  $m$ -by- $n$ , where  $m$  is the number of states in the hidden Markov model and  $n$  is the number of possible emissions. If the  $i \rightarrow k$  emission does not occur in seq, you can set PSEUDOE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size  $m$ -by- $m$ , where  $m$  is the number of states in the hidden

Markov model. If the  $i \rightarrow j$  transition does not occur in `states`, you can set `PSEUDOTR(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

## Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in `TRANS` or `EMIS`. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of `PSEUDO` or `PSEUDOTR` to 1. For example, if the transition  $i \rightarrow j$  does not occur in `states`, set `PSEUOTR(i, j) = 1`. This forces `TRANS(i, j)` to be positive.

If you have an estimate for the expected number of transitions  $i \rightarrow j$  in a sequence of the same length as `states`, and the actual number of transitions  $i \rightarrow j$  that occur in `seq` is substantially less than what you expect, you can set `PSEUOTR(i, j)` to the expected number. This increases the value of `TRANS(i, j)`. For transitions that do occur in `states` with the frequency you expect, set the corresponding entry of `PSEUDOTR` to 0, which does not increase the corresponding entry of `TRANS`.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

## References

[1] Durbin, R., S. Eddy, A. Krogh, and G. Mitchison. *Biological Sequence Analysis*. Cambridge, UK: Cambridge University Press, 1998.

## Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

**See Also**

`hmmgenerate` | `hmmdecode` | `hmmviterbi` | `hmmtrain`

# hmmgenerate

---

**Purpose** Hidden Markov model states and emissions

**Syntax** `[seq,states] = hmmgenerate(len,TRANS,EMIS)`  
`hmmgenerate(...,'Symbols',SYMBOLS)`  
`hmmgenerate(...,'Statenames',STATENAMES)`

**Description** `[seq,states] = hmmgenerate(len,TRANS,EMIS)` takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence `seq` of emission symbols
- A random sequence `states` of states

The length of both `seq` and `states` is `len`.  $\text{TRANS}(i,j)$  is the probability of transition from state  $i$  to state  $j$ .  $\text{EMIS}(k,l)$  is the probability that symbol  $l$  is emitted from state  $k$ .

---

**Note** The function `hmmgenerate` begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state  $i_1$ , with probability  $T_{1i_1}$ , and generates an emission  $a_{k_1}$  with probability  $E_{i_1k_1}$ . `hmmgenerate` returns  $i_1$  as the first entry of `states`, and  $a_{k_1}$  as the first entry of `seq`.

---

`hmmgenerate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through  $N$ , where  $N$  is the number of possible emissions.

`hmmgenerate(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array or a cell array of the names of the states. The default state names are 1 through  $M$ , where  $M$  is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of

the output states is be 1 with probability 0.95 and 2 with probability 0.05.

## Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

**Description** [ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS) estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. *seq* can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. TRGUESS and EMITGUESS are initial estimates of the transition and emission probability matrices. TRGUESS(*i*,*j*) is the estimated probability of transition from state *i* to state *j*. EMITGUESS(*i*,*k*) is the estimated probability that symbol *k* is emitted from state *i*.

hmmtrain(...,'Algorithm',*algorithm*) specifies the training algorithm. *algorithm* can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

hmmtrain(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmtrain(...,'Tolerance',tol) specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is 1e-4.

hmmtrain(...,'Maxiterations',maxiter) specifies the maximum number of iterations for the estimation process. The default maximum is 100.

`hmmtrain(..., 'Verbose', true)` returns the status of the algorithm at each iteration.

`hmmtrain(..., 'Pseudoemissions', PSEUDO_E)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. `PSEUDO_E` should be a matrix of size  $m$ -by- $n$ , where  $m$  is the number of states in the hidden Markov model and  $n$  is the number of possible emissions. If the  $i \rightarrow k$  emission does not occur in `seq`, you can set `PSEUDO_E(i, k)` to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(..., 'Pseudotransitions', PSEUDO_T)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. `PSEUDO_T` should be a matrix of size  $m$ -by- $m$ , where  $m$  is the number of states in the hidden Markov model. If the  $i \rightarrow j$  transition does not occur in `states`, you can set `PSEUDO_T(i, j)` to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

## Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

# hmmtrain

---

The default value of 'tolerance' is .0001. Increasing the tolerance decreases the number of steps the hmmtrain algorithm executes before it terminates.

## **maxiterations**

The maximum number of iterations, 'maxiterations', controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes maxiter iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of 'maxiterations' to make the algorithm reach the desired tolerance before terminating.

## **Examples**

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;  
        1/10, 1/10, 1/10, 1/10, 1/10, 1/2];  
  
seq1 = hmmgenerate(100,trans,emis);  
seq2 = hmmgenerate(200,trans,emis);  
seqs = {seq1,seq2};  
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

## **See Also**

[hmmgenerate](#) | [hmmdecode](#) | [hmmestimate](#) | [hmmviterbi](#)

**Purpose** Hidden Markov model most probable state path

**Syntax**

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

**Description** STATES = hmmviterbi(seq,TRANS,EMIS) given a sequence, seq, calculates the most likely path through the hidden Markov model specified by transition probability matrix, TRANS, and emission probability matrix EMIS. TRANS(i,j) is the probability of transition from state i to state j. EMIS(i,k) is the probability that symbol k is emitted from state i.

---

**Note** The function hmmviterbi begins with the model in state 1 at step 0, prior to the first emission. hmmviterbi computes the most likely path based on the fact that the model begins in state 1.

---

hmmviterbi(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be a numeric array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmviterbi(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be a numeric array or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

## Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis);
estimatedStates = hmmviterbi(seq,trans,emis);
```

# hmmviterbi

---

```
[seq,states] = ...  
    hmmgenerate(100,trans,emis,...  
                'Statenames',{'fair';'loaded'});  
estimatesStates = ...  
    hmmviterbi(seq,trans,emis,...  
               'Statenames',{'fair';'loaded'});
```

**Purpose**

Horizontal concatenation for categorical arrays

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
C = horzcat(dim,A,B,...)
C = horzcat(A,B)
```

**Description**

`C = horzcat(dim,A,B,...)` horizontally concatenates the categorical arrays `A,B,...`. For matrices, all inputs must have the same number of rows. For n-D arrays, all inputs must have the same sizes except in the second dimension. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs, as determined by their labels.

`C = horzcat(A,B)` is called for the syntax `[A B]`.

**See Also**

`cat` | `vertcat`

# dataset.horzcat

---

## Purpose

Horizontal concatenation for dataset arrays

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
ds = horzcat(ds1, ds2, ...)
```

## Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1`, `ds2`, ... . You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

`cat` | `vertcat`

**Purpose** Hougen-Watson model

**Syntax** `yhat = hougen(beta,x)`

**Description** `yhat = hougen(beta,x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

**References** [1] Bates, D. M., and D. G. Watts. *Nonlinear Regression Analysis and Its Applications*. Hoboken, NJ: John Wiley & Sons, Inc., 1988.

**See Also** `rsmdemo`

# hygecdf

---

**Purpose** Hypergeometric cumulative distribution function

**Syntax** `hygecdf(x,M,K,N)`  
`hygecdf(x,M,K,N,'upper')`

**Description** `hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x | M, K, N) = \sum_{i=0}^x \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}$$

The result,  $p$ , is the probability of drawing up to  $x$  of a possible  $K$  items in  $N$  drawings without replacement from a group of  $M$  objects.

## Examples **Compute Hypergeometric Distribution CDF**

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

`p = hygecdf(2,100,20,10)`

`p =`  
`0.6812`

## See Also

[cdf](#) | [hygepdf](#) | [hygeinv](#) | [hygestat](#) | [hygernd](#)

# hygeinv

---

**Purpose** Hypergeometric inverse cumulative distribution function

**Syntax** `hygeinv(P,M,K,N)`

**Description** `hygeinv(P,M,K,N)` returns the smallest integer  $X$  such that the hypergeometric cdf evaluated at  $X$  equals or exceeds  $P$ . You can think of  $P$  as the probability of observing  $X$  defective items in  $N$  drawings without replacement from a group of  $M$  items where  $K$  are defective.

**Examples** Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
```

```
x =  
    3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
```

```
x =  
    0
```

**See Also** `icdf` | `hygecdf` | `hygepdf` | `hygestat` | `hygernd`

**Purpose** Hypergeometric probability density function

**Syntax** `Y = hygepdf(X,M,K,N)`

**Description** `Y = hygepdf(X,M,K,N)` computes the hypergeometric pdf at each of the values in  $X$  using the corresponding size of the population,  $M$ , number of items with the desired characteristic in the population,  $K$ , and number of samples drawn,  $N$ .  $X$ ,  $M$ ,  $K$ , and  $N$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in  $M$ ,  $K$ , and  $N$  must all be positive integers, with  $N \leq M$ . The values in  $X$  must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x | M, K, N) = \frac{\binom{K}{x} \binom{M-K}{N-x}}{\binom{M}{N}}$$

The result,  $y$ , is the probability of drawing exactly  $x$  of a possible  $K$  items in  $n$  drawings without replacement from a group of  $M$  objects.

**Examples** Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
```

```
p =
```

```
0.0951 0.2679 0.3182 0.2092 0.0841 0.0215
```

**See Also** `pdf` | `hygecdf` | `hygeinv` | `hygestat` | `hygernd`

# hygernd

---

**Purpose** Hypergeometric random numbers

**Syntax**  
`R = hygernd(M,K,N)`  
`R = hygernd(M,K,N,m,n,...)`  
`R = hygernd(M,K,N,[m,n,...])`

**Description** `R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m`-by-`n`-by-... array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

**Examples**  
`numbers = hygernd(1000,40,50)`  
`numbers =`  
`1`

# icdf

---

**Purpose** Inverse cumulative distribution functions

**Syntax**  
`Y = icdf(name,X,A)`  
`Y = icdf(name,X,A,B)`  
`Y = icdf(name,X,A,B,C)`

**Description** `Y = icdf(name,X,A)` computes the inverse cumulative distribution function for the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`. The inverse cumulative distribution function is evaluated at the values in `X` and its values are returned in `Y`.

If `X` and `A` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`. If `A` is a scalar, it is expanded to a constant matrix the same size as `X`.

`Y` is the common size of `X` and `A` after any necessary scalar expansion.

`Y = icdf(name,X,A,B)` computes the inverse cumulative distribution function for two-parameter families of distributions, where parameter values are given in `A` and `B`.

If `X`, `A`, and `B` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A` and `B`. If either `A` or `B` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, and `B` after any necessary scalar expansion.

`Y = icdf(name,X,A,B,C)` computes the inverse cumulative distribution function for three-parameter families of distributions, where parameter values are given in `A`, `B`, and `C`.

If `X`, `A`, `B`, and `C` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`, `B`, and `C`. If any of `A`, `B` or `C` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, `B` and `C` after any necessary scalar expansion.

## Examples

Compute the icdf of the normal distribution with mean 0 and standard deviation 1 at inputs 0.1, 0.3, ..., 0.9:

```
x1 = icdf('Normal',0.1:0.2:0.9,0,1)
x1 =
    -1.2816   -0.5244    0    0.5244    1.2816
```

The order of the parameters is the same as for `norminv`.

Compute the icdfs of Poisson distributions with rate parameters 0, 1, ..., 4 at inputs 0.1, 0.3, ..., 0.9, respectively:

```
x2 = icdf('Poisson',0.1:0.2:0.9,0:4)
x2 =
    NaN    0    2    4    7
```

The order of the parameters is the same as for `poissinv`.

**Purpose** Inconsistency coefficient

**Syntax**  $Y = \text{inconsistent}(Z)$   
 $Y = \text{inconsistent}(Z, d)$

**Description**  $Y = \text{inconsistent}(Z)$  computes the inconsistency coefficient for each link of the hierarchical cluster tree  $Z$ , where  $Z$  is an  $(m-1)$ -by-3 matrix generated by the linkage function. The inconsistency coefficient characterizes each link in a cluster tree by comparing its height with the average height of other links at the same level of the hierarchy. The higher the value of this coefficient, the less similar the objects connected by the link.

$Y = \text{inconsistent}(Z, d)$  computes the inconsistency coefficient for each link in the hierarchical cluster tree  $Z$  to depth  $d$ , where  $d$  is an integer denoting the number of levels of the cluster tree that are included in the calculation. By default,  $d=2$ .

The output,  $Y$ , is an  $(m-1)$ -by-4 matrix formatted as follows.

Column	Description
1	Mean of the heights of all the links included in the calculation.
2	Standard deviation of the heights of all the links included in the calculation.
3	Number of links included in the calculation.
4	Inconsistency coefficient.

For each link,  $k$ , the inconsistency coefficient is calculated as:

$$Y(k, 4) = (z(k, 3) - Y(k, 1)) / Y(k, 2)$$

For leaf nodes, nodes that have no further nodes under them, the inconsistency coefficient is set to 0.

## Examples

### Compute Inconsistency Coefficient

Create the sample data.

```
X = gallery('uniformdata',[10 2],12);  
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y, 'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```

Compute the inconsistency coefficient for each link in the cluster tree  $Z$  to depth 3.

$W = \text{inconsistent}(Z, 3)$

$W =$

0.1313	0	1.0000	0
0.1386	0	1.0000	0

# inconsistent

<b>Purpose</b>	Increase reference data sets
<b>Syntax</b>	<code>eva_out = increaseB(eva,nref)</code>
<b>Description</b>	<code>eva_out = increaseB(eva,nref)</code> returns a gap criterion clustering evaluation object <code>eva_out</code> that uses the same evaluation criteria as the input object <code>eva</code> and an additional number of reference data sets as specified by <code>nref</code> .
<b>Input Arguments</b>	<p><b>eva - Clustering evaluation data</b> clustering evaluation object</p> <p>Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using <code>evalclusters</code>.</p> <p><b>nref - Number of additional reference data sets</b> positive integer value</p> <p>Number of additional reference data sets, specified as a positive integer value.</p>
<b>Output Arguments</b>	<p><b>eva_out - Updated clustering evaluation data</b> clustering evaluation object</p> <p>Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. <code>eva_out</code> contains evaluation data obtained using the reference data sets from the input object <code>eva</code> plus a number of additional reference data sets as specified in <code>nref</code>.</p> <p><code>increaseB</code> updates the <code>B</code> property of the input object <code>eva</code> to reflect the increase in the number of reference data sets used to compute the gap criterion values. <code>increaseB</code> also updates the <code>CriterionValues</code> property with gap criterion values computed using the total number of reference data sets. <code>increaseB</code> might also update the <code>OptimalK</code> and <code>OptimalY</code> properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference</p>

data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

## Examples

### Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
eva = evalclusters(meas, 'kmeans', 'gap', 'klist', 1:5, 'B', 50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
   InspectedK: [1 2 3 4 5]
 CriterionValues: [0.0848 0.5920 0.8750 1.0044 1.0462]
   OptimalK: 5
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is five.

The value of the `B` property of `eva` shows 50 reference data sets.

```
eva.B
```

```
ans =
```

```
50
```

Increase the number of reference data sets by 50, for a total of 100 sets.

```
eva = increaseB(eva,50)
```

```
eva =
```

```
GapEvaluation with properties:
```

```
NumObservations: 150
```

```
  InspectedK: [1 2 3 4 5]
```

```
CriterionValues: [0.0824 0.5899 0.8742 1.0044 1.0463]
```

```
  OptimalK: 4
```

The returned results now indicate that the optimal number of clusters is four.

The value of the **B** property of `eva` now shows 100 reference data sets.

```
eva.B
```

```
ans =
```

```
100
```

# ProbDist.InputData property

---

**Purpose** Read-only structure containing information about input data to ProbDist object

**Description** InputData is a read-only property of the ProbDist class. InputData is a structure containing information about input data to a ProbDist object. It includes the following fields:

- data
- cens
- freq

**Values** Possible values for the three fields in the structure are any data supplied to the `fitdist` function:

- `data` — Data passed to the `fitdist` function when creating the ProbDist object. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam.ProbDistUnivParam` constructor.
- `cens` — The vector supplied with the 'censoring' parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam.ProbDistUnivParam` constructor.
- `freq` — The vector supplied with the 'frequency' parameter when creating the ProbDist object using the `fitdist` function. This field is empty if the ProbDist object was created without fitting to data, that is by using the `ProbDistUnivParam.ProbDistUnivParam` constructor.

Use this information to view and compare the data supplied to create distributions.

**Purpose**

Convert categorical array to signed 8-bit integer array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`B = int8(A)`

**Description**

`B = int8(A)` converts the categorical array `A` to a signed 8-bit integer array. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.

Undefined elements of `A` are assigned the value 0 in `B`. If `A` contains more than `intmax('int8')` levels, the internal codes will saturate to `intmax('int8')` when cast to `int8`.

# categorical.int64

---

<b>Purpose</b>	Convert categorical array to signed 64-bit integer array The <code>nominal</code> and <code>ordinal</code> array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB <code>categorical</code> data type instead.
<b>Syntax</b>	<code>B = int64(A)</code>
<b>Description</b>	<code>B = int64(A)</code> converts the categorical array <code>A</code> to a signed 64-bit integer array. Each element of <code>B</code> contains the internal categorical level code for the corresponding element of <code>A</code> . Undefined elements of <code>A</code> are assigned the value 0 in <code>B</code> .
<b>See Also</b>	<code>double</code>   <code>uint64</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Integers”</li></ul>

**Purpose** Interaction plot for grouped data

**Syntax**

```
interactionplot(Y,GROUP)
interactionplot(Y,GROUP,'varnames',VARNAMES)
[h,AX,bigax] = interactionplot(...)
```

**Description** `interactionplot(Y,GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or a single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position  $(i,j)$  is the interaction of the two variables whose names are given at row diagonal  $(i,i)$  and column diagonal  $(j,j)$ , respectively.

`interactionplot(Y,GROUP,'varnames',VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2', ... .

`[h,AX,bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

## Examples **Display Interaction Plots**

Randomly generate data for a response variable `y` .

# interactionplot

---

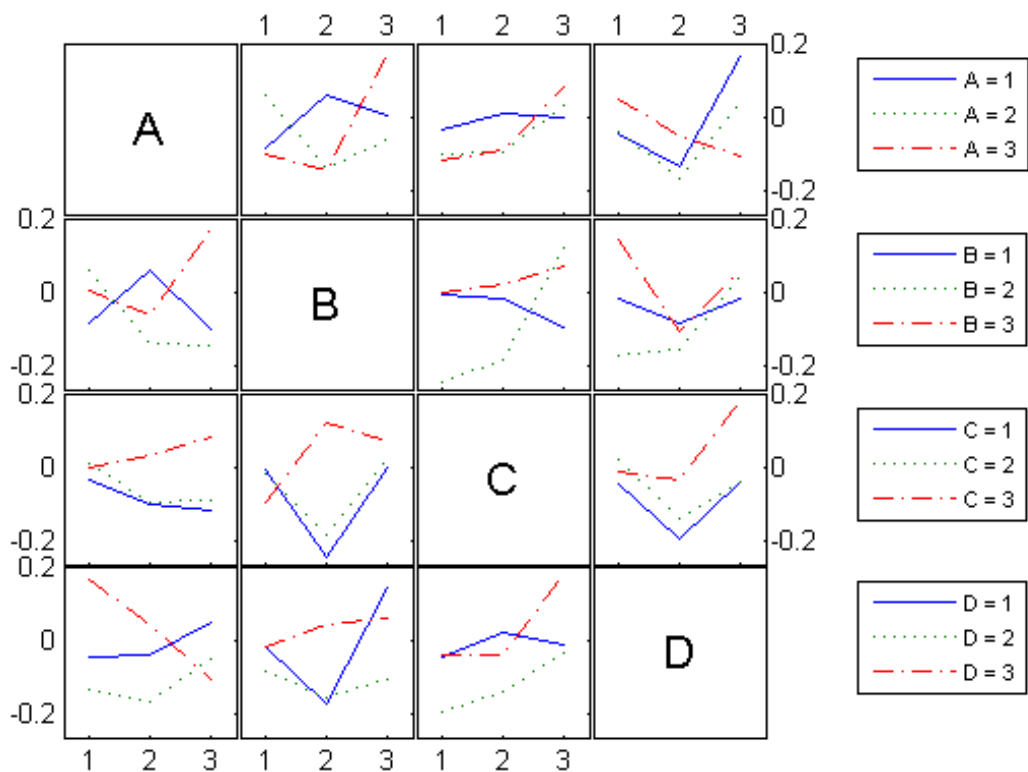

```
rng('default'); % for reproducibility  
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group,'varnames',{'A','B','C','D'})
```

**See Also** [maineffectsplot](#) | [multivarichart](#)

# categorical.intersect

---

**Purpose** Set intersection for categorical arrays

**Compatibility** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
C = intersect(A,B)
[C,IA,IB] = intersect(A,B)
[...] = intersect(A,B,'rows')
[...] = intersect(...,'legacy')
[...] = intersect(A,B,setOrder)
[...] = intersect(A,B,'rows',setOrder)
```

**Description** `C = intersect(A,B)` for categorical vectors `A` and `B`, returns a categorical vector `C` containing the values common to the two vectors with no repetitions. The result `C` is sorted. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs.

`[C,IA,IB] = intersect(A,B)` also returns index vectors `IA` and `IB` such that `C = A(IA)` and `C = B(IB)`. If there are repeated common values in `A` or `B`, then the index of the last occurrence of each repeated value is returned.

`[...] = intersect(A,B,'rows')` for categorical matrices `A` and `B` with the same number of columns, returns the rows common to the two matrices. The rows of the matrix `C` are sorted. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs. The optional outputs `IA` and `IB` are index vectors such that `C = A(IA,:)` and `C = B(IB,:)`.

`[...] = intersect(...,'legacy')` preserves the pre-2012a behavior of `intersect`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or `'rows'`.

`[...] = intersect(A,B,setOrder)` and `[...] = intersect(A,B,'rows',setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values or rows of `C` in sorted order. `setOrder='stable'` returns the values or rows of `C`

in the same order as A. If A and B are row vectors, then C is also a row vector. Otherwise, C is a column vector. IA and IB are column vectors. If there are repeated common values in A or B, then the index of the first occurrence of each repeated value is returned.

# dataset.intersect

---

## Purpose

Set intersection for dataset array observations

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( __ )
```

## Description

`C = intersect(A,B)` for dataset arrays `A` and `B` returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observations in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = intersect( __ )` also returns index vectors `iA` and `iB` such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in `A` or `B`, then `intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

## Input Arguments

**A,B**

Input dataset arrays.

**vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in A and B that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

## **setOrder**

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A.

## **Output Arguments**

### **C**

Dataset array with the common set of observations in A and B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

### **iA**

Index vector, indicating the observations in A that are common to B. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

### **iB**

Index vector, indicating the observations in B that are common to A. The vector `iB` contains the index to the first occurrence of any repeated observations in B.

## **Examples**

### **Intersection of Two Dataset Arrays**

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

# dataset.intersect

---

```
A = dataset('XLSFile', 'hospitalSmall.xlsx');  
B = dataset('XLSFile', 'hospitalSmall.xlsx', 'Sheet', 2);
```

Return the intersection and index vectors.

```
[C, iA, iB] = intersect(A, B);
```

C =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

There is one observation in common between A and B.

Find the observation in the original dataset arrays.

```
A(iA, :)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

```
B(iB, :)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Inverse Gaussian probability distribution object

**Description** `prob.InverseGaussianDistribution` is an object consisting of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('InverseGaussian')` creates an inverse Gaussian probability distribution object using the default parameter values.

`pd = makedist('InverseGaussian','mu',mu,'lambda',lambda)` creates an inverse Gaussian probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Scale parameter**

1 (default) | positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **lambda - Shape parameter**

1 (default) | positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

### **Data Types**

single | double

# prob.InverseGaussianDistribution

---

## Properties

### **mu - Scale parameter**

positive scalar value

Scale parameter for the inverse Gaussian distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **lambda - Shape parameter**

positive scalar value

Shape parameter for the inverse Gaussian distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### **Data Types**

struct

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## **Data Types**

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## **Data Types**

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

# prob.InverseGaussianDistribution

---

## Data Types

char

## ParameterIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Definitions **Inverse Gaussian Distribution**

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
mu	Scale parameter	$\mu > 0$
lambda	Shape parameter	$\lambda > 0$

The probability density function (pdf) is

$$f(x | \mu, \lambda) = \sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\} ; x > 0.$$

## Examples **Create an Inverse Gaussian Distribution Object Using Default Parameters**

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')
```

```
pd =
```

```
InverseGaussianDistribution
```

```
Inverse Gaussian distribution
```

```
mu = 1
```

```
lambda = 1
```

## Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

```
pd = makedist('InverseGaussian','mu',2,'lambda',4)
```

```
pd =
```

```
InverseGaussianDistribution
```

```
Inverse Gaussian distribution
```

```
mu = 2
```

```
lambda = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s =
```

```
1.4142
```

- Property Attributes

# invpred

**Purpose** Inverse prediction

**Syntax**  
 $X0 = \text{invpred}(X, Y, Y0)$   
 $[X0, DXLO, DXUP] = \text{invpred}(X, Y, Y0)$   
 $[X0, DXLO, DXUP] = \text{invpred}(X, Y, Y0, name1, val1, name2, val2, \dots)$

**Description**  $X0 = \text{invpred}(X, Y, Y0)$  accepts vectors  $X$  and  $Y$  of the same length, fits a simple regression, and returns the estimated value  $X0$  for which the height of the line is equal to  $Y0$ . The output,  $X0$ , has the same size as  $Y0$ , and  $Y0$  can be an array of any size.

$[X0, DXLO, DXUP] = \text{invpred}(X, Y, Y0)$  also computes 95% inverse prediction intervals.  $DXLO$  and  $DXUP$  define intervals with lower bound  $X0 - DXLO$  and upper bound  $X0 + DXUP$ . Both  $DXLO$  and  $DXUP$  have the same size as  $Y0$ .

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to  $-\text{Inf}$  or  $+\text{Inf}$ , and some may extend over the entire real line.

$[X0, DXLO, DXUP] = \text{invpred}(X, Y, Y0, name1, val1, name2, val2, \dots)$  specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 * (1 - \text{alpha})\%$ . Default is $\text{alpha} = 0.05$ for 95% confidence.
'predopt'	Either 'observation', the default value to compute the intervals for $X0$ at which a new observation could equal $Y0$ , or 'curve' to compute intervals for the $X0$ value at which the curve is equal to $Y0$ .

**Examples****Inverse Prediction**

Generate sample data.

```
x = 4*rand(25,1);  
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```

# invpred

---

Predict the  $x$  value for a given  $y$  value of 20.

```
x0 = invpred(x,y,20)
```

```
x0 =
```

```
1.9967
```

## See Also

**Purpose**

Inverse permute dimensions of categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`A = ipermute(B,order)`

**Description**

`A = ipermute(B,order)` is the inverse of `permute`. `ipermute` rearranges the dimensions of the categorical array `B` so that `permute(A,order)` will produce `B`. The array produced has the same values of `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. The elements of `order` must be a rearrangement of the numbers from 1 to `n`.

**See Also**

`permute`

# iqr

---

**Purpose** Interquartile range

**Syntax** `y = iqr(X)`  
`iqr(X,dim)`

**Description** `y = iqr(X)` returns the interquartile range of the values in `X`. For vector input, `y` is the difference between the 75th and the 25th percentiles of the sample in `X`. For matrix input, `y` is a row vector containing the interquartile range of each column of `X`. For N-dimensional arrays, `iqr` operates along the first nonsingleton dimension of `X`.

`iqr(X,dim)` calculates the interquartile range along the dimension `dim` of `X`.

**Tips** The IQR is a robust estimate of the spread of the data, since changes in the upper and lower 25% of the data do not affect it. If there are outliers in the data, then the IQR is more representative than the standard deviation as an estimate of the spread of the body of the data. The IQR is less efficient than the standard deviation as an estimate of the spread when the data is all from the normal distribution.

Multiply the IQR by 0.7413 to estimate  $\sigma$  (the second parameter of the normal distribution.)

**Examples** This Monte Carlo simulation shows the relative efficiency of the IQR to the sample standard deviation for normal data.

```
x = normrnd(0,1,100,100);
s = std(x);
s_IQR = 0.7413*iqr(x);
efficiency = (norm(s-1)./norm(s_IQR-1)).^2
efficiency =
    0.3297
```

**See Also** `std` | `mad` | `range`

<b>Purpose</b>	Return interquartile range (IQR) for ProbDistUnivKernel object	
<b>Syntax</b>	$Y = \text{iqr}(PD)$	
<b>Description</b>	$Y = \text{iqr}(PD)$ returns $Y$ , the interquartile range for the ProbDistUnivKernel object $PD$ . The interquartile range is the distance between the 75th and 25th percentiles.	
<b>Input Arguments</b>	$PD$	An object of the class ProbDistUnivKernel.
<b>Output Arguments</b>	$Y$	The value of the interquartile range for the ProbDistUnivKernel object $PD$ .
<b>See Also</b>	<a href="#">iqr</a>   <a href="#">ProbDistUnivKernel.icdf</a>	

# ProbDistUnivParam.iqr

---

<b>Purpose</b>	Return interquartile range (IQR) for ProbDistUnivParam object	
<b>Syntax</b>	$Y = \text{iqr}(PD)$	
<b>Description</b>	$Y = \text{iqr}(PD)$ returns $Y$ , the interquartile range for the ProbDistUnivParam object $PD$ . The interquartile range is the distance between the 75th and 25th percentiles.	
<b>Input Arguments</b>	$PD$	An object of the class ProbDistUnivParam.
<b>Output Arguments</b>	$Y$	The value of the interquartile range for the ProbDistUnivParam object $PD$ .
<b>See Also</b>	<a href="#">iqr</a>   <a href="#">ProbDistUnivParam.icdf</a>	

**Purpose**

Interquartile range of probability distribution object

**Syntax**

```
r = iqr(pd)
```

**Description**

`r = iqr(pd)` returns the interquartile range `r` of the probability distribution `pd`.

**Input Arguments****pd - Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

**Output Arguments****r - Interquartile range**

scalar value

Interquartile range of the probability distribution, returned as a scalar value. The value of `r` is the difference between the values of the 75th and 25th percentile of the probability distribution.

**Examples****Interquartile Range of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

# prob.TruncatableDistribution.iqr

---

```
Normal distribution
  mu = 75.0083 [73.4321, 76.5846]
  sigma = 8.7202 [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)
```

```
r =
```

```
11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd, [0.25, 0.75])
```

```
y =
```

```
69.1266 80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2) - y(1)
```

```
ans =
```

```
11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

# classregtree.isbranch

---

**Purpose** Test node for branch

**Syntax** `ib = isbranch(t)`  
`ib = isbranch(t,nodes)`

**Description** `ib = isbranch(t)` returns an  $n$ -element logical vector `ib` that is true for each branch node and false for each leaf node.

`ib = isbranch(t,nodes)` takes a vector `nodes` of node numbers and returns a vector of logical values for the specified nodes.

**Examples** Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})

t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```

**Purpose**

True for empty categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`TF = isempty(A)`

**Description**

`TF = isempty(A)` returns true (1) if `A` is an empty categorical array and false (0) otherwise. An empty array has no elements, that is `numel(A)==0`.

**See Also**

`numel` | `size`

# dataset.isempty

---

## **Purpose**

True for empty dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Syntax**

```
tf = isempty(A)
```

## **Description**

`tf = isempty(A)` returns true (1) if A is an empty dataset and false (0) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

## **See Also**

`size`

**Purpose**

True if categorical arrays are equal

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
TF = isequal(A,B)
TF = isequal(A,B,C,...)
```

**Description**

`TF = isequal(A,B)` is true (1) if the categorical arrays `A` and `B` are the same class, have the same size and the same sets of levels, and contain the same values, and false (0) otherwise.

`TF = isequal(A,B,C,...)` is true (1) if all the input arguments are equal.

Elements with undefined levels are not considered equal to each other.

**See Also**

`getlabels`

# categorical.islevel

---

## Purpose

Test for levels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
I = islevel(levels,A)
```

## Description

`I = islevel(levels,A)` returns a logical array `I` the same size as the string, cell array of strings, or 2-D character matrix `levels`. `I` is true (1) where the corresponding element of `levels` is the label of a level in the categorical array `A`, even if the level contains no elements. `I` is false (0) otherwise.

## Examples

Display age levels in the data in `hospital.mat`, before and after dropping occupied levels:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
disp(labels')
'0s' '10s' '20s' '30s' '40s' '50s' '60s' '70s' '80s' '90s'

AgeGroup = ordinal(hospital.Age, labels, [], edges);
I = islevel(labels, AgeGroup);
disp(I')
1 1 1 1 1 1 1 1 1 1

AgeGroup = droplevels(AgeGroup);
I = islevel(labels, AgeGroup);
disp(I')
0 0 1 1 1 1 0 0 0 0
```

## See Also

`ismember` | `isundefined`

## Purpose

True for elements of categorical array in set

## Compatibility

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
TF = ismember(A,B)
[TF,LOCB] = ismember(A,B)
[...] = ismember(A,B,'rows')
[...] = intersect(...,'legacy')
```

## Description

`TF = ismember(A,B)` for categorical arrays `A` and `B`, returns a logical array the same size as `A`, containing true (1) where the elements of `A` are in `B`, and false (0) otherwise. `B` can also be a cell array of strings or two-dimensional character array containing level labels.

`[TF,LOCB] = ismember(A,B)` also returns an index array `LOCB` containing the highest absolute index in `B` for each element in `A` which is a member of `B`, and 0 if there is no such index.

`[...] = ismember(A,B,'rows')`, for categorical matrices `A` and `B` with the same number of columns, returns a logical vector containing true (1) where the rows of `A` are also rows of `B`, and false (0) otherwise. The optional output `LOCB` is an index vector containing the highest absolute index in `B` for each row in `A` which is a member of `B` and 0 if there is no such index.

`[...] = intersect(...,'legacy')` preserves the pre-2012a behavior of `ismember`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or `'rows'`.

`intersect` | `islevel` | `setdiff` | `setxor` | `union` | `unique`

# dataset.ismember

---

## Purpose

Dataset array elements that are members of set

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
LiA = ismember(A,B)
LiA = ismember(A,B,vars)
[LiA,LocB] = ismember( __ )
```

## Description

`LiA = ismember(A,B)` for dataset arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B`, and 0 (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and 0 (false) otherwise.

`[LiA,LocB] = ismember( __ )` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or 0 if there is no such observation. You can use any of the previous input arguments.

## Input Arguments

### A

Query dataset array, containing the observations to be found in `B`.

### B

Set dataset array. When an observation in `A` is found in `B`, for all variables or only those variables specified in `vars`, the corresponding element of `LiA` is 1.

### vars

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating which variables to match observations on in `A` and `B`.

## Output Arguments

### LiA

Vector of logical values the same length as A. LiA has value 1 (true) when the corresponding observation in A is present in B. Otherwise, LiA has value 0 (false).

If you specify `vars`, LiA has value 1 when the corresponding observation in A is present in B for the variables in `vars` only.

### LocB

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in `vars`.

## Examples

### Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
B = hospital(1:50,1:5);
```

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

A =

# dataset.ismissing

---

## Purpose

Find dataset array elements with missing values

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

## Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes NaN as a missing value in numeric variables, '' as a missing value in string variables, and <undefined> as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ds**  
dataset array

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'NumericTreatAsMissing'**

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a NaN value as a missing value.

## 'StringTreatAsMissing'

String or cell array of strings to treat as missing value indicators in string `ds` variables. `ismissing` always treats the empty string '' as a missing value.

## Output Arguments

**I**

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value 1 for elements that contain a missing value.

## See Also

`dataset` | `isempty` | `isnan` | `isundefined` | `replaceWithMissing`

# categorical.isscalar

---

<b>Purpose</b>	True if categorical array is scalar  The <code>nominal</code> and <code>ordinal</code> array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB <code>categorical</code> data type instead.
<b>Syntax</b>	<code>TF = isscalar(A)</code>
<b>Description</b>	<code>TF = isscalar(A)</code> returns true (1) if the categorical array <code>A</code> is a 1-by-1 matrix, and false (0) otherwise.
<b>See Also</b>	<code>isempty</code>   <code>isvector</code>   <code>size</code>

## Purpose

Test for undefined elements

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
I = isundefined(A)
```

## Description

`I = isundefined(A)` returns a logical array `I` the same size as the categorical array `A`. `I` is true (1) where the corresponding element of `A` is not assigned to any level. `I` is false (0) where the corresponding element of `A` is assigned to a level.

## Examples

Create and display undefined levels in an ordinal array:

```
A = ordinal([1 2 3 2 1],{'lo','med','hi'})
```

```
A =
```

```
    lo    med    hi    med    lo
```

```
A = droplevels(A,{'med','hi'})
```

```
Warning: OLDLEVELS contains categorical levels that  
were present in A, caused some array elements to  
have undefined levels.
```

```
A =
```

```
    lo <undefined> <undefined> <undefined> lo
```

```
I = isundefined(A)
```

```
I =
```

```
    0    1    1    1    0
```

## See Also

[islevel](#) | [ismember](#)

# grandstream.isvalid

---

**Purpose** Test handle validity

**Syntax** `tf = isvalid(h)`

**Description** `tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

**See Also** `delete` | `grandstream`

**Purpose**

True if categorical array is vector

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`TF = isvector(A)`

**Description**

`TF = isvector(A)` returns true (1) if the categorical array `A` is a 1-by-`n` or `n`-by-1 vector, where `n >= 0`, and false (0) otherwise.

**See Also**

# gmdistribution.Iters property

---

**Purpose** Number of iterations

**Description** The number of iterations of the algorithm.

---

**Note** This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

---

---

<b>Purpose</b>	Inverse Wishart random numbers
<b>Syntax</b>	<pre>W = iwishrnd(Tau,df) W = iwishrnd(Tau,df,DI) [W,DI] = iwishrnd(Tau,df)</pre>
<b>Description</b>	<p><code>W = iwishrnd(Tau,df)</code> generates a random matrix <code>W</code> from the inverse Wishart distribution with parameters <code>Tau</code> and <code>df</code>. The inverse of <code>W</code> has the Wishart distribution with covariance matrix <code>Sigma = inv(Tau)</code> and with <code>df</code> degrees of freedom. <code>Tau</code> is a symmetric and positive definite matrix.</p> <p><code>W = iwishrnd(Tau,df,DI)</code> expects <code>DI</code> to be the transpose of the inverse of the Cholesky factor of <code>Tau</code>, so that <code>DI'*DI = inv(Tau)</code>, where <code>inv</code> is the MATLAB inverse function. <code>DI</code> is lower-triangular and the same size as <code>Tau</code>. If you call <code>iwishrnd</code> multiple times using the same value of <code>Tau</code>, it is more efficient to supply <code>DI</code> instead of computing it each time.</p> <p><code>[W,DI] = iwishrnd(Tau,df)</code> returns <code>DI</code> so you can use it as an input in future calls to <code>iwishrnd</code>.</p> <p>Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter <code>tau</code> so that the mean of the output matrix is <code>Tau / (df-d-1)</code> where <code>d</code> is the dimension of <code>Tau</code>.</p>
<b>See Also</b>	<code>wishrnd</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Inverse Wishart Distribution” on page B-72</li></ul>

# jackknife

---

**Purpose** Jackknife sampling

**Syntax**

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

**Description** `jackstat = jackknife(jackfun,X)` draws jackknife data samples from the  $n$ -by- $p$  data array  $X$ , computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of  $X$  as one data sample, so there are  $n$  data samples. Each of the  $n$  rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row  $i$  of `jackstat` contains the results for the sample consisting of  $X$  with the  $i$ th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If  $X$  is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set 'Options' as a structure you create with `statset`. `jackknife` uses the following field in the structure:

'UseParallel' If true and if a parpool of the Parallel Computing Toolbox is open, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, or serial computation.

## Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector  $y$  using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var, y, 1);
n = length(y);
bias = -sigma^2 / n % known bias formula
jbias = (n - 1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
    -0.2500

jbias =
    -0.3378
```

## See Also

`bootstrp` | `random` | `randsample` | `hist` | `ksdensity`

## Tutorials

- “Jackknife Resampling” on page 3-20

## Purpose

Jarque-Bera test

## Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(____)
[h,p,jbstat,critval] = jbtest(____)
```

## Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test. The alternative hypothesis is that it does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a  $p$ -value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error less than or equal to `mctol`.

`[h,p] = jbtest(____)` also returns the  $p$ -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(____)` also returns the test statistic `jbstat` and the critical value `critval` for the test.

## Input Arguments

### **x** - Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats NaN values in `x` as missing values and ignores them.

**Data Types**

single | double

**alpha - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If alpha is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbstest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

**Example:** 0.01**Data Types**

single | double

**mctol - Maximum Monte Carlo standard error**

nonnegative scalar value

Maximum Monte Carlo standard error for the  $p$ -value,  $p$ , specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbstest` computes a Monte Carlo approximation for  $p$  directly, rather than interpolating into a table of precomputed values. `jbstest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for  $p$  less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

**Example:** 0.0001**Data Types**

single | double

**Output Arguments****h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the `alpha` significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the `alpha` significance level.

### **p - p-value**

scalar value in the range (0,1)

$p$ -value of the test, returned as a scalar value in the range (0,1).  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

`jbtest` warns when  $p$  is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate  $p$ -value.

### **jbstat - Test statistic**

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

### **critval - Critical value**

nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbtest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat > critval`.

## **Examples**

### **Test for a Normal Distribution**

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbtest(MPG)
```

```
h =
```

```
1
```

The returned value of  $h = 1$  indicates that `jbtest` rejects the null hypothesis at the default 5% significance level.

### Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbtest(MPG,0.01)
```

```
h =
```

```
1
```

```
p =
```

```
0.0022
```

The returned value of  $h = 1$ , and the returned  $p$ -value less than  $\alpha = 0.01$  indicate that `jbtest` rejects the null hypothesis.

### Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig;
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact  $p$ -value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
```

```
h =
```

```
    1
```

```
p =
```

```
    0.0022
```

```
jbstat =
```

```
    18.2275
```

```
critval =
```

```
    5.8461
```

The returned value of  $h = 1$  indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

## Definitions

### Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6} \left( s^2 + \frac{(k-3)^2}{4} \right),$$

where  $n$  is the sample size,  $s$  is the sample skewness, and  $k$  is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

### Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the  $p$ -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where  $\hat{p}$  is the estimated  $p$ -value of the hypothesis test, and  $\text{mcreps}$  is the number of Monte Carlo replications performed. `jbttest` chooses the number of Monte Carlo replications, `mcreps`, large enough to make the Monte Carlo standard error for  $\hat{p}$  less than the value specified for `mcto1`.

## Algorithm

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbttest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

## Concepts

- “Generating Data Using the Pearson System” on page 6-28

**Purpose**

Johnson system random numbers

**Syntax**

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

**Description**

`r = johnsrnd(quantiles,m,n)` returns an  $m$ -by- $n$  matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles  $[-1.5 -0.5 0.5 1.5]$ . In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities  $[0.067 0.309 0.691 0.933]$ . `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

---

**Note** Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

---

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an  $m$ -by- $n$ -by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is 'SN', 'SL', 'SB', or 'SU'. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution)

- 'SL' — Exponential transformation (lognormal distribution)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, `r = lambda*h((z-gamma)/eta)+epsilon` is a random variate from the distribution type corresponding to `h`.

## Examples

### Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```
rng('default'); % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```

Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);  
figure;  
qqplot(r);
```

Generate random values that match some sample data well in the right-hand tail.

```
load carbig;  
qnorm = [.5 1 1.5 2];  
q = quantile(Acceleration, normcdf(qnorm));  
r = johnsrnd([qnorm;q],1000,1);  
[q;quantile(r,normcdf(qnorm))]
```

```
ans =  
  
    16.7000    18.2086    19.5376    21.7263  
    16.6986    18.2220    19.9078    22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)
```

```
r =
```

```
    []
```

```
type =
```

```
SU
```

```
coefs =
```

```
    1.0920    0.5829    18.4382    1.4494
```

## How To

- “Johnson System” on page B-74

# dataset.join

---

## Purpose

Merge observations

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

## Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a variable name, a cell array of variable names, or a logical vector.

`C` contains one observation for each observation in `A`. Variables in `C` include all of the variables from `A`, as well as one variable corresponding to each variable in `B` (except for the keys from `B`). If `A` and `B` contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in `C`.

`C = join(A,B,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control how the dataset variables in `A` and `B` are used in the merge. Parameters are:

- 'Keys' — Specifies the variables to use as keys in both A and B.
- 'LeftKeys' — Specifies the variables to use as keys in A.
- 'RightKeys' — Specifies the variables to use as keys in B.

You may provide either the 'Keys' parameter, or both the 'LeftKeys' and 'RightKeys' parameters. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing variable names, or a logical vector. 'LeftKeys' or 'RightKeys' must both specify the same number of key variables, and join pairs the left and right keys in the order specified.

- 'LeftVars' — Specifies which variables from A to include in C. By default, join includes all variables from A.
- 'RightVars' — Specifies which variables from B to include in C. By default, join includes all variables from B except the key variables.

You can use 'LeftVars' or 'RightVars' to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

`[C,IB] = join(...)` returns an index vector `IB`, where `join` constructs `C` by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B, and allow unmatched observations in either A or B.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by `TYPE`. `TYPE` is one of 'inner', 'leftouter', 'rightouter', 'fullouter', or 'outer' (which is a synonym for 'fullouter'). For an inner join, `C` only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, `C` also contains observations corresponding to keys in A (or B) that did not match any in B (or A). Variables in `C` taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. `C` contains variables corresponding to the key

# dataset.join

---

variables from both A and B, and `join` sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. `join` sorts the observations in the result C by the key values.

`C = join(A,B, 'Type', TYPE, 'MergeKeys', true, ...)` includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, `join` creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the 'MergeKeys' parameter to `true` overrides inclusion or exclusion of any key variables specified via the 'LeftVars' or 'RightVars' parameter. Setting the 'MergeKeys' parameter to `false` is equivalent to not passing in the 'MergeKeys' parameter.

`[C, IA, IB] = join(A,B, 'Type', TYPE, ...)` returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, `join` constructs C by horizontally concatenating `A(IA, LeftVars)` and `B(IB, RightVars)`. For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

## Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'},...
              {meas, 'SL', 'SW', 'PL', 'PW'},...
              'ObsNames', NameObs);
```

---

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa'; 'versicolor'; 'virginica'});
```

```
CC = dataset({snames, 'species'}, {[38;108;70], 'cc'})
CC =
  species      cc
  setosa       38
  versicolor   108
  virginica    70
```

Broadcast the data in CC to the rows of iris using the key variable species in each dataset:

```
iris2 = join(iris, CC);
iris2([1 2 51 52 101 102], :)
ans =
      species      SL      SW      PL      PW      cc
Obs1     setosa     5.1     3.5     1.4     0.2     38
Obs2     setosa     4.9     3      1.4     0.2     38
Obs51    versicolor  7      3.2     4.7     1.4     108
Obs52    versicolor  6.4     3.2     4.5     1.5     108
Obs101   virginica    6.3     3.3     6      2.5     70
Obs102   virginica    5.8     2.7     5.1     1.9     70
```

Create two datasets and join them using the 'MergeKeys' flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'}, [1 2 3 11 17]', ...
  'VarNames', {'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'}, [4 5 6 7]', ...
  'VarNames', {'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
```

# dataset.join

---

```
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
  'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
  'MergeKeys',true)
```

a =

Key1	Var1
'a'	1
'b'	2
'c'	3
'e'	11
'h'	17

b =

Key1	Var2
'a'	4

# KDTreeSearcher

---

**Superclasses** NeighborSearcher

**Purpose** Nearest neighbors search using *kd*-tree

**Description** A KDTreeSearcher object represents *k*NN (*k*-nearest neighbor) search using a *kd*-tree. Search objects store information about the data used, the distance metric and parameters, and the maximal number of data points in each leaf node. You cannot create this object for sparse input data. The search performance for this object, compared with the ExhaustiveSearcher object, tends to be better for smaller dimensions (10 or fewer) and worse for larger dimensions. For more information on search objects, see “What Are Search Objects?” on page 16-17.

**Construction** `NS = KDTreeSearcher(X, 'Name', Value)` constructs a *kd*-tree based on *X* and saves the information in a KDTreeSearcher object where rows of *X* correspond to observations and columns correspond to variables. You can use this tree to find neighbors in *X* nearest to the query points. See the following section for optional name/value pairs.

`NS = createns(X, 'NSMethod', 'kdtree', 'Name', Value)` creates a *kd*-tree based on *X* using `createns` and saves the information in a KDTreeSearcher object where rows of *X* correspond to observations and columns correspond to variables. You can use this tree to find neighbors in *X* nearest to the query points. See the following section for optional name/value pairs.

## Name-Value Pair Arguments

KDTreeSearcher and createns accept one or more of the following optional name/value pairs as input:

### ‘Distance’

A string specifying the default distance metric used when you call the `knnsearch` method.

- 'euclidean' — Euclidean distance (default).
- 'cityblock' — City block distance.

- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.

For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## **'p'**

A positive scalar indicating the exponent of the Minkowski distance. This parameter is only valid when `Distance` is 'minkowski'. Default is 2.

## **'BucketSize'**

A positive integer, indicating the maximum number of data points in each leaf node of the *kd*-tree. Default is 50.

## **Properties**

### **X**

A matrix used to create the object

### **Distance**

A string specifying a built-in distance metric that you provide when you create the object. This property is the default distance metric used when you call the `knsearch` method to find nearest neighbors for future query points.

### **DistParameter**

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance.
- Otherwise: Empty.

# KDTreeSearcher

---

## Methods

knnsearch	Find $k$ -nearest neighbors using KDTreeSearcher object
rangesearch	Find all neighbors within specified distance using object

## Examples

Create a KDTreeSearcher object using the constructor:

```
load fisheriris
x = meas(:,3:4);
kdtreeobj = KDTreeSearcher(x,'distance','minkowski')
```

```
kdtreeobj =
```

```
    KDTreeSearcher
```

```
    Properties:
```

```
        BucketSize: 50
```

```
            X: [150x2 double]
```

```
        Distance: 'minkowski'
```

```
    DistParameter: 2
```

---

Create a KDTreeSearcher object using createns:

```
load fisheriris
x = meas(:,3:4);
kdtreeobj = createns(x,'NsMethod','kdtree',...
    'distance','minkowski')
```

```
kdtreeobj =
```

```
    KDTreeSearcher
```

```
    Properties:
```

```
        BucketSize: 50
```

```
X: [150x2 double]
Distance: 'minkowski'
DistParameter: 2
```

For more in-depth examples using the `knnsearch` method, see the method reference page or see “Classifying Query Data Using `knnsearch`” on page 16-18.

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

# ProbDistKernel.Kernel property

---

**Purpose** Read-only string specifying name of kernel smoothing function for ProbDistKernel object

**Description** Kernel is a read-only property of the ProbDistKernel class. Kernel is a string specifying the name of the kernel smoothing function used to create a ProbDistKernel object.

**Values**

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

Use this information to view and compare the kernel smoothing function used to create distributions.

**See Also** `ksdensity`

**Superclasses** TruncatableDistribution

**Purpose** Kernel probability distribution object

**Description** `prob.KernelDistribution` is an object consisting of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution. Create a `prob.KernelDistribution` object using `fitdist` or `dfittool`.

**Construction** `pd = fitdist(x,'Kernel')` creates a probability distribution object by fitting a kernel-smoothing distribution to the data in `x`.

`pd = fitdist(x,'Kernel',Name,Value)` creates a probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can change the kernel function or specify the kernel bandwidth.

## Input Arguments

### **x** - Input data

column vector

Input data to fit with a kernel-smoothing distribution, specified as a column vector of scalar values. `fitdist` ignores NaN values in `x`.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Kernel - Kernel smoother type

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

# prob.KernelDistribution

---

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following kernel smoothing function types:

- 'normal'
- 'box'
- 'triangle'
- 'epanechnikov'

## Support - Kernel density support

'unbounded' (default) | 'positive' | two-element vector

Kernel density support, specified as the comma-separated pair consisting of 'Support' and a string or two-element vector. The string must be one of the following.

'unbounded'	Density can extend over the whole real line.
'positive'	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

## Data Types

single | double

## Width - Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes.

## Data Types

single | double

## Properties

### Kernel - Kernel smoother type

'normal' | 'box' | 'triangle' | 'epanechnikov'

Kernel function type, stored as a valid kernel function type name.

### BandWidth - Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, stored as a positive scalar value.

## Data Types

single | double

### DistributionName - Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

### InputData - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

### Data Types

logical

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

### Data Types

single | double

## Methods

mean	Mean of probability distribution object
negloglik	Negative loglikelihood
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object

iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

## Definitions

### Kernel Distribution

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

The kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x-x_i}{h}\right) ; \quad -\infty < x < \infty ,$$

where  $n$  is the sample size,  $K(\square)$  is the kernel function, and  $h$  is the bandwidth.

# prob.KernelDistribution

---

## Examples

### Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital;  
hist(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')
```

```
pd_kernel =
```

```
KernelDistribution
```

```
Kernel = normal
```

```
Bandwidth = 14.3792
```

```
Support = unbounded
```

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')
```

```
pd_normal =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 154 [148.728, 159.272]
```

```
sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;
```

```
pdf_kernel = pdf(pd_kernel,x);
```

```
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel,'Color','b','LineWidth',2);
```

```
hold on;
```

```
plot(x,pdf_normal,'Color','r','LineStyle',':','LineWidth',2);
```

```
legend('Kernel Distribution','Normal Distribution','Location','SouthEast');
```

```
hold off;
```

# prob.KernelDistribution

---

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

# ClassificationPartitionedEnsemble.kfoldEdge

## Purpose

Classification edge for observations not used for training

## Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

## Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **ens**

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'folds'**

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

**Default:** `1:ens.KFold`

### **'mode'**

# ClassificationPartitionedEnsemble.kfoldEdge

---

String representing the meaning of the output `edge`:

- 'average' — `edge` is a scalar value, the average over all folds.
- 'individual' — `edge` is a vector of length `ens.KFold` with one element per fold.
- 'cumulative' — `edge` is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

**Default:** 'average'

## Output Arguments

**E**

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

# ClassificationPartitionedEnsemble.kfoldEdge

---

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Compute the k-fold edge for an ensemble trained on the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E =
    3.2078
```

# ClassificationPartitionedModel.kfoldEdge

---

**Purpose** Classification edge for observations not used for training

**Syntax**  
E = kfoldEdge(obj)  
E = kfoldEdge(obj,Name,Value)

**Description** E = kfoldEdge(obj) returns classification edge (average classification margin) obtained by cross-validated classification model obj. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

E = kfoldEdge(obj,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**obj**  
Object of class ClassificationPartitionedModel.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

### 'folds'

Indices of folds ranging from 1 to obj.KFold. Use only these folds for predictions.

**Default:** 1:obj.KFold

### 'mode'

String representing the meaning of the output edge:

- 'average' — edge is a scalar value, the average over all folds.

- 'individual' — edge is a vector of length `obj.KFold` with one element per fold.

**Default:** 'average'

## Output Arguments

**E**

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

## Definitions

The *edge* is the weighted mean value of the classification *margin*. The weights are the class probabilities in `obj.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`. A high value of margin indicates a more reliable prediction than a low value.

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

### Score (tree)

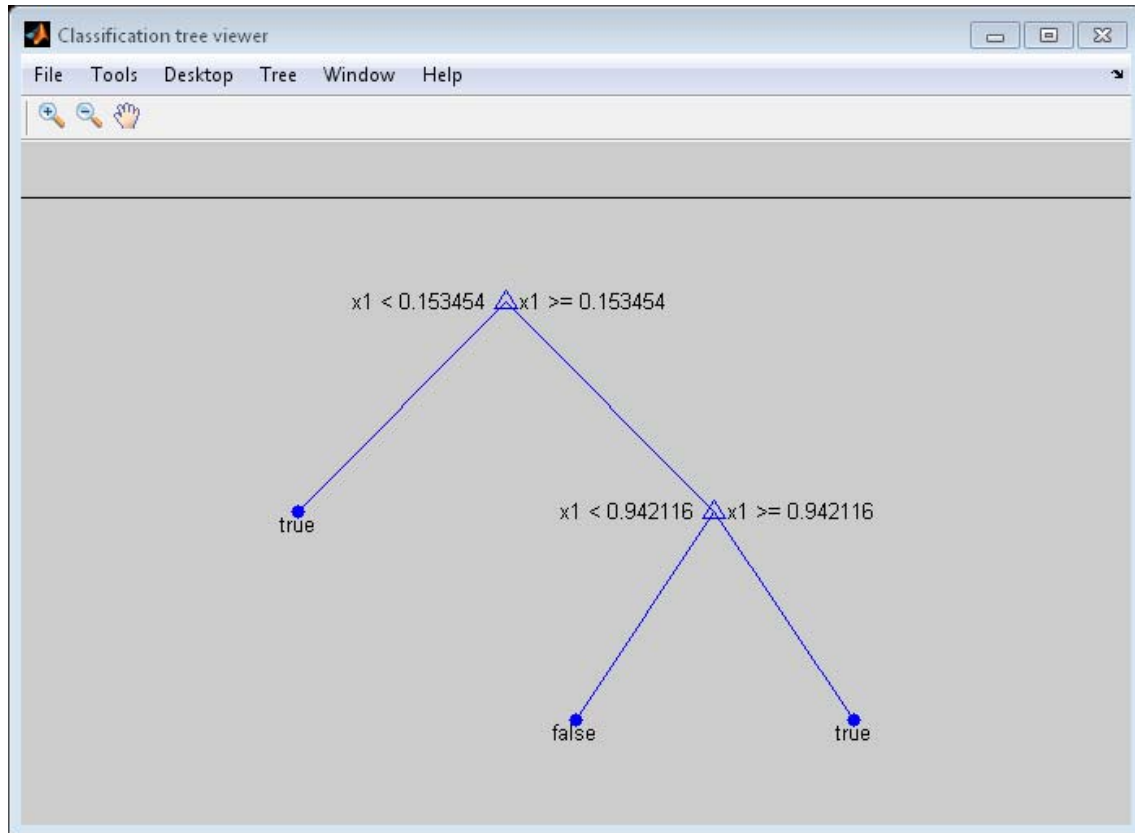

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as true when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

Generate 100 random points and classify them:

# ClassificationPartitionedModel.kfoldEdge

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

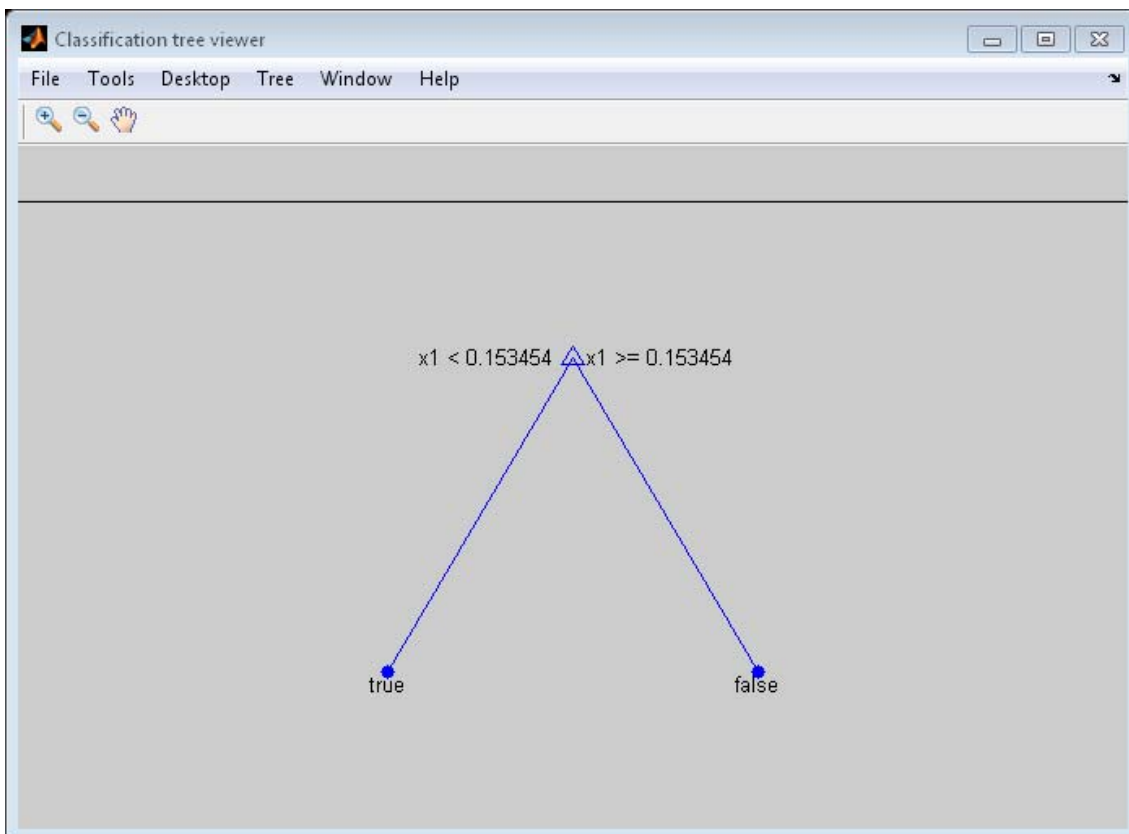

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

# ClassificationPartitionedModel.kfoldEdge

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

# ClassificationPartitionedModel.kfoldEdge

---

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Compute the k-fold edge for a model trained on the Fisher iris data:

```
load fisheriris  
tree = fitctree(meas,species);  
cvtree = crossval(tree);  
E = kfoldEdge(cvtree)
```

```
E =  
    0.8711
```

# ClassificationPartitionedModel.kfoldfun

---

## Examples

Cross validate a classification tree, and obtain the classification error (see `kfoldLoss`):

```
load fisheriris
t = fitctree(meas,species);
rng(0,'twister') % for reproducibility
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    0.0467
```

Examine the result when the error of misclassifying a flower as 'versicolor' is 10, and any other error is 1:

- 1 Write a function file that gives a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)

Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % total differences
averageCost = cost/numel(Ytest); % average error
```

- 2 Save the file as `noversicolor.m` on your MATLAB path.
- 3 Compute the mean misclassification error with the `noversicolor` cost:

```
mean(kfoldfun(cv,@noversicolor))

ans =
    0.1667
```

# ClassificationPartitionedModel.kfoldfun

---

## See Also

`ClassificationPartitionedModel` | `kfoldPredict` | `kfoldEdge` |  
`kfoldMargin` | `kfoldLoss` | `crossval`

# RegressionPartitionedModel.kfoldfun

---

**Purpose** Cross validate function

**Syntax** `vals = kfoldfun(obj,fun)`

**Description** `vals = kfoldfun(obj,fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

## Input Arguments

### **obj**

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `fitrtree` or `fitensemble` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

### **fun**

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

## Output Arguments

### vals

The arrays of testvals output, concatenated vertically over all folds. For example, if testvals from every fold is a numeric vector of length N, kfoldfun returns a KFold-by-N numeric matrix with one row per fold.

## Examples

Cross validate a regression tree, and obtain the mean squared error (see kfoldLoss):

```
load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictorname',{'length' 'width'},...
    'response', 'price');
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))
```

```
ans =
    6.3497e+007
```

# ClassificationPartitionedEnsemble.kfoldLoss

---

**Purpose** Classification loss for observations not used for training

**Syntax**  
L = kfoldLoss(ens)  
L = kfoldLoss(ens,Name,Value)

**Description** L = kfoldLoss(ens) returns loss obtained by cross-validated classification model ens. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

L = kfoldLoss(ens,Name,Value) calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ,NameN,ValueN.

## Input Arguments

### ens

Object of class ClassificationPartitionedEnsemble. Create ens with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create ens from a classification ensemble with crossval.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'folds'

Indices of folds ranging from 1 to ens.KFold. Use only these folds for predictions.

**Default:** 1:ens.KFold

### 'lossfun'

# ClassificationPartitionedEnsemble.kfoldLoss

---

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-1841
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-1841

You can write your own loss function in the syntax described in “Loss Functions” on page 21-1841.

**Default:** 'classiferror'

## **'mode'**

A string for determining the output of `kfoldLoss`:

- 'average' — L is a scalar, the loss averaged over all folds.
- 'individual' — L is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'average'

## **Output Arguments**

**L**

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

## **Definitions**

### **Loss Functions**

The built-in loss functions are:

# ClassificationPartitionedEnsemble.kfoldLoss

---

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of `ens.X`.
- $K$  is the number of classes in `ens`, represented in `ens.ClassNames`.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in `tree.ClassNames`.
- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the score output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Find the average cross-validated classification error for an ensemble model of the ionosphere data:

```
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L =
    0.0826
```

## See Also

[kfoldPredict](#) | [kfoldEdge](#) | [kfoldMargin](#) | [kfoldfun](#) | [crossval](#)

# ClassificationPartitionedModel.kfoldLoss

---

**Purpose** Classification loss for observations not used for training

**Syntax**  
L = kfoldLoss(obj)  
L = kfoldLoss(obj,Name,Value)

**Description** L = kfoldLoss(obj) returns loss obtained by cross-validated classification model obj. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

L = kfoldLoss(obj,Name,Value) calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**obj**  
Object of class ClassificationPartitionedModel.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

### 'folds'

Indices of folds ranging from 1 to Obj.KFold. Use only these folds for predictions.

**Default:** 1:Obj.KFold

### 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-1846.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-1846.
- 'exponential' — See “Loss Functions” on page 21-1846.
- 'mincost' — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-1846.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-1846.

**Default:** 'mincost'

## 'mode'

A string for determining the output of `kfoldLoss`:

- 'average' — `L` is a scalar, the loss averaged over all folds.
- 'individual' — `L` is a vector of length `obj.KFold`, where each entry is the loss for a fold.

**Default:** 'average'

## Output Arguments

### **L**

Loss, by default the fraction of misclassified data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

## Definitions

### **Classification Error**

The default classification error is the fraction of the data  $X$  that `obj` misclassifies, where  $Y$  are the true classifications.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `obj` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

# ClassificationPartitionedModel.kfoldLoss

---

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the Cost property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X.
- K is the number of classes in the classifier, represented in the ClassNames property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the ClassNames property.
- S is an N-by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from predict.

# ClassificationPartitionedModel.kfoldLoss

---

- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = ones(K) - eye(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Find the average cross-validated classification error for a model of the ionosphere data:

```
load ionosphere
tree = fitctree(X,Y);
cvtree = crossval(tree);
L = kfoldLoss(cvtree)
```

```
L =
    0.1197
```

# RegressionPartitionedEnsemble.kfoldLoss

---

**Purpose** Cross-validation loss of partitioned regression ensemble

**Syntax**  
L = kfoldLoss(cvens)  
L = kfoldLoss(cvens,Name,Value)

**Description**  
L = kfoldLoss(cvens) returns the cross-validation loss of cvens.  
L = kfoldLoss(cvens,Name,Value) returns cross-validation loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ,NameN,ValueN.

**Input Arguments**  
**cvens**  
Object of class RegressionPartitionedEnsemble. Create obj with fitensemble along with one of the cross-validation options: 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. Alternatively, create obj from a regression ensemble with crossval.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.

### **'folds'**

Indices of folds ranging from 1 to cvens.KFold. Use only these folds for predictions.

**Default:** 1:cvens.KFold

### **'lossfun'**

# RegressionPartitionedEnsemble.kfoldLoss

---

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default:** 'mse'

## 'mode'

String representing the meaning of the output `L`:

- 'ensemble' — `L` is a scalar value, the loss for the entire ensemble.
- 'individual' — `L` is a vector with one element per trained learner.
- 'cumulative' — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

### L

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

# RegressionPartitionedEnsemble.kfoldLoss

---

## Examples

Find the cross-validation loss for a regression ensemble of the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSboost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L =
    25.6935
```

## See Also

[RegressionPartitionedEnsemble](#) | [loss](#) | [kfoldPredict](#)

# RegressionPartitionedModel.kfoldLoss

---

## Purpose

Cross-validation loss of partitioned regression model

## Syntax

```
L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel,Name,Value)
```

## Description

`L = kfoldLoss(cvmodel)` returns the cross-validation loss of `cvmodel`.  
`L = kfoldLoss(cvmodel,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### `cvmodel`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree with `crossval`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'folds'**

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

**Default:** `1:obj.KFold`

### **'lossfun'**

# RegressionPartitionedModel.kfoldLoss

---

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle `fun`, `kfoldLoss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default:** 'mse'

## 'mode'

One of the following strings:

- 'average' — `L` is the average loss over all folds.
- 'individual' — `L` is a vector of the individual losses of in-fold observations trained on out-of-fold data.

**Default:** 'average'

## Output Arguments

**L**

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If `mode` is 'individual', `L` is a vector of the losses. If `mode` is 'average', `L` is the average loss.

## Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
```

```
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')

L =
    44.9635
    11.8525
    18.2046
     9.2965
    29.4329
    54.8659
    24.6446
     8.2085
    19.7593
    16.7394
```

## Alternatives

You can avoid constructing a cross-validated tree model by calling `cvLoss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

# ClassificationPartitionedModel.kfoldMargin

---

<b>Purpose</b>	Classification margins for observations not used for training
<b>Syntax</b>	<code>M = kfoldMargin(obj)</code>
<b>Description</b>	<code>M = kfoldMargin(obj)</code> returns classification margins obtained by cross-validated classification model <code>obj</code> . For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.
<b>Input Arguments</b>	<b>obj</b> A partitioned classification model of type <code>ClassificationPartitionedModel</code> or <code>ClassificationPartitionedEnsemble</code> .
<b>Output Arguments</b>	<b>M</b> The classification margin.
<b>Definitions</b>	<b>Margin</b> The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix <code>Obj.X</code> . A high value of margin indicates a more reliable prediction than a low value.  For discriminant analysis, the <i>score</i> of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.  <b>Score (ensemble)</b> For ensembles, a classification <i>score</i> represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Score (tree)

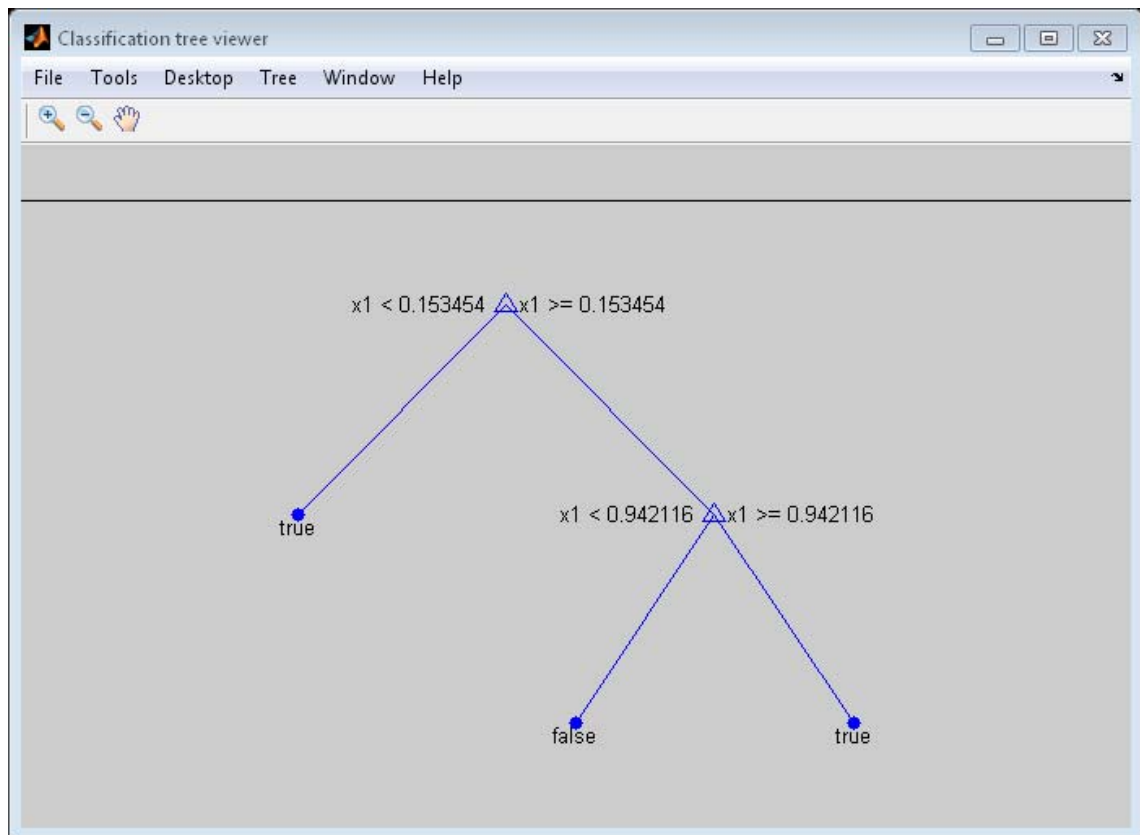

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

# ClassificationPartitionedModel.kfoldMargin

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

# ClassificationPartitionedModel.kfoldMargin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

# ClassificationPartitionedModel.kfoldMargin

---

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## Examples

Find the k-fold margins for an ensemble that classifies the ionosphere data:

```
load ionosphere  
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');  
cvens = crossval(ens);  
M = kfoldMargin(cvens);  
[min(M) mean(M) max(M)]
```

```
ans =  
    -7.6394     7.3469    22.4833
```

## See Also

[ClassificationPartitionedModel](#) | [kfoldPredict](#) | [kfoldEdge](#) | [kfoldLoss](#) | [kfoldfun](#) | [crossval](#)

# ClassificationPartitionedModel.kfoldPredict

---

## Purpose

Predict response for observations not used for training

## Syntax

```
label = kfoldPredict(obj)
[label,score] = kfoldPredict(obj)
[label,score,cost] = kfoldPredict(obj)
```

## Description

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label,score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label,score,cost] = kfoldPredict(obj)` returns misclassification costs.

## Input Arguments

### **obj**

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

## Output Arguments

### **label**

Vector of class labels of the same type as the response data used in training `obj`. Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

### **score**

Numeric matrix of size N-by-K, where N is the number of observations (rows) in `obj.X`, and K is the number of classes (in `obj.ClassNames`). `score(i,j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see “Definitions” on page 21-1860.

### **cost**

Numeric matrix of misclassification costs of size N-by-K.  $\text{cost}(i, j)$  is the average misclassification cost of predicting that row  $i$  of  $\text{obj}.X$  is of class  $j$ .

## Definitions

### Cost (discriminant analysis)

The *average misclassification cost* is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 15-8.

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

### Score (tree)

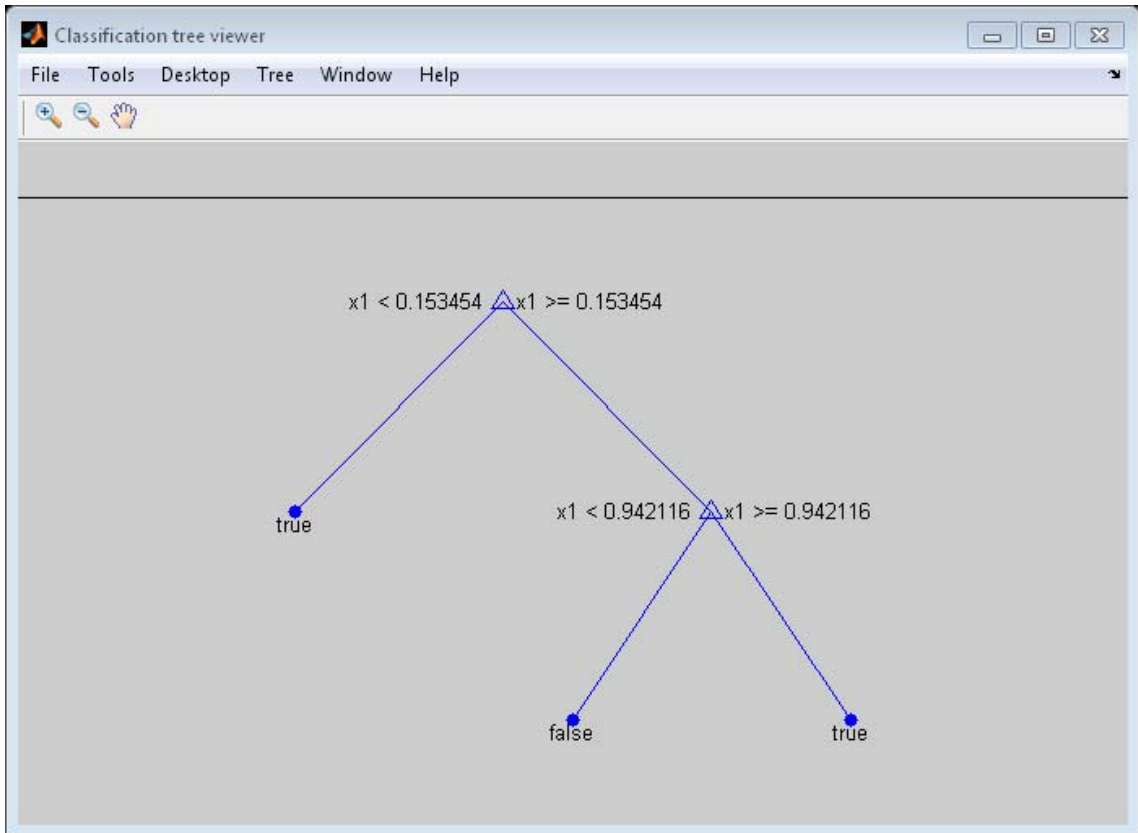

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

Generate 100 random points and classify them:

# ClassificationPartitionedModel.kfoldPredict

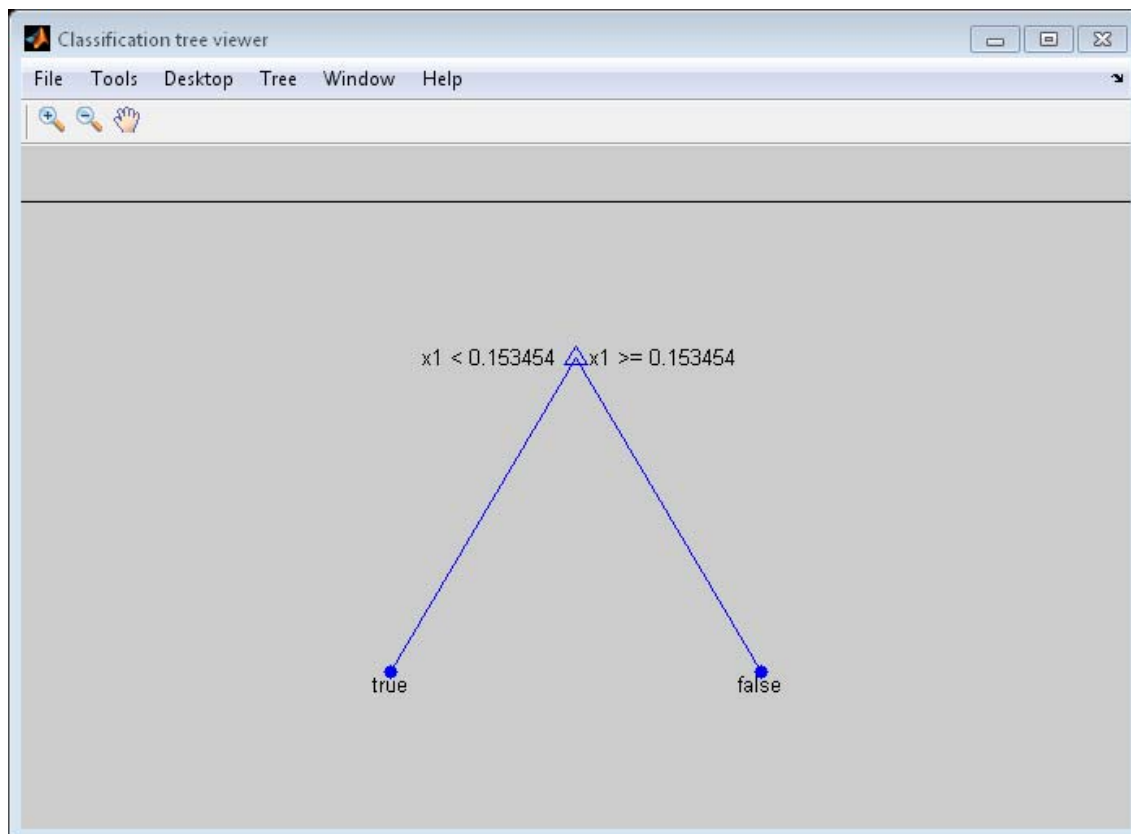

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

# ClassificationPartitionedModel.kfoldPredict

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Find the cross-validation predictions for a model based on the Fisher iris data:

```
load fisheriris  
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');  
cvens = crossval(ens);  
[elabel escore] = kfoldPredict(cvens);  
max(escore)  
  
ans =  
    9.3634    8.5624    9.3981  
  
min(escore)
```

# ClassificationPartitionedModel.kfoldPredict

---

```
ans =  
    0.0017    3.7518    0.8911
```

[kfoldLoss](#) | [fitrtree](#)

## Purpose

*K*-means clustering

## Syntax

```
IDX = kmeans(X,k)
[IDX,C] = kmeans(X,k)
[IDX,C,sumd] = kmeans(X,k)
[IDX,C,sumd,D] = kmeans(X,k)
[...] = kmeans(...,param1,val1,param2,val2,...)
```

## Description

`IDX = kmeans(X,k)` partitions the points in the *n*-by-*p* data matrix *X* into *k* clusters. This iterative partitioning minimizes the sum, over all clusters, of the within-cluster sums of point-to-cluster-centroid distances. Rows of *X* correspond to points, columns correspond to variables. `kmeans` returns an *n*-by-1 vector `IDX` containing the cluster indices of each point. By default, `kmeans` uses squared Euclidean distances. When *X* is a vector, `kmeans` treats it as an *n*-by-1 data matrix, regardless of its orientation.

`[IDX,C] = kmeans(X,k)` returns the *k* cluster centroid locations in the *k*-by-*p* matrix `C`.

`[IDX,C,sumd] = kmeans(X,k)` returns the within-cluster sums of point-to-centroid distances in the 1-by-*k* vector `sumd`.

`[IDX,C,sumd,D] = kmeans(X,k)` returns distances from each point to every centroid in the *n*-by-*k* matrix `D`.

`[...] = kmeans(...,param1,val1,param2,val2,...)` enables you to specify optional parameter/value pairs to control the iterative algorithm used by `kmeans`. Valid parameter strings are listed in the following table.

# kmeans

---

Parameter	Value
'distance'	Distance measure, in p-dimensional space. kmeans minimizes with respect to this parameter. kmeans computes centroid clusters differently for the different supported distance measures.
	'sqEuclidean' Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.
	'cityblock' Sum of absolute differences, i.e., the L1 distance. Each centroid is the component-wise median of the points in that cluster.
	'cosine' One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.
	'correlation' One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.
	'Hamming' Percentage of bits that differ (only suitable for binary data). Each centroid is the component-wise median of points in that cluster.

Parameter	Value	
'emptyaction'	Action to take if a cluster loses all its member observations.	
	'error'	Treat an empty cluster as an error (default).
	'drop'	Remove any clusters that become empty. kmeans sets the corresponding return values in C and D to NaN.
	'singleton'	Create a new cluster consisting of the one point furthest from its centroid.
'onlinephase'	Flag indicating whether kmeans should perform an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion, that is, a partition of the data where moving any single point to a different cluster increases the total sum of distances.	
	'on'	Perform online update (default).
	'off'	Do not perform online update.

# kmeans

---

Parameter	Value
'options'	Structure specifying options for the iterative algorithm used to minimize the fitting criteria. Create the options structure with <code>statset</code> . Applicable <code>statset</code> parameters are:
Display	Level of display output. Choices are <code>'off'</code> (default), <code>'iter'</code> , and <code>'final'</code> .
MaxIter	Maximum number of iterations allowed. The default is 100.
UseParallel	If true and if a <code>parpool</code> of the Parallel Computing Toolbox is open, compute in parallel. If the Parallel Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>default</code> , meaning serial computation.
UseSubstreams	Set to true to compute in parallel in a reproducible fashion. Default is false. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .
Streams	A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code> , <code>kmeans</code> uses the default stream or streams. If you choose to specify <code>Streams</code> , use a single object except in the case: <ul style="list-style-type: none"><li>• You have an open Parallel pool</li><li>• <code>UseParallel</code> is true</li></ul>

Parameter	Value								
	<ul style="list-style-type: none"> <li>• UseSubstreams is false</li> </ul> <p>In that case, use a cell array the same size as the Parallel pool. If a Parallel pool is not open, then Streams must supply a single random number stream.</p>								
'replicates'	Number of times to repeat the clustering, each with a new set of initial cluster centroid positions. kmeans returns the solution with the lowest value for sumd. You can supply 'replicates' implicitly by supplying a 3D array as the value for the 'start' parameter.								
'start'	Method used to choose the initial cluster centroid positions, sometimes known as <i>seeds</i> .								
	<table border="1"> <tr> <td>'sample'</td> <td>Select k observations from X at random (default).</td> </tr> <tr> <td>'uniform'</td> <td>Select k points uniformly at random from the range of X. Not valid with Hamming distance.</td> </tr> <tr> <td>'cluster'</td> <td>Perform a preliminary clustering phase on a random 10% subsample of X. This preliminary phase is itself initialized using 'sample'.</td> </tr> <tr> <td>Matrix</td> <td>k-by-p matrix of centroid starting locations. # kmeans

---

Parameter	Value
	'replicates' parameter from the array's third dimension.

## Algorithms

kmeans uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all k clusters:

- 1** The first phase uses *batch updates*, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum, that is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.
- 2** The second phase uses *online updates*, where points are individually reassigned if doing so will reduce the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during the second phase consists of one pass though all the points. The second phase will converge to a local minimum, although there may be other local minima with lower total sum of distances. The problem of finding the global minimum can only be solved in general by an exhaustive (or clever, or lucky) choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

## Examples

### Partition Data into Two Clusters

Randomly generate the sample data.

```
rng('default') % For reproducibility
X = [randn(100,2)+ones(100,2);...
     randn(100,2)-ones(100,2)];
```

Partition data into two clusters. Display the final output.

```
opts = statset('Display','final');
[idx,ctr] = kmeans(X,2,'Distance','city',...
                  'Replicates',5,'Options',opts);
```

```
Replicate 1, 4 iterations, total sum of distances = 310.651.
Replicate 2, 9 iterations, total sum of distances = 310.651.
Replicate 3, 5 iterations, total sum of distances = 310.651.
Replicate 4, 6 iterations, total sum of distances = 310.651.
Replicate 5, 9 iterations, total sum of distances = 310.651.
Best total sum of distances = 310.651
```

Plot the clusters and the cluster centroids.

```
plot(X(idx==1,1),X(idx==1,2),'r.','MarkerSize',12)
hold on
plot(X(idx==2,1),X(idx==2,2),'b.','MarkerSize',12)
plot(ctr(:,1),ctr(:,2),'kx',...
     'MarkerSize',12,'LineWidth',2)
plot(ctr(:,1),ctr(:,2),'ko',...
     'MarkerSize',12,'LineWidth',2)
legend('Cluster 1','Cluster 2','Centroids',...
      'Location','NW')
hold off
```

# kmeans

[linkage](#) | [clusterdata](#) | [silhouette](#)

**Purpose** Find  $k$ -nearest neighbors using ExhaustiveSearcher object

**Syntax**

```
IDX = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y,'Name',Value)
```

**Description** `IDX = knnsearch(NS,Y)` finds the nearest neighbor (closest point) in `NS.X` for each point in `Y`. Rows of `Y` correspond to observations and columns correspond to features. `Y` must have the same number of columns as `NS.X`. `IDX` is a column vector with  $n_y$  rows, where  $n_y$  is the number of rows in `Y`. Each row in `IDX` contains the index of observation in `NS.X` which has the smallest distance to the corresponding observation in `Y`.

`[IDX,D] = knnsearch(NS,Y)` returns a column vector `D` containing the distances between each observation in `Y` and the corresponding closest observation in `NS.X`. That is, `D(i)` is the distance between `NS.X(IDX(i),:)` and `Y(i,:)`.

`[IDX,D] = knnsearch(NS,Y,'Name',Value)` accepts one or more comma-separated argument name/value pairs. Specify *Name* inside single quotes.

## Input Arguments

### Name-Value Pair Arguments

#### 'K'

A positive integer,  $k$ , specifying the number of nearest neighbors in `NS.X` for each point in `Y`. Default is 1. `IDX` and `D` are  $n_y$ -by- $k$  matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the  $k$  closest neighbors in `NS.X` corresponding to the  $k$  smallest distances in `D`.

#### 'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the  $K$ th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are  $n_y$ -by-1 cell arrays. Each

# ExhaustiveSearcher.knnsearch

---

row in `IDX` and `D` contains a vector with at least `K` numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

**Default:** `false`

## 'Distance'

- `'euclidean'` — Euclidean distance (default).
- `'seuclidean'` — Standardized Euclidean distance. Each coordinate difference between `X` and each query point is scaled by dividing by a scale value `S`. The default value of `S` is `NS.DistanceParameter` if `NS.Distance` is `'seuclidean'`, otherwise the default is the standard deviation computed from `X`, `S=nanstd(X)`. To specify another value for `S`, use the `'Scale'` argument.
- `'cityblock'` — City block distance.
- `'chebychev'` — Chebychev distance (maximum coordinate difference).
- `'minkowski'` — Minkowski distance.
- `'mahalanobis'` — Mahalanobis distance, which is computed using a positive definite covariance matrix `C`. The default value of `C` is `nancov(X)`. To change the value of `C`, use the `Cov` parameter.
- `'cosine'` — One minus the cosine of the included angle between observations (treated as vectors).
- `'correlation'` — One minus the sample linear correlation between observations (treated as sequences of values).
- `'spearman'` — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using @ (for example, @distfun). A distance function must be of the form function D2 = distfun(ZI, ZJ), taking as arguments a 1-by- $n$  vector ZI containing a single row of from X or from the query points Y, an  $m2$ -by- $n$  matrix ZJ containing multiple rows of X or Y, and returning an  $m2$ -by-1 vector of distances D2, whose  $j$ th element is the distance between the observations ZI and ZJ( $j$ ,:).

Default is NS.Distance. For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## **'p'**

A positive scalar,  $p$ , indicating the exponent of the Minkowski distance. This parameter is only valid if knnsearch uses the 'minkowski' distance metric. Default is NS.Distance if NS.Distance is 'minkowski' and 2 otherwise.

## **'Cov'**

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when knnsearch uses the 'mahalanobis' distance metric. Default is NS.Distance if NS.Distance is 'mahalanobis', or nancov(X) otherwise.

## **'Scale'**

A vector S with the length equal to the number of columns in X. Each coordinate of X and each query point is scaled by the corresponding element of S when computing the standardized Euclidean distance. This parameter is only valid when Distance is 'seuclidean'. Default is nanstd(X).

# ExhaustiveSearcher.knnsearch

---

## Examples

Create an ExhaustiveSearcher object specifying 'cosine' as the distance metric. Perform a  $k$ -nearest neighbors search on the object using the mahalanobis metric and compare the results:

```
load fisheriris
x = meas(:,3:4);
exhaustiveobj = ExhaustiveSearcher(x,'Distance','cosine')

exhaustiveobj =

    ExhaustiveSearcher

    Properties:
        X: [150x2 double]
        Distance: 'cosine'
        DistParameter: []

% Perform a knnsearch between x and a query point, using
% first cosine then mahalanobis distance metrics:
newpoint = [5 1.45];
[n,d]=knnsearch(exhaustiveobj,newpoint,'k',10);
[nmah,dmah] = knnsearch(exhaustiveobj,newpoint,'k',10,...
    'distance','mahalanobis');

% Visualize the results of the two different nearest
% neighbors searches:

% First plot the training data:
gscatter(x(:,1),x(:,2),species)
% Plot an X for the query point:
line(newpoint(1),newpoint(2),'marker','x','color','k',...
    'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the cosine nearest neighbors:
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
    'linestyle','none','markersize',10)
% Use pentagrams to denote the mahalanobis nearest neighbors:
line(x(nmah,1),x(nmah,2),'color',[.5 .5 .5],'marker','p',...
```

```
'linestyle','none','markersize',10)  
legend('setosa','versicolor','virginica','query point',...  
       'cosine','mahalanobis')  
set(legend,'location','best')
```

## Algorithms

For information on a specific search algorithm, see “Distance Metrics” on page 16-9.

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

# ExhaustiveSearcher.knnsearch

---

- “Distance Metrics” on page 16-9

## Purpose

Find  $k$ -nearest neighbors using KDTreeSearcher object

## Syntax

```
IDX = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y)
[IDX,D] = knnsearch(NS,Y, 'Name', Value)
```

## Description

IDX = knnsearch(NS,Y) finds the nearest neighbor (closest point) in NS.X for each point in Y. Rows of Y correspond to observations and columns correspond to features. Y must have the same number of columns as NS.X. IDX is a column vector with  $n_y$  rows, where  $n_y$  is the number of rows in Y. Each row in IDX contains the index of observation in NS.X which has the smallest distance to the corresponding observation in Y.

[IDX,D] = knnsearch(NS,Y) returns a column vector D containing the distances between each observation in Y and the corresponding closest observation in NS.X. That is, D(i) is the distance between NS.X(IDX(i),:) and Y(i,:).

[IDX,D] = knnsearch(NS,Y, 'Name', Value) accepts one or more comma-separated name/value pairs. Specify *Name* inside single quotes.

## Input Arguments

### Name-Value Pair Arguments

#### 'K'

A positive integer,  $k$ , specifying the number of nearest neighbors in NS.X for each point in Y. Default is 1. IDX and D are  $n_y$ -by- $k$  matrices. D sorts the distances in each row in ascending order. Each row in IDX contains the indices of the  $k$  closest neighbors in NS.X corresponding to the  $k$  smallest distances in D.

#### 'Distance'

Select one of the following distance algorithms.

- 'euclidean' — Euclidean distance (default).
- 'cityblock' — City block distance.

# KDTreeSearcher.knnsearch

---

- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance.

Default is `NS.Distance`. For more information on these distance metrics, see “Distance Metrics” on page 16-9.

## 'IncludeTies'

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the  $k$ th smallest distance. If `IncludeTies` is `true`, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are  $n_y$ -by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least  $K$  numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

**Default:** `false`

## 'P'

A positive scalar,  $p$ , indicating the exponent of the Minkowski distance. This parameter is only valid when the `Distance` is 'minkowski'. Default is `NS.DistanceParameter` if `NS.Distance` is 'minkowski' and 2 otherwise.

## Examples

Create a `KDTreeSearcher` object specifying 'minkowski' as the distance metric with an exponent of 5. Perform a  $k$ -nearest neighbors search on the object using the chebychev metric and compare the results:

```
load fisheriris
x = meas(:,3:4);
kdtreeNS = KDTreeSearcher(x,'Distance','minkowski','P',5)

kdtreeNS =

    KDTreeSearcher
```

```
Properties:
    BucketSize: 50
           X: [150x2 double]
    Distance: 'minkowski'
    DistParameter: 5

% Perform a knnsearch between X and a query point, using
% first Minkowski then Chebychev distance metrics:
newpoint = [5 1.45];
[n,d]=knnsearch(kdtreeNS,newpoint,'k',10);
[ncb,dcb] = knnsearch(kdtreeNS,newpoint,'k',10,...
    'distance','chebychev');

% Visualize the results of the two different nearest
% neighbors searches:

% First plot the training data:
gscatter(x(:,1),x(:,2),species)
% Zoom in on the points of interest:
set(gca,'xlim',[4.5 5.5],'ylim',[1 2]); axis square
% Plot an X for the query point:
line(newpoint(1),newpoint(2),'marker','x','color','k',...
    'markersize',10,'linewidth',2,'linestyle','none')
% Use circles to denote the Minkowski nearest neighbors:
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...
    'linestyle','none','markersize',10)
% Use pentagrams to denote the Chebychev nearest neighbors:
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...
    'linestyle','none','markersize',10)
legend('setosa','versicolor','virginica','query point',...
    'minkowski','chebychev')
set(legend,'location','best')
```

## How To

• “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

- “Distance Metrics” on page 16-9

# knnsearch

---

**Purpose** Find  $k$ -nearest neighbors using data

**Syntax**

```
IDX = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y)
[IDX,D] = knnsearch(X,Y,'Name',Value)
```

**Description** `IDX = knnsearch(X,Y)` finds the nearest neighbor in  $X$  for each point in  $Y$ .  $X$  is an  $m_x$ -by- $n$  matrix and  $Y$  is an  $m_y$ -by- $n$  matrix. Rows of  $X$  and  $Y$  correspond to observations and columns correspond to variables. `IDX` is a column vector with  $m_y$  rows. Each row in `IDX` contains the index of nearest neighbor in  $X$  for the corresponding row in  $Y$ .

`[IDX,D] = knnsearch(X,Y)` returns an  $m_y$ -by-1 vector `D` containing the distances between each observation in  $Y$  and the corresponding closest observation in  $X$ . That is, `D(i)` is the distance between  $X(\text{IDX}(i), :)$  and  $Y(i, :)$ .

`[IDX,D] = knnsearch(X,Y,'Name',Value)` accepts one or more optional comma-separated name/value pairs. Specify *Name* inside single quotes.

`knnsearch` does not save a search object. To create a search object, use `createns`.

**Tips**

- For a fixed positive integer  $K$ , `knnsearch` finds the  $K$  points in  $X$  that are nearest each point in  $Y$ . In contrast, for a fixed positive real value  $r$ , `rangesearch` finds all the points in  $X$  that are within a distance  $r$  of each point in  $Y$ .

**Input Arguments**

**Name-Value Pair Arguments**

**'K'**

Positive integer specifying the number of nearest neighbors in  $X$  for each point in  $Y$ . Default is 1. `IDX` and `D` are  $m_y$ -by- $K$  matrices. `D` sorts the distances in each row in ascending order. Each row in `IDX` contains the indices of the  $K$  closest neighbors in  $X$  corresponding to the  $K$  smallest distances in `D`.

**'IncludeTies'**

A logical value indicating whether `knnsearch` includes all the neighbors whose distance values are equal to the *K*th smallest distance. If `IncludeTies` is true, `knnsearch` includes all these neighbors. In this case, `IDX` and `D` are *m<sub>y</sub>*-by-1 cell arrays. Each row in `IDX` and `D` contains a vector with at least *K* numeric numbers. `D` sorts the distances in each vector in ascending order. Each row in `IDX` contains the indices of the closest neighbors corresponding to these smallest distances in `D`.

**Default:** false

**'NSMethod'**

Nearest neighbors search method. Value is either:

- `'kdtree'` — Creates and uses a Kd-tree to find nearest neighbors. This is the default value when the number of columns of *X* is less than 10, *X* is not sparse, and the distance measure is one of the following measures. `'kdtree'` is only valid when the distance measure is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm by computing the distance values from all the points in *X* to each point in *Y* to find nearest neighbors.

**'Distance'**

A string or a function handle specifying the distance metric. The value can be one of the following:

- `'euclidean'` — Euclidean distance (default).

- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in  $X$  and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from  $X$ ,  $S = \text{nanstd}(X)$ . To specify another value for  $S$ , use the `Scale` argument.
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance (maximum coordinate difference).
- 'minkowski' — Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' argument.
- 'mahalanobis' — Mahalanobis distance, computed using a positive definite covariance matrix  $C$ . The default value of  $C$  is  $\text{nancov}(X)$ . To change the value of  $C$ , use the `Cov` parameter.
- 'cosine' — 1 minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). A distance function must be of the form function  $D2 = \text{distfun}(ZI, ZJ)$ , taking as arguments a 1-by- $n$  vector  $ZI$  containing a single row of  $X$  or  $Y$ , an  $m2$ -by- $n$  matrix  $ZJ$  containing multiple rows of  $X$  or  $Y$ , and returning an  $m2$ -by-1 vector of distances  $D2$ , whose  $j$ th element is the distance between the observations  $ZI$  and  $ZJ(j,:)$ .

For more information on these distance metrics, see “Distance Metrics” on page 16-9.

**'p'**

A positive scalar,  $p$ , indicating the exponent of the Minkowski distance. This parameter is only valid if the Distance is 'minkowski'. Default is 2.

**'Cov'**

A positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This parameter is only valid when Distance is 'mahalanobis'. Default is `nancov(X)`.

**'Scale'**

A vector `S` containing nonnegative values, with length equal to the number of columns in `X`. Each coordinate of `X` and each query point is scaled by the corresponding element of `S` when computing the standardized Euclidean distance. This argument is only valid when Distance is 'seuclidean'. Default is `nanstd(X)`.

**'BucketSize'**

The maximum number of data points in the leaf node of the *kd*-tree. This argument is only meaningful when using the *kd*-tree search method. Default is 50.

**Examples****Classify Using k-Nearest Neighbors**

Find the 10 nearest neighbors in `x` to each point in `y` using first the 'minkowski' distance metric with a  $p$  value of 5, and then using the 'chebychev' distance metric.

Load Fisher's iris data set

```
load fisheriris
x = meas(:,3:4);
y = [5 1.45;6 2;2.75 .75];
```

Perform a `knnsearch` between `x` and the query points in `y`, using first Minkowski then Chebychev distance metrics.

# knnsearch

---

```
[n,d]=knnsearch(x,y,'k',10,'distance','minkowski','p',5);  
[ncb,dcb] = knnsearch(x,y,'k',10,...  
    'distance','chebychev');
```

Visualize the results of the two different nearest neighbors searches. Plot the training data. Plot an X for the query points. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```
gscatter(x(:,1),x(:,2),species)  
line(y(:,1),y(:,2),'marker','x','color','k',...  
    'markersize',10,'linewidth',2,'linestyle','none')  
line(x(n,1),x(n,2),'color',[.5 .5 .5],'marker','o',...  
    'linestyle','none','markersize',10)  
line(x(ncb,1),x(ncb,2),'color',[.5 .5 .5],'marker','p',...  
    'linestyle','none','markersize',10)  
legend('setosa','versicolor','virginica','query point',...  
    'minkowski','chebychev')  
set(legend,'location','best')
```

createns | KDTreeSearcher.knnsearch |  
ExhaustiveSearcher.knnsearch | rangesearch

## How To

- “*k*-Nearest Neighbor Search and Radius Search” on page 16-12

## Purpose

Kruskal-Wallis test

## Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

## Description

`p = kruskalwallis(x)` returns the  $p$ -value for the null hypothesis that the data in each column of the matrix `x` comes from the same distribution, using a Kruskal-Wallis test. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the  $p$ -value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable `group` comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the  $p$ -value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis( ___ )` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

## Input Arguments

### **x - Sample data**

vector | matrix

Sample data for the hypothesis test, specified as a vector or an  $m$ -by- $n$  matrix. If `x` is an  $m$ -by- $n$  matrix, each of the  $n$  columns represents an independent sample containing  $m$  mutually independent observations.

### **Data Types**

single | double

# kruskalwallis

---

## **group - Grouping variable**

categorical variable | vector | character array | cell array

Grouping variable, specified as a categorical variable, vector, character array, or cell array.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty cell or empty string, that row and the corresponding observation in `x` are disregarded. NaN values in either `x` or `group` are similarly ignored.
- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

### **Example:**

```
{ 'red', 'blue', 'green', 'blue', 'red', 'blue', 'green', 'green', 'red' }
```

## **Data Types**

single | double | char

## **displayopt - Display option**

'on' (default) | 'off'

Display option, specified as 'on' or 'off'. If `displayopt` is 'on', `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`.
- A box plot of the data in each column of the data matrix `x`. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is 'off', `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

**Example:** 'off'

**Output Arguments****p - p-value**

scalar value in the range [0,1]

*p*-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

**tbl - ANOVA table**

cell array

ANOVA table of test results, returned as a cell array. *tbl* includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in *x*, as well as column and row labels.

**stats - Test data**

structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with *stats* as the input value.

**Examples****Test Data Samples for the Same Distribution**

Create two different normal probability distribution objects. The first distribution has `mu = 0` and `sigma = 1`, and the second distribution has `mu = 2` and `sigma = 1`.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2),random(pd2,20,1)];
```

# kruskalwallis

---

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution.

```
p = kruskalwallis(x)
```

```
p =
```

```
3.6896e-06
```

Kruskal-Wallis ANOVA Table					
Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	7631.1	2	3815.55	25.02	3.68957e-06
Error	10363.9	57	181.82		
Total	17995	59			

The returned value of  $p$  indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in  $x$ .

### **Conduct Followup Tests for Unequal Medians**

Create two different normal probability distribution objects. The first distribution has  $\mu = 0$  and  $\sigma = 1$ . The second distribution has  $\mu = 2$  and  $\sigma = 1$ .

# kruskalwallis

---

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility  
x = [random(pd1,20,2),random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

p =

```
3.6896e-06
```

tbl =

Columns 1 through 4

'Source'	'SS'	'df'	'MS'
'Columns'	[7.6311e+03]	[ 2]	[3.8155e+03]
'Error'	[1.0364e+04]	[57]	[ 181.8228]
'Total'	[ 17995]	[59]	[ ]

Columns 5 through 6

'Chi-sq'	'Prob>Chi-sq'
[25.0200]	[ 3.6896e-06]
[ ]	[ ]

```
[ ] [ ]
```

```
stats =
```

```
  gnames: [3x1 char]
      n: [20 20 20]
  source: 'kruskalwallis'
meanranks: [26.7500 18.9500 45.8000]
      sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing. The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)
```

Note: Intervals can be used for testing but are not simultaneous confidence intervals.

```
c =
```

```
  1.0000    2.0000   -5.1435    7.8000   20.7435
  1.0000    3.0000  -31.9935   -19.0500   -6.1065
  2.0000    3.0000  -39.7935   -26.8500  -13.9065
```

# kruskalwallis

The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

## Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, containing strings indicating the type of metal alloy from which the corresponding beam is made.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...  
           78 75 76 77 79 79 77 78 82 79];  
  
alloy = {'st','st','st','st','st','st','st','st',...  
        'al1','al1','al1','al1','al1','al1',...  
        'al2','al2','al2','al2','al2','al2'};
```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```
p = kruskalwallis(strength,alloy,'off')
```

```
p =  
  
    0.0018
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

## Definitions

### Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in  $x$  to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The  $F$ -statistic used in

# kruskalwallis

---

classical one-way ANOVA is replaced by a chi-square statistic, and the  $p$ -value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

## Concepts

- “Grouping Variables” on page 2-52

**Purpose** Kernel smoothing function estimate

**Syntax**

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity(x,pts,Name,Value)
[f,xi,bw] = ksdensity( ___ )

ksdensity( ___ )
ksdensity(ax, ___ )
```

**Description** `[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample in the vector `x`. The estimate is based on a normal kernel function, and is evaluated at 100 equally spaced points, `xi`, that cover the range of the data in `x`.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` returns a probability density estimate, `f`, for the sample in the vector `x`, evaluated at the specified values in vector `pts`. Here, the `xi` and `pts` vectors contain identical values.

`[f,xi] = ksdensity(x,pts,Name,Value)` returns a probability density estimate, `f`, for the sample in the vector `x`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity( ___ )` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity( ___ )` plots the kernel smoothing function estimate.

# ksdensity

---

`ksdensity(ax, ___)` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

## Input Arguments

### **x** - Sample data

column vector

Sample data, for which `ksdensity` returns `f` values, specified as a column vector.

**Example:** `[f,xi] = ksdensity(x)`

### Data Types

single | double

### **pts** - Points to evaluate `f`

vector

Points to evaluate `f` at, specified as a vector. `pts` can be a row or column vector. `f` has the same dimensions as `pts`.

**Example:** `pts = (0:1:25); ksdensity(x,pts);`

### Data Types

single | double

### **ax** - Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if `h` is a handle for a figure, then `ksdensity` can plot to that figure as follows.

**Example:** `ksdensity(h,x)`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:**

`'censoring',cens,'kernel','triangle','npoints',20,'function','cdf'` specifies that `ksdensity` estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector `cens`.

**'censoring' - Logical vector**

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring.

**Example:** `'censoring',censdata`

**Data Types**

logical

**'kernel' - Type of kernel smoother**

`'normal'` (default) | `'box'` | `'triangle'` | `'epanechnikov'` | function handle | string

Type of kernel smoother, specified as the comma-separated pair consisting of `'kernel'` and one of the following.

- `'normal'` (default)
- `'box'`
- `'triangle'`
- `'epanechnikov'`
- You can also specify a custom kernel function, as a function handle or as a string, e.g., `@normpdf` or `'normpdf'`. This calls the function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

# ksdensity

---

When 'function' is 'pdf', this kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'function' is 'icdf' returns an error.

If 'support' is 'positive', then `ksdensity` transforms `x` using a log function, estimates the density of the transformed values, and transforms back to the original scale. If 'support' is a vector [L U], then `ksdensity` uses the transformation  $\log((X-L)/(U-X))$ . The width parameter and `bw` outputs are on the scale of the transformed values.

**Example:** 'kernel', 'box'

## Data Types

char | function\_handle

## 'npoints' - Number of equally spaced points

100 (default) | scalar value

Number of equally spaced points in `xi`, specified as the comma-separated pair consisting of 'npoints' and a scalar value.

For instance, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

**Example:** 'npoints', 80

## Data Types

single | double

## 'support' - Support for the density

'unbounded' (default) | 'positive' | two-element vector, [L U]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

'unbounded'	Default. Allow the density to extend over the whole real line.
'positive'	Restrict the density to positive values.
Two-element vector, [L U]	Give the finite lower and upper bounds for the support of the density.

**Example:** 'support', 'positive'

**Example:** 'support', [0 10]

### Data Types

single | double | char

### 'weights' - Weights for each x value

vector

Weights for each x value, specified as the comma-separated pair consisting of 'weights' and a vector of the same length as x.

For instance, if the weights for the data values are in vector xw, then you can specify the weights as follows.

**Example:** 'weights', xw

### Data Types

single | double

### 'bandwidth' - Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value

The bandwidth of the kernel-smoothing window, which is a function of the number of points in x, specified as the comma-separated pair consisting of 'width' and a scalar. The default is optimal for estimating normal densities, but you might want to choose a larger or smaller value to smooth more or less.

**Example:** 'bandwidth', 0.8

### Data Types

single | double

# ksdensity

---

## 'function' - Function to estimate

'pdf' (default) | 'cdf' | 'icdf' | 'survivor' | 'cumhazard'

Function to estimate, specified as the comma-separated pair consisting of 'function' and one of the following.

'pdf'	Default. Probability density function.
'cdf'	Cumulative distribution function.
'icdf'	Inverse cumulative distribution function. For 'icdf', $f = \text{ksdensity}(x, pi, 'function', 'icdf')$ computes
'survivor'	Survivor function.
'cumhazard'	Cumulative hazard function.

**Example:** 'function','icdf'

## Data Types

char

## Output Arguments

### f - Estimated function values

vector

Estimated function values, returned as a vector of the same dimension as `xi` or `pts`.

### xi - Evaluation points

100 equally spaced points (default) | vector

Evaluation points at which `ksdensity` calculates `f`, returned as a vector. Default is 100 equally spaced points that cover the range of data in `x`.

### bw - Bandwidth of smoothing window

scalar value

Bandwidth of smoothing window, returned as a scalar value.

## Examples

### Estimate Density

Generate a sample data set from a mixture of two normal distributions.

```
rng('default') % For reproducibility  
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);  
figure()  
plot(xi,f);
```

The density estimate shows the bimodality of the sample.

## Estimate Cumulative Distribution Function at Specified Values

Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));  
figure()  
ecdf(hospital.Weight)  
hold on  
[f,xi,bw] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf');  
plot(xi,f,'-g','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','Location','NorthWest')  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

`bw`

# ksdensity

---

```
bw =
```

```
0.1070
```

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'support','positive',...  
    'function','cdf','bandwidth',0.05);  
plot(xi,f,'--r','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...  
    'Location','NorthWest')  
hold off
```

The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

### Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

# ksdensity

---

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()  
ksdensity(hospital.Weight,'support','positive','function','cdf',...  
  'npoints',50)  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

## **Estimate Survivor and Cumulative Hazard for Censored Failure Data**

Generate sample data from an exponential distribution with mean 3.

```
rng('default') % For reproducibility  
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;  
cens = (x>10);
```

Compute and plot the estimated density function.

```
figure()  
ksdensity(x,'support','positive','censoring',cens);
```

# ksdensity

---

Compute and plot the survivor function.

```
figure()  
ksdensity(x,'support','positive','censoring',cens,...  
  'function','survivor');
```

Compute and plot the cumulative hazard function.

```
figure()  
ksdensity(x,'support','positive','censoring',cens,...  
'function','cumhazard');
```

# ksdensity

---

## Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng('default') % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
```

```
figure()  
ksdensity(x,pi,'function','icdf');
```

## Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng('default') % For reproducibility  
x = [randn(30,1); 5+randn(30,1)];
```

# ksdensity

---

Return the bandwidth of the smoothing window for the probability density estimate.

```
[f,xi,bw] = ksdensity(x);  
bw
```

```
bw =
```

```
1.5141
```

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```
figure()  
plot(xi,f);  
xlabel('xi')  
ylabel('f')  
hold on
```

Plot the density using an increased bandwidth value.

```
[f,xi] = ksdensity(x,'width',1.8);  
plot(xi,f,'--r','LineWidth',1.5)
```

# ksdensity

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'width',0.8);  
plot(xi,f,'-.k','LineWidth',1.5)  
legend('bw = default','bw = 1.8','bw = 0.8')  
hold off
```

A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

<b>Input Arguments</b>	<p><b>x - Sample data</b> vector</p> <p>Sample data, specified as a vector.</p> <p><b>Data Types</b> single   double</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding</p>

value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'Tail','right','Alpha',0.01 specifies a right-tailed hypothesis test at the 1% significance level.

### **'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

### **Data Types**

single | double

### **'CDF' - cdf of hypothesized continuous distribution**

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of 'CDF' and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible  $x$  values, and column 2 contains the corresponding hypothesized cumulative distribution function values  $G(x)$ . The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector  $x$ . If there are values in  $x$  not found in column 1 of CDF, kstest approximates  $G(x)$  by interpolation. All values in  $x$  must lie in the interval between the smallest and largest values in the first column of CDF. By default, kstest tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test  $x$  against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

**Data Types**

single | double

**'Tail' - Type of alternative hypothesis**

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- |           |  |
|-----------|--|
| 'unequal' | Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is not equal to the cdf of the hypothesized distribution. |
| 'larger'  | Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is greater than the cdf of the hypothesized distribution. |
| 'smaller' | Test the alternative hypothesis that the cdf of the population from which $x$ is drawn is less than the cdf of the hypothesized distribution.    |

If the values in the data vector  $x$  tend to be larger than expected from the hypothesized distribution, the empirical distribution function of  $x$  tends to be smaller, and vice versa.

**Example:** 'Tail', 'larger'

**Output Arguments****h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

**p - p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

### **ksstat - Test statistic**

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

### **cv - Critical value**

nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

## **Examples**

### **Test for a Standard Normal Distribution**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector since, by default, `kstest` tests for a standard normal distribution.

```
x = (test1-75)/10;  
h = kstest(x)
```

```
h =  
0
```

The returned value of  $h = 0$  indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cumulative distribution function (cdf) and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);
F = plot(x_values,f);
set(F,'LineWidth',2);
hold on;
G = plot(x_values,normcdf(x_values,0,1),'r-');
set(G,'LineWidth',2);
legend([F G],...
      'Empirical CDF','Standard Normal CDF',...
      'Location','SE');
```

# kstest

---

The plot shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

## **Specify the Hypothesized Distribution Using a Two-Column Matrix**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector  $x$ . Column 2 contains cdf values evaluated at each value in  $x$  for a hypothesized Student's  $t$  distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x,cdf('tlocation',x,75,10,1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h =  
    1
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

### **Specify the Hypothesized Distribution Using a Probability Distribution Object**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's  $t$  distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x,'CDF',test_cdf)
```

```
h =  
    1
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

## Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;  
test1 = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's  $t$  distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation', 'mu', 75, 'sigma', 10, 'nu', 1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x, 'CDF', test_cdf, 'Alpha', 0.01)
```

```
h =  
    1  
  
p =  
    0.0021
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis at the 1% significance level.

## Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```
load stockreturns;
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x, 'Tail', 'larger')
```

```
h =
    1
p =
    5.0854e-05
k =
    0.2197
c =
    0.1207
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);
J = plot(x_values,f);
hold on;
K = plot(x_values,normcdf(x_values),'r--');
set(J,'LineWidth',2);
set(K,'LineWidth',2);
legend([J K], 'Empirical CDF', 'Standard Normal CDF', 'Location', 'SE');
```

The plot shows the difference between the empirical cdf of the data vector  $x$  and the cdf of the standard normal distribution.

## Definitions

### One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not

equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from  $x$  and the hypothesized cdf:

$$D^* = \max_x \left( \left| \hat{F}(x) - G(x) \right| \right),$$

where  $\hat{F}(x)$  is the empirical cdf and  $G(x)$  is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from  $x$  exceeds the hypothesized cdf:

$$D^* = \max_x \left( \hat{F}(x) - G(x) \right).$$

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from  $x$ :

$$D^* = \max_x \left( G(x) - \hat{F}(x) \right).$$

`kstest` computes the critical value `cv` using an approximate formula or by interpolation in a table. The formula and table cover the range  $0.01 \leq \alpha \leq 0.2$  for two-sided tests and  $0.005 \leq \alpha \leq 0.1$  for one-sided tests. `cv` is returned as `NaN` if `alpha` is outside this range.

## Algorithms

`kstest` decides to reject the null hypothesis by comparing the  $p$ -value `p` with the significance level `Alpha`, not by comparing the test statistic `ksstat` with the critical value `cv`. Since `cv` is approximate, comparing `ksstat` with `cv` occasionally leads to a different conclusion than comparing `p` with `Alpha`.

## See Also

kstest2 | lillietest | adtest

**Purpose** Two-sample Kolmogorov-Smirnov test

**Syntax**

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2( ___ )
[h,p,ks2stat] = kstest2( ___ )
```

**Description** `h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors `x1` and `x2` are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test. The alternative hypothesis is that `x1` and `x2` are from different continuous distributions. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2( ___ )` also returns the asymptotic  $p$ -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2( ___ )` also returns the test statistic `ks2stat`.

## Input Arguments

### **x1 - Sample data**

vector

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

### **Data Types**

single | double

### **x2 - Sample data**

vector

Sample data from the second sample, specified as a vector. Data vectors  $x_1$  and  $x_2$  do not need to be the same size.

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:**

## 'Alpha' - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

## Data Types

single | double

## 'Tail' - Type of alternative hypothesis

'unequal' (default) | 'larger' | 'smaller'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'unequal' Test the alternative hypothesis that the empirical cdf of  $x_1$  is unequal to the empirical cdf of  $x_2$ .
- 'larger' Test the alternative hypothesis that the empirical cdf of  $x_1$  is larger than the empirical cdf of  $x_2$ .
- 'smaller' Test the alternative hypothesis that the empirical cdf of  $x_1$  is smaller than the empirical cdf of  $x_2$ .

If the data values in `x1` tend to be larger than those in `x2`, the empirical distribution function of `x1` tends to be smaller than that of `x2`, and vice versa.

**Example:** 'Tail', 'larger'

## Output Arguments

### **h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If `h = 1`, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If `h = 0`, this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p - Asymptotic p-value**

scalar value in the range (0,1)

Asymptotic *p*-value of the test, returned as a scalar value in the range (0,1). *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic *p*-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes `n1` and `n2`, such that  $(n1*n2)/(n1 + n2) \geq 4$ .

### **ks2stat - Test statistic**

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

## Examples

### **Test Two Samples for the Same Distribution**

Generate sample data from two different Weibull distributions.

```
rng(1);          % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h =  
1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

## Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2, 'Alpha',0.01)
```

```
h =  
0  
p =  
0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

## One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility  
x1 = wblrnd(1,1,1,50);  
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors  $x_1$  and  $x_2$  comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of  $x_1$  is larger than the cdf of the distribution of  $x_2$ .

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h =
    1
p =
    0.0158
k =
    0.2800
```

The returned value of  $h = 1$  indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of  $x_1$  is larger than the cdf of the distribution of  $x_2$ , at the default 5% significance level. The returned value of  $k$  is the test statistic for the two-sample Kolmogorov-Smirnov test.

## Definitions

### Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of  $x$  in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x (|F_1(x) - F_2(x)|),$$

where  $\hat{F}_1(x)$  is the proportion of  $x_1$  values less than or equal to  $x$  and  $\hat{F}_2(x)$  is the proportion of  $x_2$  values less than or equal to  $x$ .

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x (F_1(x) - F_2(x)).$$

## Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the  $p$ -value `p` with the significance level `Alpha`, not by comparing the test statistic `ks2stat` with a critical value.

**Purpose**

Kurtosis

**Syntax**

```
k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,dim)
```

**Description**

`k = kurtosis(X)` returns the sample kurtosis of  $X$ . For vectors, `kurtosis(x)` is the kurtosis of the elements in the vector  $x$ . For matrices `kurtosis(X)` returns the sample kurtosis for each column of  $X$ . For  $N$ -dimensional arrays, `kurtosis` operates along the first nonsingleton dimension of  $X$ .

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is 0) or not (`flag` is 1, the default). When  $X$  represents a sample from a population, the kurtosis of  $X$  is biased, that is, it will tend to differ from the population kurtosis by a systematic amount that depends on the size of the sample. You can set `flag` to 0 to correct for this systematic bias.

`k = kurtosis(X,flag,dim)` takes the kurtosis along dimension `dim` of  $X$ .

`kurtosis` treats NaNs as missing values and removes them.

**Algorithms**

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3.

The kurtosis of a distribution is defined as

$$k = \frac{E(x - \mu)^4}{\sigma^4}$$

where  $\mu$  is the mean of  $x$ ,  $\sigma$  is the standard deviation of  $x$ , and  $E(t)$  represents the expected value of the quantity  $t$ . `kurtosis` computes a sample version of this population value.

# kurtosis

---

---

**Note** Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The `kurtosis` function does not use this convention.

---

When you set `flag` to 1, the following equation applies:

$$k_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^4}{\left( \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \right)^2}$$

When you set `flag` to 0, the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)} ((n+1)k_1 - 3(n-1)) + 3$$

This bias-corrected formula requires that `X` contain at least four elements.

## Examples

```
X = randn([5 4])
X =
  1.1650  1.6961  -1.4462  -0.3600
  0.6268  0.0591  -0.7012  -0.1356
  0.0751  1.7971  1.2460  -1.3493
  0.3516  0.2641  -0.6390  -1.2704
 -0.6965  0.8717  0.5774  0.9846

k = kurtosis(X)
k =
  2.1658  1.2967  1.6378  1.9589
```

**Purpose**

Text labels for levels

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Description**

Text labels for levels. Access labels with `getLabels`.

# lasso

---

**Purpose** Regularized least-squares regression using lasso or elastic net algorithms

**Syntax**

```
B = lasso(X,Y)
[B,FitInfo] = lasso(X,Y)
[B,FitInfo] = lasso(X,Y,Name,Value)
```

**Description** `B = lasso(X,Y)` returns fitted least-squares regression coefficients for a set of regularization coefficients `Lambda`.

`[B,FitInfo] = lasso(X,Y)` returns a structure containing information about the fits.

`[B,FitInfo] = lasso(X,Y,Name,Value)` fits regularized regressions with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **X**

Numeric matrix with `n` rows and `p` columns. Each row represents one observation, and each column represents one predictor (variable).

### **Y**

Numeric vector of length `n`, where `n` is the number of rows of `X`. `Y(i)` is the response to row `i` of `X`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Alpha'**

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso ( $L^1$ ) versus ridge ( $L^2$ ) optimization. `Alpha = 1` represents lasso regression, `Alpha` close to 0 approaches ridge regression, and other

values represent elastic net optimization. See “Definitions” on page 21-1950.

**Default:** 1

### **‘CV’**

Method `lasso` uses to estimate mean squared error:

- `K`, a positive integer — `lasso` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lasso`.
- 'resubstitution' — `lasso` uses `X` and `Y` to fit the model and to estimate the mean squared error, without cross validation.

**Default:** 'resubstitution'

### **‘DFmax’**

Maximum number of nonzero coefficients in the model. `lasso` returns results only for `Lambda` values that satisfy this criterion.

**Default:** Inf

### **‘Lambda’**

Vector of nonnegative `Lambda` values. See “Definitions” on page 21-1950.

- If you do not supply `Lambda`, `lasso` calculates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, `lasso` ignores `LambdaRatio` and `NumLambda`.

**Default:** Geometric sequence of `NumLambda` values, the largest just sufficient to produce  $B = 0$

### **‘LambdaRatio’**

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not set `Lambda`.

If you set `LambdaRatio = 0`, `lasso` generates a default sequence of `Lambda` values, and replaces the smallest one with 0.

**Default:** 1e-4

## **'MCReps'**

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a `cvpartition` of type 'resubstitution', `MCReps` must be 1.
- If CV is a `cvpartition` of type 'holdout', `MCReps` must be greater than 1.

**Default:** 1

## **'NumLambda'**

Positive integer, the number of `Lambda` values `lasso` uses when you do not set `Lambda`. `lasso` can return fewer than `NumLambda` fits if the if the residual error of the fits drops below a threshold fraction of the variance of `Y`.

**Default:** 100

## **'Options'**

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to true to compute in parallel. Default is false.
- `UseSubstreams` — Set to true to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: 'mlfg6331\_64' or 'mrg32k3a'. Default is false.

- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lasso` uses the default stream.

**'PredictorNames'**

Cell array of strings representing names of the predictor variables, in the order in which they appear in `X`.

**Default:** {}

**'RelTol'**

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the  $L^2$  norm by a relative amount less than `RelTol`.

**Default:** 1e-4

**'Standardize'**

Boolean value specifying whether `lasso` scales `X` before fitting the models.

**Default:** true

**'Weights'**

Observation weights, a nonnegative vector of length `n`, where `n` is the number of rows of `X`. `lasso` scales `Weights` to sum to 1.

**Default:** 1/n \* ones(n,1)

**Output Arguments****B**

Fitted coefficients, a `p`-by-`L` matrix, where `p` is the number of predictors (columns) in `X`, and `L` is the number of `Lambda` values.

**FitInfo**

Structure containing information about the model fits.

Field in FitInfo	Description
Intercept	Intercept term $\beta_0$ for each linear model, a 1-by-L vector
Lambda	Lambda parameters in ascending order, a 1-by-L vector
Alpha	Value of Alpha parameter, a scalar
DF	Number of nonzero coefficients in B for each value of Lambda, a 1-by-L vector
MSE	Mean squared error (MSE), a 1-by-L vector

If you set the CV name-value pair to cross validate, the FitInfo structure contains additional fields.

Field in FitInfo	Description
SE	The standard error of MSE for each Lambda, as calculated during cross validation, a 1-by-L vector
LambdaMinMSE	The Lambda value with minimum MSE, a scalar
Lambda1SE	The largest Lambda such that MSE is within one standard error of the minimum, a scalar
IndexMinMSE	The index of Lambda with value LambdaMinMSE, a scalar
Index1SE	The index of Lambda with value Lambda1SE, a scalar

## Definitions

### Lasso

For a given value of  $\lambda$ , a nonnegative parameter, lasso solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- $N$  is the number of observations.
- $y_i$  is the response at observation  $i$ .
- $x_i$  is data, a vector of  $p$  values at observation  $i$ .
- $\lambda$  is a nonnegative regularization parameter corresponding to one value of  $\Lambda$ .
- The parameters  $\beta_0$  and  $\beta$  are scalar and  $p$ -vector respectively.

As  $\lambda$  increases, the number of nonzero components of  $\beta$  decreases.

The lasso problem involves the  $L^1$  norm of  $\beta$ , as contrasted with the elastic net algorithm.

### Elastic Net

For an  $\alpha$  strictly between 0 and 1, and a nonnegative  $\lambda$ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when  $\alpha = 1$ . As  $\alpha$  shrinks toward 0, elastic net approaches ridge regression. For other values of  $\alpha$ , the penalty term  $P_\alpha(\beta)$  interpolates between the  $L^1$  norm of  $\beta$  and the squared  $L^2$  norm of  $\beta$ .

## Examples

### Remove Redundant Predictors

Construct a data set with redundant predictors, and identify those predictors using cross-validated lasso.

Create a matrix  $X$  of 100 five-dimensional normal variables and a response vector  $Y$  from just two components of  $X$ , with small added noise.

```
X = randn(100,5);  
r = [0;2;0;-3;0]; % only two nonzero coefficients  
Y = X*r + randn(100,1)*.1; % small added noise
```

Construct the default lasso fit.

```
B = lasso(X,Y);
```

Find the coefficient vector for the 25th value in  $B$ .

```
B(:,25)
```

```
ans =
```

```
    0  
  1.6093  
    0  
 -2.5865  
    0
```

lasso identifies and removes the redundant predictors.

### Plot a Regularized Fit with Cross Validation

Visually examine the cross-validated error of various levels of regularization.

Load the acetylene data and prepare the data with interactions for fitting.

```
load acetylene  
Xs = [x1 x2 x3];
```

```
X = x2fx(Xs,'interaction');
X(:,1) = []; % No constant term
```

Construct the lasso fit using ten-fold cross validation. Include the FitInfo output so you can plot the result.

```
[B FitInfo] = lasso(X,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
```

## How To

- “Lasso and Elastic Net” on page 9-140

<b>Purpose</b>	Lasso or elastic net regularization for generalized linear model regression
<b>Syntax</b>	<pre>B = lassoglm(X,Y) [B,FitInfo] = lassoglm(X,Y) [B,FitInfo] = lassoglm(X,Y,distr) [B,FitInfo] = lassoglm(X,Y,distr,Name,Value)</pre>
<b>Description</b>	<p><code>B = lassoglm(X,Y)</code> returns penalized maximum-likelihood fitted coefficients for a generalized linear model of the response <code>Y</code> to the data matrix <code>X</code>. <code>Y</code> are assumed to have a Gaussian probability distribution.</p> <p><code>[B,FitInfo] = lassoglm(X,Y)</code> returns a structure containing information about the fits.</p> <p><code>[B,FitInfo] = lassoglm(X,Y,distr)</code> fits the model using the probability distribution type for <code>Y</code> as specified in <code>distr</code>.</p> <p><code>[B,FitInfo] = lassoglm(X,Y,distr,Name,Value)</code> fits regularized generalized linear regressions with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Input Arguments</b>	<p><b>X</b></p> <p>Numeric matrix with <code>n</code> rows and <code>p</code> columns. Each row represents one observation, and each column represents one predictor (variable).</p> <p><b>Y</b></p> <p>When <code>distr</code> is not 'binomial', <code>Y</code> is a numeric vector or categorical array of length <code>n</code>, where <code>n</code> is the number of rows of <code>X</code>. <code>Y(i)</code> is the response to row <code>i</code> of <code>X</code>.</p> <p>When <code>distr</code> is 'binomial', <code>Y</code> is either a:</p> <ul style="list-style-type: none"><li>• Numeric vector of length <code>n</code>, where each entry represents success (1) or failure (0)</li><li>• Logical vector of length <code>n</code>, where each entry represents success or failure</li></ul>

- Categorical array of length  $n$ , where each entry represents success or failure
- Two column numeric matrix, where the first column contains the number of successes for each observation, and the second column contains the total number of trials

## **distr**

Distributional family for the nonsystematic variation in the responses, a string. Choices:

- 'normal'
- 'binomial'
- 'poisson'
- 'gamma'
- 'inverse gaussian'

By default, `lassoglm` uses the canonical link function corresponding to `distr`. Specify another link function using the 'link' name-value pair.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'Alpha'**

Scalar value from 0 to 1 (excluding 0) representing the weight of lasso ( $L^1$ ) versus ridge ( $L^2$ ) optimization. `Alpha = 1` represents lasso regression, and other values represent elastic net optimization. `Alpha` close to 0 approaches ridge regression. See “Definitions” on page 21-1950.

**Default:** 1

**'CV'**

Method `lassoglm` uses to estimate deviance:

- `K`, a positive integer — `lassoglm` uses `K`-fold cross validation.
- `cvp`, a `cvpartition` object — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lassoglm`.
- 'resubstitution' — `lassoglm` uses `X` and `Y` to fit the model and to estimate the deviance, without cross validation.

**Default:** 'resubstitution'

**'DFmax'**

Maximum number of nonzero coefficients in the model. `lassoglm` returns results for `Lambda` values that satisfy this criterion.

**Default:** `Inf`

**'Lambda'**

Vector of nonnegative `Lambda` values. See “Lasso” on page 21-1963.

- If you do not supply `Lambda`, `lassoglm` estimates the largest value of `Lambda` that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply `Lambda`, `lassoglm` ignores `LambdaRatio` and `NumLambda`.

**Default:** Geometric sequence of `NumLambda` values, the largest just sufficient to produce  $B = 0$

**'LambdaRatio'**

Positive scalar, the ratio of the smallest to the largest `Lambda` value when you do not explicitly set `Lambda`.

# lassoglm

---

If you set `LambdaRatio = 0`, `lassoglm` generates a default sequence of Lambda values, and replaces the smallest one with 0.

**Default:** `1e-4`

## 'Link'

Specify the mapping between the mean  $\mu$  of the response and the linear predictor  $Xb$ .

Value	Description
'comloglog'	$\log(-\log((1-\mu))) = Xb$
'identity', default for the distribution 'normal'	$\mu = Xb$
'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
'logit', default for the distribution 'binomial'	$\log(\mu/(1-\mu)) = Xb$
'loglog'	$\log(-\log(\mu)) = Xb$
'probit'	$\Phi^{-1}(\mu) = Xb$ , where $\Phi$ is the normal (Gaussian) CDF function
'reciprocal', default for the distribution 'gamma'	$\mu^{-1} = Xb$

Value	Description
$p$ (a number), default for the distribution 'inverse gaussian' (with $p = -2$ )	$\mu^p = Xb$
Cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI). Equivalently, can be a structure of function handles with field Link containing FL, field Derivative containing FD, and field Inverse containing FI.	User-specified link function (see "Custom Link Function" on page 10-16)

**'MCReps'**

Positive integer, the number of Monte Carlo repetitions for cross validation.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', MCReps must be 1.
- If CV is a cvpartition of type 'holdout', MCReps must be greater than 1.

**Default:** 1

**'NumLambda'**

Positive integer, the number of Lambda values lassoglm uses when you do not set Lambda. lassoglm can return fewer than NumLambda fits if the

deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors  $X$ ).

**Default:** 100

## 'Offset'

Numeric vector with the same number of rows as  $X$ . `lassoglm` uses `Offset` as an additional predictor variable, but keeps its coefficient value fixed at 1.0.

## 'Options'

Structure that specifies whether to cross validate in parallel, and specifies the random stream or streams. Create the `Options` structure with `statset`. Option fields:

- `UseParallel` — Set to `true` to compute in parallel. Default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. Default is `false`.
- `Streams` — `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, `lassoglm` uses the default stream.

## 'PredictorNames'

Cell array of strings representing names of the predictor variables, in the order in which they appear in  $X$ .

**Default:** {}

## 'RelTol'

Convergence threshold for the coordinate descent algorithm (see Friedman, Tibshirani, and Hastie [3]). The algorithm terminates when successive estimates of the coefficient vector differ in the  $L^2$  norm by a relative amount less than `RelTol`.

**Default:** 1e-4

### 'Standardize'

Boolean value specifying whether `lassoglm` scales  $X$  before fitting the models.

**Default:** true

### 'Weights'

Observation weights, a nonnegative vector of length  $n$ , where  $n$  is the number of rows of  $X$ . At least two values must be positive.

**Default:**  $1/n * \text{ones}(n,1)$

## Output Arguments

### **B**

Fitted coefficients, a  $p$ -by- $L$  matrix, where  $p$  is the number of predictors (columns) in  $X$ , and  $L$  is the number of `Lambda` values.

### **FitInfo**

Structure containing information about the model fits.

Field in FitInfo	Description
Alpha	Value of Alpha parameter, a scalar.
Deviance	Deviance of the fitted model for each value of Lambda, a 1-by- $L$ vector. If cross validation was performed, the values for Deviance represent the estimated expected deviance of the model applied to new data, as calculated by cross validation. Otherwise, Deviance is the deviance of the fitted model applied to the data used to perform the fit.
DF	Number of nonzero coefficients in $B$ for each Lambda value, a 1-by- $L$ vector.

Field in FitInfo	Description
Intercept	Intercept term $\beta_0$ for each linear model, a 1-by-L vector.
Lambda	Lambda parameters in ascending order, a 1-by-L vector.

If you set the CV name-value pair to cross validate, the FitInfo structure contains additional fields.

Field in FitInfo	Description
IndexMinDeviance	Index of Lambda with value LambdaMinDeviance, a scalar.
Index1SE	Index of Lambda with value Lambda1SE, a scalar.
LambdaMinDeviance	Lambda value with minimum expected deviance, as calculated by cross validation, a scalar.
Lambda1SE	Largest Lambda such that Deviance is within one standard error of the minimum, a scalar.
SE	Standard error of Deviance for each Lambda, as calculated during cross validation, a 1-by-L vector.

## Definitions

### Link Function

A link function  $f(\mu)$  maps a distribution with mean  $\mu$  to a linear model with data  $X$  and coefficient vector  $b$  using the formula

$$f(\mu) = Xb.$$

Find the formulas for the link functions in the Link name-value pair description. Here, “typical” means a link function that is typically used for the listed distribution.

Distributional Family	Link Function (typical, {default})
'normal'	{'identity'}
'binomial'	'comploglog', 'loglog', 'probit', {'logit'}
'poisson'	{'log'}
'gamma'	{'reciprocal'}
'inverse gaussian'	{-2}

### Lasso

For a nonnegative value of  $\lambda$ , lasso solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda \sum_{j=1}^p |\beta_j| \right),$$

where

- Deviance is the deviance of the model fit to the responses using intercept  $\beta_0$  and predictor coefficients  $\beta$ . The formula for Deviance depends on the `distr` parameter you supply to `lassoglm`. Minimizing the  $\lambda$ -penalized deviance is equivalent to maximizing the  $\lambda$ -penalized log likelihood.
- $N$  is the number of observations.
- $\lambda$  is a nonnegative regularization parameter corresponding to one value of `Lambda`.
- Parameters  $\beta_0$  and  $\beta$  are scalar and  $p$ -vector respectively.

As  $\lambda$  increases, the number of nonzero components of  $\beta$  decreases.

The lasso problem involves the  $L^1$  norm of  $\beta$ , as contrasted with the elastic net algorithm.

## Elastic Net

For an  $\alpha$  strictly between 0 and 1, and a nonnegative  $\lambda$ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left( \frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left( \frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when  $\alpha = 1$ . For other values of  $\alpha$ , the penalty term  $P_\alpha(\beta)$  interpolates between the  $L^1$  norm of  $\beta$  and the squared  $L^2$  norm of  $\beta$ . As  $\alpha$  shrinks toward 0, elastic net approaches ridge regression.

## Examples

### Lasso Regularization of a Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors using `lassoglm`.

Create data with 20 predictors, and Poisson responses using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15]) * [.4;.2;.3] + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the Lambda regularization parameter.

```
lassoPlot(B,FitInfo,'plottype','CV');
```

The green circle and dashed line locate the Lambda with minimal cross-validation error. The blue circle and dashed line locate the point with minimal cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
minpts = find(B(:,FitInfo.IndexMinDeviance))
```

```
min1pts =  
    3  
    5  
    6  
   10  
   11  
   15  
   16  
  
min1pts = find(B(:,FitInfo.Index1SE))  
  
min1pts =  
    5  
   10  
   15
```

The coefficients from the minimal plus one standard error point are exactly those coefficients used to create the data.

# lassoPlot

---

**Purpose** Trace plot of lasso fit

**Syntax**

```
ax = lassoPlot(B)
ax = lassoPlot(B,FitInfo)
ax = lassoPlot(B,FitInfo,Name,Value)
[ax,figh] = lassoPlot(B,...)
```

**Description**

`ax = lassoPlot(B)` creates a trace plot of the values in `B` against the  $L^1$  norm of `B`. `ax` is a handle to the plot axis.

`ax = lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the `plotType` name-value pair.

`ax = lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more `Name,Value` pair arguments.

`[ax,figh] = lassoPlot(B,...)` returns a handle to the figure window.

## Input Arguments

### **B**

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. `B` is a `p`-by-`NLambda` matrix, where `p` is the number of predictors, and each column of `B` is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

### **FitInfo**

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.
- `FitInfo` is a vector — `lassoPlot` forms the  $x$ -axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Parent'

Axis in which to draw the plot.

**Default:** New plot

### 'PlotType'

Choose the plot type when you give a `FitInfo` vector or structure:

FitInfo Type	PlotType	Plot
Vector or Structure	'L1'	<code>plotLasso</code> creates the <i>x</i> -axis from the $L^1$ norm of the coefficients in <code>B</code> . The <i>x</i> -axis at the top of the plot contains the degrees of freedom ( <code>df</code> ), meaning the number of nonzero coefficients of <code>B</code> .
Structure	'Lambda'	<code>plotLasso</code> creates the <i>x</i> -axis from the <code>Lambda</code> field of <code>FitInfo</code> . The <i>x</i> -axis at the top of the plot contains the degrees of freedom ( <code>df</code> ), meaning the number of nonzero coefficients of <code>B</code> .
Cross-Validated Structure	'CV'	<ul style="list-style-type: none"> <li>• For each <code>Lambda</code>, plots an estimate of the mean squared prediction error on new data for the model fitted by lasso with that value of <code>Lambda</code>.</li> <li>• Plots error bars for the estimates.</li> <li>• Plots the value of <code>Lambda</code> with minimum cross-validated MSE.</li> </ul>

# lassoPlot

---

FitInfo Type	PlotType	Plot
		<ul style="list-style-type: none"><li>• Plots the greatest Lambda that is within one standard error of minimum MSE (so makes the sparsest model within that region).</li></ul>

**Default:** 'L1'

## 'PredictorNames'

Cell array of strings to label each coefficient of **B**. If the length of **PredictorNames** is less than the number of rows of **B**, the remaining labels are padded with default values.

`lassoPlot` uses the predictor names in **FitInfo** only if:

- You created **FitInfo** with a call to `lasso` that included a **PredictorNames** name-value pair.
- You call `lassoPlot` *without* a **PredictorNames** name-value pair.
- You include **FitInfo** in your `lassoPlot` call.

**Default:** {'B1', 'B2', ...}

## 'XScale'

- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

**Default:** 'linear', except 'log' for the 'CV' plot type

## Output Arguments

### **ax**

Handle to the axis of the plot (see “Coordinate System”).

### **figh**

Handle to the figure window (see “Graphics Windows — the Figure”).

## Examples

### Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data using lasso .

```
B = lasso(D,y);
```

Plot the fits with the default plot type.

```
lassoPlot(B);
```

# lassoPlot

## Lasso Plot with Lambda Plot Type

Load the sample data.

```
load acetylene
```

Prepare the data for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');
```

```
D(:,1) = []; % No constant term
```

```
Fit a regularized model of the data with lasso .
```

```
[B FitInfo] = lasso(D,y);
```

```
Plot the fits with the Lambda plot type and logarithmic scaling.
```

```
lassoPlot(B,FitInfo,'PlotType','Lambda','XScale','log');
```

Trace Plot of coefficients fit by Lasso

## Lasso Plot with Cross-Validated Fits

Load the sample data.

```
load acetylene
```

Prepare the design matrix for a lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso and cross validation.

```
[B FitInfo] = lasso(D,y, 'CV', 10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo, 'PlotType', 'CV');
```

**How To**

- “Lasso and Elastic Net” on page 9-140

# grandstream.le

---

**Purpose** Less than or equal relation for handles

**Syntax** `h1 <= h2`

**Description** Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

`h1 <= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = le(h1, h2)` stores the result in a logical array of the same dimensions.

**See Also** `grandstream` | `eq` | `ge` | `gt` | `lt` | `ne`

## Purpose

Interval between points

## Description

Number of points to leap over and omit for each point taken from the sequence. The Leap property of a point set contains a positive integer which specifies the number of points in the sequence to leap over and omit for every point taken. The default Leap value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the Leap values with care; many Leap values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube, and so fail to be a uniform quasi-random point set.

### Choosing Leap Values for Halton Sets

A known rule for choosing Leap values for Halton sets is to set it to  $(P-1)$  where  $P$  is a prime number that has not been used to generate one of the dimensions, i.e. for a  $k$ -dimensional point set  $P$  would be the  $(k+1)$ th or greater prime.

## Examples

Experiment with different leap values:

```
% No leaping produces the standard Halton sequence.  
P = haltonset(5);  
P(1:5,:)
```

```
% Set a leap of 1. The point set now includes every other  
% point from the sequence.  
P.Lean = 1;  
P(1:5,:)
```

# dataset.length

---

**Purpose**

Length of dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

`n = length(A)`

**Description**

`n = length(A)` returns the number of observations in the dataset A. `length` is equivalent to `size(A,1)`.

**See Also**

`size`

**Purpose** Length of point set

**Syntax** length(p)

**Description** length(p) returns the number of points in the point set p. It is equivalent to size(p, 1).

**See Also** grandset | size

# categorical.length

---

## **Purpose**

Length of categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`n = length(A)`

## **Description**

`n = length(A)` returns the size of the longest dimension of the categorical array `A` when `A` is not empty. If `A` is a vector, this is the same as its length. `length` is equivalent to `max(size(x))` for nonempty arrays, and 0 for empty arrays.

## **See Also**

`isempty` | `isscalar` | `size`

## Purpose

Element counts by level

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
C = levelcounts(A)
C = levelcounts(A,dim)
```

## Description

`C = levelcounts(A)` for a categorical vector `A` counts the number of elements in `A` equal to each of the possible levels in `A`. The output is a vector `C` containing those counts, and has as many elements as `A` has levels. For matrix `A`, `C` is a matrix of column counts. For  $N$ -dimensional arrays, `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension `dim`.

## Examples

Count the number of patients in each age group in the data in `hospital.mat`:

```
load hospital
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
disp(labels')
'0s' '10s' '20s' '30s' '40s' '50s' '60s' '70s' '80s' '90s'

AgeGroup = ordinal(hospital.Age, labels, [], edges);
I = islevel(labels, AgeGroup);
disp(I')
0 1 1 1 1 1 1 1 1 1
c = levelcounts(AgeGroup);
disp(c')
0 0 15 41 42 2 0 0 0 0

AgeGroup = droplevels(AgeGroup);
I = islevel(labels, AgeGroup);
disp(I')
0 0 1 1 1 1 0 0 0 0
```

# categorical.levelcounts

---

```
c = levelcounts(AgeGroup);  
disp(c')  
15 41 42 2
```

# leverage

---

## How To

- regstats

**Purpose** Latin hypercube sample

**Syntax**

```
X = lhsdesign(n,p)
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)
```

**Description**

`X = lhsdesign(n,p)` returns an  $n$ -by- $p$  matrix,  $X$ , containing a latin hypercube sample of  $n$  values on each of  $p$  variables. For each column of  $X$ , the  $n$  values are randomly distributed with one from each interval  $(0, 1/n)$ ,  $(1/n, 2/n)$ , ...,  $(1-1/n, 1)$ , and they are randomly permuted.

`X = lhsdesign(...,'smooth','off')` produces points at the midpoints of the above intervals:  $0.5/n$ ,  $1.5/n$ , ...,  $1-0.5/n$ . The default is 'on'.

`X = lhsdesign(...,'criterion',criterion)` iteratively generates latin hypercube samples to find the best one according to the criterion *criterion*, which can be one of the following strings.

Criterion	Description
'none'	No iteration.
'maximin'	Maximize minimum distance between points. This is the default.
'correlation'	Reduce correlation.

`X = lhsdesign(...,'iterations',k)` iterates up to  $k$  times in an attempt to improve the design according to the specified criterion. The default is  $k = 5$ .

**See Also** haltonset | sobolset | lhsnorm | unifrnd

# lhsnorm

---

**Purpose** Latin hypercube sample from normal distribution

**Syntax**  
`X = lhsnorm(mu,sigma,n)`  
`X = lhsnorm(mu,sigma,n,flag)`  
`[X,Z] = lhsnorm(...)`

**Description** `X = lhsnorm(mu,sigma,n)` returns an  $n$ -by- $p$  matrix,  $X$ , containing a latin hypercube sample of size  $n$  from a  $p$ -dimensional multivariate normal distribution with mean vector,  $\mu$ , and covariance matrix,  $\sigma$ .

$X$  is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu,sigma,n,flag)` controls the amount of smoothing in the sample. If `flag` is 'off', each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values  $G(0.5/n)$ ,  $G(1.5/n)$ , ...,  $G(1-0.5/n)$  where  $G$  is the inverse normal cumulative distribution for that column's marginal distribution. If `flag` is 'on' (the default), each column has points uniformly distributed on the probability scale. For example, in place of  $0.5/n$  you use a value having a uniform distribution on the interval  $(0/n, 1/n)$ .

`[X,Z] = lhsnorm(...)` also returns  $Z$ , the original multivariate normal sample before the marginals are adjusted to obtain  $X$ .

**References** [1] Stein, M. "Large sample properties of simulations using latin hypercube sampling." *Technometrics*. Vol. 29, No. 2, 1987, pp. 143–151. Correction, Vol. 32, p. 367.

**See Also** lhsdesign | mvnrnd

**Purpose**

Lilliefors test

**Syntax**

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( ___ )
[h,p,kstat,critval] = lillietest( ___ )
```

**Description**

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the  $p$ -value using a Monte Carlo approximation.

`[h,p] = lillietest( ___ )` also returns the  $p$ -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest( ___ )` also returns the test statistic `kstat` and the critical value `critval` for the test.

**Input Arguments****x - Sample data**

vector

Sample data, specified as a vector.

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'Distr','exp','Alpha',0.01 tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

### **'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

- If MCTol is not used, Alpha must be in the range [0.001,0.50].
- If MCTol is used, Alpha must be in the range (0,1).

**Example:** 'Alpha',0.01

### **Data Types**

single | double

### **'Distr' - Distribution family**

'norm' (default) | 'exp' | 'ev'

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of 'Distr' and one of the following.

'norm'	Normal distribution
'exp'	Exponential distribution
'ev'	Extreme value distribution

**Example:** 'Distr','exp'

### **'MCTol' - Maximum Monte Carlo standard error**

scalar value in the range (0,1)

Maximum Monte Carlo standard error for  $p$ , the  $p$ -value of the test, specified as the comma-separated pair consisting of 'MCTol' and a scalar value in the range (0,1).

**Example:** 'MCTol',0.001

### Data Types

single | double

## Output Arguments

### **h** - Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p** - $p$ -value

scalar value in the range (0,1)

$p$ -value of the test, returned as a scalar value in the range (0,1).  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

- If MCTol is not used,  $p$  is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. lillietest warns when  $p$  is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If MCTol is used, lillietest conducts a Monte Carlo simulation to compute a more accurate  $p$ -value, and  $p$  is returned as a scalar value in the range (0,1).

### **kstat** - Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

## **critval - Critical value**

nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

## **Examples**

### **Test for a Normal Distribution**

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
load carbig.mat;  
[h,p,k,c] = lillietest(MPG)
```

```
Warning: P is less than the smallest tabulated value, returning 0.001.  
h =  
    1  
p =  
 1.0000e-003  
k =  
    0.0789  
c =  
    0.0451
```

The test statistic  $k$  is greater than the critical value  $c$ , so `lillietest` returns a result of  $h = 1$  to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned  $p$ -value is the smallest value in the table of precomputed values. To find a more accurate  $p$ -value, use `MCTol` to run a Monte Carlo approximation.

### **Test the Hypothesis at Different Significance Levels**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x,'Alpha',0.01)
```

```
h =  
0  
p =  
0.0348
```

The returned value of  $h = 0$  indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

### Test for an Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```
load carbig.mat;  
h = lillietest(MPG,'Distr','exp')
```

```
h =  
1
```

The returned value of  $h = 1$  indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

### Determine the $p$ -value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the  $p$ -value using a Monte Carlo approximation with a maximum Monte Carlo standard error of  $1e-4$ .

```
load carbig.mat;  
[h,p] = lillietest(MPG,'MCTol',1e-4)
```

h =  
1  
p =  
0

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

## Definitions

### Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x |F(x) - G(x)|,$$

where  $\hat{F}(x)$  is the empirical cdf of the sample data and  $G(x)$  is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector  $\mathbf{x}$  has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test  $\mathbf{x}$  for a lognormal distribution, test if  $\log(\mathbf{x})$  has a normal distribution.
- To test  $\mathbf{x}$  for a Weibull distribution, test if  $\log(\mathbf{x})$  has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

### Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the  $p$ -value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where  $\hat{p}$  is the estimated  $p$ -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mcreps`, is determined such that the Monte Carlo standard error for  $\hat{p}$  less than the value specified for `MCTol`.

### Algorithms

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate  $p$ -value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the `MCTol` input argument can be used to run a Monte Carlo simulation to calculate the  $p$ -value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level `Alpha`.

`lillietest` treats NaN values in `x` as missing values and ignores them.

**Purpose** Linear regression model class

**Description** An object comprising training data, model description, diagnostic information, and fitted coefficients for a linear regression. Predict model responses with the `predict` or `feval` methods.

**Construction** `mdl = fitlm(tbl)` or `mdl = fitlm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitlm`.

`mdl = stepwiselm(tbl)` or `mdl = stepwiselm(X,y)` create a linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiselm`.

## Input Arguments

### **tbl** - Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### **X** - Predictor variables

matrix

# LinearModel

---

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## Properties

### CoefficientCovariance

Covariance matrix of coefficient estimates.

### CoefficientNames

Cell array of strings containing a label for each coefficient.

### Coefficients

Coefficient values stored as a table. `Coefficients` has one row for each coefficient and these columns:

- Estimate — Estimated coefficient value
- SE — Standard error of the estimate
- tStat —  $t$  statistic for a test that the coefficient is zero
- pValue —  $p$ -value for the  $t$  statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in `mdl` the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use `coefTest` to perform other tests on the coefficients.

## DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

## Diagnostics

Table with the same number of rows as the input data (`tbl` or `X`). `Diagnostics` contains diagnostics helpful in finding outliers and influential observations. Many diagnostics describe the effect on the fit of deleting single observations. `Diagnostics` contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	<code>Leverage</code> indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with <code>P</code> coefficients and <code>N</code> observations, the average value of <code>Leverage</code> is $P/N$ . An observation with <code>Leverage</code> larger than $2 * P/N$ can be regarded as having high leverage.
<code>CooksDistance</code>	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.

# LinearModel

Field	Meaning	Utility
Dffits	Delete-1 scaled differences in fitted values vs. observation number	Dffits is the scaled change in the fitted values for each observation that would result from excluding that observation from the fit. Values with an absolute value larger than $2 \cdot \sqrt{P/N}$ may be considered influential.
S2_i	Delete-1 variance vs. observation number	S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These can be compared with the value of the MSE property.
CovRatio	Delete-1 ratio of determinant of covariance vs. observation number	CovRatio is the ratio of the determinant of the coefficient covariance matrix with each observation deleted in turn to the determinant of the covariance matrix for the full model. Values larger than $1+3 \cdot P/N$ or smaller than $1-3 \cdot P/N$ indicate influential points.
Dfbetas	Delete-1 scaled differences in covariance estimates vs. observation number	Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that would result from excluding each observation in turn. Values larger than $3/\sqrt{N}$ in absolute value indicate that the observation has a large influence on the corresponding coefficient.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $\text{Fitted} = \text{HatMatrix} \cdot Y$ , where Y is the response vector and Fitted is the vector of fitted response values.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exception: Delete-1 diagnostics refer to the statistic with and without that observation (row) included in the fit. These diagnostics help identify important observations.

**Fitted**

Predicted response to the input data by using the model. Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

**Formula**

Object containing information about the model.

**LogLikelihood**

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

**ModelCriterion**

AIC and other information criteria for comparing models. A structure with fields:

- `AIC` — Akaike information criterion
- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

**MSE**

Mean squared error (residuals),  $SSE/DFE$ .

**NumCoefficients**

Number of coefficients in the model, a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

# LinearModel

---

## **NumEstimatedCoefficients**

Number of estimated coefficients in the model, a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

## **NumObservations**

Number of observations the fitting function used in fitting. This is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the `Excluded` name-value pair) or rows with missing values.

## **NumPredictors**

Number of variables `fitlm` used as predictors for fitting.

## **NumVariables**

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

## **ObservationInfo**

Table with the same number of rows as the input data (`tbl` or `X`).

<b>Field</b>	<b>Description</b>
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.

Field	Description
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

## ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

## PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

## Residuals

Table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.

# LinearModel

---

Field	Description
Standardized	Raw residuals divided by their estimated standard deviation.
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation $i$ is divided by an estimate of the error standard deviation based on all observations except for observation $i$ .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

## **ResponseName**

String giving naming the response variable.

## **RMSE**

Root mean squared error (residuals),  $\sqrt{\text{MSE}}$ .

## **Robust**

Structure that is empty unless `fitlm` constructed the model using robust regression.

Field	Description
WgtFun	Robust weighting function, such as 'bisquare' (see <code>robustfit</code> )
Tune	Value specified for tuning parameter (can be [])
Weights	Vector of weights used in final iteration of robust fit

## **Rsquared**

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

Rsquared is a structure with two fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

## **SSE**

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

# LinearModel

---

## SSR

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## SST

Total sum of squares, the sum of squared deviations of  $y$  from  $\text{mean}(y)$ .

The Pythagorean theorem implies

$$SST = SSE + SSR.$$

## Steps

Structure that is empty unless `stepwiselm` constructed the model.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model, these terms that must remain in the model
Upper	Formula representing the upper bound model, model cannot contain more terms than Upper
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Value of the parameter, such as 0.05
PRemove	Value of the parameter, such as 0.10
History	Table representing the steps taken in the fit

The History table has one row for each step including the initial fit, and the following variables (columns).

Field	Description
Action	Action taken during this step, one of: <ul style="list-style-type: none"> <li>'Start' — First step</li> <li>'Add' — A term is added</li> <li>'Remove' — A term is removed</li> </ul>
TermName	<ul style="list-style-type: none"> <li>'Start' step: The starting model specification</li> <li>'Add' or 'Remove' steps: The term moved in that step</li> </ul>
Terms	Terms matrix (see <code>modelspec</code> of <code>fitlm</code> )
DF	Regression degrees of freedom after this step
delDF	Change in regression degrees of freedom from previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at that step
FStat	$F$ statistic that led to this step
PValue	$p$ -value of the $F$ statistic

## VariableInfo

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

# LinearModel

---

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"><li>• Continuous variable — Two-element vector <math>[min, max]</math>, the minimum and maximum values</li><li>• Categorical variable — Cell array of distinct variable values</li></ul>
InModel	Logical vector, where true indicates the variable is in the model
IsCategorical	Logical vector, where true indicates a categorical variable

## VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

## Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix  $X$  and response vector  $y$ .

## Methods

<code>addTerms</code>	Add terms to linear regression model
<code>anova</code>	Analysis of variance for linear model
<code>coefCI</code>	Confidence intervals of coefficient estimates of linear model
<code>coefTest</code>	Linear hypothesis test on linear regression model coefficients
<code>disp</code>	Display linear regression model
<code>dwtest</code>	Durbin-Watson test of linear model
<code>feval</code>	Evaluate linear regression model prediction
<code>fit</code>	Create linear regression model
<code>plot</code>	Scatter plot or added variable plot of linear model
<code>plotAdded</code>	Added variable plot or leverage plot for linear model
<code>plotAdjustedResponse</code>	Adjusted response plot for linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of linear regression model
<code>plotEffects</code>	Plot main effects of each predictor in linear regression model
<code>plotInteraction</code>	Plot interaction effects of two predictors in linear regression model
<code>plotResiduals</code>	Plot residuals of linear regression model

# LinearModel

---

plotSlice	Plot of slices through fitted linear regression surface
predict	Predict response of linear regression model
random	Simulate responses for linear regression model
removeTerms	Remove terms from linear model
step	Improve linear regression model by adding or removing terms
stepwise	Create linear regression model by stepwise regression

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$ :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

### Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the

number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance,  $D_i$ , of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $\text{MSE}$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where  $r_i$  is the  $i$ th residual, and  $h_{ii}$  is the  $i$ th leverage value.

`CooksDistance` is an  $n$ -by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

# LinearModel

---

## Examples

### Linear Regression Model of Matrix Data

Fit a linear model of the Hald data.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

```
Linear regression model:
  y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 2.45

R-squared: 0.982, Adjusted R-Squared 0.974

F-statistic vs. constant model: 111, p-value = 4.76e-07

### Linear Regression with Categorical Predictor and Nonlinear Model

Fit a model of a table that contains a categorical predictor. Use a nonlinear response formula.

Load the carsmall data.

```
load carsmall
```

Construct a table containing continuous predictor variable `Weight`, nominal predictor variable `Year`, and response variable `MPG`.

```
tbl = table(MPG,Weight);  
tbl.Year = nominal(Model_Year);
```

Create a fitted model of `MPG` as a function of `Year`, `Weight`, and `Weight2`. (You don't have to include `Weight` explicitly in your formula because it is a lower-order term of `Weight2`. For details, see "Formula" on page 21-1043.)

```
mdl = fitlm(tbl,'MPG ~ Year + Weight^2')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
```

```
Root Mean Squared Error: 2.78
```

```
R-squared: 0.885, Adjusted R-Squared 0.88
```

```
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`fitlm` creates two dummy (indicator) variables for the nominal variate, `Year`. The dummy variable `Year_76` takes the value 1 if model year is 1976 and takes the value 0 if it is not. The dummy variable `Year_82` takes the value 1 if model year is 1982 and takes the value 0 if it is not. And the year 1970 is the reference year (for more information on

# LinearModel

---

dummy variables see “Dummy Indicator Variables” on page 2-56). The corresponding model is

$$\hat{MPG} = 54.206 - 0.0164Weight + 2.0887(Year\_76) + 8.1864(Year\_82) + 1.557e - 06Weight^2$$

## Robust Linear Regression Model

Fit a linear regression model of the Hald data using robust fitting.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a robust linear model to the data.

```
mdl = fitlm(X,y,'linear','RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

```
y ~ 1 + x1 + x2 + x3 + x4
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8
```

```
Root Mean Squared Error: 2.65
```

```
R-squared: 0.979, Adjusted R-Squared 0.969
```

```
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

## Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

## Alternatives

To remove redundant predictors in linear regression using lasso or elastic net, use the `lasso` function.

To regularize a regression with correlated terms using ridge regression, use the `ridge` or `lasso` functions.

To regularize a regression with correlated terms using partial least squares, use the `plsregress` function.

# LinearMixedModel

---

**Purpose** Linear mixed-effects model class

**Description** A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

**Construction** You can fit a linear mixed-effects model using `fitlme(tbl, formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

## Input Arguments

### **tbl - Input data**

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-52). You must specify the model for the variables using `formula`.

### **Data Types**

single | double | char | cell

### **formula - Formula for model specification**

string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a string of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'. For a full description, see “Formula” on page 21-2028.

**Example:** 'y ~ treatment +(1|block)'

## **X - Fixed-effects design matrix**

*n*-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of *X* corresponds to one observation, and each column of *X* corresponds to one variable.

### **Data Types**

single | double

## **y - Response values**

*n*-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

### **Data Types**

single | double

## **Z - Random-effects design**

*n*-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then *Z* must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then *Z* must be a cell array of length *R*. Each cell of *Z* contains an *n*-by-*q*(*r*) design matrix *Z*{*r*}, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, *Z*{*r*}.

### **Data Types**

single | double | cell

## **G - Grouping variable or variables**

*n*-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables, specified as either of the following.

# LinearMixedModel

---

- If there is one random-effects term, then  $G$  must be an  $n$ -by-1 vector corresponding to a single grouping variable with  $M$  levels or groups.

$G$  can be a categorical vector, numeric vector, character array, or cell array of strings.

- If there are multiple random-effects terms, then  $G$  must be a cell array of length  $R$ . Each cell of  $G$  contains a grouping variable  $G\{r\}$ ,  $r = 1, 2, \dots, R$ , with  $M(r)$  levels.

$G\{r\}$  can be a categorical vector, numeric vector, character array, or cell array of strings.

## Data Types

single | double | char | cell

## Properties

### Coefficients - Fixed-effects coefficient estimates

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

Name	Name of the term.
Estimate	Estimated value of the coefficient.
SE	Standard error of the coefficient.
tStat	$t$ -statistics for testing the null hypothesis that the coefficient is equal to zero.

DF	Degrees of freedom for the $t$ -test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. <code>Coefficients</code> always uses the 'Residual' method for 'DFMethod'.
pValue	$p$ -value for the $t$ -test.
Lower	Lower limit of the confidence interval for coefficient. <code>Coefficients</code> always uses the 95% confidence level, i.e. 'alpha' is 0.05.
Upper	Upper limit of confidence interval for coefficient. <code>Coefficients</code> always uses the 95% confidence level, i.e. 'alpha' is 0.05.

You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

## **CoefficientCovariance - Covariance of the estimated fixed-effects coefficients**

$p$ -by- $p$  matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

## **Data Types**

double

## **CoefficientNames - Names of the fixed-effects coefficients**

# LinearMixedModel

---

1-by- $p$  cell array of strings

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by- $p$  cell array of strings.

## Data Types

cell

## DFE - Residual degrees of freedom

positive integer value

Residual degrees of freedom, stored as a positive integer value.

$DFE = n - p$ , where  $n$  is the number of observations, and  $p$  is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

## Data Types

double

## FitMethod - Method used to fit the linear mixed-effects model

ML | REML

Method used to fit the linear mixed-effects model, stored as either of the following strings.

- ML, if the fitting method is maximum likelihood
- REML, if the fitting method is restricted maximum likelihood

## Data Types

char

## Formula - Specification of the fixed- and random-effects terms, and grouping variables

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 21-2028.

## **LogLikelihood - Maximized log or restricted log likelihood**

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

## **Data Types**

double

## **ModelCriterion - Model criterion**

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

AIC	Akaike Information Criterion
BIC	Bayesian Information Criterion
Loglikelihood	Log likelihood value of the model
Deviance	-2 times the log likelihood of the model

If  $n$  is the number of observations used in fitting the model, and  $p$  is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is  $nc + p + 1$ , where  $nc$  is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
  - $n$ , when the fitting method is maximum likelihood (ML)

# LinearMixedModel

---

- $n - p$ , when the fitting method is restricted maximum likelihood (REML)

## **MSE - ML or REML estimate**

positive scalar value

ML or REML estimate, based on the fitting method used for estimating  $\sigma^2$ , stored as a positive scalar value.  $\sigma^2$  is the residual variance or variance of the observation error term of the linear mixed-effects model.

## **Data Types**

double

## **NumCoefficients - Number of fixed-effects coefficients**

positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

## **Data Types**

double

## **NumEstimatedCoefficients - Number of estimated fixed-effects coefficients**

positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

## **Data Types**

double

## **NumObservations - Number of observations**

positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with NaN values.

## Data Types

double

### **NumPredictors - Number of predictors**

positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

## Data Types

double

### **NumVariables - Total number of variables**

positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.
- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

## Data Types

double

### **ObservationInfo - Information about the observations**

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

# LinearMixedModel

---

Weights	The value of the weighted variable for that observation. Default value is 1.
Excluded	true, if the observation was excluded from the fit using the 'Exclude' name-value pair argument, false, otherwise. 1 stands for true and 0 stands for false.
Missing	true, if the observation was excluded from the fit because any response or predictor value is missing, false, otherwise. Missing values include NaN for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <undefined> value for categorical arrays.
Subset	true, if the observation was used in the fit, false, if it was not used because it is missing or excluded.

## Data Types

table

### **ObservationNames - Names of observations**

cell array of strings

Names of observations used in the fit, stored as a cell array of strings.

- If the data is in a table or dataset array, `tbl`, containing observation names, `ObservationNames` has those names.

- If the data is provided in matrices, or a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

## Data Types

cell

## PredictorNames - Names of predictors

cell array of strings

Names of the variables that you use as predictors in the fit, stored as a cell array of strings that has the same length as `NumPredictors`.

## Data Types

cell

## ResponseName - Names of response variable

character string

Name of the variable used as the response variable in the fit, stored as a character string.

## Data Types

char

## Rsquared - Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. `Rsquared` has two fields.

# LinearMixedModel

---

Ordinary	R-squared value, stored as a scalar value in a structure. <code>Rsquared.Ordinary = 1 - SSE./SST</code>
Adjusted	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. <code>Rsquared.Adjusted = 1 - (SSE./SST)*(DFT./DFE)</code> , where $DFE = n - p$ , $DFT = n - 1$ , and $n$ is the total number of observations, $p$ is the number of fixed-effects coefficients.

## Data Types

struct

### SSE - Error sum of squares

positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

$SSE = \sum (y - F)^2$ , where  $y$  is the response vector, and  $F$  is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

## Data Types

double

### SSR - Regression sum of squares

positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar

value. It is the sum of squared deviations of the conditional fitted values from their mean.

$SSR = \sum (F - \text{mean}(F))^2$ , where  $F$  is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

## Data Types

double

## SST - Total sum of squares

positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

$SST = \sum (y - \text{mean}(y))^2 = SSR + SSE$ , where  $y$  is the response vector.

## Data Types

double

## Variables - Variables

table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.
- If the fit is based on matrix input, then `Variables` is a table containing all the variables in the predictor matrix or matrices, and response variable.

## Data Types

table

## VariableInfo - Information about the variables

table

Information about the variables used in the fit, stored as a table.

# LinearMixedModel

---

`VariableInfo` has one row for each variable and contains the following four columns.

<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none"><li>• For a numerical variable, it is a two-element vector of the form <code>[min,max]</code>.</li><li>• For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.</li></ul>
<code>InModel</code>	<code>true</code> , if the variable is a predictor in the fitted model. <code>false</code> , if the variable is not in the fitted model.
<code>IsCategorical</code>	<code>true</code> , if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the 'Categorical' name-value pair argument of the <code>fit</code> method. <code>false</code> , if it is a continuous predictor.

## Data Types

table

## VariableNames - Names of the variables

cell array of strings

Names of the variables used in the fit, stored as a cell array of strings.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

## Data Types

`cell`

## Methods

<code>anova</code>	Analysis of variance for linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of linear mixed-effects model
<code>compare</code>	Compare linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices
<code>disp</code>	Display linear mixed-effects model
<code>fit</code>	Fit linear mixed-effects model using tables

# LinearMixedModel

---

<code>fitmatrix</code>	Fit linear mixed-effects model using design matrices
<code>fitted</code>	Fitted responses from a linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of linear mixed-effects model
<code>predict</code>	Predict response of linear mixed-effects model
<code>random</code>	Generate random responses from fitted linear mixed-effects model
<code>randomEffects</code>	Estimates of random effects and related statistics
<code>residuals</code>	Residuals of fitted linear mixed-effects model
<code>response</code>	Response vector of the linear mixed-effects model

## Definitions

## Formula

In general, a formula for model specification is a string of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable,  $y$
- Predictor variables,  $X_j$ , which can be continuous or grouping variables
- Grouping variables,  $g_1, g_2, \dots, g_R$ ,

where the grouping variables in  $X_j$  and  $g_r$  can be categorical, logical, character arrays, or cell arrays of strings.

Then, in a formula of the form, 'y ~ fixed + (random<sub>1</sub>|g<sub>1</sub>) + ... + (random<sub>R</sub>|g<sub>R</sub>)', the term **fixed** corresponds to a specification of the fixed-effects design matrix  $X$ , random<sub>1</sub> is a specification of the random-effects design matrix  $Z_1$  corresponding to grouping variable  $g_1$ , and similarly random<sub>R</sub> is a specification of the random-effects design matrix  $Z_R$  corresponding to grouping variable  $g_R$ . You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X <sup>k</sup> , where k is a positive integer	X, X <sup>2</sup> , ..., X <sup>k</sup>
X1 + X2	X1, X2
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

### Examples:

# LinearMixedModel

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1   g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1   g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1   g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1   g1) + (-1 + X1   g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1   g1) + (1   g2) + (1   g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into a tall array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example,  $I[MidAtl]$  is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables” on page 2-56.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[MidAtl]_i + \beta_2 I[ENCentral]_i + \beta_3 I[WNCentral]_i + \beta_4 I[SATl]_i \\ + \beta_5 I[ESCentral]_i + \beta_6 I[WSCentral]_i + \beta_7 I[Mtn]_i + \beta_8 I[Pac]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where  $y_{im}$  is the observation  $i$  for level  $m$  of grouping variable `Date`,  $\beta_j$ ,  $j = 0, 1, \dots, 8$ , are the fixed-effects coefficients,  $b_{0m}$  is the random effect for level  $m$  of the grouping variable `Date`, and  $\varepsilon_{im}$  is the observation error for observation  $i$ . The random effect has the prior distribution,  $b \sim N(0, \sigma_b^2)$  and the error term has the distribution,  $\varepsilon \sim N(0, \sigma_\varepsilon^2)$ .

```
lme = fitlme(flu2,'FluRate ~ 1 + Region + (1|Date)')
```

# LinearMixedModel

---

Linear mixed-effects model fit by ML

Model information:

Number of observations	468
Fixed effects coefficients	9
Random effects coefficients	52
Covariance parameters	2

Formula:

FluRate ~ 1 + Region + (1|Date)

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
318.71	364.35	-148.36	296.71

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF
'(Intercept)'	1.2233	0.096678	12.654	459
'Region_MidAtl'	0.010192	0.052221	0.19518	459
'Region_ENCentral'	0.051923	0.052221	0.9943	459
'Region_WNCentral'	0.23687	0.052221	4.5359	459
'Region_SAtl'	0.075481	0.052221	1.4454	459
'Region_ESCentral'	0.33917	0.052221	6.495	459
'Region_WSCentral'	0.069	0.052221	1.3213	459
'Region_Mtn'	0.046673	0.052221	0.89377	459
'Region_Pac'	-0.16013	0.052221	-3.0665	459

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.6443

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The  $p$ -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term,  $\sigma_b^2$ , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week `10/9/2005` is

$$\begin{aligned}\hat{y}_{WNCentral,10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[WNCentral] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
```

```
y_hat =
    1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

# LinearMixedModel

---

```
1.2884
```

Compute the fitted marginal response for region WNCentral in week 10/9/2005.

```
F = fitted(lme, 'Conditional', false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
```

```
ans =
```

```
1.4602
```

## Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year. This model corresponds to

$$MPG_{im} = \beta_0 + \beta_1 Acc_i + \beta_2 HP + b_{0m} + b_{1m} Acc_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N \left( \mathbf{0}, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix} \right),$$

where  $D(\theta)$  is the covariance matrix.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];  
Z = [ones(406,1) Acceleration];  
Model_Year = nominal(Model_Year);
```

```
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the 'fminunc' optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...  
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...  
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...  
'FitMethod','REML')
```

```
lme =
```

```
Linear mixed-effects model fit by REML
```

```
Model information:
```

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

```
Formula:
```

```
y ~ Intercept + Acceleration + Horsepower + (Intercept + Acceleration | Model_Year)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
2202.9	2230.7	-1094.5	2188.9

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	p
'Intercept'	50.064	2.3176	21.602	389	1.0e-04
'Acceleration'	-0.57897	0.13843	-4.1825	389	3.0e-05
'Horsepower'	-0.16958	0.0073242	-23.153	389	3.0e-05

```
Random effects covariance parameters (95% CIs):
```

```
Group: Model_Year (13 Levels)
```

Name1	Name2	Type	Estimate	Lower	Upper
-------	-------	------	----------	-------	-------

# LinearMixedModel

---

```
'Intercept'      'Intercept'      'std'      3.72
'Acceleration'   'Intercept'      'corr'     -0.8769
'Acceleration'   'Acceleration'   'std'      0.3593
```

Group: Error

```
Name      Estimate  Lower  Upper
'Res Std'  3.6913   3.4331 3.9688
```

The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (Lower and Upper). The  $p$ -values for (pValue) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the `compare` method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans =
```

```
 5.3711  -0.2809  -0.0126
-0.2809   0.0192   0.0005
-0.0126   0.0005   0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is  $-0.2809$  and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans =
```

```
  Ordinary: 0.7826
```

```
  Adjusted: 0.7815
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

# linhpytest

---

**Purpose** Linear hypothesis test

**Syntax** `p = linhpytest(beta,COVB,c,H,dfe)`  
`[p,t,r] = linhpytest(...)`

**Description** `p = linhpytest(beta,COVB,c,H,dfe)` returns the  $p$  value  $p$  of a hypothesis test on a vector of parameters. `beta` is a vector of  $k$  parameter estimates. `COVB` is the  $k$ -by- $k$  estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form  $H*b = c$ , where `b` is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have  $k$  elements and it specifies the null hypothesis values for the entire parameter vector.

---

**Note** The following functions return outputs suitable for use as the `COVB` input argument to `linhpytest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

---

`[p,t,r] = linhpytest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with `r` degrees of freedom. If `dfe` is specified as a finite value, `t` is an  $F$  statistic with `r` and `dfe` degrees of freedom.

`linhpytest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation

procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the  $p$ -values are exact. For other procedures, the  $p$ -values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

## Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
    62.4054
     1.5511
     0.5102
     0.1019
    -0.1441
```

Perform an  $F$ -test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linhpytest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

## See Also

`regstats` | `glmfit` | `robustfit` | `mnrfit` | `nlinfit` | `coxphfit`

# linkage

---

## Purpose

Agglomerative hierarchical cluster tree

## Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,pdist_inputs)
Z = linkage(X,method,metric,'savememory',value)
Z = linkage(Y)
Z = linkage(Y,method)
```

## Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree of hierarchical clusters of the rows of the real matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

`Z = linkage(X,method,metric)` performs clustering using the distance measure *metric* to compute distances between the rows of `X`.

`Z = linkage(X,method,pdist_inputs)` passes parameters to the `pdist` function, which is the function that computes the distance between rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when *value* is 'true', and uses the standard algorithm when *value* is 'false'.

`Z = linkage(Y)` uses a vector representation `Y` of a distance matrix. `Y` can be a distance matrix as computed by `pdist`, or a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(Y,method)` creates the tree using the specified *method*, where *method* describes how to measure the distance between clusters.

## Tips

- Computing `linkage(Y)` can be slow when `Y` is a vector representation of the distance matrix. For the 'centroid', 'median', and 'ward' methods, `linkage` checks whether `Y` is a Euclidean distance. Avoid this time-consuming check by passing in `X` instead of `Y`.

- The centroid and median methods can produce a cluster tree that is not monotonic. This occurs when the distance from the union of two clusters,  $r$  and  $s$ , to a third cluster is less than the distance between  $r$  and  $s$ . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this, use another method. The following image shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, while the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. This leads to a nonmonotonic tree.

- You can provide the output  $Z$  to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

## Input Arguments

### **X**

Matrix with two or more rows. The rows represent observations, the columns represent categories or dimensions.

### **method**

# linkage

---

Algorithm for computing distance between clusters.

Method	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Furthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

**Default:** 'single'

## **metric**

Any distance metric that the `pdist` function accepts.

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>X</code> is scaled by dividing by the corresponding element of the standard deviation <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use <code>D=pdist(X, 'seuclidean', S)</code> .
'cityblock'	City block metric.

Metric	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use <code>D = pdist(X, 'minkowski', P)</code> , where <code>P</code> is a scalar
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of <code>X</code> as computed by <code>nancov</code> . To compute the distance with a different covariance, use <code>D = pdist(X, 'mahalanobis', C)</code> , where the matrix <code>C</code> is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	<p>A distance function specified using <code>@</code>:</p> $D = \text{pdist}(X, @\text{distfun})$ <p>A distance function must be of form</p> $d2 = \text{distfun}(XI, XJ)$ <p>taking as arguments a 1-by-<math>n</math> vector <math>XI</math>, corresponding to a single row of <math>X</math>, and an <math>m2</math>-by-<math>n</math> matrix <math>XJ</math>, corresponding to multiple rows of <math>X</math>. <code>distfun</code> must accept a matrix <math>XJ</math></p>

# linkage

---

Metric	Description
	with an arbitrary number of rows. <code>distfun</code> must return an $m2$ -by-1 vector of distances <code>d2</code> , whose $k$ th element is the distance between $XI$ and $XJ(k, :)$ .

**Default:** 'euclidean'

## **pdist\_inputs**

A cell array of parameters accepted by the `pdist` function. For example, to set the *metric* to `minkowski` and use an exponent of 5, set `pdist_inputs` to {'minkowski', 5}.

## **savememory**

A string, either 'on' or 'off'. When applicable, the 'on' setting causes `linkage` to construct clusters without computing the distance matrix. `savememory` is applicable when:

- `linkage` is 'centroid', 'median', or 'ward'
- `distance` is 'euclidean' (default)

When `savememory` is 'on', `linkage` run time is proportional to the number of dimensions (number of columns of  $X$ ). When `savememory` is 'off', `linkage` memory requirement is proportional to  $N^2$ , where  $N$  is the number of observations. So choosing the best (least-time) setting for `savememory` depends on the problem dimensions, number of observations, and available memory. The default `savememory` setting is a rough approximation of an optimal setting.

**Default:** 'on' when  $X$  has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix; otherwise 'off'

## **Y**

A vector of distances with the same format as the output of the `pdist` function:

- A row vector of length  $m(m-1)/2$ , corresponding to pairs of observations in a matrix  $X$  with  $m$  rows
- Distances arranged in the order  $(2,1)$ ,  $(3,1)$ , ...,  $(m,1)$ ,  $(3,2)$ , ...,  $(m,2)$ , ...,  $(m,m-1)$

$Y$  can be a more general dissimilarity matrix conforming to the output format of `pdist`.

## Output Arguments

### **Z**

$Z$  is a  $(m-1)$ -by-3 matrix, where  $m$  is the number of observations in the original data. Columns 1 and 2 of  $Z$  contain cluster indices linked in pairs to form a binary tree. The leaf nodes are numbered from 1 to  $m$ . Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly-formed cluster, corresponding to row  $Z(I, :)$ , is assigned the index  $m+I$ .  $Z(I, 1:2)$  contains the indices of the two component clusters that form cluster  $m+I$ . There are  $m-1$  higher clusters which correspond to the interior nodes of the clustering tree.  $Z(I, 3)$  contains the linkage distances between the two clusters merged in row  $Z(I, :)$ .

For example, suppose there are 30 initial nodes and at step 12 cluster 5 and cluster 7 are combined. Suppose their distance at that time is 1.5. Then  $Z(12, :)$  will be  $[5, 7, 1.5]$ . The newly formed cluster will have index  $12 + 30 = 42$ . If cluster 42 appears in a later row, it means the cluster created at step 12 is being combined into some larger cluster.

## Definitions

### **Linkages**

The following notation is used to describe the linkages used by the various methods:

- Cluster  $r$  is formed from clusters  $p$  and  $q$ .
- $n_r$  is the number of objects in cluster  $r$ .
- $x_{ri}$  is the  $i$ th object in cluster  $r$ .

# linkage

---

- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters:

$$d(r, s) = \min(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Complete linkage*, also called *furthest neighbor*, uses the largest distance between objects in the two clusters:

$$d(r, s) = \max(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters:

$$d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters:

$$d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters,

$$d(r, s) = \|\tilde{x}_r - \tilde{x}_s\|_2$$

where  $\tilde{x}_r$  and  $\tilde{x}_s$  are weighted centroids for the clusters  $r$  and  $s$ . If cluster  $r$  was created by combining clusters  $p$  and  $q$ ,  $\tilde{x}_r$  is defined recursively as

$$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares; that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all objects in the cluster and the centroid of the cluster. The sum of squares measure is equivalent to the following distance measure  $d(r,s)$ , which is the formula linkage uses:

$$d(r,s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)}} \|\bar{x}_r - \bar{x}_s\|_2,$$

where

- $\|\cdot\|_2$  is Euclidean distance
- $\bar{x}_r$  and  $\bar{x}_s$  are the centroids of clusters  $r$  and  $s$
- $n_r$  and  $n_s$  are the number of elements in clusters  $r$  and  $s$

In some references the Ward linkage does not use the factor of 2 multiplying  $n_r n_s$ . The linkage function uses this factor so the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster  $r$  was created by combining clusters  $p$  and  $q$ , the distance between  $r$  and another cluster  $s$  is defined as the average of the distance between  $p$  and  $s$  and the distance between  $q$  and  $s$ :

$$d(r,s) = \frac{(d(p,s) + d(q,s))}{2}$$

# linkage

---

## Examples

### Compare Cluster Assignments to Clusters

Load the sample data.

```
load fisheriris
```

Compute four clusters of the Fisher iris data using Ward linkage and ignoring species information.

```
Z = linkage(meas,'ward','euclidean');  
c = cluster(Z,'maxclust',4);
```

See how the cluster assignments correspond to the three species.

```
crosstab(c,species)
```

```
ans =
```

```
    0    25    1  
    0    24   14  
    0     1   35  
   50     0    0
```

Display the first five rows of Z.

```
firstfive = Z(1:5,:)
```

```
firstfive =
```

```
102.0000 143.0000     0  
   8.0000  40.0000  0.1000  
   1.0000  18.0000  0.1000  
  10.0000  35.0000  0.1000  
 129.0000 133.0000  0.1000
```

Create a dendrogram plot of Z .

```
dendrogram(Z)
```

### Cluster Data and Plot the Result

Randomly generate the sample data with 20000 observations.

```
rng('default') % For reproducibility
```

# linkage

---

```
X = rand(20000,3);
```

Create a hierarchical cluster tree using Ward's linkage.

```
Z = linkage(X, 'ward', 'euclidean', 'savememory', 'on');
```

If you set `savememory` to `'off'`, you can get an out-of-memory error if your machine doesn't have enough memory to hold the distance matrix.

Cluster data into four groups and plot the result.

```
c = cluster(Z, 'maxclust', 4);  
scatter3(X(:,1), X(:,2), X(:,3), 10, c)
```

**Superclasses**    `ToolboxFittableParametricDistribution`

**Purpose**            `Logistic` probability distribution object

**Description**      `prob.LogisticDistribution` is an object consisting of parameters, a model description, and sample data for a logistic probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction**     `pd = makedist('Logistic')` creates a logistic probability distribution object using the default parameter values.

`pd = makedist('Logistic','mu',mu,'sigma',sigma)` creates a logistic probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Mean**

0 (default) | scalar value

Mean of the logistic distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma - Scale parameter**

1 (default) | nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

**Properties**        **mu - Mean**

scalar value

Mean of the logistic distribution, stored as a scalar value.

## Data Types

single | double

## sigma - Scale parameter

nonnegative scalar value

Scale parameter of the logistic distribution, stored as a nonnegative scalar value.

## Data Types

single | double

## DistributionName - Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## IsTruncated - Logical flag for truncated distribution

0 | 1

# prob.LogisticDistribution

---

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance - Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

### **Data Types**

char

## **ParameterValues - Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

### **Data Types**

### Logistic Distribution

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{\exp\left\{\frac{x - \mu}{\sigma}\right\}}{\sigma \left(1 + \exp\left\{\frac{x - \mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty.$$

## Examples

### Create a Logistic Distribution Object Using Default Parameters

### Loglogistic Distribution

The loglogistic distribution is closely related to the logistic distribution. If  $x$  is distributed loglogistically with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$\mu > 0$
sigma	Log scale parameter	$\sigma > 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1 + e^z)^2} ; \quad x \geq 0,$$

$$\text{where } z = \frac{\log(x) - \mu}{\sigma}.$$

## Examples

### Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')
```

```
pd =
```

```
LoglogisticDistribution
```

```
Log-Logistic distribution
```

```
mu = 0  
sigma = 1
```

## Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

```
pd = makedist('Loglogistic','mu',5,'sigma',2)
```

```
pd =
```

```
LoglogisticDistribution  
  
Log-Logistic distribution  
mu = 5  
sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility  
x = random(pd,10000,1);  
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

```
4.9828
```

The mean of the log of  $x$  is equal to the  $\mu$  parameter of  $x$ , since  $x$  has a loglogistic distribution.

Plot  $\log x$ .

# prob.LoglogisticDistribution

---

```
hist(logx,50)
```

The plot shows that the log values of x have a logistic distribution.

## Concepts

- “Loglogistic Distribution” on page B-88
- Class Attributes
- Property Attributes

**Purpose**

Lognormal cumulative distribution function

**Syntax**

```
p = logncdf(x,mu,sigma)
[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = logncdf( __ , 'upper' )
```

**Description**

`p = logncdf(x,mu,sigma)` returns values at `x` of the lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[p,plo,pup] = logncdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies  $100(1 - \alpha)\%$  confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = logncdf( __ , 'upper' )` returns the complement of the lognormal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use 'upper' with any of the previous syntaxes.

`logncdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{x - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal cdf is

# logncdf

---

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}}}{t} dt$$

## Examples

### Compute the Lognormal Distribution cdf

Compute the cdf of a lognormal distribution with  $\mu = 0$  and  $\sigma = 1$ .

```
x = (0:0.2:10);  
y = logncdf(x,0,1);
```

Plot the cdf.

```
plot(x,y);  
grid;  
xlabel('x');  
ylabel('p');
```

**How To**

• “Lognormal Distribution” on page B-90

# lognfit

---

## Purpose

Lognormal parameter estimates

## Syntax

```
parmhat = lognfit(data)
[parmhat,parmci] = lognfit(data)
[parmhat,parmci] = lognfit(data,alpha)
[...] = lognfit(data,alpha,censoring)
[...] = lognfit(data,alpha,censoring,freq)
[...] = lognfit(data,alpha,censoring,freq,options)
```

## Description

`parmhat = lognfit(data)` returns a vector of maximum likelihood estimates `parmhat(1) = mu` and `parmhat(2) = sigma` of parameters for a lognormal distribution fitting data. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution.

`[parmhat,parmci] = lognfit(data)` returns 95% confidence intervals for the parameter estimates `mu` and `sigma` in the 2-by-2 matrix `parmci`. The first column of the matrix contains the lower and upper confidence bounds for parameter `mu`, and the second column contains the confidence bounds for parameter `sigma`.

`[parmhat,parmci] = lognfit(data,alpha)` returns  $100(1 - \alpha)\%$  confidence intervals for the parameter estimates, where `alpha` is a value in the range (0 1) specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = lognfit(data,alpha,censoring)` accepts a Boolean vector `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = lognfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = lognfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The lognormal fit function accepts an `options`

structure which can be created using the function `statset`. Enter `statset('lognfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

---

**Note** With no censoring, `lognfit` computes `sigma` using the square root of the unbiased estimator of the variance. With censoring, `sigma` is the maximum likelihood estimate.

---

## Examples

This example generates 100 independent samples of lognormally distributed data with  $\mu = 0$  and  $\sigma = 3$ . `parmhat` estimates  $\mu$  and  $\sigma$  and `parmci` gives 99% confidence intervals around `parmhat`. Notice that `parmci` contains the true values of  $\mu$  and  $\sigma$ .

```
data = lognrnd(0,3,100,1);
[parmhat,parmci] = lognfit(data,0.01)
parmhat =
    -0.2480    2.8902
parmci =
    -1.0071    2.4393
     0.5111    3.5262
```

## See Also

`mle` | `lognlike` | `lognpdf` | `logncdf` | `logninv` | `lognstat` | `lognrnd`

## How To

- “Lognormal Distribution” on page B-90

# logninv

---

**Purpose** Lognormal inverse cumulative distribution function

**Syntax** `X = logninv(P,mu,sigma)`  
`[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)`

**Description** `X = logninv(P,mu,sigma)` returns values at `P` of the inverse lognormal cdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

`[X,XLO,XUP] = logninv(P,mu,sigma,pcov,alpha)` returns confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies  $100(1 - \alpha)\%$  confidence bounds. The default value of `alpha` is 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

`logninv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where  $q$  is the  $P$ th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p \mid \mu, \sigma) = \{x : F(x \mid \mu, \sigma) = p\}$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x e^{-\frac{(\ln(t)-\mu)^2}{2\sigma^2}} \frac{1}{t} dt$$

## Examples

### Compute the Lognormal Distribution Inverse cdf

Compute the inverse cdf of a lognormal distribution with  $\mu = 0$  and  $\sigma = 0.5$ .

```
p = (0.005:0.01:0.995);  
crit = logninv(p,1,0.5);
```

Plot the inverse cdf.

```
figure;  
plot(p,crit)  
xlabel('Probability');  
ylabel('Critical Value');  
grid
```

# prob.LognormalDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Lognormal probability distribution object

**Description** prob.LognormalDistribution is an object consisting of parameters, a model description, and sample data for a lognormal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Lognormal')` creates a lognormal probability distribution object using the default parameter values.

`pd = makedist('Lognormal','mu',mu,'sigma',sigma)` creates a lognormal probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Log mean**

0 (default) | scalar value

Log mean for the lognormal distribution, specified as a scalar value. `mu` is the mean of the log of  $x$ , when  $x$  has a lognormal distribution.

### **Data Types**

single | double

### **sigma - Log standard deviation**

1 (default) | nonnegative scalar value

Log standard deviation for the lognormal distribution, specified as a nonnegative scalar value. `sigma` is the standard deviation of the log of  $x$ , when  $x$  has a lognormal distribution.

### **Data Types**

single | double

## Properties

### **mu - Log mean**

scalar value

Log mean for the lognormal distribution, stored as a scalar value.

### **Data Types**

single | double

### **sigma - Log standard deviation**

nonnegative scalar value

Log standard deviation for the lognormal distribution, stored as a nonnegative scalar value.

### **Data Types**

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### **Data Types**

struct

### **IsTruncated - Logical flag for truncated distribution**

# prob.LognormalDistribution

---

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance - Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

# prob.LognormalDistribution

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Lognormal Distribution

The lognormal distribution is closely related to the normal distribution. If  $x$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ . The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(x)$  exists only when  $x$  is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$-\infty < \mu < \infty$
sigma	Log standard deviation	$\sigma \geq 0$

The probability density function (pdf) of the lognormal distribution is

$$f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\ln x - \mu)^2}{2\sigma^2}\right\} ; \quad x > 0.$$

## Examples

### Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')
```

```
pd =
```

```
LognormalDistribution
```

```
Lognormal distribution
```

```
mu = 0
```

```
sigma = 1
```

# prob.LognormalDistribution

---

## Create a Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal','mu',5,'sigma',2)
```

```
pd =
```

```
LognormalDistribution
```

```
Lognormal distribution
```

```
mu = 5
```

```
sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)
```

```
ans =
```

```
1.0966e+03
```

The mean of the lognormal distribution is not equal to the mu parameter.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng(47); % for reproducibility
```

```
x = random(pd,10000,1);
```

```
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m =
```

4.9999

The mean of the log of  $x$  is equal to the  $\mu$  parameter of  $x$ , since  $x$  has a lognormal distribution.

Plot  $\log x$ .

```
hist(logx,50)
```

The plot shows that the log values of  $x$  are normally distributed with a mean equal to 5 and a standard deviation equal to 2.

# prob.LognormalDistribution

---

## Concepts

- “Lognormal Distribution” on page B-90
- Class Attributes
- Property Attributes

**Purpose** Lognormal probability density function

**Syntax** `Y = lognpdf(X,mu,sigma)`

**Description** `Y = lognpdf(X,mu,sigma)` returns values at `X` of the lognormal pdf with distribution parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `mu`, or `sigma` is expanded to a constant array with the same dimensions as the other inputs.

The lognormal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln x - \mu)^2}{2\sigma^2}}$$

The normal and lognormal distributions are closely related. If  $X$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(X)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ .

The mean  $m$  and variance  $v$  of a lognormal random variable are functions of  $\mu$  and  $\sigma$  that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$

$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean  $m$  and variance  $v$  has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$

$$\sigma = \sqrt{\log\left(v / m^2 + 1\right)}$$

# lognpdf

---

The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(X)$  exists only when  $X$  is positive.

## Examples

### Compute the Lognormal Distribution pdf

Compute the pdf of a lognormal distribution with  $\mu = 0$  and  $\sigma = 1$ .

```
x = (0:0.02:10);  
y = lognpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y); grid;  
xlabel('x'); ylabel('p')
```

**How To**

• “Lognormal Distribution” on page B-90

# lognrnd

---

**Purpose** Lognormal random numbers

**Syntax**  
`R = lognrnd(mu,sigma)`  
`R = lognrnd(mu,sigma,m,n,...)`  
`R = lognrnd(mu,sigma,[m,n,...])`

**Description** `R = lognrnd(mu,sigma)` returns an array of random numbers generated from the lognormal distribution with parameters `mu` and `sigma`. `mu` and `sigma` are the mean and standard deviation, respectively, of the associated normal distribution. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = lognrnd(mu,sigma,m,n,...)` or `R = lognrnd(mu,sigma,[m,n,...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

The normal and lognormal distributions are closely related. If  $X$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(X)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ .

The mean  $m$  and variance  $v$  of a lognormal random variable are functions of  $\mu$  and  $\sigma$  that can be calculated with the `lognstat` function. They are:

$$m = \exp\left(\mu + \sigma^2 / 2\right)$$
$$v = \exp\left(2\mu + \sigma^2\right)\left(\exp\left(\sigma^2\right) - 1\right)$$

A lognormal distribution with mean  $m$  and variance  $v$  has parameters

$$\mu = \log\left(m^2 / \sqrt{v + m^2}\right)$$
$$\sigma = \sqrt{\log\left(v / m^2 + 1\right)}$$

**Examples**

Generate one million lognormally distributed random numbers with mean 1 and variance 2:

```
m = 1;
v = 2;
mu = log((m^2)/sqrt(v+m^2));
sigma = sqrt(log(v/(m^2)+1));

[M,V]= lognstat(mu,sigma)
M =
     1
V =
    2.0000

X = lognrnd(mu,sigma,1,1e6);

MX = mean(X)
MX =
    0.9974
VX = var(X)
VX =
    1.9776
```

## How To

• “Lognormal Distribution” on page B-90

# CompactClassificationDiscriminant.logP

---

**Purpose** Log of the unconditional probability density

**Syntax** `lp = logP(obj, Xnew)`

**Description** `lp = logP(obj, Xnew)` returns the log of the unconditional probability density of each row of `Xnew`, computed using the discriminant analysis model `obj`.

**Input Arguments**

**obj**  
Discriminant analysis classifier, produced using `fitcdiscr`.

**Xnew**  
Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `Xnew` must equal the number of predictors in `obj`.

**Output Arguments**

**lp**  
Column vector with the same number of rows as `Xnew`. Each entry is the logarithm of the unconditional probability density of the corresponding row of `Xnew`.

## Definitions **Unconditional Probability Density**

The unconditional probability density of a point  $x$  of a discriminant analysis model is

$$P(x) = \sum_{k=1}^K P(x, k),$$

where  $P(x, k)$  is the conditional density of the model at  $x$  for class  $k$ , when the total number of classes is  $K$ .

The conditional density  $P(x, k)$  is

$$P(x, k) = P(k)P(x | k),$$

where  $P(k)$  is the prior probability of class  $k$ , and  $P(x|k)$  is the conditional density of  $x$  given class  $k$ . The conditional density function of the multivariate normal with mean  $\mu_k$  and covariance  $\Sigma_k$  at a point  $x$  is

$$P(x|k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x-\mu_k)^T \Sigma_k^{-1}(x-\mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

## Examples

### logP Calculation

Construct a discriminant analysis classifier for the Fisher iris data, and examine its prediction for an average measurement.

Load the Fisher iris data and construct a default discriminant analysis classifier.

```
load fisheriris
mdl = fitcdiscr(meas,species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logpaverage = logP(mdl,mean(meas))
```

```
logpaverage =
```

```
-1.7254
```

## Concepts

- “Discriminant Analysis” on page 15-3

# ClassificationKNN.loss

---

**Purpose** Loss of  $k$ -nearest neighbor classifier

**Syntax**  
`L = loss mdl, X, Y`  
`L = loss mdl, X, Y, Name, Value`

**Description** `L = loss mdl, X, Y` returns a scalar representing how well `mdl` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `mdl`.

`L = loss mdl, X, Y, Name, Value` returns the loss with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### **mdl - Classifier model**

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

### **X - Matrix of predictor values**

matrix

Matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

### **Y - Categorical variables**

categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as `X`. Each row of `Y` represents the classification of the corresponding row of `X`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'lossfun'

Function handle or string representing a loss function. The built-in loss functions are:

- `'binodeviance'` — See “Loss Functions” on page 21-2096.
- `'exponential'` — See “Loss Functions” on page 21-2096.
- `'classiferror'` — Fraction of misclassified observations. See “Loss Functions” on page 21-2096.
- `'mincost'` — Smallest misclassification cost as given by the `mdl.Cost` matrix. See “Loss Functions” on page 21-2096.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-2096.

**Default:** `'mincost'`

### 'weights'

Numeric vector of length `N`, where `N` is the number of rows of `X`. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

# ClassificationKNN.loss

---

**Default:** ones(N,1)

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-2101.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `mdl` misclassifies, where  $Y$  represents the true classifications.

The weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `mdl` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier

(a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of X.
- K is the number of classes in the classifier, represented in the `ClassNames` property.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in the `ClassNames` property.
- S is an N-by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- W is a numeric vector with N elements, the observation weights. If you pass W, the elements are normalized to sum to the prior probabilities in the respective classes.
- COST is a K-by-K numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class j if its true class is i. By default,

# ClassificationKNN.loss

---

$\text{Cost}(i, j) = 1$  if  $i \neq j$ , and  $\text{Cost}(i, j) = 0$  if  $i = j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### Loss Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
L = loss(mdl,X,Y)
```

```
L =
```

```
0
```

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

# CompactClassificationDiscriminant.loss

---

**Purpose** Classification error

**Syntax**  
`L = loss(obj,X,Y)`  
`L = loss(obj,X,Y,Name,Value)`

**Description** `L = loss(obj,X,Y)` returns a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `obj`.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**obj**  
Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

**X**  
Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

**Y**  
Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2102.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-2102.
- 'exponential' — See “Loss Functions” on page 21-2102.
- 'mincost' — Smallest misclassification cost as given by the `obj.Cost` matrix. See “Loss Functions” on page 21-2102.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-2102.

**Default:** 'mincost'

## 'weights'

Numeric vector of length  $N$ , where  $N$  is the number of rows of  $X$ . `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

**Default:** `ones(N,1)`

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-2101.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `obj` misclassifies, where  $Y$  represents the true classifications.

# CompactClassificationDiscriminant.loss

---

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when obj misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in the classifier, represented in the `ClassNames` property.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in the `ClassNames` property.

# CompactClassificationDiscriminant.loss

- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Posterior Probability

The posterior probability that a point  $z$  belongs to class  $j$  is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean  $\mu_j$  and covariance  $\Sigma_j$  at a point  $z$  is

$$P(x | k) = \frac{1}{(2\pi |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

Let  $P(k)$  represent the prior probability of class  $k$ . Then the posterior probability that an observation  $x$  is of class  $k$  is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where  $P(x)$  is a normalization constant, the sum over  $k$  of  $P(x | k)P(k)$ .

## Prior Probability

The prior probability is one of three choices:

# CompactClassificationDiscriminant.loss

---

- 'uniform' — The prior probability of class  $k$  is one over the total number of classes.
- 'empirical' — The prior probability of class  $k$  is the number of training samples of class  $k$  divided by the total number of training samples.
- Custom — The prior probability of class  $k$  is the  $k$ th element of the prior vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

## Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
L = loss(obj,meas,species)
```

```
L =
    0.0200
```

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.loss

---

## Purpose

Classification error

## Syntax

```
L = loss(ens,X,Y)
L = loss(ens,X,Y,Name,Value)
```

## Description

`L = loss(ens,X,Y)` returns the classification error for ensemble `ens` computed using matrix of predictors `X` and true class labels `Y`.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `ens`.

`L = loss(ens,X,Y,Name,Value)` computes classification error with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

Classification ensemble created with `fitensemble`, or a compact classification ensemble created with `compact`.

### **X**

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

### **Y**

Classification of `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# CompactClassificationEnsemble.loss

---

specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## **'learners'**

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. loss uses only these learners for calculating loss.

**Default:** 1:NumTrained

## **'lossfun '**

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2108
- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-2108

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2108.

**Default:** 'classiferror'

## **'mode'**

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## 'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i, j)` is true, learner `j` is used in predicting the class of row `i` of X.

**Default:** `true(N, T)`

## 'weights'

Vector of observation weights, with nonnegative entries. The length of `weights` must equal the number of rows in X. When you specify weights, `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class.

**Default:** `ones(size(X, 1), 1)`

## Output Arguments

**L**

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

## Definitions

### Classification Error

The default classification error is the fraction of the data X that ens misclassifies, where Y are the true classifications.

Weighted classification error is the sum of weight *i* times the Boolean value that is 1 when `tree` misclassifies the *i*th row of X, divided by the sum of the weights.

# CompactClassificationEnsemble.loss

---

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of `ens.X`.
- K is the number of classes in `ens`, represented in `ens.ClassNames`.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in `tree.ClassNames`.
- S is an N-by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the score output from `predict`.
- W is a numeric vector with N elements, the observation weights.
- COST is a K-by-K numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Create a compact classification ensemble for the ionosphere data, and find the fraction of training data that the ensemble misclassifies:

```
load ionosphere
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
adb = compact(ada);
L = loss(adb,X,Y)
```

```
L =
    0.0085
```

## See Also

[loss](#) | [edge](#) | [margin](#) | [predict](#)

# CompactClassificationSVM.loss

---

**Purpose** Classification error

**Syntax** `L = loss(SVMModel,X,Y)`  
`L = loss(SVMModel,X,Y,Name,Value)`

**Description** `L = loss(SVMModel,X,Y)` returns the classification error (L), a scalar representing how well the trained support vector machine (SVM) classifier `SVMModel` classifies the predictor data (X) as compared to the true class labels (Y).

`loss` normalizes the class probabilities in Y to the prior class probabilities `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel,X,Y,Name,Value)` returns the classification error with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **SVMModel - SVM classifier**

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier that was trained using `fitcsvm`, specified as a `ClassificationSVM` or `CompactClassificationSVM` classifier.

### **X - Predictor data**

matrix of numeric values

Predictor data, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained the `SVMModel` classifier.

The length of Y and the number of rows of X must be equal.

If you set `'Standardize',true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of X using the

corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

## Data Types

double | single

## Y - Class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. Y must be the same as the data type of `SVMModel.Y`.

The length of Y and the number of rows of X must be equal.

## Data Types

cell | char | double | logical

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'LossFun' - Loss function

'ClassifError' (default) | function handle | string

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or string.

- The following lists available loss functions. Specify one using its corresponding string.

Loss Function	String
Binomial deviance	'BinoDeviance'
Classification error	'ClassifError'

# CompactClassificationSVM.loss

---

Loss Function	String
Exponential loss	'Exponential'
Hinge loss	'Hinge'

- Specify your own function using function handle notation.  
Suppose that  $n = \text{size}(X,1)$  is the sample size and  $k = \text{size}(\text{SVMModel.ClassNames},1)$  is the number of classes. Your function must have the signature `loss = lossfun(C,S,W,Cost)`, where:
  - The output argument `loss` is a scalar.
  - You choose the function name (`lossfun`).
  - `C` is an  $n$ -by- $k$  logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.  
Construct `C` by setting  $C(p,q) = 1$  if observation  $p$  is in class  $q$ , for each row. Set all other elements of row  $p$  to 0.
  - `S` is an  $n$ -by- $k$  numeric matrix of classification scores. The column order corresponds to the class order in `SVMModel.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
  - `W` is an  $n$ -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
  - `Cost` is a  $k$ -by- $k$  numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.Specify your function using `'LossFun', @lossfun`.

## 'Weights' - Observation weights

`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector.

The size of `Weights` must be equal to the number of rows of `X`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

If you do not specify your own loss function, then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

## Data Types

double

## Output Arguments

### L - Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme.

## Definitions

### Binomial Deviance

The binomial deviance is a binary classification error measure that has the form

$$L = \sum_{j=1}^n w_j \log\left(1 + \exp\left(-2y_j f(X_j)\right)\right),$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [1].

# CompactClassificationSVM.loss

---

## Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n \sum_{k=1}^K w_j c_{jk}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is the weight for observation  $j$ . The software renormalizes the weights to sum to 1.
- $c_{jk} = 1$  if the true class of observation  $j$  is  $k$ , and 0 otherwise.

The default classification error (`ClassifError`) is the proportion of observations that the classifier misclassifies.

## Exponential Loss

A binary classification error measure that is similar to binomial deviance, and has the form

$$L = \sum_{j=1}^n w_j \exp(-y_j f(X_j)),$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

## Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \sum_{j=1}^n w_j \max\{0, 1 - y_j f(X_j)\},$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

Hinge loss linearly penalizes for misclassified observations, and is related to the SVM objective function used for optimization. For more details on hinge loss, see [1].

## Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Determine the Test Sample Classification Error of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

# CompactClassificationSVM.loss

---

```
CVSVMMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...  
    'Standardize',true);  
CompactSVMModel = CVSVMMModel.Trained{1}; % Extract the trained, compact c  
testInds = test(CVSVMMModel.Partition); % Extract the test indices  
XTest = X(testInds,:);  
YTest = Y(testInds,:);
```

CVSVMMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CompactSVMModel,XTest,YTest)
```

```
L =  
  
    0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample radar returns.

## Determine the Test Sample Hinge Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere  
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...  
    'Standardize',true);  
CompactSVMModel = CVSVMMModel.Trained{1}; % Extract the trained, compact c
```

```
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```
L = loss(CompactSVMModel,XTest,YTest,'LossFun','Hinge')
```

```
L =
```

```
0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are desirable.

# CompactClassificationTree.loss

---

**Purpose** Classification error

**Syntax**

```
L = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
L = loss(tree,X,Y,'subtrees',subtreevector)
[L,se] = loss(tree,X,Y,'subtrees',subtreevector)
[L,se,NLeaf] = loss(tree,X,Y,'subtrees',subtreevector)
[L,se,NLeaf,bestlevel] =
loss(tree,X,Y,'subtrees',subtreevector)
[L,...] =
loss(tree,X,Y,'subtrees',subtreevector,Name,Value)
```

**Description** `L = loss(tree,X,Y)` returns a scalar representing how well tree classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `tree`.

`L = loss(tree,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

`L = loss(tree,X,Y,'subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = loss(tree,X,Y,'subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

---

**Note** `loss` returns `se` and further outputs only when the `lossfun` name-value pair is the default `'classiferror'`.

---

`[L,se,NLeaf] = loss(tree,X,Y,'subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

```
[L,se,NLeaf,bestlevel] =  
loss(tree,X,Y,'subtrees',subtreevector) returns the best  
pruning level as defined in the treesize name-value pair. By  
default, bestlevel is the pruning level that gives loss within one  
standard deviation of minimal loss.
```

```
[L,...] =  
loss(tree,X,Y,'subtrees',subtreevector,Name,Value)  
returns loss statistics with additional options specified by one or  
more Name,Value pair arguments.
```

## Input Arguments

### **tree**

A classification tree or compact classification tree constructed by `fitctree` or `compact`.

### **X**

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` should have the same number of rows as the number of elements in `Y`.

### **Y**

Classification of `X`. `Y` should be of the same type as the classification used to train `tree`, and its number of elements should equal the number of rows of `X`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'lossfun'**

# CompactClassificationTree.loss

---

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2122
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-2122.
- 'exponential' — See “Loss Functions” on page 21-2122
- 'mincost' — Smallest misclassification cost as given by the `tree.Cost` matrix. See “Loss Functions” on page 21-2122.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2122.

**Default:** 'mincost'

## 'weights'

A numeric vector of length  $N$ , where  $N$  is the number of rows of `X`. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

**Default:** `ones(N,1)`

Name, Value arguments associated with pruning subtrees:

## 'subtrees'

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. You can set subtrees to 'all', meaning the entire pruning sequence.

**Default:** 0

## 'treesize'

One of the following strings:

- 'se' — loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- 'min' — loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Output Arguments

**L**

Classification error, a vector the length of subtrees. The meaning of the error depends on the values in `weights` and `lossfun`; see “Classification Error” on page 21-2121.

**se**

Standard error of loss, a vector the length of subtrees.

**Nleaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

**bestlevel**

A scalar whose value depends on `treesize`:

- `treesize = 'se'` — loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- `treesize = 'min'` — loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `tree` misclassifies, where  $Y$  represents the true classifications.

# CompactClassificationTree.loss

---

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `tree` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in the classifier, represented in the `ClassNames` property.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in the `ClassNames` property.

- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default, `Cost(i, j)=1` if  $i \neq j$ , and `Cost(i, j)=0` if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have  $K$  classes. You place the observations into a matrix `Xnew` with one observation per row.

# CompactClassificationTree.loss

---

The expected cost matrix CE has size Nobs-by-K. Each row of CE contains the expected (average) cost of classifying the observation into each of the K classes.  $CE(n, k)$  is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Score (tree)

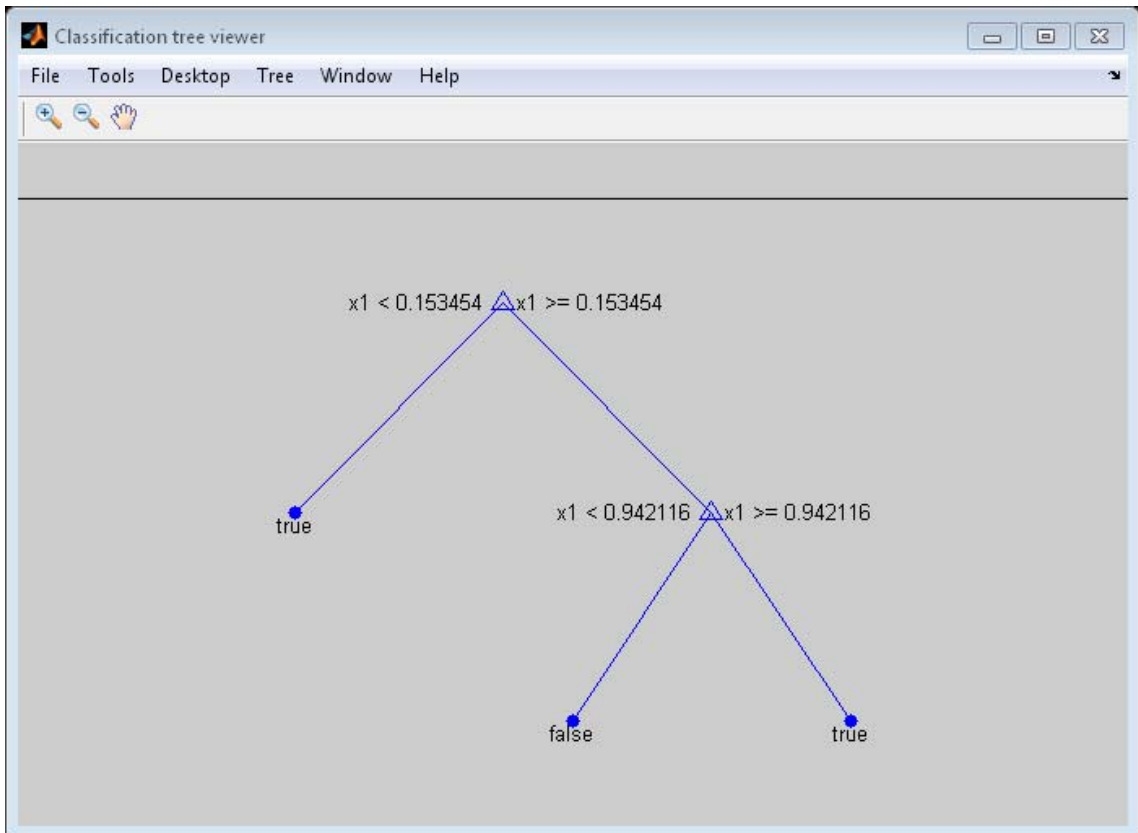

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100, 1);
Y = (abs(X - .55) > .4);
tree = fitctree(X, Y);
view(tree, 'Mode', 'Graph')
```

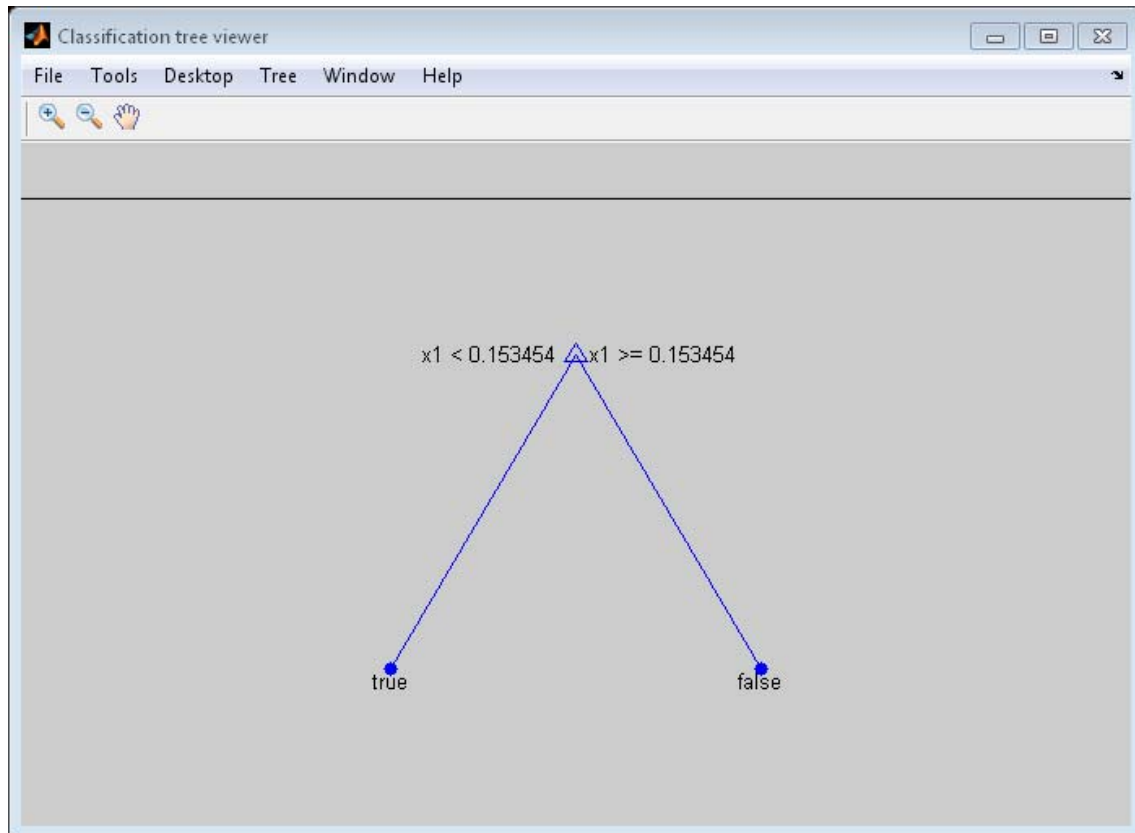

# CompactClassificationTree.loss

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

# CompactClassificationTree.loss

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Compute the resubstituted classification error for the ionosphere data:

```
load ionosphere  
tree = fitctree(X,Y);  
L = loss(tree,X,Y)
```

```
L =  
    0.0114
```

## See Also

# CompactRegressionEnsemble.loss

---

**Purpose** Regression error

**Syntax**  
`L = loss(ens,X,Y)`  
`L = loss(ens,X,Y,Name,Value)`

**Description**  
`L = loss(ens,X,Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.  
`L = loss(ens,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A regression ensemble created with `fitensemble`, or the compact method.

### **X**

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

NaN values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of loss.

### **Y**

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

NaN values in `Y` are taken to be missing values. Observations with missing values for `Y` are not used in the calculation of loss.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NumTrained`

## 'lossfun'

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

**Default:** `'mse'`

## 'mode'

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

# CompactRegressionEnsemble.loss

---

**Default:** 'ensemble'

## 'UseObsForLearner'

A logical matrix of size N-by-NumTrained, where N is the number of observations in `ens.X`, and NumTrained is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner J in predicting observation I.

**Default:** `true(N,NumTrained)`

## 'weights'

Numeric vector of observation weights with the same number of elements as Y. The formula for loss with weights is in “Weighted Mean Squared Error” on page 21-2130.

**Default:** `ones(size(Y))`

## Output Arguments

**L**

Weighted mean squared error of predictions. The formula for loss is in “Weighted Mean Squared Error” on page 21-2130.

## Definitions

### Weighted Mean Squared Error

Let  $n$  be the number of rows of data,  $x_j$  be the  $j$ th row of data,  $y_j$  be the true response to  $x_j$ , and let  $f(x_j)$  be the response prediction of `ens` to  $x_j$ . Let  $w$  be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one:  $w \rightarrow w/\sum w$ . The mean squared error  $L$  is

$$L = \sum_{j=1}^n w_j (f(x_j) - y_j)^2.$$

## Examples

Find the loss of an ensemble predictor of the `carsmall` data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
L = loss(ens,X,MPG)
```

```
L =
    4.3904
```

## See Also

[predict](#) | [fitensemble](#)

# CompactRegressionTree.loss

---

**Purpose** Regression error

**Syntax**

```
L = loss(tree,X,Y)
[L,se] = loss(tree,X,Y)
[L,se,NLeaf] = loss(tree,X,Y)
[L,se,NLeaf,bestlevel] = loss(tree,X,Y)
L = loss(tree,X,Y,Name,Value)
```

**Description**

`L = loss(tree,X,Y)` returns the mean squared error between the predictions of `tree` to the data in `X`, compared to the true responses `Y`.

`[L,se] = loss(tree,X,Y)` returns the standard error of the loss.

`[L,se,NLeaf] = loss(tree,X,Y)` returns the number of leaves (terminal nodes) in the tree.

`[L,se,NLeaf,bestlevel] = loss(tree,X,Y)` returns the optimal pruning level for `tree`.

`L = loss(tree,X,Y,Name,Value)` computes the error in prediction with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**tree** Regression tree created with `fitrtree`, or the compact method.

**X** A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

**Y** A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## **'lossfun'**

Function handle for loss, or the string `'mse'` representing mean-squared error. If you pass a function handle `fun`, `loss` calls `fun` as:

```
fun(Y, Yfit, W)
```

- `Y` is the vector of true responses.
- `Yfit` is the vector of predicted responses.
- `W` is the observation weights. If you pass `W`, the elements are normalized to sum to 1.

All the vectors have the same number of rows as `Y`.

**Default:** `'mse'`

## **'subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. You can set `subtrees` to `'all'`, meaning the entire pruning sequence.

**Default:** 0

## **'treesize'**

A string, either:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.
- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

# CompactRegressionTree.loss

---

## 'weights'

Numeric vector of observation weights with the same number of elements as  $Y$ .

**Default:** `ones(size(Y))`

## Output Arguments

### L

Classification error, a vector the length of subtrees. The error for each tree is the mean squared error, weighted with weights. If you include `lossfun`, L reflects the loss calculated with `lossfun`.

### se

Standard error of loss, a vector the length of subtrees.

### Nleaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

### bestlevel

A scalar whose value depends on `treesize`:

- `treesize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- `treesize = 'min'` — `loss` returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Definitions

### Mean Squared Error

The mean squared error  $m$  of the predictions  $f(X_n)$  with weight vector  $w$  is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

## Examples

Find the loss of a regression tree predictor of the `carsmall` data to find MPG as a function of engine displacement, horsepower, and vehicle weight:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
L = loss(tree,X,MPG)
```

```
L =
    4.8952
```

---

Find the pruning level that gives the optimal level of loss for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
[L,se,NLeaf,bestlevel] = loss(tree,X,MPG,'Subtrees','all');
bestlevel
```

```
bestlevel =
    4
```

## See Also

[predict](#) | [fitrtree](#)

# paretotails.lowerparams

---

**Purpose** Lower Pareto tails parameters

**Syntax** `params = lowerparams(obj)`

**Description** `params = lowerparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the lower tail of the Pareto tails object `obj`. `lowerparams` does not return a location parameter.

**Examples** Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
lowerparams(obj)  
ans =  
    -0.1901    1.1898  
upperparams(obj)  
ans =  
    0.3646    0.5103
```

**See Also** `paretotails` | `upperparams`

**Purpose** Less than relation for handles

**Syntax** `h1 < h2`

**Description** `h1 < h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = lt(h1, h2)` stores the result in a logical array of the same dimensions.

**See Also** `grandstream | eq | ge | gt | le | ne`

# lsline

---

**Purpose** Add least-squares line to scatter plot

**Syntax** `lsline`  
`h = lsline`

**Description** `lsline` superimposes a least-squares line on each scatter plot in the current axes. Scatter plots are produced by the MATLAB `scatter` and `plot` functions. Data points connected with solid, dashed, or dash-dot lines ('-', '--', or '-.') are not considered to be scatter plots by `lsline`, and are ignored.

`h = lsline` returns a column vector of handles `h` to the least-squares lines.

## **Examples** **Plot a Least-Squares Line**

Generate three sets of sample data and plot on the same figure.

```
x = 1:10;  
rng('default'); % For reproducibility  
figure;  
  
y1 = x + randn(1,10);  
scatter(x,y1,25,'b','*')  
hold on  
  
y2 = 2*x + randn(1,10);  
plot(x,y2,'mo')  
  
y3 = 3*x + randn(1,10);  
plot(x,y3,'rx')
```

Add a least-squares line for each set of sample data.

lsline

# lslines

## See Also

`scatter` | `plot` | `refline` | `refcurve` | `gline`

**Purpose**

Mean or median absolute deviation

**Syntax**

```
y = mad(X)
Y = mad(X,1)
Y = mad(X,0)
```

**Description**

`y = mad(X)` returns the mean absolute deviation of the values in `X`. For vector input, `y` is `mean(abs(X-mean(X)))`. For a matrix input, `y` is a row vector containing the mean absolute deviation of each column of `X`. For  $N$ -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,1)` returns the median absolute deviation of the values in `X`. For vector input, `y` is `median(abs(X-median(X)))`. For a matrix input, `y` is a row vector containing the median absolute deviation of each column of `X`. For  $N$ -dimensional arrays, `mad` operates along the first nonsingleton dimension of `X`.

`Y = mad(X,0)` is the same as `mad(X)`, and returns the mean absolute deviation of the values in `X`.

`mad(X,flag,dim)` computes absolute deviations along the dimension `dim` of `X`. `flag` is 0 or 1 to indicate mean or median absolute deviation, respectively.

`mad` treats NaNs as missing values and removes them.

For normally distributed data, multiply `mad` by one of the following factors to obtain an estimate of the normal scale parameter  $\sigma$ :

- `sigma = 1.253*mad(X,0)` — For mean absolute deviation
- `sigma = 1.4826*mad(X,1)` — For median absolute deviation

**Examples**

The following compares the robustness of different scale estimates for normally distributed data in the presence of outliers:

```
x = normrnd(0,1,1,50);
xo = [x 10]; % Add outlier
```

# mad

---

```
r1 = std(xo) / std(x)
```

```
r1 =  
    1.7385
```

```
r2 = mad(xo, 0) / mad(x, 0)
```

```
r2 =  
    1.2306
```

```
r3 = mad(xo, 1) / mad(x, 1)
```

```
r3 =  
    1.0602
```

<b>Purpose</b>	Mahalanobis distance
<b>Syntax</b>	<code>d = mahal(Y,X)</code>
<b>Description</b>	<p><code>d = mahal(Y,X)</code> computes the Mahalanobis distance (in squared units) of each observation in <code>Y</code> from the reference sample in matrix <code>X</code>. If <code>Y</code> is <math>n</math>-by-<math>m</math>, where <math>n</math> is the number of observations and <math>m</math> is the dimension of the data, <code>d</code> is <math>n</math>-by-1. <code>X</code> and <code>Y</code> must have the same number of columns, but can have different numbers of rows. <code>X</code> must have more rows than columns.</p> <p>For observation <code>I</code>, the Mahalanobis distance is defined by <math>d(I) = (Y(I,:) - \mu) * \text{inv}(\text{SIGMA}) * (Y(I,:) - \mu)'</math>, where <code>mu</code> and <code>SIGMA</code> are the sample mean and covariance of the data in <code>X</code>. <code> mahal </code> performs an equivalent, but more efficient, computation.</p>

### Examples **Compare Mahalanobis and Squared Euclidean Distances**

Generate correlated bivariate data.

```
X = mvnrnd([0;0],[1 .9;.9 1],100);
```

Input observations.

```
Y = [1 1;1 -1;-1 1;-1 -1];
```

Compute the Mahalanobis distance of observations in `Y` from the reference sample in `X`.

```
d1 = mahal(Y,X)
```

```
d1 =
    0.6288
   19.3520
   21.1384
    0.9404
```

Compute their squared Euclidean distances from the mean of X .

```
d2 = sum((Y-repmat(mean(X),4,1)).^2, 2)
```

```
d2 =
```

```
    1.6170  
    1.9334  
    2.1094  
    2.4258
```

Plot the observations with Y values colored according to the Mahalanobis distance.

```
scatter(X(:,1),X(:,2))  
hold on  
scatter(Y(:,1),Y(:,2),100,d1,'*', 'LineWidth',2)  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance')  
legend('X','Y','Location','NW')
```

The observations in Y with equal coordinate values are much closer to X in Mahalanobis distance than observations with opposite coordinate values, even though all observations are approximately equidistant from the mean of X in Euclidean distance. The Mahalanobis distance, by considering the covariance of the data and the scales of the different variables, is useful for detecting outliers in such cases.

# CompactClassificationDiscriminant.mahal

---

**Purpose** Mahalanobis distance to class means

**Syntax**  
M = mahal(obj,X)  
M = mahal(obj,X,Name,Value)

**Description** M = mahal(obj,X) returns the squared Mahalanobis distances from observations in X to the class means in obj.  
M = mahal(obj,X,Name,Value) computes the squared Mahalanobis distance with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

**obj**  
Discriminant analysis classifier of class ClassificationDiscriminant or CompactClassificationDiscriminant, typically constructed with fitcdiscr.

**X**  
Numeric matrix of size n-by-p, where p is the number of predictors in obj, and n is any positive integer. mahal computes the Mahalanobis distances from the rows of X to each of the K means of the classes in obj.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## 'ClassLabels'

Class labels consisting of n elements of obj.Y, where n is the number of rows of X.

## Output Arguments

### M

Size and meaning of output M depends on whether the `ClassLabels` name-value pair is present:

- No `ClassLabels` — M is a numeric matrix of size n-by-K, where K is the number of classes in `obj`, and n is the number of rows in X.  $M(i, j)$  is the squared Mahalanobis distance from the *i*th row of X to the mean of class *j*.
- `ClassLabels` exists — M is a column vector with n elements.  $M(i)$  is the squared Mahalanobis distance from the *i*th row of X to the mean for the class of the *i*th element of `ClassLabels`.

## Definitions

### Mahalanobis Distance

The Mahalanobis distance  $d(x,y)$  between *n*-dimensional points *x* and *y*, with respect to a given *n*-by-*n* covariance matrix *S*, is

$$d(x,y) = \sqrt{(x-y)^T S^{-1} (x-y)}.$$

## Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = fitcdiscr(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))

mahadist =
    220.0667    5.0254    30.5804
```

## How To

- “Discriminant Analysis” on page 15-3

# gmdistribution.mahal

---

**Purpose** Mahalanobis distance to component means

**Syntax** `D = mahal(obj,X)`

**Description** `D = mahal(obj,X)` computes the Mahalanobis distance (in squared units) of each observation in `X` to the mean of each of the  $k$  components of the Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`. `X` is an  $n$ -by- $d$  matrix, where  $n$  is the number of observations and  $d$  is the dimension of the data. `D` is  $n$ -by- $k$ , with `D(I,J)` the distance of observation `I` from the mean of component `J`.

## **Examples**      **Measure Mahalanobis Distances in Gaussian Mixture Data**

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

```
MU1 = [1 2];
SIGMA1 = [2 0; 0 .5];
MU2 = [-3 -5];
SIGMA2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```

Fit a two-component Gaussian mixture model.

```
obj = fitgmdist(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

# gmdistribution.mahal

Compute the Mahalanobis distance of each point in  $X$  to the mean of each component of  $obj$ .

```
D = mahal(obj,X);
```

```
delete(h)  
scatter(X(:,1),X(:,2),10,D(:,1),'.')  
hb = colorbar;  
ylabel(hb,'Mahalanobis Distance to Component 1')
```

# maineffectsplot

---

**Purpose** Main effects plot for grouped data

**Syntax** `maineffectsplot(Y, GROUP)`  
`maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)`  
`[figh, AXESH] = maineffectsplot(...)`

**Description** `maineffectsplot(Y, GROUP)` displays main effects plots for the group means of matrix `Y` with groups defined by entries in the cell array `GROUP`. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of `Y` as a function of one grouping variable.

`maineffectsplot(Y, GROUP, param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are `'X1'`, `'X2'`, ... .
- `'statistic'` — String values that indicate whether the group mean or the group standard deviation should be plotted. Use `'mean'` or `'std'`. The default is `'mean'`. If the value is `'std'`, `Y` is required to have multiple columns.
- `'parent'` — A handle to the figure window for the plots. The default is the current figure window.

`[figh, AXESH] = maineffectsplot(...)` returns the handle `figh` to the figure window and an array of handles `AXESH` to the subplot axes.

## Examples

### Main Effects Plot

Load the sample data.

```
load carsmall;
```

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

```
maineffectsplot(Weight,{Model_Year,Cylinders}, ...  
               'varnames',{'Model Year','# of Cylinders'})
```

# maineffectsplot

# ClassificationDiscriminant.make

---

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'ClassNames' - Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

`ClassNames` names the classes, as ordered in `Mu`.

Default is `1:K`, where `K` is the number of classes (the number of rows of `Mu`).

## Data Types

single | double | logical | char | cell

## 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where `Cost(i,j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i,j)=1` if `i~=j`, and `Cost(i,j)=0` if `i=j`.

## Data Types

single | double | struct

### 'PredictorNames' - Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in  $x$ .

## Data Types

cell

### 'Prior' - Prior probabilities

'uniform' (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- 'uniform', a string meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure  $S$  with two fields:
  - $S.ClassNames$  containing the class names as a variable of the same type as  $ClassNames$ .
  - $S.ClassProbs$  containing a vector of corresponding probabilities.

## Data Types

single | double | struct

### 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable  $y$ .

# ClassificationDiscriminant.make

---

**Example:** 'ResponseName', 'Response'

## Data Types

char

## Output Arguments

### **cobj** - Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

## Examples

### **Construct a Compact Linear Discriminant Analysis Classifier**

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}
    ResponseName: 'Y'
```

```
ClassNames: {'setosa' 'versicolor' 'virginica'}  
ScoreTransform: 'none'  
DiscrimType: 'linear'  
    Mu: [3x4 double]  
    Coeffs: [3x3 struct]
```

## See Also

`fitcdiscr` | `makecdiscr` | `compact` |  
`CompactClassificationDiscriminant`

## How To

- “Discriminant Analysis” on page 15-3

# makecdiscr

---

**Purpose** Construct discriminant analysis classifier from parameters

**Syntax**  
`cobj = makecdiscr(Mu, Sigma)`  
`cobj = makecdiscr(Mu, Sigma, Name, Value)`

**Description** `cobj = makecdiscr(Mu, Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = makecdiscr(Mu, Sigma, Name, Value)` constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

## Input Arguments

**Mu - Class means**  
matrix of scalar values

Class means, specified as a  $K$ -by- $p$  matrix of scalar values class means of size.  $K$  is the number of classes, and  $p$  is the number of predictors. Each row of `Mu` represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

**Data Types**  
single | double

**Sigma - Within-class covariance**  
matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, `Sigma` is a symmetric, positive semidefinite matrix of size  $p$ -by- $p$ , where  $p$  is the number of predictors.
- For a quadratic discriminant, `Sigma` is an array of size  $p$ -by- $p$ -by- $K$ , where  $K$  is the number of classes. For each  $i$ , `Sigma(:, :, i)` is a symmetric, positive semidefinite matrix.

**Data Types**  
single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'ClassNames',{ 'setosa' 'versicolor' 'virginica' }` specifies a discriminant analysis classifier that uses 'setosa', 'versicolor', and 'virginica' as the grouping variables.

### 'ClassNames' - Class names

numeric vector | categorical vector | logical vector | character array | cell array of strings

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of 'ClassNames' and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of strings.

The default is  $1:K$ , where  $K$  is the number of classes (the number of rows of `Mu`).

**Example:** `'ClassNames',{ 'setosa' 'versicolor' 'virginica' }`

### Data Types

single | double | logical | char | cell

### 'Cost' - Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of 'Cost' and a square matrix, where  $\text{Cost}(i,j)$  is the cost of classifying a point into class  $j$  if its true class is  $i$ . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is  $\text{Cost}(i,j)=1$  if  $i \neq j$ , and  $\text{Cost}(i,j)=0$  if  $i=j$ .

## Data Types

single | double | struct

### 'PredictorNames' - Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in  $x$ .

## Data Types

cell

### 'Prior' - Prior probabilities

'uniform' (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'uniform', a string meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure  $S$  with two fields:
  - $S.ClassNames$  containing the class names as a variable of the same type as  $ClassNames$
  - $S.ClassProbs$  containing a vector of corresponding probabilities

## Data Types

single | double | struct

### 'ResponseName' - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable  $y$ .

**Example:** 'ResponseName', 'Response'

**Data Types**

char

**Output Arguments****cobj - Discriminant analysis classifier**

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

**Examples****Construct a Compact Linear Discriminant Analysis Classifier**

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
classreg.learning.classif.CompactClassificationDiscriminant:
  PredictorNames: {'x1' 'x2' 'x3' 'x4'}
  ResponseName: 'Y'
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
  DiscrimType: 'linear'
```

# makecdiscr

---

```
Mu: [3x4 double]  
Coeffs: [3x3 struct]
```

## Tips

- You can change the discriminant type using dot notation after constructing `cobj`:

```
cobj.DiscrimType = 'discrimType'
```

where *discrimType* is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.

## Concepts

- “Discriminant Analysis” on page 15-3

**Purpose** Create probability distribution object

**Syntax**  
`pd = makedist(distname)`  
`pd = makedist(distname,Name,Value)`

**Description** `pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

**Input Arguments**

**distname - Distribution name**

string

Distribution name, specified as one of the following strings. The distribution specified by `distname` determines the class type of the returned probability distribution object.

Distribution Name	Description	Distribution Class
'Beta'	Beta distribution	prob.BetaDistribution
'Binomial'	Binomial distribution	prob.BinomialDistribution
'BirnbbaumSaunders'	Birnbbaum-Saunders distribution	prob.BirnbbaumSaundersDistribu
'Burr'	Burr distribution	prob.BurrDistribution
'Exponential'	Exponential distribution	prob.ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	prob.ExtremeValueDistribution
'Gamma'	Gamma distribution	prob.GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	prob.GeneralizedExtremeValueE

Distribution Name	Description	Distribution Class
'GeneralizedPareto'	Generalized Pareto distribution	prob.GeneralizedParetoDistribution
'InverseGaussian'	Inverse Gaussian distribution	prob.InverseGaussianDistribution
'Logistic'	Logistic distribution	prob.LogisticDistribution
'Loglogistic'	Loglogistic distribution	prob.LoglogisticDistribution
'Lognormal'	Lognormal distribution	prob.LognormalDistribution
'Multinomial'	Multinomial distribution	prob.MultinomialDistribution
'Nakagami'	Nakagami distribution	prob.NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	prob.NegativeBinomialDistribution
'Normal'	Normal distribution	prob.NormalDistribution
'PiecewiseLinear'	Piecewise Linear distribution	prob.PiecewiseLinearDistribution
'Poisson'	Poisson distribution	prob.PoissonDistribution
'Rayleigh'	Rayleigh distribution	prob.RayleighDistribution
'Rician'	Rician distribution	prob.RicianDistribution
'tLocationScale'	$t$ Location-Scale distribution	prob.tLocationScaleDistribution
'Triangular'	Triangular distribution	prob.TriangularDistribution
'Uniform'	Uniform distribution	prob.UniformDistribution
'Weibull'	Weibull distribution	prob.WeibullDistribution

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `makedist('Normal','mu',10)` specifies a normal distribution with parameter `mu` equal to 10, and parameter `sigma` equal to the default value of 1.

## Beta Distribution

### 'a' - First shape parameter

1 (default) | nonnegative scalar value

**Example:** `'a',3`

### Data Types

single | double

### 'b' - Second shape parameter

1 (default) | nonnegative scalar value

**Example:** `'b',5`

### Data Types

single | double

## Binomial Distribution

### 'N' - Number of trials

1 (default) | positive integer value

**Example:** `'N',25`

### Data Types

single | double

### 'p' - Probability of success

0.5 (default) | scalar value in the range [0,1]

**Example:** 'p',0.25

### **Data Types**

single | double

## **Birnbaum-Saunders Distribution**

### **'beta' - Scale parameter**

1 (default) | positive scalar value

**Example:** 'beta',2

### **Data Types**

single | double

### **'gamma' - Shape parameter**

1 (default) | nonnegative scalar value

**Example:** 'gamma',0

### **Data Types**

single | double

## **Burr Distribution**

### **'alpha' - Scale parameter**

1 (default) | positive scalar value

**Example:** 'alpha',2

### **Data Types**

single | double

### **'c' - First shape parameter**

1 (default) | positive scalar value

**Example:** 'c',2

### **Data Types**

single | double

**'k' - Second shape parameter**

1 (default) | positive scalar value

Example: 'k',5

**Data Types**

single | double

**Exponential Distribution****'mu' - Mean parameter**

1 (default) | positive scalar value

Example: 'mu',5

**Data Types**

single | double

**Extreme Value Distribution****'mu' - Location parameter**

0 (default) | scalar value

## Output Arguments

### pd - Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by `distname`.

## Examples

### Create a Normal Distribution Object

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =  
  
1.3490
```

### Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')
```

```
pd =  
  
GammaDistribution  
  
Gamma distribution  
a = 1  
b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)
```

```
mean =  
  
1
```

### Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values  $\mu = 75$  and  $\sigma = 10$ .

```
pd = makedist('Normal','mu',75,'sigma',10)
```

```
pd =  
  
NormalDistribution  
  
Normal distribution
```

```
mu = 75  
sigma = 10
```

## Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value  $a = 3$  and the default value  $b = 1$ .

```
pd = makedist('Gamma','a',3)
```

```
pd =
```

```
GammaDistribution
```

```
Gamma distribution
```

```
a = 3
```

```
b = 1
```

## Alternative Functionality

### App

The Distribution Fitting app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitting app using `dfittool`, or click Distribution Fitting on the Apps tab.

`fitdist` | `dfittool`

## Purpose

Multivariate analysis of variance

## Syntax

```
manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova( ___ )
```

## Description

`manovatbl = manova(rm)` returns the results of multivariate analysis of variance (`manova`) for the repeated measures model `rm`.

`manovatbl = manova(rm,Name,Value)` also returns `manova` results with additional options, specified by one or more `Name,Value` pair arguments.

`[manovatbl,A,C,D] = manova( ___ )` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form  $A*B*C = D$ , where `D` is zero.

## Tips

- The multivariate response for each observation (subject) is the vector of repeated measures.
- To test a more general hypothesis  $A*B*C = D$ , use `coefstest`.

## Input Arguments

### **rm - Repeated measures model**

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

# RepeatedMeasuresModel.manova

---

## 'WithinModel' - Model specifying within-subjects hypothesis test

'separatemeans' (default) | model specification using formula

Model specifying the within-subjects hypothesis test, specified as one of the following:

- 'separatemeans' — Compute a separate mean for each group, and test for equality among the means.
- Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, `tbl` contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.
- An  $r$ -by- $nc$  matrix,  $C$ , specifying  $nc$  contrasts among the  $r$  repeated measures. If  $Y$  represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate manova for each column of  $Y^*C$ .

**Example:** 'WithinModel', 'separatemeans'

## 'By' - Single between-subjects factor

string

Single between-subjects factor, specified as the comma-separated pair consisting of 'By' and a string. `manova` performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, `Drug`, then you can specify that factor to perform `manova` as follows.

**Example:** 'By', 'Drug'

## Output Arguments

### `manovatbl` - Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model `rm`, returned as a table.

manova uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks' Lambda
- Pillai's trace
- Hotelling-Lawley trace
- Roy's maximum root statistic

For details, see "Multivariate Analysis of Variance for Repeated Measures" on page 8-60.

manova returns the results for these tests for each group. manovatbl contains the following columns.

Column Name	Definition
Within	Within-subject terms
Between	Between-subject terms
Statistic	Name of the statistic computed
Value	Value of the corresponding statistic
F	<i>F</i> -statistic value
RSquare	Measure for variance explained
df1	Numerator degrees of freedom
df2	Denominator degrees of freedom
pValue	<i>p</i> -value for the corresponding <i>F</i> -statistic value

**Data Types**  
table

# RepeatedMeasuresModel.manova

---

## **A - Specification based on between-subjects model**

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of **B** (within time hypothesis). If `manovatbl` contains multiple hypothesis tests, **A** might be a cell array.

### **Data Types**

single | double | cell

## **C - Specification based on within-subjects model**

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of **B** (between time hypotheses). If `manovatbl` contains multiple hypothesis tests, **C** might be a cell array.

### **Data Types**

single | double | cell

## **D - Hypothesis value**

0

Hypothesis value, returned as 0.

## **Examples**

### **Perform Multivariate Analysis of Variance**

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
```

# RepeatedMeasuresModel.manova

```
'VariableNames',{ 'species', 'meas1', 'meas2', 'meas3', 'meas4'});  
Meas = table([1 2 3 4], 'VariableNames',{ 'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4-species', 'WithinDesign', Meas);
```

Perform multivariate analysis of variance.

```
manova(rm)
```

```
ans =
```

Within	Between	Statistic	Value	F	RS
Constant	(Intercept)	Pillai	0.99013	4847.5	0.9

## Concepts

- “Model Specification for Repeated Measures Models” on page 8-54
- “Multivariate Analysis of Variance for Repeated Measures” on page 8-60

**Purpose**

One-way multivariate analysis of variance

**Syntax**

```
d = manova1(X,group)
d = manova1(X,group,alpha)
[d,p] = manova1(...)
[d,p,stats] = manova1(...)
```

**Description**

`d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an  $m$ -by- $n$  matrix of data values, and each row is a vector of measurements on  $n$  variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, string array, or cell array of strings. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same  $n$ -dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in  $n$ -dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having  $p > \alpha$ , where  $p$  is a  $p$ -value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of  $p$ -values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.

If the  $i$ th  $p$ -value is near zero, this casts doubt on the hypothesis that the group means lie on a space of  $i-1$  dimensions. The choice of a

# manova1

---

critical  $p$ -value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument `alpha`. It is common to declare a result significant if the  $p$ -value is less than 0.05 or 0.01.

`[d,p,stats] = manova1(...)` also returns `stats`, a structure containing additional MANOVA results. The structure contains the following fields.

Field	Contents
W	Within-groups sum of squares and cross-products matrix
B	Between-groups sum of squares and cross-products matrix
T	Total sum of squares and cross-products matrix
dfW	Degrees of freedom for W
dfB	Degrees of freedom for B
dfT	Degrees of freedom for T
lambda	Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.
chisq	Transformation of lambda to an approximate chi-square distribution
chisqdf	Degrees of freedom for chisq
eigenval	Eigenvalues of $W^{-1}B$
eigenvec	Eigenvectors of $W^{-1}B$ ; these are the coefficients for the canonical variables C, and they are scaled so the within-group variance of the canonical variables is 1
canon	Canonical variables C, equal to $XC * \text{eigenvec}$ , where XC is X with columns centered by subtracting their means

Field	Contents
mdist	A vector of Mahalanobis distances from each point to the mean of its group
gmdist	A matrix of Mahalanobis distances between each pair of group means

The canonical variables  $C$  are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically,  $C(:, 1)$  is the linear combination of the  $X$  columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant  $F$  statistic in a one-way analysis of variance.  $C(:, 2)$  has the maximum separation subject to it being orthogonal to  $C(:, 1)$ , and so on.

You may find it useful to use the outputs from `manova1` along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using `gplotmatrix`. You can use `gscatter` to visualize the group separation using the first two canonical variables. You can use `manovacluster` to graph a dendrogram showing the clusters among the group means.

### Assumptions

The MANOVA test makes the following assumptions about the data in  $X$ :

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

### Examples

you can use `manova1` to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
```

# manova1

---

```
                                Origin)
d =
    3
p =
    0
    0.0000
    0.0075
    0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. `manova1` shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

## How To

- “Grouping Variables” on page 2-52

**Purpose** Dendrogram of group mean clusters following MANOVA

**Syntax**  
`manovacluster(stats)`  
`manovacluster(stats,method)`  
`H = manovacluster(stats,method)`

**Description** `manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. `method` can be any of the following character strings that identify ways to create the cluster hierarchy. (See `linkage` for additional information.)

<b>Method</b>	<b>Description</b>
'single'	Shortest distance (default)
'complete'	Largest distance
'average'	Average distance
'centroid'	Centroid distance
'ward'	Incremental sum of squares

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.

**Examples** **Dendrogram of Group Means After MANOVA**

Load the sample data.

```
load carbig
```

# manovacluster

---

Define the variable matrix.

```
X = [MPG Acceleration Weight Displacement];
```

Perform one-way MANOVA to compare the means of MPG, Acceleration, Weight, and Displacement grouped by Origin.

```
[d,p,stats] = manova1(X,Origin);
```

Create a dendrogram plot of the group means.

```
manovacluster(stats)
```

**See Also**

`cluster` | `dendrogram` | `linkage` | `manova1`

# ClassificationKNN.margin

---

**Purpose** Margin of  $k$ -nearest neighbor classifier

**Syntax** `m = margin mdl,X,Y`

**Description** `m = margin mdl,X,Y` returns the classification margins for the matrix of predictors  $X$  and class labels  $Y$ . For the definition, see “Margin” on page 21-2197.

**Input Arguments** **mdl - Classifier model**  
classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `mdl` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

**X - Matrix of predictor values**

matrix

Matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

**Y - Categorical variables**

categorical array | cell array of strings | character array | logical vector | numeric vector

A categorical array, cell array of strings, character array, logical vector, or a numeric vector with the same number of rows as  $X$ . Each row of  $Y$  represents the classification of the corresponding row of  $X$ .

## Output Arguments

**m**

Numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `mdl`.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes.

### Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-2997.

## Examples

### Margin Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the margin of the classifier for a mean observation classified 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
m = margin(mdl,X,Y)
```

```
m =
```

# ClassificationKNN.margin

---

1

The classifier has no doubt that 'versicolor' is the correct classification (all five nearest neighbors classify as 'versicolor').

# CompactClassificationDiscriminant.margin

---

<b>Purpose</b>	Classification margins
<b>Syntax</b>	<code>m = margin(obj,X,Y)</code>
<b>Description</b>	<code>m = margin(obj,X,Y)</code> returns the classification margins for the matrix of predictors <code>X</code> and class labels <code>Y</code> . For the definition, see “Definitions” on page 21-2199.
<b>Input Arguments</b>	<p><b>obj</b></p> <p>Discriminant analysis classifier of class <code>ClassificationDiscriminant</code> or <code>CompactClassificationDiscriminant</code>, typically constructed with <code>fitcdiscr</code>.</p> <p><b>X</b></p> <p>Matrix where each row represents an observation, and each column represents a predictor. The number of columns in <code>X</code> must equal the number of predictors in <code>obj</code>.</p> <p><b>Y</b></p> <p>Class labels, with the same data type as exists in <code>obj</code>. The number of elements of <code>Y</code> must equal the number of rows of <code>X</code>.</p>
<b>Output Arguments</b>	<p><b>m</b></p> <p>Numeric column vector of length <code>size(X,1)</code>. Each entry in <code>m</code> represents the margin for the corresponding rows of <code>X</code> and (true class) <code>Y</code>, computed using <code>obj</code>.</p>
<b>Definitions</b>	<p><b>Margin</b></p> <p>The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes.</p>

# CompactClassificationDiscriminant.margin

---

The classification margin is a column vector with the same number of rows as in the matrix  $X$ . A high value of margin indicates a more reliable prediction than a low value.

## Score (discriminant analysis)

For discriminant analysis, the *score* of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 15-7.

## Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
M = margin(obj,X,species);
M(end-10:end)
```

```
ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);
M = margin(obj,meas,species);
M(end-10:end)
```

```
ans =  
    0.9983  
    1.0000  
    0.9991  
    0.9978  
    1.0000  
    1.0000  
    0.9999  
    0.9882  
    0.9937  
    1.0000  
    0.9649
```

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.margin

---

**Purpose** Classification margins

**Syntax**  
M = margin(ens,X,Y)  
M = margin(ens,X,Y,Name,Value)

**Description** M = margin(ens,X,Y) returns the classification margin for the predictions of ens on data X, when the true classifications are Y.  
M = margin(ens,X,Y,Name,Value) calculates margin with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### ens

Classification ensemble created with fitensemble, or a compact classification ensemble created with compact.

### X

Matrix of data to classify. Each row of X represents one observation, and each column represents one predictor. X must have the same number of columns as the data used to train ens. X should have the same number of rows as the number of elements in Y.

### Y

Classification of X. Y should be of the same type as the classification used to train ens, and its number of elements should equal the number of rows of X.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NumTrained`

## 'UseObsForLearner'

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is `true`, learner `j` is used in predicting the class of row `i` of X.

**Default:** `true(N,T)`

## Output Arguments

### M

A numeric column vector with the same number of rows as X. Each row of M gives the classification margin for that row of X.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

# CompactClassificationEnsemble.margin

---

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the margin for classifying an average flower from the Fisheriris data as 'versicolor':

```
load fisheriris % X = meas, Y = species
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
flower = mean(meas);
predict(ens,flower)
```

```
ans =
    'versicolor'
```

```
margin(ens,mean(meas),'versicolor')
```

```
ans =
    3.2140
```

## See Also

[predict](#) | [edge](#) | [loss](#)

<b>Purpose</b>	Classification margins
<b>Syntax</b>	<code>m = margin(SVMModel,X,Y)</code>
<b>Description</b>	<code>m = margin(SVMModel,X,Y)</code> returns the classification margins ( <code>m</code> ) for the trained support vector machine (SVM) classifier <code>SVMModel</code> using the predictor data <code>X</code> and class labels <code>Y</code> .
<b>Input Arguments</b>	<p><b>SVMModel - SVM classifier</b> ClassificationSVM classifier   CompactClassificationSVM classifier</p> <p>SVM classifier that was trained using <code>fitcsvm</code>, specified as a <code>ClassificationSVM</code> or <code>CompactClassificationSVM</code> classifier.</p> <p><b>X - Predictor data</b> matrix of numeric values</p> <p>Predictor data, specified as a matrix of numeric values.</p> <p>Each row of <code>X</code> corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of <code>X</code> should be the same as the variables that trained the <code>SVMModel</code> classifier.</p> <p>The length of <code>Y</code> and the number of rows of <code>X</code> must be equal.</p> <p>If you set <code>'Standardize',true</code> in <code>fitcsvm</code> to train <code>SVMModel</code>, then the software standardizes the columns of <code>X</code> using the corresponding means in <code>SVMModel.Mu</code> and standard deviations in <code>SVMModel.Sigma</code>.</p> <p><b>Data Types</b> double   single</p> <p><b>Y - Class labels</b> categorical array   character array   logical vector   vector of numeric values   cell array of strings</p>

# CompactClassificationSVM.margin

---

Class labels, specified as a categorical or character array, logical or numeric vector, or cell array of strings. `Y` must be the same as the data type of `SVMModel.Y`.

The length of `Y` and the number of rows of `X` must be equal.

## Data Types

`cell` | `char` | `double` | `logical`

## Output Arguments

### `m` - Classification margins

numeric vector

Classification margins, returned as a numeric vector.

`m` has the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

## Definitions

### Margins

The *margins* are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [2].

### Edge

The *edge* is the weighted mean of the *classification margins*.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

## Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Estimate Test Sample Classification Margins of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample classification margins.

# CompactClassificationSVM.margin

---

```
m = margin(CompactSVMModel,XTest,YTest);  
m(10:20)
```

```
ans =  
  
    3.5461  
    5.5939  
    4.9948  
    4.5611  
   -4.7963  
    5.5127  
   -2.8776  
    1.8673  
    9.4986  
    9.5018  
   20.9954
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

## Select SVM Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load the ionosphere data set.

```
load ionosphere  
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```
fullM = margin(FCSVMModel,XTest,YTest);
partM = margin(PCSVModel,XTest(:,end-20:end),YTest);
n = size(X,1);
p = sum(fullM < partM)/n
```

# CompactClassificationSVM.margin

---

p =  
0.0370

Approximately 4% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained using all of the predictors is better.

## Algorithms

For binary classification, the software defines the margin for observation  $j$ ,  $m_j$ , as

$$m_j = 2y_j f(x_j),$$

where  $y_j \in \{-1, 1\}$ , and  $f(x_j)$  is the predicted score of observation  $j$  for the positive class. However, the literature commonly uses  $m_j = y_j f(x_j)$  to define the margin.

<b>Purpose</b>	Classification margins
<b>Syntax</b>	<code>m = margin(tree,X,Y)</code>
<b>Description</b>	<code>m = margin(tree,X,Y)</code> returns the classification margins for the matrix of predictors <code>X</code> and class labels <code>Y</code> . For the definition, see “Margin” on page 21-2211.
<b>Input Arguments</b>	<p><b>tree</b></p> <p>A classification tree created by <code>fitctree</code>, or a compact classification tree created by <code>compact</code>.</p> <p><b>X</b></p> <p>A matrix where each row represents an observation, and each column represents a predictor. The number of columns in <code>X</code> must equal the number of predictors in <code>tree</code>.</p> <p><b>Y</b></p> <p>Class labels, with the same data type as exists in <code>tree</code>.</p>
<b>Output Arguments</b>	<p><b>m</b></p> <p>A numeric column vector of length <code>size(X,1)</code>. Each entry in <code>m</code> represents the margin for the corresponding rows of <code>X</code> and (true class) <code>Y</code>, computed using <code>tree</code>.</p>
<b>Definitions</b>	<p><b>Margin</b></p> <p>The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix <code>X</code>.</p> <p><b>Score (tree)</b></p> <p>For trees, the <i>score</i> of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that</p>

# CompactClassificationTree.margin

---

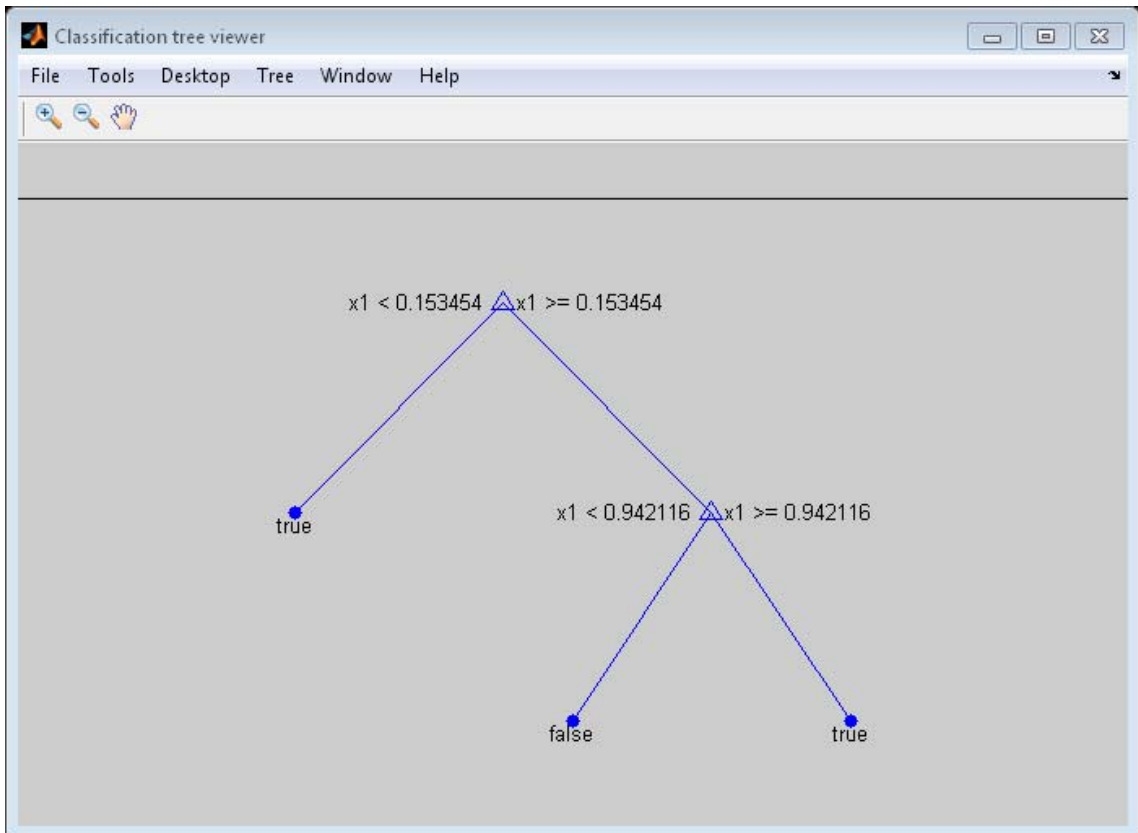

lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor  $X$  as true when  $X < 0.15$  or  $X > 0.95$ , and  $X$  is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

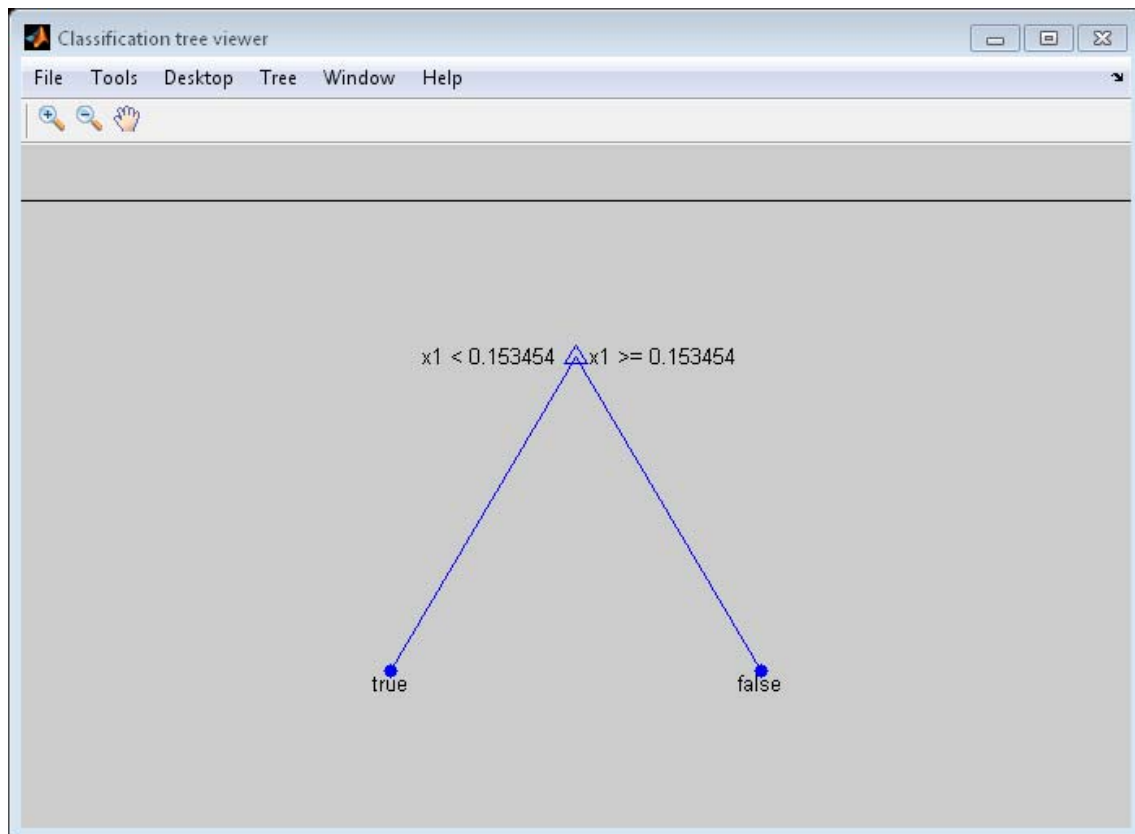

# CompactClassificationTree.margin

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

# CompactClassificationTree.margin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```
load fisheriris  
X = meas(:,1:2);  
tree = fitctree(X,species);  
M = margin(tree,X,species);  
M(end-10:end)
```

```
ans =  
    0.1111  
    0.1111  
    0.1111  
   -0.2857  
    0.6364
```

# CompactClassificationTree.margin

---

```
0.6364
0.1111
0.7500
1.0000
0.6364
0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);
M = margin(tree,meas,species);
M(end-10:end)
```

```
ans =
0.9565
0.9565
0.9565
0.9565
0.9565
0.9565
0.9565
0.9565
0.9565
0.9565
0.9565
```

## Purpose

Classification margin

## Syntax

```
mar = margin(B,X,Y)
mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)
```

## Description

`mar = margin(B,X,Y)` computes the classification margins for predictors  $X$  given true response  $Y$ . The  $Y$  can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `mar` is a numeric array of size `Nobs`-by-`NTrees`, where `Nobs` is the number of rows of  $X$  and  $Y$ , and `NTrees` is the number of trees in the ensemble  $B$ . For observation  $I$  and tree  $J$ , `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,X,Y, 'param1',val1, 'param2',val2, ...)` specifies optional parameter name/value pairs:

- 'mode' String indicating how the method computes errors. If set to 'cumulative' (default), `margin` computes cumulative errors and `mar` is an `Nobs`-by-`NTrees` matrix, where the first column gives error from `trees(1)`, second column gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to 'individual', `mar` is a `Nobs`-by-`NTrees` matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', `mar` a single column of length `Nobs` showing the cumulative margins for the entire ensemble.
- 'trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element

## CompactTreeBagger.margin

---

gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.

'useifort' Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`CompactTreeBagger.margin`

# RepeatedMeasuresModel.margmean

---

## Purpose

Estimate marginal means

## Syntax

```
tbl = margmean(rm,vars)
tbl = margmean(rm,vars,'alpha',alpha)
```

## Description

`tbl = margmean(rm,vars)` returns the estimated marginal means for the variables `vars`, in the table `tbl`.

`tbl = margmean(rm,vars,'alpha',alpha)` returns the  $100*(1-\alpha)\%$  confidence intervals for the marginal means.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **vars - Variables for which to compute the marginal means**

string | cell array of strings

Variables for which to compute the marginal means, specified as a string representing the name of a between or within-subjects factor in `rm`, or a cell array of strings representing the names of multiple variables. Each between-subjects factor must be categorical.

For example, if you want to compute the marginal means for the variables `Drug` and `Gender`, then you can specify as follows.

**Example:** `{'Drug','Gender'}`

### **Data Types**

char | cell

### **alpha - Confidence level**

0.05 (default) | scalar value in the range of 0 to 1

# RepeatedMeasuresModel.margmean

---

Confidence level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is  $100 \cdot (1 - \alpha)\%$ .

For example, you can specify a 99% confidence level as follows.

**Example:** 'alpha',0.01

## Data Types

double | single

## Output Arguments

### tbl - Estimated marginal means

table

Estimated marginal means, returned as a table. `tbl` contains one row for each combination of the groups of the variables you specify in `vars`, one column for each variable, and the following columns.

Column name	Description
Mean	Estimated marginal means
StdErr	Standard errors of the estimates
Lower	Lower limit of a 95% confidence interval for the true population mean
Upper	Upper limit of a 95% confidence interval for the true population mean

## Examples

### Compute Marginal Means Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` to `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

# RepeatedMeasuresModel.margmean

Fit a repeated measures model, where the repeated measures  $y_1$  to  $y_8$  are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', w
```

Compute the marginal means grouped by the between-subjects factor Group and the within-subject factor Time.

```
M = margmean(rm, {'Group' 'Time'})
```

M =

Group	Time	Mean	StdErr	Lower	Upper
A	1	20.03	11.966	-4.7859	44.846
A	2	5.8101	8.0942	-10.976	22.597
A	3	20.694	5.1928	9.9247	31.463
A	4	16.802	5.1693	6.0813	27.522

Display the description for table M.

M.Properties.Description

ans =

Estimated marginal means  
Means computed with Age=13.7, IQ=98.2667

## Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Compute the marginal means grouped by the factor species.

```
margmean(rm,'species')
```

# RepeatedMeasuresModel.margmean

```
ans =
```

species	Mean	StdErr	Lower	Upper
'setosa'	2.5355	0.042807	2.4509	2.6201
'versicolor'	3.573	0.042807	3.4884	3.6576
'virginica'	4.285	0.042807	4.2004	4.3696

StdError field shows the standard errors of the estimated marginal means. The Lower and Upper fields show the lower and upper bounds for the 95% confidence intervals of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm, 'species', 'alpha', 0.01)
```

```
ans =
```

species	Mean	StdErr	Lower	Upper
'setosa'	2.5355	0.042807	2.4238	2.6472
'versicolor'	3.573	0.042807	3.4613	3.6847
'virginica'	4.285	0.042807	4.1733	4.3967

# RepeatedMeasuresModel.mauchly

---

**Purpose** Mauchly's test for sphericity

**Syntax**  
`tbl = mauchly(rm)`  
`tbl = mauchly(rm,C)`

**Description** `tbl = mauchly(rm)` returns the result of the Mauchly's test for sphericity for the repeated measures model `rm`.  
It tests the null hypothesis that the sphericity assumption is true for the response variables in `rm`.  
For more information, see "Mauchly's Test of Sphericity" on page 8-58.

`tbl = mauchly(rm,C)` returns the result of the Mauchly's test based on the contrast matrix `C`.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **C - Contrasts**

matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

### **Data Types**

single | double

## Output Arguments

### tbl - Results of Mauchly's test of sphericity

table

Results of Mauchly's test for sphericity for the repeated measures model `rm`, returned as a `table`.

`tbl` contains the following columns.

Column Name	Definition
W	Value of Mauchly's $W$ statistic
ChiStat	Chi-square statistic value
DF	Degrees of freedom of the Chi-square statistic
pValue	$p$ -value corresponding to the Chi-square statistic

### Data Types

table

## Examples

### Perform Mauchly's Test

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

# RepeatedMeasuresModel.mauchly

---

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Perform Mauchly's test to assess the sphericity assumption.

```
mauchly(rm)
```

```
ans =
```

W	ChiStat	DF	pValue
0.55814	84.976	5	1.1102e-16

The small  $p$ -value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the  $p$ -values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected  $p$ -values using the `ranova` method.

- “Compound Symmetry Assumption and Epsilon Corrections” on page 8-56

**Purpose**

Convert matrix to dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)
```

**Description**

`ds = mat2dataset(X)` converts a matrix to a dataset array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments****X - Input matrix**

matrix

Input matrix to convert to a dataset array, specified as an  $M$ -by- $N$  numeric matrix. Each column of `X` becomes a variable in the output  $M$ -by- $N$  dataset array.

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'NumCols',[1,1,2,1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

**'VarNames' - Variable names for output dataset array**

cell array of strings

Variable names for the output dataset array, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

**Example:** 'VarNames', {'myVar1', 'myVar2', 'myVar3'}

## **'ObsNames' - Observation names for output dataset array**

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings. The names do not need to be valid MATLAB identifiers, but they must be unique.

## **'NumCols' - Number of columns for each variable**

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in `X` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1,1,3,1,2].

## **Output Arguments**

### **ds - Output dataset array**

dataset array

Output dataset array, returned by default with a variable for each column of `X`, and an observation for each row of `X`. If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

## **Examples**

### **Convert Matrix to Dataset Array**

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)
```

ans =

```
    150     4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);
size(ds)
```

ans =

```
    150     4
```

```
ds(1:5,:)
```

ans =

X1	X2	X3	X4
5.1	3.5	1.4	0.2
4.9	3	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5	3.6	1.4	0.2

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

## **Convert Matrix to Dataset Array with Variable Names**

Load sample data.

```
load('fisheriris')
X = meas;
```

# mat2dataset

---

```
size(X)
```

```
ans =
```

```
    150     4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of X.

```
ds = mat2dataset(X,'VarNames',{'SLength',...  
'SWidth','PLength','PWidth'});  
size(ds)
```

```
ans =
```

```
    150     4
```

```
ds(1:5,:)
```

```
ans =
```

SWidth	SLength	PWidth	PLength
5.1	3.5	1.4	0.2
4.9	3	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5	3.6	1.4	0.2

## Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```
load('fisheriris')  
X = meas;  
size(X)
```

```
ans =
```

```
150    4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named `SepalMeas`, and the petal measurements (third and fourth columns) into one variable names `PetalMeas`.

```
ds = mat2dataset(X, 'NumCols', [2,2], ...
    'VarNames', { 'SepalMeas', 'PetalMeas' });
ds(1:5,:)
```

```
ans =
```

SepalMeas		PetalMeas	
5.1	3.5	1.4	0.2
4.9	3	1.4	0.2
4.7	3.2	1.3	0.2
4.6	3.1	1.5	0.2
5	3.6	1.4	0.2

The output dataset array has 150 observations and 2 variables.

```
size(ds)
```

```
ans =
```

```
150    2
```

# mdscale

---

**Purpose** Nonclassical multidimensional scaling

**Syntax**

```
Y = mdscale(D,p)
[Y,stress] = mdscale(D,p)
[Y,stress,disparities] = mdscale(D,p)
[...] = mdscale(D,p,'Name',value)
```

**Description** `Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the  $n$ -by- $n$  dissimilarity matrix  $D$ , and returns  $Y$ , a configuration of  $n$  points (rows) in  $p$  dimensions (columns). The Euclidean distances between points in  $Y$  approximate a monotonic transformation of the corresponding dissimilarities in  $D$ . By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify  $D$  as either a full  $n$ -by- $n$  matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats NaNs in  $D$  as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify  $D$  as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in  $Y$  approximate  $\sqrt{1-D}$ . To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y,stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at  $Y$ .

`[Y,stress,disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities  $D$ .

`[...] = mdscale(D,p,'Name',value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *Name* in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that mdscale performs. Choices for non-metric scaling are:
  - 'stress' — Stress normalized by the sum of squares of the inter-point distances, also known as stress1. This is the default.
  - 'sstress' — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- 'metricstress' — Stress, normalized with the sum of squares of the dissimilarities.
  - 'metricsstress' — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
  - 'sammon' — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
  - 'strain' — A criterion equivalent to that used in classical multidimensional scaling.
- **Weights** — A matrix or vector the same size as D, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of D in computing and minimizing stress. Elements of D corresponding to zero weights are effectively ignored.

---

**Note** When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of D do not enter into the stress calculation.

---

- **Start** — Method used to choose the initial configuration of points for Y. The choices are

# mdscale

---

- 'cmdscale' — Use the classical multidimensional scaling solution. This is the default. 'cmdscale' is not valid when there are zero weights.
- 'random' — Choose locations randomly from an appropriately scaled  $p$ -dimensional normal distribution with uncorrelated coordinates.
- An  $n$ -by- $p$  matrix of initial locations, where  $n$  is the size of the matrix  $D$  and  $p$  is the number of columns of the output matrix  $Y$ . In this case, you can pass in `[]` for  $p$  and `mdscale` infers  $p$  from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- Replicates — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.
- Options — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```
opts = statset(param1, val1, param2, val2, ...);  
[...] = mdscale(..., 'Options', opts)
```

The choices of `statset` parameters are

- 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' — Maximum number of iterations allowed. The default is 200.
- 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is  $1e-4$ .
- 'TolX' — Termination tolerance for the configuration location step size. The default is  $1e-4$ .

## Examples

```
load cereal.mat  
X = [Calories Protein Fat Sodium Fiber ...
```

```
Carbo Sugars Shelf Potass Vitamins];

% Take a subset from a single manufacturer.
X = X(strcmp('K',cellstr(Mfg)),:);

% Create a dissimilarity matrix.
dissimilarities = pdist(X);

% Use non-metric scaling to recreate the data in 2D,
% and make a Shepard plot of the results.
[Y, stress, disparities] = mdscale(dissimilarities, 2);
distances = pdist(Y);
[dum, ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities, distances, 'bo', ...
dissimilarities(ord), disparities(ord), 'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'}, 'Location', 'NW');
```

# mdscale

```
% Do metric scaling on the same dissimilarities.  
figure  
[Y, stress] = ...  
mdscale(dissimilarities, 2, 'criterion', 'metricsstress');  
distances = pdist(Y);  
plot(dissimilarities, distances, 'bo', ...  
[0 max(dissimilarities)], [0 max(dissimilarities)], 'r.-');  
xlabel('Dissimilarities'); ylabel('Distances')
```

**See Also** `cmdscale` | `pdist` | `statset`

# CompactTreeBagger.mdsProx

---

**Purpose**            Multidimensional scaling of proximity matrix

**Syntax**            `[SC,EIGEN] = mdsProx(B,X)`  
`[SC,EIGEN] = mdsProx(B,X, 'param1',val1, 'param2',val2,...)`

**Description**        `[SC,EIGEN] = mdsProx(B,X)` applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix `X`, and returns scaled coordinates `SC` and eigenvalues `EIGEN` of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as `1-prox`, where `prox` is the proximity matrix returned by the proximity method.

You can supply the proximity matrix directly by using the `'data'` parameter.

`[SC,EIGEN] = mdsProx(B,X, 'param1',val1, 'param2',val2,...)` specifies optional parameter name/value pairs:

- `'data'`            Flag indicating how the method treats the `X` input argument. If set to `'predictors'` (default), `mdsProx` assumes `X` to be a matrix of predictors and used for computation of the proximity matrix. If set to `'proximity'`, the method treats `X` as a proximity matrix returned by the proximity method.
- `'colors'`        If you supply this argument, `mdsProx` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsProx` only plots the first `C` classes, where `C` is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in `X`.

- 'labels' Vector of true class labels for a classification ensemble. True class labels can be either a numeric vector, character matrix, or cell array of strings. If supplied, this vector must have as many elements as there are observations (rows) in X. This argument has no effect unless you also supply the 'colors' argument.
- 'mdscoords' Indices of the two scaled coordinates to plot. By default, mdsProx makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

# TreeBagger.mdsProx

---

**Purpose** Multidimensional scaling of proximity matrix

**Syntax** `[S,E] = mdsProx(B)`  
`[S,E] = mdsProx(B, 'param1', val1, 'param2', val2, ...)`

**Description** `[S,E] = mdsProx(B)` returns scaled coordinates, S, and eigenvalues, E, for the proximity matrix in the ensemble B. An earlier call to `fillProximities(B)` must create the proximity matrix.

`[S,E] = mdsProx(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

- 'keep' Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues.
- 'colors' If you supply this argument, `mdsProx` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a string with one character for each color. If there are more classes in the data than characters in the supplied string, `mdsProx` only plots the first C classes, where C is the length of the string. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in X.
- 'mdscoords' Indices of the two scaled coordinates to plot. By default, `mdsProx` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'colors' argument.

<b>Purpose</b>	Mean of probability distribution object
<b>Syntax</b>	<code>m = mean(pd)</code>
<b>Description</b>	<code>m = mean(pd)</code> returns the mean <code>m</code> of the probability distribution <code>pd</code> .
<b>Input Arguments</b>	<b>pd - Probability distribution</b> probability distribution object  Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using <code>makedist</code> .
<b>Output Arguments</b>	<b>m - Mean</b> scalar value  Mean of the probability distribution, returned as a scalar value.

## Examples **Mean of a Uniform Distribution**

Create a uniform distribution object

```
pd = makedist('Uniform','lower',-3,'upper',5)
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = -3
```

```
Upper = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1
```

**See Also**      `makedist`

# prob.ToolboxFittableParametricDistribution.mean

---

**Purpose** Mean of probability distribution object

**Syntax** `m = mean(pd)`

**Description** `m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

**Input Arguments**

**pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

**Output Arguments**

**m - Mean**  
scalar value

Mean of the probability distribution, returned as a scalar value.

## Examples **Mean of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]
```

```
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

```
m =
```

```
75.0083
```

The mean of the normal distribution is equal to the parameter  $\mu$ .

## Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean =

# CompactTreeBagger.meanMargin

---

**Purpose** Mean classification margin

**Syntax**  
`mar = meanMargin(B,X,Y)`  
`mar = meanMargin(B,X,Y, 'param1',val1, 'param2',val2,...)`

**Description** `mar = meanMargin(B,X,Y)` computes average classification margins for predictors `X` given true response `Y`. The `Y` can be either a numeric vector, character matrix, cell array of strings, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `X` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B,X,Y, 'param1',val1, 'param2',val2,...)` specifies optional parameter name/value pairs:

`'mode'` String indicating how `meanMargin` computes errors. If set to `'cumulative'` (default), is a vector of length `NTrees` where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to `'individual'`, `mar` is a vector of length `NTrees`, where each element is a mean margin from each tree in the ensemble. If set to `'ensemble'`, `mar` is a scalar showing the cumulative mean margin for the entire ensemble.

`'trees'` Vector of indices indicating what trees to include in this calculation. By default, this argument is set to `'all'` and the method uses all trees. If `'trees'` is a numeric vector, the method returns a vector of length `NTrees` for `'cumulative'` and `'individual'` modes, where `NTrees` is the number of elements in the input vector, and a scalar for `'ensemble'` mode. For example, in the `'cumulative'` mode, the first element

gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.

'`treeweights`' Vector of tree weights. This vector must have the same length as the '`trees`' vector. `meanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the '`individual`' mode.

# classregtree.meansurrvarassoc

---

**Purpose** Mean predictive measure of association for surrogate splits in decision tree

**Syntax** MA = meansurrvarassoc(T)  
MA = meansurrvarassoc(T,N)

**Description** MA = meansurrvarassoc(T) returns a  $p$ -by- $p$  matrix, MA, with predictive measures of association for  $p$  predictors. Element MA( $i,j$ ) is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

MA = meansurrvarassoc(T,N) takes an array N of node numbers and returns the predictive measure of association averaged over the specified nodes.

# CompactClassificationTree.meanSurrVarAssoc

---

**Purpose** Mean predictive measure of association for surrogate splits in decision tree

**Syntax** `ma = meanSurrVarAssoc(tree)`  
`ma = meanSurrVarAssoc(tree,N)`

**Description** `ma = meanSurrVarAssoc(tree)` returns a matrix of predictive measures of association for the predictors in tree.  
`ma = meanSurrVarAssoc(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector N.

**Input Arguments** **tree**  
A classification tree constructed with `fitctree`, or a compact regression tree constructed with `compact`.

**N**  
Vector of node numbers in tree.

**Output Arguments** **ma**

- `ma = meanSurrVarAssoc(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association between the optimal split on variable `i` and a surrogate split on variable `j`. See “Predictive Measure of Association” on page 21-2255.
- `ma = meanSurrVarAssoc(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector N. N contains node numbers from 1 to `max(tree.NumNodes)`.

## **Definitions** **Predictive Measure of Association**

The predictive measure of association between the optimal split on variable *i* and a surrogate split on variable *j* is:

# CompactClassificationTree.meanSurrVarAssoc

---

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R_i R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

Element  $\text{ma}(i, j)$  is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

## Examples

Find the mean predictive measure of association between the variables in the Fisher iris data:

```
load fisheriris
obj = fitctree(meas, species, 'surrogate', 'on');
msva = meanSurrVarAssoc(obj)
```

```
msva =
    1.0000         0         0         0
         0    1.0000         0         0
    0.4633    0.2500    1.0000    0.5000
```

# CompactClassificationTree.meanSurrVarAssoc

---

```
0.2065    0.1413    0.4022    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in obj:

```
N = 1:2:obj.NumNodes;  
msva = meanSurrVarAssoc(obj,N)
```

```
msva =  
    1.0000         0         0         0  
         0    1.0000         0         0  
    0.7600    0.5000    1.0000    1.0000  
    0.4130    0.2826    0.8043    1.0000
```

`ma = meanSurrVarAssoc(tree,N)`

**Description**  
`ma = meanSurrVarAssoc(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.  
`ma = meanSurrVarAssoc(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

**Input Arguments**  
**tree**  
A regression tree constructed with `fitrtree`, or a compact regression tree constructed with `compact`.

**N**  
Vector of node numbers in `tree`.

**Output Arguments**  
**ma**

- `ma = meanSurrVarAssoc(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association between the optimal split on variable `i` and a surrogate split on variable `j`. See “Predictive Measure of Association” on page 21-2258.
- `ma = meanSurrVarAssoc(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from 1 to `max(tree.NumNodes)`.

## Definitions **Predictive Measure of Association**

The predictive measure of association between the optimal split on variable *i* and a surrogate split on variable *j* is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R_i R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

Element  $\text{ma}(i, j)$  is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

## Examples

Find the mean predictive measure of association between the Displacement, Horsepower, and Weight variables in the carsmall data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG, 'surrogate', 'on');
ma = meanSurrVarAssoc(tree)

ma =
    1.0000    0.2708    0.3854
    0.4764    1.0000    0.4568
```

# CompactRegressionTree.meanSurrVarAssoc

---

```
0.3472    0.2326    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in tree:

```
N = 1:2:tree.NumNodes;  
ma = meanSurrVarAssoc(tree,N)
```

```
ma =  
    1.0000    0.2500    0.3750  
    0.5910    1.0000    0.5861  
    0.5000    0.2361    1.0000
```

[prune](#) | [RegressionTree](#) | [fitrtree](#)

**Purpose** Return median of ProbDistUnivKernel object

**Syntax**  $M = \text{median}(PD)$

**Description**  $M = \text{median}(PD)$  returns  $M$ , the median of the ProbDistUnivKernel object  $PD$ .

**Input Arguments**  $PD$  An object of the class ProbDistUnivKernel.

**Output Arguments**  $M$  The median of the ProbDistUnivKernel object  $PD$ .

**See Also** median

# ProbDistUnivParam.median

---

**Purpose** Return median of ProbDistUnivParam object

**Syntax**  $M = \text{median}(PD)$

**Description**  $M = \text{median}(PD)$  returns  $M$ , the median of the ProbDistUnivParam object  $PD$ .

**Input Arguments**  $PD$  An object of the class ProbDistUnivParam.

**Output Arguments**  $M$  The median of the ProbDistUnivParam object  $PD$ .

**See Also** median

**Purpose** Median of probability distribution object

**Syntax** `m = median(pd)`

**Description** `m = median(pd)` returns the median `m` for the probability distribution `pd`.

**Input Arguments** **pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

**Output Arguments** **m - Median**  
scalar value

Median of the probability distribution, returned as a scalar value. The value of `m` is the 50th percentile of the probability distribution.

**Examples** **Median of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

# prob.TruncatableDistribution.median

---

```
Normal distribution
  mu = 75.0083 [73.4321, 76.5846]
  sigma = 8.7202 [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

```
m =
```

```
75.0083
```

For a symmetrical distribution such as the normal distribution, the median will be equal to the mean,  $\mu$ .

## Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m =
```

```
4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean =  
    4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];  
pdf = pdf(pd,x);  
plot(x,pdf)
```

# prob.TruncatableDistribution.median

# TreeBagger.MergeLeaves property

---

<b>Purpose</b>	Flag to merge leaves that do not improve risk
<b>Description</b>	The MergeLeaves property is true if decision trees have their leaves with the same parent merged for splits that do not decrease the total risk, and false otherwise. The default value is false.
<b>See Also</b>	<code>classregtree</code>

# categorical.mergelevels

---

## Purpose

Merge levels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
B = mergelevels(A,oldlevels,newlevel)
B = mergelevels(A,oldlevels)
```

## Description

`B = mergelevels(A,oldlevels,newlevel)` merges two or more levels of the categorical array `A` into a single new level. `oldlevels` is a cell array of strings or a 2-D character matrix that specifies the levels to be merged. Any elements of `A` that have levels in `oldlevels` are assigned the new level in the corresponding elements of `B`. `newlevel` is a character string that specifies the label for the new level. For ordinal arrays, the levels of `A` specified by `oldlevels` must be consecutive, and `mergelevels` inserts the new level to preserve the order of the levels.

`B = mergelevels(A,oldlevels)` merges two or more levels of `A`. For nominal arrays, `mergelevels` uses the first label in `oldlevels` as the label for the new level. For ordinal arrays, `mergelevels` uses the label corresponding to the lowest level in `oldlevels` as the label for the new level.

## Examples

### Merge Levels in Nominal Array

Load the sample data. Create a nominal array containing the iris species data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a nominal array containing the iris species data. Display the levels in the nominal array.

```
species = nominal(species);
```

```
getlevels(species)
```

```
ans =
```

```
      setosa      versicolor      virginica
```

Merge the 'setosa' and 'virginica' levels into a single new level called 'parent'.

```
species = mergelevels(species,...  
                      {'setosa','virginica'}, 'parent');
```

Display the new level labels.

```
getlabels(species)
```

```
ans =
```

```
'parent'      'versicolor'
```

# categorical.mergelevels

---

## Merge Levels in Ordinal Array

Create an ordinal array.

```
A = ordinal([1 2 3 2 1], {'lo', 'med', 'hi'})
```

```
A =  
   lo      med      hi      med      lo
```

Merge the 'lo' and 'med' levels into a single new level labeled 'bad'.

```
A = mergelevels(A, {'lo', 'med'}, 'bad')
```

```
A =  
   bad      bad      hi      bad      bad
```

Any element previous belonging to the levels 'lo' or 'med' now belongs to the level 'bad'.

# TreeBagger.Method property

---

**Purpose**

Method used by trees (classification or regression)

**Description**

The Method property is 'classification' for classification ensembles and 'regression' for regression ensembles.

# mhsample

---

## Purpose

Metropolis-Hastings sample

## Syntax

```
smp1 = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf, 'proprnd',  
               proprnd)  
smp1 = mhsample(...,'symmetric',sym)  
smp1 = mhsample(...,'burnin',K)  
smp1 = mhsample(...,'thin',m)  
smp1 = mhsample(...,'nchain',n)  
[smp1,accept] = mhsample(...)
```

## Description

`smp1 = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf, 'proprnd', proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smp1` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution  $q(x,y)$  gives the probability density for choosing  $x$  as the next point when  $y$  is the current point. It is sometimes written as  $q(x|y)$ .

If the `proppdf` or `logproppdf` satisfies  $q(x,y) = q(y,x)$ , that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If the `proppdf` or `logproppdf` satisfies  $q(x,y) = q(x)$ , that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smpl = mhsample(..., 'symmetric', sym)` draws `nsamples` random samples from a target stationary distribution pdf using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is `false`, which corresponds to the asymmetric proposal distribution. If `sym` is `true`, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smpl = mhsample(..., 'burnin', K)` generates a Markov chain with values between the starting point and the  $k^{\text{th}}$  point omitted in the generated sequence. Values beyond the  $k^{\text{th}}$  point are kept. `k` is a nonnegative integer with default value of 0.

`smpl = mhsample(..., 'thin', m)` generates a Markov chain with  $m-1$  out of  $m$  values omitted in the generated sequence. `m` is a positive integer with default value of 1.

`smpl = mhsample(..., 'nchain', n)` generates `n` Markov chains using the Metropolis-Hastings algorithm. `n` is a positive integer with a default value of 1. `smpl` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smpl, accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

## Examples

### Estimate Moments Using Independent Metropolis-Hastings Sampling

Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```
rng('default'); % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
    exprnd(floor(alpha)/alpha,floor(alpha),1));
```

# mhsample

---

```
nsamples = 5000;  
smp1 = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...  
               'proppdf',proppdf);
```

Plot the results.

```
xxhat = cumsum(smp1.^2)./(1:nsamples)';  
figure;  
plot(1:nsamples,xxhat)
```

## Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```
rng('default'); % For reproducibility
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
```

Plot the sample data.

```
figure;
histfit(x,50);
h = get(gca,'Children');
set(h(2),'FaceColor',[.8 .8 1]);
```

# mhsample

# mle

---

## Purpose

Maximum likelihood estimates

## Syntax

```
phat = mle(data)
phat = mle(data, 'distribution', dist)

phat = mle(data, 'pdf', pdf, 'start', start)
phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)

phat = mle(data, 'logpdf', logpdf, 'start', start)
phat =
mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)

phat = mle(data, 'nloglf', nloglf, 'start', start)

phat = mle( __, Name, Value)
[phat, pci] = mle( __ )
```

## Description

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data, 'distribution', dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data, 'pdf', pdf, 'start', start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data, 'logpdf', logpdf, 'start', start)` returns parameter estimates for a custom distribution specified by the log

probability density function `logpdf`. You must also specify the initial parameter values, `start`.

```
phat =  
mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)
```

 returns parameter estimates for a custom distribution specified by the log probability density function `logpdf` and custom log survival function `logsf`.

```
phat = mle(data, 'nloglf', nloglf, 'start', start)
```

 returns parameter estimates for the custom distribution specified by the negative loglikelihood function `nloglf`. You must also specify the initial parameter values, `start`.

`phat = mle( ___, Name, Value)` also returns the parameter estimates with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

`[phat, pci] = mle( ___ )` also returns the 95% confidence intervals for the parameters.

## Input Arguments

### **data** - Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

### **Data Types**

single | double

### **dist** - Distribution type

'normal' (default) | string

Distribution type to estimate parameters for, specified as one of the following.

<b>dist</b>	<b>Description</b>	<b>Parameter 1</b>	<b>Parameter 2</b>	<b>Parameter 3</b>
'bernoulli'	"Bernoulli Distribution" on page B-3	p: probability of success for each trial	—	—
'beta' or 'Beta'	"Beta Distribution" on page B-5	a	b	—
'bino' or 'Binomial'	"Binomial Distribution" on page B-9	n: number of trials	p: probability of success for each trial	—
'birnbaumsaunders'	"Birnbbaum-Saunders Distribution" on page B-13	$\beta$ : scale	$\gamma$ : shape	—
'burr' or 'Burr'	"Burr Type XII Distribution" on page B-15	$\alpha$ : scale	c: first shape	k: second shape
'Discrete Uniform' or 'unid'	"Uniform Distribution (Discrete)" on page B-153	N: maximum observable value	—	—
'exp' or 'Exponential'	"Exponential Distribution" on page B-33	$\mu$ : mean	—	—
'ev' or 'Extreme Value'	"Extreme Value Distribution" on page B-37	$\mu$ : location	$\sigma$ : scale	—
'gam' or 'Gamma'	"Gamma Distribution" on page B-47	a: shape	b: scale	—
'gev' or 'Generalized Extreme Value'	"Generalized Extreme Value Distribution" on page B-53	k: shape	$\sigma$ : scale	$\mu$ : location

<b>dist</b>	<b>Description</b>	<b>Parameter 1</b>	<b>Parameter 2</b>	<b>Parameter 3</b>
'gp' or 'Generalized Pareto'	“Generalized Pareto Distribution” on page B-60	k: tail index (shape)	$\sigma$ : scale	$\theta$ : threshold
'geo' or 'Geometric'	“Geometric Distribution” on page B-65	p: probability	—	—
'inversegaussian'	“Inverse Gaussian Distribution” on page B-71	$\mu$ : scale	$\lambda$ : shape	—
'logistic'	“Logistic Distribution” on page B-86	$\mu$ : location	$\sigma$ : scale	—
'loglogistic'	“Loglogistic Distribution” on page B-88	$\mu$ : log location	$\sigma$ : log scale	—
'logn' or 'Lognormal'	“Lognormal Distribution” on page B-90	$\mu$ : log location	$\sigma$ : log scale	—
'nakagami'	“Nakagami Distribution” on page B-108	$\mu$ : shape	$\omega$ : scale	—
'nbin' or 'Negative Binomial'	“Negative Binomial Distribution” on page B-109	r: number of successes	p: probability of success in a single trial	—
'norm' or 'Normal'	“Normal Distribution” on page B-123	$\mu$ : location (mean)	$\sigma$ : scale (standard deviation)	—
'poiss' or 'Poisson'	“Poisson Distribution” on page B-130	$\lambda$ : mean	—	—
'rayl' or 'Rayleigh'	“Rayleigh Distribution” on page B-133	b: scale	—	—

dist	Description	Parameter 1	Parameter 2	Parameter 3
'rician'	“Rician Distribution” on page B-136	s: noncentrality	$\sigma$ : scale	—
'tlocationscale'	“t Location-Scale Distribution” on page B-140	$\mu$ : location	$\sigma$ : scale	$\nu$ : degrees of freedom
'unif' or 'Uniform'	“Uniform Distribution (Continuous)” on page B-147	a: lower endpoint (minimum)	b: upper endpoint (maximum)	—
'wbl' or 'Weibull'	“Weibull Distribution” on page B-156	a: scale	b: shape	—

**Example:** 'rician'

## pdf - Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mle` as follows.

**Example:** @newpdf

## Data Types

function\_handle

## cdf - Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

**Example:** @newcdf

### Data Types

function\_handle

### logpdf - Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

**Example:** @customlogpdf

### Data Types

function\_handle

### logsf - Custom log survival function

function handle

Custom log survival function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mle` as follows.

**Example:** @logsurvival

## Data Types

function\_handle

## nloglf - Custom negative loglikelihood function

function\_handle

Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.

params	Vector of distribution parameter values. <code>mle</code> detects the number of parameters from the number of
data	Vector of data.
cens	Boolean vector of censored values.
freq	Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the 'censoring' or 'frequency' name-value pair arguments. You can write 'nloglf' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

**Example:** `@negloglik`

### Data Types

`function_handle`

### start - Initial parameter values

`scalar` | `vector`

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

**Example:** `0.05`

**Example:** `[100,2]`

### Data Types

`single` | `double`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'censoring',Cens,'alpha',0.01,'options',Opt` specifies that `mle` estimates the parameters for the distribution of censored data specified by array `Cens`, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure `Opt`.

### 'censoring' - Indicator for censoring

`array of 0s (default)` | `array of 0s and 1s`

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

Censoring is not supported for all distributions.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

**Example:** 'censoring',`Censored`

### **Data Types**

logical

### **'frequency' - Frequency of observations**

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

**Example:** 'frequency',`Freq`

### **Data Types**

single | double

### **'alpha' - Confidence level**

0.05 (default) | scalar value in the range (0,1)

Confidence level for the confidence interval of parameter estimates, `p_ci`, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range (0,1). The confidence level of `p_ci` is  $100(1-\alpha)\%$ . The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

**Example:** 'alpha',0.01

### **Data Types**

single | double

### **'ntrials' - Number of trials**

scalar value | vector

Number of trials for the corresponding element of data, specified as the comma-separated pair consisting of 'ntrials' and a scalar or a vector of the same size as data.

Applies only to binomial distribution.

**Example:** 'ntrials',total

### **Data Types**

single | double

### **'options' - Fitting algorithm control parameters**

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'options' and a structure returned by `statset`.

Not applicable to all distributions.

Use the 'options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
'GradObj'	<p>Default is 'off'.</p> <p>'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output.</p>
'DerivStep'	<p>Default is <math>\text{eps}^{(1/3)}</math>.</p> <p>The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'.</p> <p><code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</p>
'FunValCheck'	<p>Default is 'on'.</p> <p>'on' or 'off', indicating whether or not <code>mle</code> should check the values returned by the custom distribution functions for validity.</p> <p>A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</p>
'TolBnd'	<p>Default is <math>1\text{e-}6</math>. An offset for upper and lower bounds when using <code>fmincon</code>.</p> <p><code>mle</code> treats upper and lower bounds as strict inequalities, that is, open bounds. With <code>fmincon</code>, this is approximated by creating closed bounds inset from the specified upper and lower bounds by <code>TolBnd</code>.</p>

**Example:** `'options', statset('mlecustom')`

**Data Types**  
struct

**'lowerbound' - Lower bounds for distribution parameters**

$-\infty$  (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of 'lowerbound' and a vector the same size as `start`.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logcdf`, or `nloglf` input arguments.

**Example:** 'lowerbound',0

**Data Types**

single | double

**'upperbound' - Upper bounds for distribution parameters**

$\infty$  (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of 'upperbound' and a vector the same size as `start`.

This name-value pair argument is valid only when you use the `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

**Example:** 'upperbound',1

**Data Types**

single | double

**'optimfun' - Optimization function**

'fminsearch' (default) | 'fmincon'

Optimization function `mle` uses in maximizing the likelihood, specified as the comma-separated pair consisting of 'optimfun' and either 'fminsearch' or 'fmincon'.

Default is 'fminsearch'.

You can only specify 'fmincon' if Optimization Toolbox is available.

The 'optimfun' name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

**Example:** 'optimfun', 'fmincon'

## Output Arguments

### **phat** - Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

### **pci** - Confidence intervals for parameter estimates

2-by- $k$  matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of phat.

pci is a 2-by- $k$  matrix, where  $k$  is the number of parameters mle estimates. The first and second rows of the pci show the upper and lower confidence limits, respectively.

## Examples

### **Estimate Parameters of Burr Distribution**

Load the sample data.

```
load carbig
```

The variable MPG has the miles per gallon for different models of cars.

Draw a histogram of MPG data.

```
hist(MPG)
```

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG,'distribution','burr')
```

```
phat =
```

```
34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter  $\alpha$  is 34.6447. The estimates for the two shape parameters  $c$  and  $k$  of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

## Fit Custom Distribution to Censored Data

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter,  $\lambda$ , of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'pdf',custpdf,...
'cdf',custcdf,'start',0.05,'Censoring',Censored)
phat
```

```
phat =
```

```
0.1096
```

## Fit Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k) - k*log(lambda) ...
             + (k-1)*log(data) - (data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
           'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
```

```
phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

## Fit Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf=@(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
0.1462
```

## **Estimate Probability of Success**

Generate 100 random observations from a binomial distribution with the number of trials,  $n = 20$ , and the probability of success,  $p = 0.75$ .

```
data = binornd(20,0.75,100,1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat,pci] = mle(data,'distribution','binomial',...
                'alpha',.05,'ntrials',20)
```

```
phat =
```

```
0.7370
```

```
pci =
```

```
0.7171
```

0.7562

The estimate of probability of success is 0.737 and the lower and upper limits of the 95% confidence interval are 0.7171 and 0.7562. This interval covers the true value used to simulate the data.

## Definitions

### Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function,  $F(t)$ , is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution,  $S(t)$ , is the complement of the cumulative distribution function:  $S(t) = 1 - F(t)$ .

## Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

## See Also

## Concepts

- “What Is Survival Analysis?” on page 12-2

**Purpose** Asymptotic covariance of maximum likelihood estimators

**Syntax**

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov( ___,Name,Value)
```

**Description** `acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed data, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution

specified by the custom log probability density function `logpdf` and custom log survival function `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov( ___,Name,Value)` also returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters with additional options specified by one or more name-value pair arguments. You can use any of the input arguments in the previous syntaxes.

## Input Arguments

### **params - Parameter estimates**

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

### **Data Types**

single | double

### **data - Sample data**

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

### **Data Types**

single | double

### **pdf - Custom probability density function**

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@newpdf`

### **Data Types**

function\_handle

### **cdf - Custom cumulative distribution function**

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@newcdf`

### **Data Types**

function\_handle

### **logpdf - Custom log probability density function**

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@customlogpdf`

### **Data Types**

function\_handle

### **logsf - Custom log survival function**

function handle

Custom log survival function, specified as a function handle created using `@`.

This custom function accepts the vector data and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the 'censoring' name-value pair argument. If 'censoring' is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@logsurvival`

### **Data Types**

function\_handle

### **nloglf - Custom negative loglikelihood function**

function handle

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

params	Vector of distribution parameter values
data	Vector of data
cens	Boolean vector of censored values
freq	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the 'censoring' or 'frequency' name-value pair arguments. You can write 'nloglf' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

**Example:** `@negloglik`

### Data Types

`function_handle`

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** 'censoring', `cens`, 'options', `opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new options structure `opt`.

### 'censoring' - Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of 'censoring' and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

**Example:** 'censoring',`Censored`

### Data Types

logical

### 'frequency' - Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of 'frequency' and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

**Example:** 'frequency',`Freq`

### Data Types

single | double

### 'options' - Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of 'options' and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
'GradObj'	Default is 'off'.  'on' or 'off', indicating whether or not the function provided with the <code>nloglf</code> input argument can return the gradient vector of the negative log-likelihood as a second output.
'DerivStep'	Default is $\text{eps}^{(1/4)}$ .  Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as <code>params</code> . A smaller value than the default might be appropriate if 'GradObj' is 'on'.

**Example:** `'options',statset('mlecov')`

**Data Types**  
struct

## Output Arguments

**acov - Approximation to asymptotic covariance matrix**  
*p*-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`.

## Examples

### Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
```

```
newpdf = exp((-log(data)-mu).^2)/(2*sigma^2)./(data*sigma*sqrt(2*pi))
```

Estimate the parameters, mu and sigma, of the custom-defined distribution.

```
phat = mle(Weight,'pdf',@lognormpdf,'start',[4.5 0.3])
```

```
phat =
```

```
    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,Weight,'pdf',@lognormpdf)
```

```
acov =
```

```
    1.0e-03 *  
    0.1937    -0.0000  
   -0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))
```

```
se =
```

```
    0.0139  
    0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

## Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```
function logpdf = betalogpdf(x,a,b)
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaln(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')
x = betarnd(1.23,3.45,25,1);
phat = mle(x,'dist','beta')
```

```
phat =

    1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)
```

```
acov =

    0.0810    0.1646
    0.1646    0.6074
```

## Custom Log pdf and Survival Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k) - k*log(lambda) ...
             + (k-1)*log(data) - (data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime, 'logpdf', custlogpdf, ...
           'logsf', custlogsf, 'start', [1, 0.75], 'Censoring', Censored)
```

```
phat =
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat, ReadmissionTime, ...
              'logpdf', custlogpdf, 'logsf', custlogsf, 'Censoring', Censored)
```

```
acov =
```

```
    0.5653    0.0102
    0.0102    0.0163
```

## Custom Log Negative Likelihood Function

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load readmissiontimes
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)
```

```
phat =
```

```
    0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)
```

```
acov =
```

```
    2.1374e-04
```

Compute the standard error.

```
sqrt(acov)
```

```
ans =
```

0.0146

**Definitions****Survival Function**

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function,  $F(t)$ , is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution,  $S(t)$ , is the complement of the cumulative distribution function:  $S(t) = 1 - F(t)$ .

**See Also**

mle

**Concepts**

- “What Is Survival Analysis?” on page 12-2

**Purpose** Multinomial probability density function

**Syntax** `Y = mnpdf(X,PROB)`

**Description** `Y = mnpdf(X,PROB)` returns the pdf for the multinomial distribution with probabilities `PROB`, evaluated at each row of `X`. `X` and `PROB` are  $m$ -by- $k$  matrices or 1-by- $k$  vectors, where  $k$  is the number of multinomial bins or categories. Each row of `PROB` must sum to one, and the sample sizes for each observation (rows of `X`) are given by the row sums `sum(X,2)`. `Y` is an  $m$ -by- $k$  matrix, and `mnpdf` computes each row of `Y` using the corresponding rows of the inputs, or replicates them if needed.

## **Examples**      **Compute the Multinomial Distribution pdf**

Compute the pdf of a multinomial distribution with a sample size of  $n = 10$ . The probabilities are  $p = 1/2$  for outcome 1,  $p = 1/3$  for outcome 2, and  $p = 1/6$  for outcome 3.

```
p = [1/2 1/3 1/6];  
n = 10;  
x1 = 0:n;  
x2 = 0:n;  
[X1,X2] = meshgrid(x1,x2);  
X3 = n - (X1+X2);
```

Compute the pdf of the distribution.

```
Y = mnpdf([X1(:),X2(:),X3(:)], repmat(p, (n+1)^2, 1));
```

Plot the pdf on a 3-dimensional figure.

```
Y = reshape(Y,n+1,n+1);  
bar3(Y)  
set(gca, 'XTickLabel', 0:n)  
set(gca, 'YTickLabel', 0:n)  
xlabel('x_1')  
ylabel('x_2')
```

```
zlabel('Probability Mass')
title('Trinomial Distribution')
```

Note that the visualization does not show  $x_3$ , which is determined by the constraint  $x_1 + x_2 + x_3 = n$ .

**How To**

- “Multinomial Distribution” on page B-93

# mnrfit

---

**Purpose** Multinomial logistic regression

**Syntax**  
B = mnrfi(X,Y)  
B = mnrfi(X,Y,Name,Value)  
[B,dev,stats] = mnrfi( \_\_\_ )

**Description** B = mnrfi(X,Y) returns a matrix, B, of coefficient estimates for a multinomial logistic regression of the nominal responses in Y on the predictors in X.

B = mnrfi(X,Y,Name,Value) returns a matrix, B, of coefficient estimates for a multinomial model fit with additional options specified by one or more Name,Value pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

[B,dev,stats] = mnrfi( \_\_\_ ) also returns the deviance of the fit, dev, and the structure stats for any of the previous input arguments. stats contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

## Input Arguments

### **X - Observations on predictor variables**

*n*-by-*p* matrix

Observations on predictor variables, specified as an *n*-by-*p* matrix. X contains *n* observations for *p* predictors.

---

**Note** mnrfi automatically includes a constant term (intercept) in all models. Do not include a column of 1s in X.

---

### **Data Types**

single | double

## **Y - Response values**

*n*-by-*k* matrix | *n*-by-1 column vector

Response values, specified as a column vector or a matrix. Y can be one of the following:

- An *n*-by-*k* matrix, where  $Y(i,j)$  is the number of outcomes of the multinomial category *j* for the predictor combinations given by  $X(i,:)$ . In this case, the number of observations are made at each predictor combination.
- An *n*-by-1 column vector of scalar integers from 1 to *k* indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An *n*-by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** 'Model', 'ordinal', 'Link', 'probit' specifies an ordinal model with a probit link function.

## **'Model' - Type of model to fit**

'nominal' (default) | 'ordinal' | 'hierarchical'

Type of model to fit, specified as the comma-separated pair consisting of 'Model' and one of the following.

'nominal'	Default. There is no ordering among the response categories.
'ordinal'	There is a natural ordering among the response categories.
'hierarchical'	The choice of response category is sequential/nested.

**Example:** 'Model', 'ordinal'

**'Interactions' - Indicator for interaction between multinomial categories and coefficients**

'on' | 'off'

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of 'Interactions' and one of the following.

'on'	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
'off'	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or the <i>proportional odds model</i> .

In all cases, the model has different intercepts across categories. The choice of 'Interactions' determines the dimensions of the output array B.

**Example:** 'Interactions', 'off'

**Data Types**

logical

**'Link' - Link function**

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'Link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1-\gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1-\gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors,  $X\beta$ . The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model,  $\gamma$  represents the cumulative probability of being in categories 1 to  $j$  and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1-\gamma}\right) = \ln\left(\frac{\pi_1 + \pi_2 + \dots + \pi_j}{\pi_{j+1} + \dots + \pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p,$$

where  $k$  represents the last category.

You cannot specify the 'Link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \dots + \beta_{jp} X_{jp}, \quad j = 1, \dots, k-1,$$

where  $\pi$  stands for a categorical probability, and  $r$  corresponds to the reference category. mnrfit uses the last category as the reference category for nominal models.

**Example:** 'Link', 'loglog'

**'EstDisp' - Indicator for estimating dispersion parameter**

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'EstDisp' and one of the following.

'off'	Default. Use the theoretical dispersion value of 1.
'on'	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

**Example:** 'EstDisp', 'on'

## Output Arguments

### **B - Coefficient estimates**

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in  $Y$ , returned as a vector or a matrix.

- If 'Interaction' is 'off', then  $B$  is a  $k - 1 + p$  vector. The first  $k - 1$  rows of  $B$  correspond to the intercept terms, one for each  $k - 1$  multinomial categories, and the remaining  $p$  rows correspond to the predictor coefficients, which are common for all of the first  $k - 1$  categories.
- If 'Interaction' is 'on', then  $B$  is a  $(p + 1)$ -by- $(k - 1)$  matrix. Each column of  $B$  corresponds to the estimated intercept term and predictor coefficients, one for each of the first  $k - 1$  multinomial categories.

The estimates for the  $k$ th category are taken to be zero as `mnrfit` takes the last category as the reference category.

### **dev - Deviance of the fit**

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_i^n \sum_j^k y_{ij} * \log \left( \frac{y_{ij}}{\pi_{ij} * m_i} \right) = \sum_i^n rd_i,$$

where  $rd_i$  are the deviance residuals. For deviance residuals see `stats`.

**stats - Model statistics**

structure

Model statistics, returned as a structure that contains the following fields.

beta	The coefficient estimates. These are the same as B.
dfe	Degrees of freedom for error <ul style="list-style-type: none"> <li>• If 'Interactions' is 'off', then degrees of freedom is <math>n*(k - 1) - (k - 1 + p)</math>.</li> <li>• If 'Interactions' is 'on', then degrees of freedom is <math>(n - p + 1)*(k - 1)</math>.</li> </ul>
sfit	Estimated dispersion parameter.
s	Theoretical or estimated dispersion parameter. <ul style="list-style-type: none"> <li>• If 'Estdisp' is 'off', then s is the theoretical dispersion parameter, 1.</li> <li>• If 'Estdisp' is 'on', then s is equal to the estimated dispersion parameter, sfit.</li> </ul>
estdisp	Indicator for a theoretical or estimated dispersion parameter.
se	Standard errors of coefficient estimates, B.
coeffcorr	Estimated correlation matrix for B.
covb	Estimated covariance matrix for B.
t	<i>t</i> statistics for B.
p	<i>p</i> -values for B.

resid	<p>Raw residuals. Observed minus fitted values,</p> $r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where <math>\pi_{ij}</math> is the categorical, cumulative or conditional probability, and <math>m_i</math> is the corresponding sample size.</p>
residp	<p>Pearson residuals, which are the raw residuals scaled by the estimated standard deviation:</p> $rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k \end{cases}$ <p>where <math>\pi_{ij}</math> is the categorical, cumulative, or conditional probability, and <math>m_i</math> is the corresponding sample size.</p>
residd	<p>Deviance residuals:</p> $rd_i = 2 * \sum_j^k y_{ij} * \log\left(\frac{y_{ij}}{\pi_{ij} * m_i}\right), \quad i = 1, \dots, n.$ <p>where <math>\pi_{ij}</math> is the categorical, cumulative, or conditional probability, and <math>m_i</math> is the corresponding sample size.</p>

## Examples

### Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

```
sp = categorical(species);
```

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfit(meas,sp);  
B
```

B =

13.3860	15.4492
2.4623	1.8196
5.2948	2.5700
-7.4916	-4.3714
-8.9322	-7.6467

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, `setosa` and `versicolor` versus the reference category, `virginica`. The last four rows contain the slopes for the models for the first two categories. `mnrfit` accepts the third category as the reference category.

The models for the relative risk of an iris flower being a `setosa` versus a `virginica`, and the relative risk of an iris flower being a `versicolor` species versus a `virginica` species are respectively

$$\ln\left(\frac{\pi_{setosa}}{\pi_{virginica}}\right) = 13.38 + 2.46X_1 + 5.29X_2 - 7.49X_3 - 8.93X_4$$

and

$$\ln\left(\frac{\pi_{versicolor}}{\pi_{virginica}}\right) = 15.45 + 1.82X_1 + 2.57X_2 - 4.37X_3 - 7.65X_4.$$

The coefficients express the effects of the predictor variables on the relative risk or the log odds of being in one category versus the reference category.

For example, the estimated coefficient 2.46 indicates that the probability of being species 1 (setosa) compared to the probability of being species 3 (virginica) (the relative risk of being a setosa versus a virginica) increases  $\exp(2.46)$  times for each unit increase in  $X_1$ , the first measurement, given all else equal.

In terms of log odds, you can say that the relative log odds of being a setosa versus a virginica increases 2.46 times with a one-unit increase in  $X_1$  given all else is equal.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans =
```

```
0.2457    0.0031
0.4543    0.1048
0.0773    0.0815
0.0258    0.0007
0.1856    0.0002
```

The  $p$ -value of 0.0258 indicates that the third measure is significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3). The  $p$ -values of 0.0007 and 0.0002 indicate that the third

and fourth measures are significant on the relative risk of being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```
stats.se
```

```
ans =
```

```

11.5316    5.2201
 3.2905    1.1218
 2.9976    1.4753
 3.3609    1.2869
 6.7474    2.0846

```

Calculate the 95% confidence limits for the coefficients.

```
LL = stats.beta - 1.96.*stats.se;
UL = stats.beta + 1.96.*stats.se;
```

Display the confidence intervals for the coefficients of the model for the relative risk of being a setosa versus a virginica (the first column of coefficients in B).

```
[LL(:,1) UL(:,1)]
```

```
ans =
```

```

-9.2160    35.9880
-3.9869     8.9116
-0.5805    11.1701
-14.0790   -0.9043
-22.1570     4.2926

```

Find the confidence intervals for the coefficients of the model for the relative risk of being a versicolor versus a virginica (the second column of coefficients in B).

```
[LL(:,2) UL(:,2)]
```

```
ans =  
  
    5.2177    25.6807  
   -0.3791     4.0184  
   -0.3216     5.4615  
   -6.8938    -1.8490  
  -11.7324    -3.5610
```

### **Multinomial Regression for Ordinal Responses**

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load('carbig.mat')  
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9–19 as 1, 20–29 as 2, 30–39 as 3, and 40–48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfits(X,miles,'model','ordinal');  
B
```

```
B =  
  
   -16.6895  
   -11.7208  
    -8.0606  
     0.1048
```

```
0.0103
0.0645
0.0017
```

The first three elements of **B** are the intercept terms for the models, and the last four elements of **B** are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions', 'off' name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans =
-16.6895 -11.7208 -8.0606
 0.1048  0.1048  0.1048
 0.0103  0.0103  0.0103
 0.0645  0.0645  0.0645
 0.0017  0.0017  0.0017
```

The link function in the model is `logit('link','logit')`, which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln\left(\frac{P(\text{mpg} \leq 19)}{P(\text{mpg} > 19)}\right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 29)}{P(\text{mpg} > 29)}\right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 39)}{P(\text{mpg} > 39)}\right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of  $\exp(0.1048)$  given all else is equal.

Assess the significance of the coefficients.

```
stats.p
```

```
ans =
```

```
0.0000
0.0000
0.0000
0.1899
0.0350
0.0000
0.0118
```

The  $p$ -values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

## Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load smoking
```

The data set `smoking` contains five variables: `sex`, `age`, `weight`, and `systolic` and `diastolic` blood pressure. `Sex` is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = categorical(smoking.Smoker);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1–5 cigarettes a day
- 2: Smoker, 6–10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
     smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfity(X,Y,'model','hierarchical');
```

```
B
```

```
B =
```

43.8148	5.9571	44.0712
1.8709	-0.0230	0.0662
0.0188	0.0625	0.1335
0.0046	-0.0072	-0.0130
-0.2170	0.0416	-0.0324
-0.2273	-0.1449	-0.4824

The first column of **B** includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1–5 cigarettes a day versus more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}$$

$$\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A + 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}$$

$$\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by  $\exp(1.8709) = 6.49$  times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

```
0.0000    0.5363    0.2149
0.3549    0.9912    0.9835
0.6850    0.2676    0.2313
0.9032    0.8523    0.8514
0.0009    0.5187    0.8165
0.0004    0.0483    0.0545
```

Sex, age, or weight don't appear significant on any level. The  $p$ -values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The  $p$ -value of 0.0483 shows that only diastolic blood pressure is significant on the odds of a person smoking 0–5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the  $p$ -value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6–10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()
gscatter(smoking.Age,smoking.Weight,smoking.Sex)
legend('Male','Female')
xlabel('Age')
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...
```

```
smoking.DiastolicBP]);
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');
B
```

```
B =
```

```
    44.8456    5.3230    25.0248
     1.6045    0.2330    0.4982
    -0.2161    0.0497    0.0179
    -0.2222   -0.1358   -0.3092
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by  $\exp(1.6045) = 4.97$  times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an  $\exp(-.2161) = 0.8056$  decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an  $\exp(-.2222) = 0.8007$  decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans =
```

```
    0.0000    0.4715    0.2325
    0.0210    0.7488    0.6362
    0.0010    0.4107    0.8899
    0.0003    0.0483    0.0718
```

The  $p$ -values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the  $p$ -value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the  $p$ -values on the third column are less than 0.05,

you can say that none of the variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

**Algorithms**     `mnrfit` treats NaNs in either X or Y as missing values, and ignores them.

**Purpose** Multinomial random numbers

**Syntax**

```
r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)
```

**Description** `r = mnrnd(n,p)` returns random values `r` from the multinomial distribution with parameters `n` and `p`. `n` is a positive integer specifying the number of trials (sample size) for each multinomial outcome. `p` is a 1-by-`k` vector of multinomial probabilities, where `k` is the number of multinomial bins or categories. `p` must sum to one. (If `p` does not sum to one, `r` consists entirely of NaN values.) `r` is a 1-by-`k` vector, containing counts for each of the `k` multinomial bins.

`R = mnrnd(n,p,m)` returns `m` random vectors from the multinomial distribution with parameters `n` and `p`. `R` is a `m`-by-`k` matrix, where `k` is the number of multinomial bins or categories. Each row of `R` corresponds to one multinomial outcome.

`R = mnrnd(N,P)` generates outcomes from different multinomial distributions. `P` is a `m`-by-`k` matrix, where `k` is the number of multinomial bins or categories and each of the `m` rows contains a different set of multinomial probabilities. Each row of `P` must sum to one. (If any row of `P` does not sum to one, the corresponding row of `R` consists entirely of NaN values.) `N` is a `m`-by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a `m`-by-1 vector). `R` is a `m`-by-`k` matrix. Each row of `R` is generated using the corresponding rows of `N` and `P`.

**Examples** Generate 2 random vectors with the same probabilities:

```
n = 1e3;
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
    215    282    503
    194    303    503
```

# mnrnd

---

Generate 2 random vectors with different probabilities:

```
n = 1e3;  
P = [0.2, 0.3, 0.5; ...  
     0.3, 0.4, 0.3;];  
R = mnrnd(n,P)  
R =  
    186    290    524  
    290    389    321
```

## How To

- “Multinomial Distribution” on page B-93

**Purpose**

Multinomial logistic regression values

**Syntax**

```
pihat = mnrvl(B,X)
[pihat,dlow,dhi] = mnrvl(B,X,stats)
[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)

yhat = mnrvl(B,X,ssize)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)
```

**Description**

`pihat = mnrvl(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors,  $X$ , and the coefficient estimates,  $B$ .

`pihat` is an  $n$ -by- $k$  matrix of predicted probabilities for each multinomial category.  $B$  is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And  $X$  is an  $n$ -by- $p$  matrix which contains  $n$  observations for  $p$  predictors.

---

**Note** `mnrvl` automatically includes a constant term in all models. Do not enter a column of 1s in  $X$ .

---

`[pihat,dlow,dhi] = mnrvl(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

# mnrval

---

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrvl(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

## Input Arguments

### **B - Coefficient estimates**

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

**Example:** `B = mnrfit(X,y); pihat = mnrvl(B,X)`

### **Data Types**

single | double

### **X - Sample data**

matrix

Sample data on predictors, specified as an  $n$ -by- $p$ .  $X$  contains  $n$  observations for  $p$  predictors.

---

**Note** `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in  $X$ .

---

**Example:** `pihat = mnrval(B,X)`

### Data Types

single | double

### stats - Model statistics

structure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

**Example:** `[B,dev,stats] = mnrfit(X,y);[pihat,dlo,dhi] = mnrval(B,X,stats)`

### ssize - Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an  $n$ -by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is  $y_1$ ,  $y_2$ , and  $y_3$ , respectively, then the sample size,  $m$ , for that observation is  $m = y_1 + y_2 + y_3$ .

If the sample sizes for  $n$  observations are in vector `sample`, then you can enter the sample sizes as follows.

**Example:** `yhat = mnrval(B,X,sample)`

## Data Types

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### Example:

`'model','ordinal','link','probit','type','cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

## 'model' - Type of multinomial model

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

<code>'nominal'</code>	Default. Specify when there is no ordering among the response categories.
<code>'ordinal'</code>	Specify when there is a natural ordering among the response categories.
<code>'hierarchical'</code>	Specify when the choice of response category is sequential.

Example: `'model','ordinal'`

## 'interactions' - Indicator for interaction between multinomial categories and coefficients

`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of `'interactions'` and one of the following.

'on'	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
'off'	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or <i>proportional odds model</i> .

**Example:** 'interactions','off'

### Data Types

logical

### 'link' - Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors,  $X\beta$ .

$\gamma$  might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \cdots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k-1,$$

where  $\pi$  stands for a categorical probability, and  $r$  corresponds to the reference category,  $k$  is the total number of response categories,  $p$  is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

**Example:** 'link','loglog'

### 'type' - Type of probabilities or counts to estimate

'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including 'type' and one of the following.

'category'	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the $k$ multinomial categories.
'cumulative'	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first $k - 1$ multinomial categories, as an $n$ -by- $(k - 1)$ matrix. The predicted cumulative probability for the $k$ th category is always 1.
'conditional'	Specify to return predictions and error bounds in terms of the first $k - 1$ conditional category probabilities (counts), i.e., the probability (count) for category $j$ , given an outcome in category $j$ or higher. When 'type' is 'conditional', and you supply the sample size argument <code>ssize</code> , the predicted counts at each row of $X$ are conditioned on the corresponding element of <code>ssize</code> , across all categories.

**Example:** 'type','cumulative'

## Output Arguments

### 'confidence' - Confidence level

0.95 (default) | Scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

**Example:** 'confidence',0.99

### Data Types

single | double

### pihat - Probability estimates

$n$ -by- $(k - 1)$  matrix

Probability estimates for each multinomial category, returned as an  $n$ -by- $(k - 1)$  matrix, where  $n$  is the number of observations, and  $k$  is the number of response categories.

### yhat - Count estimates

$n$ -by- $k - 1$  matrix

Count estimates for the number in each response category, returned as an  $n$ -by- $k - 1$  matrix, where  $n$  is the number of observations, and  $k$  is the number of response categories.

### dlow - Lower error bound

column vector

Lower error bound to compute the lower confidence bound for pihat or yhat, returned as a column vector.

The lower confidence bound for pihat is pihat minus dlow. Similarly, the lower confidence bound for yhat is yhat minus dlow. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

### dhi - Upper error bound

column vector

Upper error bound to compute the upper confidence bound for `pihat` or `yhat`, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

## Examples

### Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2, 3.7, 5.8, 0.2];
```

```
pihat = mnrval(B,x);  
pihat  
  
pihat =  
  
    0.0017    0.9982    0.0001
```

The probability of an iris flower having the measurements (6.2, 3.7, 5.8, 0.2) being a setosa is 0.0017, a versicolor is 0.9982, and a virginica is 0.0001.

### **Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses**

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')  
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);  
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable miles. For an ordinal model, the default 'link' is logit and the default 'interactions' is 'off'.

```
[B,dev,stats] = mnrfit(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with  $x = (12, 113, 110, 2670)$ .

```
x = [12,113,110,2670];  
[pihat,dlow,hi] = mnrvl(B,x,stats,'model','ordinal');  
pihat
```

```
pihat =
```

```
    0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;  
UL = pihat + hi;  
[LL;UL]
```

```
ans =
```

```
    0.0073    0.7829    0.0283   -0.0003  
    0.1157    0.9022    0.1580    0.0057
```

## Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load('fisheriris.mat')
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);  
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.2, 3.7, 5.8, 0.2).

```
x = [6.2,3.7,5.8,0.2];  
yhat = mnrval(B,x,18)
```

```
yhat =
```

```
0.0314    17.9671    0.0016
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;  
UL = yhat + hi;  
[LL;UL]
```

```
ans =
```

```
-0.7084    17.2272   -0.0115  
0.7711    18.7069    0.0146
```

## Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';  
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10; ...  
     5 14 6; 7 13 5; 8 11 6];  
[Y x]
```

```
ans =
```

```
1    11    13    -3  
2     9    14    -2  
6    14     5    -1  
5    10    10     0  
5    14     6     1  
7    13     5     2  
8    11     6     3
```

There are observations on seven different values of the predictor variable  $x$ . The response variable  $Y$  has three categories and the data shows how many of the 25 individuals are in each category of  $Y$  for each observation of  $x$ . For example, when  $x$  is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when  $x$  is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the  $x$  values, on a stacked bar graph.

```
bar(x,Y,'stacked');  
ylim([0 25]);
```

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable,  $x$ , for each category.

```
betaHatNom = mnrfit(x,Y,'model','nominal',...  
    'interactions','on')
```

```
betaHatNom =  
  
    -0.6028    0.3832  
    0.4068    0.1948
```

The first row of `betaHatOrd` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfit` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';  
piHatNom = mnrvl(betaHatNom,xx,'model','nominal',...  
    'interactions','on');
```

The probability of being in the third category is simply  $1 - P(Y = 1) - P(Y = 2)$ .

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```

The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable,  $x$ , across all categories:

```
betaHatOrd = mnrfits(x,Y,'model','ordinal',...
    'interactions','off')
```

```
betaHatOrd =  
  
    -1.5001  
     0.7266  
     0.2642
```

The first two elements of `betaHatOrd` are the intercept terms for the first two response categories. The last element of `betaHatOrd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHatOrd = mnrvl(betaHatOrd,xx,'type','cumulative',...  
                'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()  
bar(x,cumsum(Y,2),'grouped');  
ylim([0 25]);  
line(xx,25*piHatOrd,'LineWidth',2);
```

## **Concepts**

- “Multinomial Models for Nominal Responses” on page 10-2
- “Multinomial Models for Ordinal Responses” on page 10-5
- “Hierarchical Multinomial Models” on page 10-9

**Purpose**

Central moments

**Syntax**

```
m = moment(X,order)
moment(X,order,dim)
```

**Description**

`m = moment(X,order)` returns the central sample moment of  $X$  specified by the positive integer order. For vectors, `moment(x,order)` returns the central moment of the specified order for the elements of  $x$ . For matrices, `moment(X,order)` returns central moment of the specified order for each column. For N-dimensional arrays, `moment` operates along the first nonsingleton dimension of  $X$ .

`moment(X,order,dim)` takes the moment along dimension `dim` of  $X$ .

**Tips**

Note that the central first moment is zero, and the second central moment is the variance computed using a divisor of  $n$  rather than  $n - 1$ , where  $n$  is the length of the vector  $x$  or the number of rows in the matrix  $X$ .

The central moment of order  $k$  of a distribution is defined as

$$m_k = E(x - \mu)^k$$

where  $E(x)$  is the expected value of  $x$ .

**Examples**

```
X = randn([6 5])
X =
    1.1650    0.0591    1.2460   -1.2704   -0.0562
    0.6268    1.7971   -0.6390    0.9846    0.5135
    0.0751    0.2641    0.5774   -0.0449    0.3967
    0.3516    0.8717   -0.3600   -0.7989    0.7562
   -0.6965   -1.4462   -0.1356   -0.7652    0.4005
    1.6961   -0.7012   -1.3493    0.8617   -1.3414

m = moment(X,3)
m =
   -0.0282    0.0571    0.1253    0.1460   -0.4486
```

# moment

---

## **See Also**

kurtosis | mean | skewness | std | var

**Purpose** Input matrix of means  $\mu$

**Description** Input matrix of means  $\mu$ .

# multcompare

---

**Purpose** Multiple comparison test

**Syntax**

```
c = multcompare(stats)
c = multcompare(stats,param1,val1,param2,val2,...)
[c,m] = multcompare(...)
[c,m,h] = multcompare(...)
[c,m,h,gnames] = multcompare(...)
```

**Description** `c = multcompare(stats)` performs a multiple comparison test using the information in the `stats` structure, and returns a matrix `c` of pairwise comparison results. It also displays an interactive graph of the estimates with comparison intervals around them. See “Examples” on page 21-2358.

In a one-way analysis of variance, you compare the means of several groups to test the hypothesis that they are all the same, against the general alternative that they are not all the same. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A test that can provide such information is called a *multiple comparison procedure*.

When you perform a simple *t*-test of one group mean against another, you specify a significance level that determines the cutoff value of the *t* statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary *t*-test in this situation, the `alpha` value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

The output `c` contains the results of the test in the form of a six-column matrix. Each row of the matrix represents one test, and there is one row for each pair of groups. The entries in the row indicate the means being compared, the estimated difference in means, a confidence

interval for the difference, and a  $p$ -value for the hypothesis test that the corresponding mean difference is different from zero.

For example, suppose one row contains the following entries.

```
2.0000  5.0000  1.9442  8.2206  14.4971  0.0432
```

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971]. The  $p$ -value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0.0, so the difference is significant at the 0.05 level. If the confidence interval did contain 0.0, the difference would not be significant at the 0.05 level. The  $p$ -value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from zero.

The `multcompare` function also displays a graph with each group mean represented by a symbol and an interval around the symbol. Two means are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. You can use the mouse to select any group, and the graph will highlight any other groups that are significantly different from it.

`c = multcompare(stats,param1,val1,param2,val2,...)` specifies one or more of the parameter name/value pairs described in the following table.

# multcompare

---

Parameter	Values
'alpha'	Scalar between 0 and 1 that determines the confidence levels of the intervals in the matrix <code>c</code> and in the figure (default is 0.05). The confidence level is $100(1 - \alpha)\%$ .
'display'	Either 'on' (the default) to display a graph of the estimates with comparison intervals around them, or 'off' to omit the graph. See “Examples” on page 21-2358.
'ctype'	Specifies the type of critical value to use for the multiple comparison. “Values of <code>ctype</code> ” on page 21-2355 describes the allowed values for <code>ctype</code> .
'dimension'	A vector specifying the dimension or dimensions over which the population marginal means are to be calculated. Use only if you create stats with the function <code>anovan</code> . The default is 1 to compute over the first dimension. See “Dimension Parameter” on page 21-2357 for more information.
'estimate'	Specifies the estimate to be compared. The allowable values of <code>estimate</code> depend on the function that was the source of the stats structure, as described in “Values of <code>estimate</code> ” on page 21-2356

`[c,m] = multcompare(...)` returns an additional matrix `m`. The first column of `m` contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

`[c,m,h] = multcompare(...)` returns a handle `h` to the comparison graph. Note that the title of this graph contains instructions for interacting with the graph, and the *x*-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit

the title and the *x*-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')
xlabel('')
```

`[c,m,h,gnames] = multcompare(...)` returns `gnames`, a cell array with one row for each group, containing the names of the groups.

The intervals shown in the graph are computed so that to a very close approximation, two estimates being compared are significantly different if their intervals are disjoint, and are not significantly different if their intervals overlap. (This is exact for multiple comparison of means from `anova1`, if all means are based on the same sample size.) You can click on any estimate to see which means are significantly different from it.

### Values of `ctype`

The following table describes the allowed values for the parameter `ctype`.

Value	Description
'hsd' or 'tukey-kramer'	Use Tukey's honestly significant difference criterion. This is the default, and it is based on the Studentized range distribution. It is optimal for balanced one-way ANOVA and similar procedures with equal sample sizes. It has been proven to be conservative for one-way ANOVA with different sample sizes. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.
'lsd'	Use Tukey's least significant difference procedure. This procedure is a simple <i>t</i> -test. It is reasonable if the preliminary test (say, the one-way ANOVA <i>F</i> statistic) shows a significant difference. If it is

# multcompare

Value	Description
	used unconditionally, it provides no protection against multiple comparisons.
'bonferroni'	Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. This procedure is conservative, but usually less so than the Scheffé procedure.
'dunn-sidak'	Use critical values from the t distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. This procedure is similar to, but less conservative than, the Bonferroni procedure.
'scheffe'	Use critical values from Scheffé's S procedure, derived from the F distribution. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.

## Values of estimate

The allowable values of the parameter 'estimate' depend on the function that was the source of the stats structure, according to the following table.

Source	Values
'anova1'	Ignored. Always compare the group means.
'anova2'	Either 'column' (the default) or 'row' to compare column or row means.
'anovan'	Ignored. Always compare the population marginal means as specified by the dim argument.

Source	Values
'aoctool'	Either 'slope', 'intercept', or 'pmm' to compare slopes, intercepts, or population marginal means. If the analysis of covariance model did not include separate slopes, then 'slope' is not allowed. If it did not include separate intercepts, then no comparisons are possible.
'friedman'	Ignored. Always compare average column ranks.
'kruskalwallis'	Ignored. Always compare average group ranks.

### Dimension Parameter

The dimension parameter is a vector specifying the dimension or dimensions over which the population marginal means are to be calculated. For example, if  $\text{dim} = 1$ , the estimates that are compared are the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If  $\text{dim} = [1 \ 3]$ , population marginal means are computed for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by  $\text{dim}$ , and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of

# multcompare

---

observations at each combination does have meaning, population marginal means may be harder to interpret.

## **Examples**      **Multiple Comparison of Group Means**

Load the sample data.

```
load carsmall
```

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

```
[p,t,stats] = anova1(MPG,Origin,'off');
```

Perform a multiple comparison of the group means.

```
[c,m,h,nms] = multcompare(stats);
```

multcompare displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

```
[nms num2cell(m)]
```

```
ans =  
  
      'USA'      [21.1328]      [0.8814]  
      'Japan'    [31.8000]      [1.8206]  
      'Germany'  [28.4444]      [2.3504]  
      'France'   [23.6667]      [4.0711]  
      'Sweden'   [22.5000]      [4.9860]  
      'Italy'    [      28]      [7.0513]
```

## Multiple Comparison of Material Strength

Input the data.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...  
            78 75 76 77 79 79 77 78 82 79];  
alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...  
         'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...  
         'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

The data are from a study of the strength of structural beams in Hogg (1987). The vector `strength` measures deflections of beams in thousandths of an inch under 3,000 pounds of force. The vector `alloy` identifies each beam as steel ('st'), alloy 1 ('al1'), or alloy 2 ('al2'). Although `alloy` is sorted in this example, grouping variables do not need to be sorted.

First perform one-way ANOVA.

```
[p,a,s] = anova1(strength,alloy);
```

ANOVA Table

Source	SS	df	MS	F	Prob>F
Groups	184.8	2	92.4	15.4	0.0002
Error	102	17	6		
Total	286.8	19			

# multcompare

---

The small  $p$ -value suggests that the strength of the beams is not the same.

Now, perform a multiple comparison of the mean strength of the beams.

```
[c,m,h,nms] = multcompare(s);
```

Display the comparison results with the corresponding group names.

```
[nms(c(:,1)), nms(c(:,2)), num2cell(c(:,3:6))]
```

ans =

'st'	'al1'	[ 3.6064]	[ 7]	[10.3936]	[1.6831e-04]
'st'	'al2'	[ 1.6064]	[ 5]	[ 8.3936]	[ 0.0040]
'al1'	'al2'	[-5.6280]	[-2]	[ 1.6280]	[ 0.3560]

The third row of the output matrix shows that the differences in strength between the two alloys is not significant. A 95% confidence interval for the difference is [-5.6, 1.6], so you cannot reject the hypothesis that the true difference is zero. This is also confirmed by the corresponding  $p$ -value of 0.3560 in the sixth column.

The first two rows show that both comparisons involving the first group (steel) have confidence intervals that do not include zero. And the corresponding  $p$ -values (1.6831e-04 and 0.0040, respectively) are small. In other words, those differences are significant. The graph shows the same information.

# RepeatedMeasuresModel.multcompare

---

**Purpose** Multiple comparison of estimated marginal means

**Syntax**  
`tbl = multcompare(rm,var)`  
`tbl = multcompare(rm,var,Name,Value)`

**Description** `tbl = multcompare(rm,var)` returns multiple comparisons of the estimated marginal means based on the variable `var` in the repeated measures model `rm`.

`tbl = multcompare(rm,var,Name,Value)` returns multiple comparisons of the estimated marginal means with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the comparison type or which variable to group by.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **var - Variables for which to compute marginal means**

string

Variables for which to compute the marginal means, specified as a string representing the name of a between- or within-subjects factor in `rm`. If `var` is a between-subjects factor, it must be categorical.

### **Data Types**

char | cell

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

# RepeatedMeasuresModel.multcompare

---

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'Alpha' - Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 through 1. The confidence level is  $100 \times (1 - \alpha)\%$ .

**Example:** 'alpha',0.01

## Data Types

double | single

## 'By' - Factor to perform comparisons by

string

Factor to do the comparisons by, specified as the comma-separated pair consisting of 'By' and a string. The comparison between levels of var occurs separately for each value of the factor you specify.

If you have more than one between-subjects factors, *A*, *B*, and *C*, and if you want to do the comparisons of *A* levels separately for each level of *C*, then specify *A* as the var argument and specify *C* using the 'By' argument as follows.

**Example:** 'By',C

## Data Types

char

## 'ComparisonType' - Type of critical value to use

'tukey-kramer' (default) | 'dunn-sidak' | 'bonferroni' | 'scheffe' | 'lsd'

Type of critical value to use, specified as the comma-separated pair consisting of 'ComparisonType' and one of the following.

# RepeatedMeasuresModel.multcompare

Comparison Type	Definition
'tukey-kramer'	Default. Also called Tukey's Honest Significant Difference procedure. It is based on the Studentized range distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.
'dunn-sidak'	Use critical values from the $t$ distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is $t_{1-\eta/2, v}$ where $\eta = 1 - (1 - \alpha)^{1/\binom{ng}{2}}$ and $ng$ is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure.

# RepeatedMeasuresModel.multcompare

Comparison Type	Definition
'bonferroni'	<p>Use critical values from the <math>t</math> distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is</p> $t_{\alpha/2\left(\frac{ng}{2}\right),v},$ <p>where <math>ng</math> is the number of groups (marginal means), and <math>v</math> is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure.</p>
'scheffe'	<p>Use critical values from Scheffé's <math>S</math> procedure, derived from the <math>F</math> distribution. The critical value is</p> $\sqrt{(ng-1)F_{\alpha,ng-1,v}},$ <p>where <math>ng</math> is the number of groups (marginal means), and <math>v</math> is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative</p>

Comparison Type	Definition
	for comparisons of simple differences of pairs.
'lsd'	Least significant difference. This option uses plain <i>t</i> -tests. The critical value is $t_{\alpha/2,v}$ , where <i>v</i> is the error degrees of freedom. It provides no protection against the multiple comparison problem.

Example: 'ComparisonType', 'dunn-sidak'

## Output Arguments

### **tbl** - Results of multiple comparison

table

Results of multiple comparisons of estimated marginal means, returned as a table. **tbl** has the following columns.

Column Name	Description
Difference	Estimated difference between the corresponding two marginal means
StdErr	Standard error of the estimated difference between the corresponding two marginal means
pValue	<i>p</i> -value for a test that the difference between the corresponding two marginal means is 0
Lower	Lower limit of simultaneous 95% confidence intervals for the true difference
Upper	Upper limit of simultaneous 95% confidence intervals for the true difference

# RepeatedMeasuresModel.multcompare

---

## Examples

### Multiple Comparison of Estimated Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```
tbl = multcompare(rm,'species')
```

```
tbl =
```

species_1	species_2	Difference	StdErr	pValue
'setosa'	'versicolor'	-1.0375	0.060539	9.5606e-10
'setosa'	'virginica'	-1.7495	0.060539	9.5606e-10
'versicolor'	'setosa'	1.0375	0.060539	9.5606e-10
'versicolor'	'virginica'	-0.712	0.060539	9.5606e-10
'virginica'	'setosa'	1.7495	0.060539	9.5606e-10
'virginica'	'versicolor'	0.712	0.060539	9.5606e-10

# RepeatedMeasuresModel.multcompare

The small  $p$ -values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

## Perform Multiple Comparisons with Specified Options

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
R = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within)
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`.

```
T = multcompare(R, 'Group')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower
A	B	4.9875	5.6271	0.65436	-9.1482
A	C	23.094	5.9261	0.0021493	8.2074
B	A	-4.9875	5.6271	0.65436	-19.123
B	C	18.107	5.8223	0.013588	3.4805
C	A	-23.094	5.9261	0.0021493	-37.98
C	B	-18.107	5.8223	0.013588	-32.732

# RepeatedMeasuresModel.multcompare

The small  $p$ -value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The  $p$ -values of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```
T = multcompare(R, 'Group', 'ComparisonType', 'Scheffe')
```

```
T =
```

Group_1	Group_2	Difference	StdErr	pValue	Lower
A	B	4.9875	5.6271	0.67981	-9.7795
A	C	23.094	5.9261	0.0031072	7.5426
B	A	-4.9875	5.6271	0.67981	-19.755
B	C	18.107	5.8223	0.018169	2.8273
C	A	-23.094	5.9261	0.0031072	-38.646
C	B	-18.107	5.8223	0.018169	-33.386

The Scheffe test produces larger  $p$ -values, but similar conclusions.

Perform multiple comparisons of estimated marginal means based on the variable `Group` for each gender separately.

```
T = multcompare(R, 'Group', 'By', 'Gender')
```

```
T =
```

Gender	Group_1	Group_2	Difference	StdErr	pValue
Female	A	B	4.1883	8.0177	0.86128
Female	A	C	24.565	8.2083	0.017697
Female	B	A	-4.1883	8.0177	0.86128
Female	B	C	20.376	8.1101	0.049957

# RepeatedMeasuresModel.multcompare

---

Female	C	A	-24.565	8.2083	0.017697
Female	C	B	-20.376	8.1101	0.049957
Male	A	B	5.7868	7.9498	0.74977
Male	A	C	21.624	8.1829	0.038022
Male	B	A	-5.7868	7.9498	0.74977
Male	B	C	15.837	8.0511	0.14414
Male	C	A	-21.624	8.1829	0.038022
Male	C	B	-15.837	8.0511	0.14414

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding  $p$ -values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding  $p$ -values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females ( $p$ -value is 0.049957), it is not significantly different from 0 for males ( $p$ -value is 0.14414).

# prob.MultinomialDistribution

---

**Superclasses** ParametricTruncatableDistribution

**Purpose** Multinomial probability distribution object

**Description** prob.MultinomialDistribution is an object consisting of parameters and a model description for a multinomial probability distribution. Create a probability distribution object with specified parameters using `makedist`.

**Construction** `pd = makedist('Multinomial')` creates a multinomial probability distribution object using the default parameter values.

`pd = makedist('Multinomial','Probabilities',probabilities)` creates a multinomial distribution object using the specified parameter value.

## Input Arguments

### probabilities - outcome probabilities

[0.500 0.500] (default) | vector of scalar values in the range [0,1]

Outcome probabilities, specified as a vector of scalar values in the range [0,1]. Each vector element is the probability that a multinomial trial has a particular corresponding outcome. The values in `probabilities` must sum to 1.

### Data Types

single | double

## Properties

### probabilities - outcome probabilities

vector of scalar values in the range [0,1]

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range [0,1]. The values in `probabilities` must sum to 1.

### Data Types

single | double

### DistributionName - Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

# prob.MultinomialDistribution

---

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object

random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Multinomial Distribution

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in  $n$  independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in  $n$  independent trials of a  $k$ -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities  $p_1, \dots, p_k$ .

The multinomial distribution uses the following parameters.

Parameter	Description	Support
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

The probability density function (pdf) is

$$f(x | n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k} \quad ; \quad \sum_1^k x_i = n, \sum_1^k p_i = 1,$$

# prob.MultinomialDistribution

---

where  $x = (x_1, \dots, x_k)$  gives the number of each  $k$  outcome in  $n$  trials of a process with fixed probabilities  $p = (p_1, \dots, p_k)$  of individual outcomes in any one trial.

## Examples

### Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
```

```
    0.5000    0.5000
```

### Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])
```

```
pd =
```

```
    MultinomialDistribution
```

```
    Probabilities:
```

```
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility
```

```
r = random(pd)
```

```
r =
```

```
2
```

The result of this trial is outcome 2. By default, the number of trials in each experiment,  $n$ , equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment,  $n$ , equals 1, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility  
r = random(pd,10,1)
```

```
r =
```

```
2
```

```
3
```

```
1
```

```
3
```

```
2
```

```
1
```

```
1
```

```
2
```

```
3
```

```
3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment,  $n$ , equals 5, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility  
r = random(pd,10,5)
```

```
r =
```

# prob.MultinomialDistribution

---

2	1	2	2	1
3	3	1	1	1
1	3	3	1	2
3	1	3	1	2
2	2	2	1	1
1	1	2	2	1
1	1	2	2	1
2	3	1	1	2
3	2	2	3	2
3	3	1	1	2

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

## Concepts

- “Multinomial Distribution” on page B-93
- Class Attributes
- Property Attributes

**Purpose**                    Multivari chart for grouped data

**Syntax**                    `multivarichart(y, GROUP)`  
                               `multivarichart(Y)`  
                               `multivarichart(..., param1, val1, param2, val2, ...)`  
                               `[charthandle, AXESH] = multivarichart(...)`

**Description**              `multivarichart(y, GROUP)` displays the multivari chart for the vector `y` grouped by entries in the cell array `GROUP`. Each cell of `GROUP` must contain a grouping variable that can be a categorical variable, numeric vector, character matrix, or single-column cell array of strings. `GROUP` can also be a matrix whose columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The *x*-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position  $(i,j)$  is the multivari chart for the subset of `y` at the *i*th level of the third grouping variable and the *j*th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(..., param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- 'varnames' — Grouping variable names in a character matrix or a cell array of strings, one per grouping variable. Default names are 'X1', 'X2', ... .
- 'plotorder' — A string with the value 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

# multivarichart

---

If 'plotorder' is a string with value 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2,3,1,4] indicates that the second grouping variable should be used as the x-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

[charthandle,AXESH] = multivarichart(...) returns a handle charthandle to the figure window and a matrix AXESH of handles to the subplot axes.

## Examples

### Multivari Chart for Grouped Data

Display a multivari chart for data with two grouping variables.

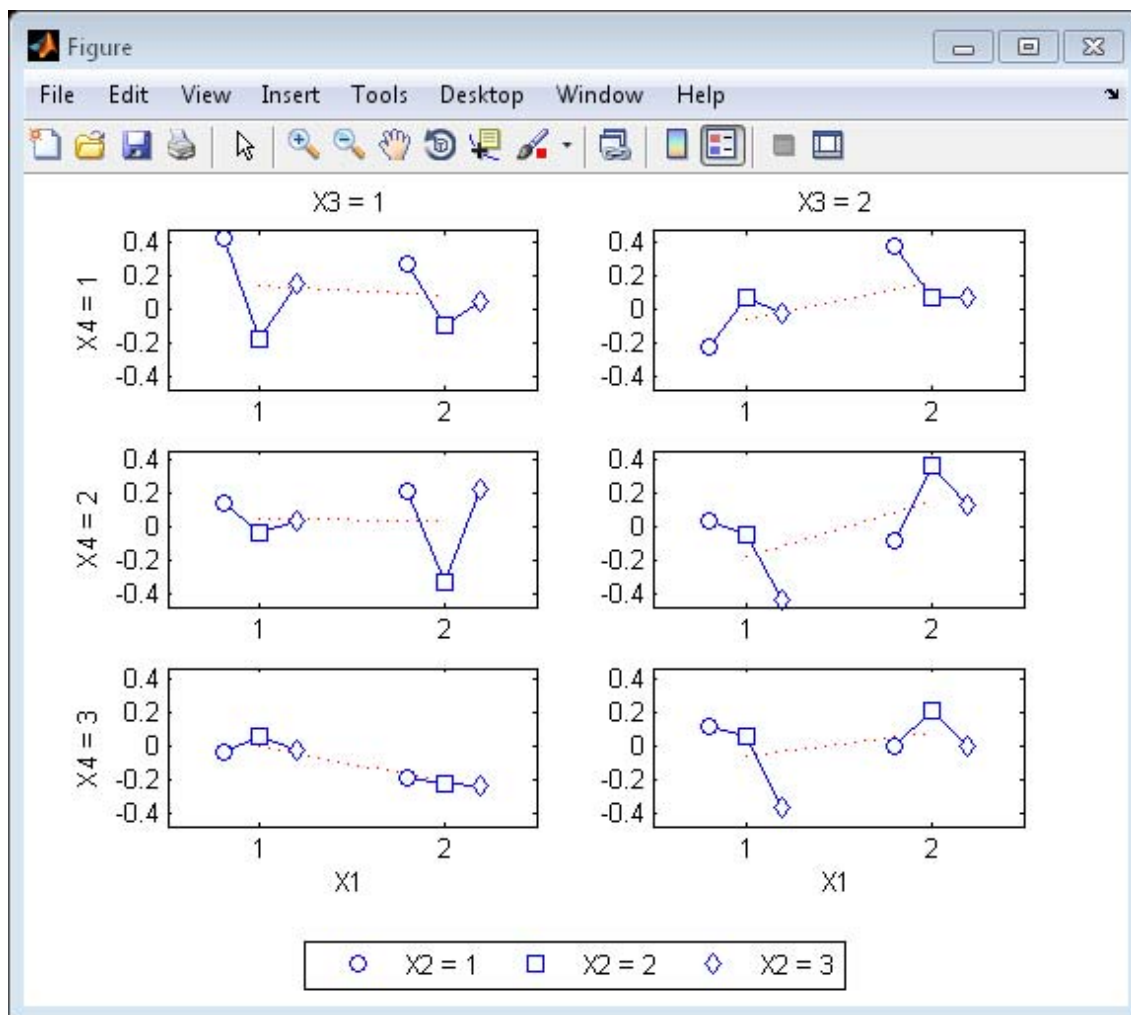

```
rng('default') % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

Display a multivari chart for data with four grouping variables.

```
y = randn(1000,1); % Randomly generate response  
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...  
         ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};  
multivarichart(y,group)
```

# multivarichart

## How To

- “Grouping Variables” on page 2-52

**Purpose**

Multivariate normal cumulative distribution function

**Syntax**

```
y = mvncdf(X)
y = mvncdf(X,mu,SIGMA)
y = mvncdf(xl,xu,mu,SIGMA)
[y,err] = mvncdf(...)
[...] = mvncdf(...,options)
```

**Description**

`y = mvncdf(X)` returns the cumulative probability of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of `X`. Rows of the  $n$ -by- $d$  matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `y` is an  $n$ -by-1 vector.

`y = mvncdf(X,mu,SIGMA)` returns the cumulative probability of the multivariate normal distribution with mean `mu` and covariance `SIGMA`, evaluated at each row of `X`. `mu` is a 1-by- $d$  vector, and `SIGMA` is a  $d$ -by- $d$  symmetric, positive definite matrix. `mu` can also be a scalar value, which `mvncdf` replicates to match the size of `X`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- $d$  vector containing just the diagonal. Pass in the empty matrix `[]` for `mu` to use as its default value when you want to only specify `SIGMA`.

The multivariate normal cumulative probability at `X` is defined as the probability that a random vector `V`, distributed as multivariate normal, will fall within the semi-infinite rectangle with upper limits defined by `X`, for example,  $\Pr\{V(1) \leq X(1), V(2) \leq X(2), \dots, V(d) \leq X(d)\}$ .

`y = mvncdf(xl,xu,mu,SIGMA)` returns the multivariate normal cumulative probability evaluated over the rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`[y,err] = mvncdf(...)` returns an estimate of the error in `y`. For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the  $t$  density, based on methods developed by Drezner and Wesolowsky and by Genz, as described in the references. The default absolute error tolerance for these cases is  $1e-8$ . For four or more dimensions, `mvncdf` uses a quasi-Monte Carlo integration

algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is  $1e-4$ .

`[...] = mvncdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters:

- `'TolFun'` — Maximum absolute error tolerance. Default is  $1e-8$  when  $d < 4$ , or  $1e-4$  when  $d \geq 4$ .
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when  $d \geq 4$ . Default is  $1e7$ . `'MaxFunEvals'` is ignored when  $d < 4$ .
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when  $d < 4$ .

## Examples

### Compute the Multivariate Normal cdf

Compute and plot the cdf of a multivariate normal distribution with parameters `mu = [1 -1]` and `SIGMA = [.9 .4; .4 .3]`.

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
figure;
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');
X = [X1(:) X2(:)];
p = mvncdf(X,mu,SIGMA);
surf(X1,X2,reshape(p,25,25));
```

## How To

- “Multivariate Normal Distribution” on page B-96

**Purpose**

Multivariate normal probability density function

**Syntax**

```
y = mvnpdf(X)
y = mvnpdf(X,MU)
y = mvnpdf(X,MU,SIGMA)
```

**Description**

`y = mvnpdf(X)` returns the  $n$ -by-1 vector `y`, containing the probability density of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the  $n$ -by- $d$  matrix `X`. Rows of `X` correspond to observations and columns correspond to variables or coordinates.

`y = mvnpdf(X,MU)` returns the density of the multivariate normal distribution with mean `mu` and identity covariance matrix, evaluated at each row of `X`. `MU` is a 1-by- $d$  vector, or an  $n$ -by- $d$  matrix. If `MU` is a matrix, the density is evaluated for each row of `X` with the corresponding row of `MU`. `MU` can also be a scalar value, which `mvnpdf` replicates to match the size of `X`.

`y = mvnpdf(X,MU,SIGMA)` returns the density of the multivariate normal distribution with mean `MU` and covariance `SIGMA`, evaluated at each row of `X`. `SIGMA` is a  $d$ -by- $d$  matrix, or a  $d$ -by- $d$ -by- $n$  array, in which case the density is evaluated for each row of `X` with the corresponding page of `SIGMA`, i.e., `mvnpdf` computes `y(i)` using `X(i,:)` and `SIGMA(:, :, i)`. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal, `SIGMA` may also be specified as a 1-by- $d$  vector or a 1-by- $d$ -by- $n$  array, containing just the diagonal. Specify `[]` for `MU` to use its default value when you want to specify only `SIGMA`.

If `X` is a 1-by- $d$  vector, `mvnpdf` replicates it to match the leading dimension of `mu` or the trailing dimension of `SIGMA`.

**Examples**

```
mu = [1 -1];
SIGMA = [.9 .4; .4 .3];
X = mvnrnd(mu,SIGMA,10);
p = mvnpdf(X,mu,SIGMA);
```

# **mvnpdf**

## **How To**

- “Multivariate Normal Distribution” on page B-96

**Purpose** Multivariate linear regression

**Syntax**

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

**Description** `beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression of the  $d$ -dimensional responses in  $Y$  on the design matrices in  $X$ .

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress( ___ )` also returns the estimated  $d$ -by- $d$  variance-covariance matrix of  $Y$ , using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress( ___ )` also returns a matrix of residuals  $E$ , estimated variance-covariance matrix of the regression coefficients  $CovB$ , and the value of the log likelihood objective function after the last iteration  $logL$ .

## Input Arguments

### **X - Design matrices**

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices.  $n$  is the number of observations in the data,  $K$  is the number of regression coefficients to estimate,  $p$  is the number of predictor variables, and  $d$  is the number of dimensions in the response variable matrix  $Y$ .

- If  $d = 1$ , then specify  $X$  as a single  $n$ -by- $K$  design matrix.

- If  $d > 1$  and all  $d$  dimensions have the same design matrix, then you can specify  $X$  as a single  $n$ -by- $p$  design matrix (not in a cell array).
- If  $d > 1$  and all  $n$  observations have the same design matrix, then you can specify  $X$  as a cell array containing a single  $d$ -by- $K$  design matrix.
- If  $d > 1$  and all  $n$  observations do not have the same design matrix, then specify  $X$  as a cell array of length  $n$  containing  $d$ -by- $K$  design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in  $X$  as missing values, and ignores rows in  $X$  with missing values.

### Data Types

single | double | cell

### Y - Response variables

matrix

Response variables, specified as an  $n$ -by- $d$  matrix.  $n$  is the number of observations in the data, and  $d$  is the number of dimensions in the response. When  $d = 1$ , `mvregress` treats the values in  $Y$  like  $n$  independent response values.

`mvregress` treats NaN values in  $Y$  as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** 'algorithm','cwls','covar0',C specifies covariance-weighted least squares estimation using the covariance matrix C.

### 'algorithm' - Estimation algorithm

'mvn' | 'ecm' | 'cwls'

Estimation algorithm, specified as the comma-separated pair consisting of 'algorithm' and one of the following.

'mvn'	Ordinary multivariate normal maximum likelihood estimation.
'ecm'	Maximum likelihood estimation via the ECM algorithm.
'cwls'	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is 'mvn'.
- If there are any missing responses (indicated by NaN), the default is 'ecm', provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is 'cwls'.

---

**Note** If algorithm has the value 'mvn', then mvregress removes observations with missing response values before estimation.

---

**Example:** 'algorithm','ecm'

### 'beta0' - Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of 'beta0' and a vector with  $K$  elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation algorithm is `'mvm'`.

## **'covar0' - Initial estimate for variance-covariance matrix**

matrix

Initial estimate for the variance-covariance matrix, `Sigma`, specified as the comma-separated pair consisting of `'covar0'` and a symmetric, positive definite,  $d$ -by- $d$  matrix. The default value is the identity matrix.

If the estimation algorithm is `'cwlsl'`, then `mvregress` uses `covar0` as the weighting matrix at each iteration, without changing it.

## **'covtype' - Type of variance-covariance matrix**

`'full'` (default) | `'diagonal'`

Type of variance-covariance matrix to estimate for `Y`, specified as the comma-separated pair consisting of `'covtype'` and one of the following.

<code>'full'</code>	Estimate all $d(d + 1)/2$ variance-covariance elements.
<code>'diagonal'</code>	Estimate only the $d$ diagonal elements of the variance-covariance matrix.

**Example:** `'covtype','diagonal'`

## **'maxiter' - Maximum number of iterations**

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of `'maxiter'` and a positive integer.

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

**Example:** `'maxiter',50`

**'outputfcn' - Function to evaluate each iteration**

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of 'outputfcn' and a function handle. The function must return a logical true or false. At each iteration, mvregress evaluates the function. If the result is true, iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns true if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

Covar	Current value of the variance-covariance matrix
iteration	Current iteration number
fval	Current value of the loglikelihood objective function

- Text string that takes these three values:

'init'	When the function is called during initialization
'iter'	When the function is called after an iteration
'done'	When the function is called after completion

**'tolbeta' - Convergence tolerance for regression coefficients**

sqrt(eps) (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of 'tolbeta' and a positive scalar value.

Let  $\mathbf{b}^t$  denote the estimate of the coefficient vector at iteration  $t$ , and  $\tau_\beta$  be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\|\mathbf{b}^t - \mathbf{b}^{t-1}\| < \tau_\beta \sqrt{K} (1 + \|\mathbf{b}^t\|),$$

where  $K$  is the length of  $\mathbf{b}^t$  and  $\|\mathbf{v}\|$  is the norm of a vector  $\mathbf{v}$ .

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

**Example:** `'tolbeta', 1e-5`

## **'tolobj' - Convergence tolerance for loglikelihood objective function**

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of `'tolobj'` and a positive scalar value.

Let  $L^t$  denote the value of the loglikelihood objective function at iteration  $t$ , and  $\tau_\ell$  be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$|L^t - L^{t-1}| < \tau_\ell (1 + |L^t|).$$

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

**Example:** `'tolobj', 1e-5`

**'varformat' - Format for parameter estimate variance-covariance matrix**`'beta' (default) | 'full'`

Format for the parameter estimate variance-covariance matrix, `COVB`, specified as the comma-separated pair consisting of `'varformat'` and one of the following.

<code>'beta'</code>	Return the variance-covariance matrix for only the regression coefficient estimates, <code>beta</code> .
<code>'full'</code>	Return the variance-covariance matrix for both the regression coefficient estimates, <code>beta</code> , and the variance-covariance matrix estimate, <code>Sigma</code> .

**Example:** `'varformat','full'`

**'vartype' - Type of variance-covariance matrix for parameter estimates**`'hessian' (default) | 'fisher'`

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of `'vartype'` and either `'hessian'` or `'fisher'`.

- If the value is `'hessian'`, then `mvregress` uses the Hessian, or observed information, matrix to compute `COVB`.
- If the value is `'fisher'`, then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute `COVB`.

The `'hessian'` method takes into account the increase uncertainties due to missing data, while the `'fisher'` method does not.

**Example:** `'vartype','fisher'`

## Output Arguments

### **beta** - Estimated regression coefficients

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify  $X$  as a single  $n$ -by- $K$  design matrix, then `mvregress` returns **beta** as a column vector of length  $K$ . For example, if  $X$  is a 20-by-5 design matrix, then **beta** is a 5-by-1 column vector.
- If you specify  $X$  as a cell array containing one or more  $d$ -by- $K$  design matrices, then `mvregress` returns **beta** as a column vector of length  $K$ . For example, if  $X$  is a cell array containing 2-by-10 design matrices, then **beta** is a 10-by-1 column vector.
- If you specify  $X$  as a single  $n$ -by- $p$  design matrix (not in a cell array), and  $Y$  has dimension  $d > 1$ , then `mvregress` returns **beta** as a  $p$ -by- $d$  matrix. For example, if  $X$  is a 20-by-5 design matrix, and  $Y$  has two dimensions such that  $d = 2$ , then **beta** is a 5-by-2 matrix, and the fitted  $Y$  values are  $X \times \text{beta}$ .

### **Sigma** - Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in  $Y$ , returned as a  $d$ -by- $d$  square matrix.

---

**Note** The estimated variance-covariance matrix, **Sigma**, is not the sample covariance matrix of the residual matrix, **E**.

---

### **E** - Residuals

matrix

Residuals for the fitted regression model, returned as an  $n$ -by- $d$  matrix.

If `algorithm` has the value 'ecm' or 'cwlsl', then `mvregress` computes the residual values corresponding to missing values in  $Y$  as

the difference between the conditionally imputed values and the fitted values.

---

**Note** If `algorithm` has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

---

### **CovB - Parameter estimate variance-covariance matrix**

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If `varformat` has the value `'beta'` (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in `beta`.
- If `varformat` has the value `'full'`, then `CovB` is the estimated variance-covariance matrix of the combined estimates in `beta` and `Sigma`.

### **logL - Loglikelihood objective function value**

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

## **Examples**

### **Multivariate Regression Model for Panel Data with Different Intercepts**

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google query data.

## mvregress

---

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));  
[n,d] = size(Y);  
x = flu.WtdILI;
```

The responses in  $Y$  are the nine regional flu estimates. Observations exist for every week over a one-year period, so  $n = 52$ . The dimension of the responses corresponds to the regions, so  $d = 9$ . The predictors in  $x$  are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;  
regions = flu.Properties.VarNames(2:end-1);  
plot(x,Y,'x')  
legend(regions,'Location','NorthWest')
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{i'j'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are  $K = 10$  regression coefficients to estimate: nine intercept terms and a common slope. The input argument  $X$  should be an  $n$ -element cell array of  $d$ -by- $K$  design matrices.

```
X = cell(n,1);
for i=1:n
    X{i} = [eye(d) repmat(x(i),d,1)];
```

# mvregress

---

```
end  
[beta,Sigma] = mvregress(X,Y);
```

beta contains estimates of the  $K$ -dimensional coefficient vector

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta)'$$

Sigma contains estimates of the  $d$ -by- $d$  variance-covariance matrix for the between-region concurrent correlations

$$\begin{pmatrix} \sigma_{11} & \cdots & \sigma_{1,9} \\ \vdots & \ddots & \vdots \\ \sigma_{9,1} & \cdots & \sigma_{9,9} \end{pmatrix}.$$

Plot the fitted regression model.

```
B = [beta(1:d)'; repmat(beta(end),1,d)];  
xx = linspace(.5,3.5)';  
fits = [ones(size(xx)),xx]*B;  
  
figure;  
h = plot(x,Y,'x',xx,fits,'-');  
for i = 1:d  
    set(h(d+i),'color',get(h(i),'color'));  
end  
legend(regions,'Location','NorthWest');
```

The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

### **Multivariate Regression for Panel Data with Different Slopes**

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));  
[n,d] = size(Y);  
x = flu.WtdILI;
```

The responses in  $Y$  are the nine regional flu estimates. Observations exist for every week over a one-year period, so  $n = 52$ . The dimension of the responses corresponds to the regions, so  $d = 9$ . The predictors in  $x$  are the weekly national flu estimates.

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{ij'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are  $K = 18$  regression coefficients to estimate: nine intercept terms, and nine slope terms.  $X$  is an  $n$ -element cell array of  $d$ -by- $K$  design matrices.

```
X = cell(n,1);  
for i=1:n  
    X{i} = [eye(d) x(i)*eye(d)];  
end  
[beta,Sigma] = mvregress(X,Y, 'algorithm', 'cwls');
```

$\beta$  contains estimates of the  $K$ -dimensional coefficient vector,

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta_1, \beta_2, \dots, \beta_9)'$$

Plot the fitted regression model.

```
B = [beta(1:d)'; beta(d+1:end)'];  
xx = linspace(.5,3.5)';  
fits = [ones(size(xx)), xx]*B;
```

```

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

### Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single  $n$ -by- $P$  design matrix for all response dimensions.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));  
[n,d] = size(Y);  
x = flu.WtdILI;
```

The responses in  $Y$  are the nine regional flu estimates. Observations exist for every week over a one-year period, so  $n = 52$ . The dimension of the responses corresponds to the regions, so  $d = 9$ . The predictors in  $x$  are the weekly national flu estimates.

Create an  $n$ -by- $P$  design matrix  $X$ . Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)), x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \varepsilon_{ij}, \quad i = 1, \dots, n; \quad j = 1, \dots, d,$$

with between-region concurrent correlation

$$COV(\varepsilon_{ij}, \varepsilon_{i'j'}) = \sigma_{jj'}, \quad j = 1, \dots, d.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta, Sigma, E, CovB, logL] = mvregress(X, Y);
```

`beta` contains estimates of the  $P$ -by- $d$  coefficient matrix. `Sigma` contains estimates of the  $d$ -by- $d$  variance-covariance matrix for the between-region concurrent correlations. `E` is a matrix of the residuals.

CovB is the estimated variance-covariance matrix of the regression coefficients. logL is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```
B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions,'Location','NorthWest');
```

The plot shows that each regression line has a different intercept and slope.

## Definitions **Multivariate Normal Regression**

Multivariate normal regression is the regression of a  $d$ -dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\beta + \mathbf{e}_i, \quad i = 1, \dots, n,$$

where

- $\mathbf{y}_i$  is a  $d$ -dimensional vector of responses.
- $\mathbf{X}_i$  is a design matrix of predictor variables.
- $\beta$  is vector or matrix of regression coefficients.
- $\mathbf{e}_i$  is a  $d$ -dimensional vector of error terms, with multivariate normal distribution

$$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \Sigma).$$

### Conditionally Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwlsls') estimation algorithms include imputation of missing response values.

Let  $\tilde{\mathbf{y}}$  denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data,  $E(\tilde{\mathbf{y}} | \mathbf{y})$ .

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN \left\{ \begin{pmatrix} \tilde{\mathbf{X}}\beta \\ \mathbf{X}\beta \end{pmatrix}, \begin{pmatrix} \Sigma_{\tilde{\mathbf{y}}} & \Sigma_{\tilde{\mathbf{y}}\mathbf{y}} \\ \Sigma_{\mathbf{y}\tilde{\mathbf{y}}} & \Sigma_{\mathbf{y}} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$E(\tilde{\mathbf{y}} | \mathbf{y}) = \tilde{\mathbf{X}}\beta + \Sigma_{\tilde{\mathbf{y}}\mathbf{y}}\Sigma_{\mathbf{y}}^{-1}(\mathbf{y} - \mathbf{X}\beta).$$

---

**Note** `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

---

## Concepts

- “Multivariate Linear Regression” on page 13-3
- “Estimation of Multivariate Regression Models” on page 13-6

**Purpose**

Negative log-likelihood for multivariate regression

**Syntax**

```
nlogL = mvregresslike(X,Y,b,SIGMA,alg)
[nlogL,COVB] = mvregresslike(...)
[nlogL,COVB] = mvregresslike(...,type,format)
```

**Description**

`nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the  $d$ -dimensional multivariate observations in the  $n$ -by- $d$  matrix `Y` on the predictor variables in the matrix or cell array `X`, evaluated for the  $p$ -by-1 column vector `b` of coefficient estimates and the  $d$ -by- $d$  matrix `SIGMA` specifying the covariance of a row of `Y`. If  $d = 1$ , `X` can be an  $n$ -by- $p$  design matrix of predictor variables. For any value of  $d$ , `X` can also be a cell array of length  $n$ , with each cell containing a  $d$ -by- $p$  design matrix for one multivariate observation. If all observations have the same  $d$ -by- $p$  design matrix, `X` can be a single cell.

NaN values in `X` or `Y` are taken as missing. Observations with missing values in `X` are ignored. Treatment of missing values in `Y` depends on the algorithm specified by `alg`.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates `b`, and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwlsl' — Least squares conditionally weighted by `SIGMA`
- 'mvm' — Multivariate normal estimates computed after omitting rows with any missing values in `Y`

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates `b`.

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

`type` is either:

# mvregresslike

---

- 'hessian' — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

*format* is either:

- 'beta' — To compute COVB for b only. This is the default.
- 'full' — To compute COVB for both b and SIGMA.

## How To

- “Multivariate Normal Distribution” on page B-96

**Purpose**

Multivariate normal random numbers

**Syntax**

```
R = mvnrnd(MU,SIGMA)
r = mvnrnd(MU,SIGMA,cases)
```

**Description**

`R = mvnrnd(MU, SIGMA)` returns an  $n$ -by- $d$  matrix  $R$  of random vectors chosen from the multivariate normal distribution with mean  $MU$ , and covariance  $SIGMA$ .  $MU$  is a vector or  $n$ -by- $d$  matrix, and `mvnrnd` generates each row of  $R$  using the corresponding row of  $mu$ .  $SIGMA$  is a  $d$ -by- $d$  symmetric positive semi-definite matrix, or a  $d$ -by- $d$ -by- $n$  array. If  $SIGMA$  is an array, `mvnrnd` generates each row of  $R$  using the corresponding page of  $SIGMA$ , i.e., `mvnrnd` computes  $R(i, :)$  using  $MU(i, :)$  and  $SIGMA(:, :, i)$ . If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off the diagonal,  $SIGMA$  may also be specified as a 1-by- $d$  vector or a 1-by- $d$ -by- $n$  array, containing just the diagonal. If  $MU$  is a 1-by- $d$  vector, `mvnrnd` replicates it to match the trailing dimension of  $SIGMA$ .

`r = mvnrnd(MU, SIGMA, cases)` returns a cases-by- $d$  matrix  $R$  of random vectors chosen from the multivariate normal distribution with a common 1-by- $d$  mean vector  $MU$ , and a common  $d$ -by- $d$  covariance matrix  $SIGMA$ .

**Examples****Generate Multivariate Normal Random Numbers**

Generate random numbers from a multivariate normal distribution with parameters  $mu = [2 \ 3]$  and  $SIGMA = [1 \ 1.5; \ 1.5 \ 3]$ .

```
mu = [2 3];
SIGMA = [1 1.5; 1.5 3];
rng('default'); % For reproducibility
r = mvnrnd(mu, SIGMA, 100);
```

Plot the random numbers.

```
figure;
plot(r(:,1), r(:,2), '+')
```

# mvnrnd

[mvnpdf](#) | [mvncdf](#) | [normrnd](#)

**How To**

- “Multivariate Normal Distribution” on page B-96

**Purpose**

Multivariate  $t$  cumulative distribution function

**Syntax**

```
y = mvtcdf(X,C,DF)
y = mvtcdf(xl,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

**Description**

`y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate  $t$  distribution with correlation parameters `C` and degrees of freedom `DF`, evaluated at each row of `X`. Rows of the  $n$ -by- $d$  matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `y` is an  $n$ -by-1 vector.

`C` is a symmetric, positive definite,  $d$ -by- $d$  matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `DF` is a scalar, or a vector with  $n$  elements.

The multivariate  $t$  cumulative probability at `X` is defined as the probability that a random vector `T`, distributed as multivariate  $t$ , will fall within the semi-infinite rectangle with upper limits defined by `X`, i.e.,  $\Pr\{T(1) \leq X(1), T(2) \leq X(2), \dots, T(d) \leq X(d)\}$ .

`y = mvtcdf(xl,xu,C,DF)` returns the multivariate  $t$  cumulative probability evaluated over the rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in `y`. For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the  $t$  density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is  $1e-8$ . For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is  $1e-4$ .

`[...] = mvntdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`. Choices of `statset` parameters are:

- 'TolFun' — Maximum absolute error tolerance. Default is  $1e-8$  when  $d < 4$ , or  $1e-4$  when  $d \geq 4$ .
- 'MaxFunEvals' — Maximum number of integrand evaluations allowed when  $d \geq 4$ . Default is  $1e7$ . 'MaxFunEvals' is ignored when  $d < 4$ .
- 'Display' — Level of display output. Choices are 'off' (the default), 'iter', and 'final'. 'Display' is ignored when  $d < 4$ .

## Examples

### Compute the Multivariate $t$ Distribution cdf

Compute the cdf of a multivariate  $t$  distribution with correlation parameters  $C = [1 \ .4; \ .4 \ 1]$  and 2 degrees of freedom.

```
C = [1 .4; .4 1];  
df = 2;  
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
p = mvtcdf(X,C,df);
```

Plot the cdf.

```
figure;  
surf(X1,X2,reshape(p,25,25));
```

## How To

- “Multivariate  $t$  Distribution” on page B-102

<b>Purpose</b>	Multivariate $t$ probability density function
<b>Syntax</b>	<code>y = mvtpdf(X,C,df)</code>
<b>Description</b>	<code>y = mvtpdf(X,C,df)</code> returns the probability density of the multivariate $t$ distribution with correlation parameters <code>C</code> and degrees of freedom <code>df</code> , evaluated at each row of <code>X</code> . Rows of the $n$ -by- $d$ matrix <code>X</code> correspond to observations or points, and columns correspond to variables or coordinates. <code>C</code> is a symmetric, positive definite, $d$ -by- $d$ matrix, typically a correlation matrix. If its diagonal elements are not 1, <code>mvtpdf</code> scales <code>C</code> to correlation form. <code>mvtcdf</code> does not rescale <code>X</code> . <code>df</code> is a scalar, or a vector with $n$ elements. <code>y</code> is an $n$ -by-1 vector.

### Examples **Compute the Multivariate $t$ Distribution pdf**

Compute the pdf of a multivariate  $t$  distribution with correlation parameters `C = [1 .4; .4 1]` and 2 degrees of freedom.

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
C = [1 .4; .4 1];  
df = 2;  
p = mvtpdf(X,C,df);
```

Plot the pdf.

```
figure;  
surf(X1,X2,reshape(p,25,25))
```

**See Also**

[mvtcdf](#) | [mvtrnd](#)

**How To**

- “Multivariate  $t$  Distribution” on page B-102

**Purpose** Multivariate  $t$  random numbers

**Syntax**  
`R = mvtrnd(C,df,cases)`  
`R = mvtrnd(C,df)`

**Description** `R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate  $t$  distribution, where `C` is a correlation matrix. `df` is the degrees of freedom and is either a scalar or is a vector with `cases` elements. If `p` is the number of columns in `C`, then the output `R` has `cases` rows and `p` columns.

Let `t` represent a row of `R`. Then the distribution of `t` is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix `C`, divided by an independent chi-square random value having `df` degrees of freedom. The rows of `R` are independent.

`C` must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if `C` is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales `C` to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate  $t$  distribution.

## Examples **Generate Multivariate $t$ Distribution Random Numbers**

Generate random numbers from a multivariate  $t$  distribution with correlation parameters `SIGMA = [1 0.8;0.8 1]` and 3 degrees of freedom.

```
rng('default'); % For reproducibility
SIGMA = [1 0.8;0.8 1];
R = mvtrnd(SIGMA,3,100);
```

Plot the random numbers.

```
figure;
plot(R(:,1),R(:,2),'+')
```

## How To

- “Multivariate  $t$  Distribution” on page B-102

<b>Purpose</b>	Number of observations (including observations with missing group values)
<b>Description</b>	Number of observations (including observations with missing group values).

# NaiveBayes

---

<b>Purpose</b>	Naive Bayes classifier	
<b>Description</b>	A NaiveBayes object defines a Naive Bayes classifier. A Naive Bayes classifier assigns a new observation to the most probable class, assuming the features are conditionally independent given the class value.	
<b>Construction</b>	NaiveBayes	Create NaiveBayes object
<b>Methods</b>	disp	Display NaiveBayes classifier object
	display	Display NaiveBayes classifier object
	fit	Create Naive Bayes classifier object by fitting training data
	posterior	Compute posterior probability of each class for test data
	predict	Predict class label for test data
	subsasgn	Subscripted reference for NaiveBayes object
	suboref	Subscripted reference for NaiveBayes object
<b>Properties</b>	CIIsEmpty	Flag for non-empty classes
	ClassLevels	Class levels
	Dist	Distribution names
	NClasses	Number of classes

NDims	Number of dimensions
Params	Parameter estimates
Prior	Class priors

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

Predict the class label using the Naive Bayes classifier:

```
load fisheriris
```

Use the default Gaussian distribution and a confusion matrix:

```
O1 = fitNaiveBayes(meas,species);  
C1 = O1.predict(meas);  
cMat1 = confusionmat(species,C1)
```

This returns:

```
cMat1 =  
  
    50     0     0  
     0    47     3  
     0     3    47
```

Use the Gaussian distribution for features 1 and 3 and use the kernel density estimation for features 2 and 4:

```
O2 = fitNaiveBayes(meas,species,'dist',...  
{'normal','kernel','normal','kernel'});  
C2 = O2.predict(meas);  
cMat2 = confusionmat(species,C2)
```

This returns:

```
cMat2 =
```

## How To

- “Naive Bayes Classification” on page 15-38
- “Grouping Variables” on page 2-52

**Purpose** Create NaiveBayes object

**Description** You cannot create a NaiveBayes classifier by calling the constructor. Use `fitNaiveBayes` to create a NaiveBayes classifier by fitting the object to training data.

**See Also** `fitNaiveBayes`

# prob.NakagamiDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Nakagami probability distribution object

**Description** prob.NakagamiDistribution is an object consisting of parameters, a model description, and sample data for a Nakagami probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Nakagami')` creates a Nakagami probability distribution object using the default parameter values.

`pd = makedist('Nakagami','mu',mu,'omega',omega)` creates a Nakagami probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Shape parameter**

1 (default) | positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **omega - Scale parameter**

1 (default) | positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

### **Data Types**

single | double

## Properties

### **mu - Shape parameter**

positive scalar value

Shape parameter for the Nakagami distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **omega - Scale parameter**

positive scalar value

Scale parameter for the Nakagami distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

### **Data Types**

struct

# prob.NakagamiDistribution

---

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## **Data Types**

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## **Data Types**

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

# prob.NakagamiDistribution

---

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Nakagami Distribution

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
mu	Shape parameter	$\mu > 0$
omega	Scale parameter	$\omega > 0$

The probability density function (pdf) is

$$f(x | \mu, \omega) = 2 \left( \frac{\mu^\mu}{\omega} \right) \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} \exp\left\{ \frac{-\mu}{\omega} x^2 \right\} ; x > 0,$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')
```

```
pd =
```

```
  NakagamiDistribution
```

```
  Nakagami distribution
```

```
    mu = 1
```

```
    omega = 1
```

# prob.NakagamiDistribution

---

## Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami','mu',5,'omega',2)
```

```
pd =
```

```
    NakagamiDistribution
```

```
    Nakagami distribution
```

```
        mu = 5
```

```
        omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
    1.3794
```

## Concepts

- “Nakagami Distribution” on page B-108
- Class Attributes
- Property Attributes

**Purpose** Covariance ignoring NaN values

**Syntax**

```
Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')
```

**Description** `Y = nancov(X)` is the covariance `cov` of `X`, computed after removing observations with NaN values.

For vectors `x`, `nancov(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nancov(X)` is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

`Y = nancov(X1,X2)`, where `X1` and `X2` are matrices with the same number of elements, is equivalent to `nancov(X)`, where `X = [X1(:) X2(:)]`.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If  $n$  is the number of remaining observations after removing observations with NaN values, `nancov` normalizes `Y` by either  $n - 1$  or  $n$ , depending on whether  $n > 1$  or  $n = 1$ , respectively. To specify normalization by  $n$ , use `Y = nancov(...,1)`.

`Y = nancov(...,'pairwise')` computes `Y(i,j)` using rows with no NaN values in columns `i` or `j`. The result `Y` may not be a positive definite matrix.

**Examples** Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
     NaN     NaN
    0.1270    0.9572
```

```
0.9134      NaN
0.6324      NaN
0.0975      0.1419
0.2785      0.4218
0.5469      0.9157
0.9575      0.7922
0.9649      NaN
```

Establish a correlation between a third variable and the other two variables:

```
X(:,3) = sum(X,2)
```

```
X =
    0.8147    0.1576    0.9723
         NaN         NaN         NaN
    0.1270    0.9572    1.0842
    0.9134         NaN         NaN
    0.6324         NaN         NaN
    0.0975    0.1419    0.2394
    0.2785    0.4218    0.7003
    0.5469    0.9157    1.4626
    0.9575    0.7922    1.7497
    0.9649         NaN         NaN
```

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```
Y = nancov(X)
```

```
Y =
    0.1311    0.0096    0.1407
    0.0096    0.1388    0.1483
    0.1407    0.1483    0.2890
```

## See Also

[NaN](#) | [cov](#) | [var](#) | [nanvar](#)

**Purpose** Maximum ignoring NaN values

**Syntax**

```
y = nanmax(X)
Y = nanmax(X1,X2)
y = nanmax(X,[],dim)
[y,indices] = nanmax(...)
```

**Description** `y = nanmax(X)` is the maximum max of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmax(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmax(...)` also returns the row indices of the maximum values for each column in the vector `indices`.

**Examples** Find column maxima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
[y,indices] = nanmax(X)
y =
     4     5    NaN
indices =
     3     2     1
```

**See Also** NaN | max | nanmin

# nanmean

---

**Purpose** Mean ignoring NaN values

**Syntax**  
`y = nanmean(X)`  
`y = nanmean(X,dim)`

**Description** `y = nanmean(X)` is the mean of `X`, computed after removing NaN values. For vectors `x`, `nanmean(x)` is the mean of the remaining elements, once NaN values are removed. For matrices `X`, `nanmean(X)` is a row vector of column means, once NaN values are removed. For multidimensional arrays `X`, `nanmean` operates along the first nonsingleton dimension. `y = nanmean(X,dim)` takes the mean along dimension `dim` of `X`.

---

**Note** If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. Since the mean involves division by 0, its value is NaN. The output NaN is not a mean of NaN values.

---

**Examples** Find column means for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanmean(X)
y =
    3.5000    3.0000    NaN
```

**See Also** NaN | mean | nanmedian

**Purpose** Median ignoring NaN values

**Syntax**  
`y = nanmedian(X)`  
`y = nanmedian(X,dim)`

**Description** `y = nanmedian(X)` is the median of `X`, computed after removing NaN values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once NaN values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once NaN values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X,dim)` takes the mean along dimension `dim` of `X`.

**Examples** Find column medians for data with missing values:

```
X = magic(3);  
X([1 6:9]) = repmat(NaN,1,5)  
X =  
    NaN     1    NaN  
     3     5    NaN  
     4    NaN    NaN  
y = nanmedian(X)  
y =  
    3.5000    3.0000    NaN
```

**See Also** [NaN](#) | [median](#) | [nanmean](#)

# nanmin

---

**Purpose** Minimum ignoring NaN values

**Syntax**

```
y = nanmin(X)
Y = nanmin(X1,X2)
y = nanmin(X,[],dim)
[y,indices] = nanmin(...)
```

**Description** `y = nanmin(X)` is the minimum `min` of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(...)` also returns the row indices of the minimum values for each column in the vector `indices`.

**Examples** Find column minima and their indices for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
[y,indices] = nanmin(X)
y =
     3     1    NaN
indices =
     2     1     1
```

**See Also** NaN | min | nanmax

**Purpose** Standard deviation ignoring NaN values

**Syntax**

```
y = nanstd(X)
y = nanstd(X,1)
y = nanstd(X,flag,dim)
```

**Description** `y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing NaN values.

For vectors `x`, `nanstd(x)` is the sample standard deviation of the remaining elements, once NaN values are removed. For matrices `X`, `nanstd(X)` is a row vector of column sample standard deviations, once NaN values are removed. For multidimensional arrays `X`, `nanstd` operates along the first nonsingleton dimension.

If  $n$  is the number of remaining observations after removing observations with NaN values, `nanstd` normalizes `y` by  $n-1$ . To specify normalization by  $n$ , use `y = nanstd(X,1)`.

`y = nanstd(X,flag,dim)` takes the standard deviation along the dimension `dim` of `X`. The `flag` is 0 or 1 to specify normalization by  $n-1$  or  $n$ , respectively, where  $n$  is the number of remaining observations after removing observations with NaN values.

**Examples** Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanstd(X)
y =
    0.7071    2.8284    NaN
```

**See Also** NaN | std | nanvar | nanmean

# nansum

---

**Purpose** Sum ignoring NaN values

**Syntax**  
`y = nansum(X)`  
`y = nansum(X,dim)`

**Description** `y = nansum(X)` is the sum of `X`, computed after removing NaN values. For vectors `x`, `nansum(x)` is the sum of the remaining elements, once NaN values are removed. For matrices `X`, `nansum(X)` is a row vector of column sums, once NaN values are removed. For multidimensional arrays `X`, `nansum` operates along the first nonsingleton dimension. `y = nansum(X,dim)` takes the sum along dimension `dim` of `X`.

---

**Note** If `X` contains a vector of all NaN values along some dimension, the vector is empty once the NaN values are removed, so the sum of the remaining elements is 0. The output 0 is not a sum of NaN values.

---

**Examples** Find column sums for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nansum(X)
y =
     7     6     0
```

**See Also** NaN | sum

**Purpose** Variance, ignoring NaN values

**Syntax**

```
y = nanvar(X)
y = nanvar(X,1)
y = nanvar(X,w)
y = nanvar(X,w,dim)
```

**Description** `y = nanvar(X)` is the variance `var` of `X`, computed after removing NaN values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nancov` removes the mean from each variable (column for matrix `X`) before calculating `Y`. If  $n$  is the number of remaining observations after removing observations with NaN values, `nanvar` normalizes `y` by either  $n - 1$  or  $n$ , depending on whether  $n > 1$  or  $n = 1$ , respectively. To specify normalization by  $n$ , use `y = nanvar(X,1)`.

`y = nanvar(X,w)` computes the variance using the weight vector `w`. The length of `w` must equal the length of the dimension over which `nanvar` operates, and its elements must be nonnegative. Elements of `X` corresponding to NaN values of `w` are ignored.

`y = nanvar(X,w,dim)` takes the variance along the dimension `dim` of `X`. Set `w` to `[]` to use the default normalization by  $n - 1$ .

**Examples** Find column standard deviations for data with missing values:

```
X = magic(3);
X([1 6:9]) = repmat(NaN,1,5)
X =
    NaN     1    NaN
     3     5    NaN
     4    NaN    NaN
y = nanvar(X)
```

# nanvar

---

```
y =  
    0.5000    8.0000    NaN
```

## See Also

**Purpose** Negative binomial cumulative distribution function

**Syntax**  
`y = nbincdf(x,R,p)`  
`y = nbincdf(x,R,p,'upper')`

**Description** `y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p,'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x | r, p) = \sum_{i=0}^x \binom{r+i-1}{i} p^r q^i I_{(0,1,\dots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

**Examples** **Compute Negative Binomial Distribution CDF**

```
x = (0:15);
```

# nbincdf

---

```
p = nbincdf(x,3,0.5);  
stairs(x,p)
```

## How To

- “Negative Binomial Distribution” on page B-109

---

<b>Purpose</b>	Negative binomial parameter estimates
<b>Syntax</b>	<pre>parmhat = nbinfit(data) [parmhat,parmci] = nbinfit(data,alpha) [...] = nbinfit(data,alpha,options)</pre>
<b>Description</b>	<p><code>parmhat = nbinfit(data)</code> returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector <code>data</code>.</p> <p><code>[parmhat,parmci] = nbinfit(data,alpha)</code> returns MLEs and 100(1-alpha) percent confidence intervals. By default, <code>alpha = 0.05</code>, which corresponds to 95% confidence intervals.</p> <p><code>[...] = nbinfit(data,alpha,options)</code> accepts a structure, <code>options</code>, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an <code>options</code> structure which you can create using the function <code>statset</code>. Enter <code>statset('nbinfit')</code> to see the names and default values of the parameters that <code>nbinfit</code> accepts in the <code>options</code> structure. See the reference page for <code>statset</code> for more information about these options.</p>
	<hr/> <p><b>Note</b> The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in <code>data</code> is less than its sample mean, <code>nbinfit</code> cannot compute MLEs. You should use the <code>poissfit</code> function instead.</p> <hr/>
<b>See Also</b>	<code>nbincdf</code>   <code>nbiniinv</code>   <code>nbinpdf</code>   <code>nbinrnd</code>   <code>nbinstat</code>   <code>mle</code>   <code>statset</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Negative Binomial Distribution” on page B-109</li></ul>

# nbininv

---

**Purpose** Negative binomial inverse cumulative distribution function

**Syntax** `X = nbininv(Y,R,P)`

**Description** `X = nbininv(Y,R,P)` returns the inverse of the negative binomial cdf with corresponding number of successes, `R` and probability of success in a single trial, `P`. Since the binomial distribution is discrete, `nbininv` returns the least integer `X` such that the negative binomial cdf evaluated at `X` equals or exceeds `Y`. `Y`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `Y`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbininv` allows `R` to be any positive value, including nonintegers.

**Examples** How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

```
flips = nbininv(0.99,10,0.5) + 10
flips =
    33
```

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.

**See Also** `icdf` | `nbincdf` | `nbinpdf` | `nbinstat` | `nbinfit` | `nbinrnd`

**How To** • “Negative Binomial Distribution” on page B-109

**Purpose** Negative binomial probability density function

**Syntax** `Y = nbinpdf(X,R,P)`

**Description** `Y = nbinpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

## Examples **Compute the Negative Binomial Distribution pdf**

Compute the pdf of a negative binomial distribution with parameters `R = 3` and `p = 0.5`.

```
x = (0:10);
y = nbinpdf(x,3,0.5);
```

# nbinpdf

---

Plot the pdf.

```
figure;  
plot(x,y,'+')  
set(gca,'Xlim',[-0.5,10.5])
```

# nbinstat

---

**Purpose** Negative binomial mean and variance

**Syntax** `[M,V] = nbinstat(R,P)`

**Description** `[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters  $r$  and  $p$  is  $rq / p$ , where  $q = 1 - p$ . The variance is  $rq / p^2$ .

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows `R` to be any positive value, including nonintegers.

## Examples

```
p = 0.1:0.2:0.9;
r = 1:5;
[R,P] = meshgrid(r,p);
[M,V] = nbinstat(R,P)
M =
    9.0000    18.0000    27.0000    36.0000    45.0000
    2.3333    4.6667    7.0000    9.3333    11.6667
    1.0000    2.0000    3.0000    4.0000    5.0000
    0.4286    0.8571    1.2857    1.7143    2.1429
    0.1111    0.2222    0.3333    0.4444    0.5556

V =
   90.0000  180.0000  270.0000  360.0000  450.0000

**How To**

- “Negative Binomial Distribution” on page B-109

# ncfcdf

---

**Purpose** Noncentral  $F$  cumulative distribution function

**Syntax**  
`p = ncfcdf(x, nu1, nu2, delta)`  
`p = ncfcdf(x, nu1, nu2, delta, 'upper')`

**Description** `p = ncfcdf(x, nu1, nu2, delta)` computes the noncentral  $F$  cdf at each value in `x` using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x, nu1, nu2, delta, 'upper')` returns the complement of the noncentral  $F$  cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral  $F$  cdf is

$$F(x | v_1, v_2, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \middle| \frac{v_1}{2} + j, \frac{v_2}{2}\right)$$

where  $I(x | a, b)$  is the incomplete beta function with parameters  $a$  and  $b$ .

## Examples

### Compute Noncentral F Distribution cdf

Compare the noncentral  $F$  cdf with  $\delta = 10$  to the  $F$  cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';  
p1 = ncfcdf(x,5,20,10);  
p = fcdf(x,5,20);  
plot(x,p, '- ', x,p1, '-')
```

**How To**

- “Noncentral F Distribution” on page B-117

# ncfinv

---

**Purpose** Noncentral  $F$  inverse cumulative distribution function

**Syntax** `X = ncfinv(P,NU1,NU2,DELTA)`

**Description** `X = ncfinv(P,NU1,NU2,DELTA)` returns the inverse of the noncentral  $F$  cdf with numerator degrees of freedom NU1, denominator degrees of freedom NU2, and positive noncentrality parameter DELTA for the corresponding probabilities in P. P, NU1, NU2, and DELTA can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of X. A scalar input for P, NU1, NU2, or DELTA is expanded to a constant array with the same dimensions as the other inputs.

**Examples** One hypothesis test for comparing two sample variances is to take their ratio and compare it to an  $F$  distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - nfcdf(critical,5,20,2)
prob =
    0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the  $F$  statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

icdf | nfcdf | ncfpdf | ncfstat | ncfnd

**How To**

• “Noncentral F Distribution” on page B-117

**Purpose** Noncentral  $F$  probability density function

**Syntax**  $Y = \text{ncfpdf}(X, \text{NU1}, \text{NU2}, \text{DELTA})$

**Description**  $Y = \text{ncfpdf}(X, \text{NU1}, \text{NU2}, \text{DELTA})$  computes the noncentral  $F$  pdf at each of the values in  $X$  using the corresponding numerator degrees of freedom in  $\text{NU1}$ , denominator degrees of freedom in  $\text{NU2}$ , and positive noncentrality parameters in  $\text{DELTA}$ .  $X$ ,  $\text{NU1}$ ,  $\text{NU2}$ , and  $\text{DELTA}$  can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of  $Y$ . A scalar input for  $\text{NU1}$ ,  $\text{NU2}$ , or  $\text{DELTA}$  is expanded to a constant array with the same dimensions as the other inputs.

The  $F$  distribution is a special case of the noncentral  $F$  where  $\delta = 0$ . As  $\delta$  increases, the distribution flattens like the plot in the example.

## Examples **Compute Noncentral $F$ Distribution pdf**

Compute the pdf of a noncentral  $F$  distribution with degrees of freedom  $\text{NU1} = 5$  and  $\text{NU2} = 20$ , and noncentrality parameter  $\text{DELTA} = 10$ . For comparison, also compute the pdf of an  $F$  distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x,5,20,10);  
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral  $F$  distribution and the pdf of the  $F$  distribution on the same figure.

```
figure;  
plot(x,p1,'b-', 'LineWidth',2)  
hold on  
plot(x,p,'g--', 'LineWidth',2)  
legend('Noncentral F', 'F distribution')
```

## How To

• “Noncentral F Distribution” on page B-117

# ncfrnd

---

**Purpose** Noncentral  $F$  random numbers

**Syntax**  
R = ncfrnd(NU1,NU2,DELTA)  
R = ncfrnd(NU1,NU2,DELTA,m,n,...)  
R = ncfrnd(NU1,NU2,DELTA,[m,n,...])

**Description** R = ncfrnd(NU1,NU2,DELTA) returns a matrix of random numbers chosen from the noncentral  $F$  distribution with corresponding numerator degrees of freedom in NU1, denominator degrees of freedom in NU2, and positive noncentrality parameters in DELTA. NU1, NU2, and DELTA can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for NU1, NU2, or DELTA is expanded to a constant matrix with the same dimensions as the other inputs.

R = ncfrnd(NU1,NU2,DELTA,m,n,...) or R = ncfrnd(NU1,NU2,DELTA,[m,n,...]) generates an m-by-n-by-... array. The NU1, NU2, DELTA parameters can each be scalars or arrays of the same size as R.

**Examples** Compute six random numbers from a noncentral  $F$  distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter,  $\delta$ , of 4.0. Compare this to the  $F$  distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
  2.5995  0.8824  0.8220  1.4485  1.4415  1.4864
```

```
r1 = frnd(10,100,1,6)
r1 =
  0.9826  0.5911  1.0967  0.9681  2.0096  0.6598
```

**How To**      • “Noncentral F Distribution” on page B-117

**Purpose** Noncentral  $F$  mean and variance

**Syntax** `[M,V] = ncfstat(NU1,NU2,DELTA)`

**Description** `[M,V] = ncfstat(NU1,NU2,DELTA)` returns the mean of and variance for the noncentral  $F$  pdf with corresponding numerator degrees of freedom in NU1, denominator degrees of freedom in NU2, and positive noncentrality parameters in DELTA. NU1, NU2, and DELTA can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V. A scalar input for NU1, NU2, or DELTA is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral  $F$  distribution with parameters  $\nu_1$ ,  $\nu_2$ , and  $\delta$  is

$$\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}$$

where  $\nu_2 > 2$ .

The variance is

$$2\left(\frac{\nu_2}{\nu_1}\right)^2 \left[ \frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]$$

where  $\nu_2 > 4$ .

**Examples** `[m,v]= ncfstat(10,100,4)`

`m =`  
`1.4286`

`v =`  
`0.4252`

<b>How To</b>	• “Noncentral $t$ Distribution” on page B-120

# nctstat

---

**Purpose** Noncentral  $t$  mean and variance

**Syntax** `[M,V] = nctstat(NU,DELTA)`

**Description** `[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral  $t$  pdf with  $NU$  degrees of freedom and noncentrality parameter  $DELTA$ .  $NU$  and  $DELTA$  can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of  $M$  and  $V$ . A scalar input for  $NU$  or  $DELTA$  is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral  $t$  distribution with parameters  $\nu$  and  $\delta$  is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where  $\nu > 1$ .

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2) - \frac{\nu}{2}\delta^2 \left[ \frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)} \right]^2$$

where  $\nu > 2$ .

**Examples** `[m,v] = nctstat(10,1)`

`m =`  
`1.0837`

`v =`  
`1.3255`

**How To**

- “Noncentral t Distribution” on page B-120

**Purpose** Noncentral chi-square cumulative distribution function

**Syntax**  
`p = ncx2cdf(x,v,delta)`  
`p = ncx2cdf(x,v,delta,'upper')`

**Description** `p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x | v, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{v+2j}^2 \leq x]$$

## Examples **Compute Noncentral Chi-Square cdf**

Compare the noncentral chi-square cdf with `DELTA = 2` to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';  
ncx2 = ncx2cdf(x,4,2);  
chi2 = chi2cdf(x,4);  
  
plot(x,ncx2,'b-','LineWidth',2)
```

```
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2','Location','NW')
```

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

## **Examples** **Compute Noncentral Chi-Square Distribution pdf**

Compute the pdf of a noncentral chi-square distribution with degrees of freedom  $V = 4$  and noncentrality parameter  $\text{DELTA} = 2$ . For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';  
ncx2 = ncx2pdf(x,4,2);  
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2')
```

**How To**

- “Noncentral Chi-Square Distribution” on page B-114

# ncx2rnd

---

**Purpose** Noncentral chi-square random numbers

**Syntax**  
R = ncx2rnd(V,DELTA)  
R = ncx2rnd(V,DELTA,m,n,...)  
R = ncx2rnd(V,DELTA,[m,n,...])

**Description** R = ncx2rnd(V,DELTA) returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in V and positive noncentrality parameters in DELTA. V and DELTA can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of R. A scalar input for V or DELTA is expanded to a constant array with the same dimensions as the other input.

R = ncx2rnd(V,DELTA,m,n,...) or R = ncx2rnd(V,DELTA,[m,n,...]) generates an m-by-n-by-... array. The V, DELTA parameters can each be scalars or arrays of the same size as R.

**Examples**

```
ncx2rnd(4,2,6,3)
ans =
    6.8552    5.9650   11.2961
    5.2631    4.2640    5.9495
    9.1939    6.7162    3.8315
   10.3100    4.4828    7.1653
    2.1142    1.9826    4.6400
    3.8852    5.3999    0.9282
```

# categorical.ndims

---

**Purpose**

Number of dimensions of categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`n = ndims(A)`

**Description**

`n = ndims(A)` returns the number of dimensions in the categorical array `A`. The number of dimensions in an array is always greater than or equal to 2. Trailing singleton dimensions are ignored. Put simply, `ndims(A)` is `length(size(A))`.

**See Also**

`size`

# gmdistribution.NDimensions property

---

**Purpose** Dimension  $d$  of multivariate Gaussian distributions

**Description** The dimension  $d$  of the multivariate Gaussian distributions.

# dataset.ndims

---

**Purpose**

Number of dimensions of dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

`n = ndims(A)`

**Description**

`n = ndims(A)` returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

**See Also**

`size`

**Purpose** Number of dimensions in matrix

**Syntax** `n = ndims(p)`

**Description** `n = ndims(p)` returns the number of dimensions in the matrix that is created by the syntax `p(:, :)`. Since this is always a 2-D matrix, `n` is always equal to 2.

**See Also** `grandset` | `size`

# NaiveBayes.NDims property

---

**Purpose**            Number of dimensions

**Description**        The NDim property specifies the number of dimensions, which is equal to the number of features in the training data used to create the Naive Bayes classifier.

**Purpose** Not equal relation for handles

**Syntax** `h1 ~= h2`

**Description** Handles are equal if they are handles for the same object and are unequal otherwise.

`h1 ~= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `~=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ne(h1, h2)` stores the result in a logical array of the same dimensions.

# prob.NegativeBinomialDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Negative binomial distribution object

**Description** prob.NegativeBinomialDistribution is an object consisting of parameters, a model description, and sample data for a negative binomial probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('NegativeBinomial')` creates a negative binomial probability distribution object using the default parameter values.

`pd = makedist('NegativeBinomial', 'R', r, 'p', p)` creates a negative binomial probability distribution object using the specified parameter values.

## Input Arguments

### **r - Number of successes**

1 (default) | positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **p - Probability of success**

0.5 (default) | positive scalar value in the range (0, 1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0, 1].

### **Data Types**

single | double

## Properties

### **r - Number of successes**

positive scalar value

Number of successes for the negative binomial distribution, stored as a positive scalar value.

### **Data Types**

single | double

### **p - Probability of success**

positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

### **Data Types**

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

### **Data Types**

char

### **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

# prob.NegativeBinomialDistribution

---

## Data Types

struct

### **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

### **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

### **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

### **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

# prob.NegativeBinomialDistribution

## Definitions

### Negative Binomial Distribution

The negative binomial distribution models the number of failures  $x$  before a specified number of successes is reached in a series of independent, identical trials. This distribution can also model count data, in which case  $r$  does not need to be an integer value.

The negative binomial distribution uses the following parameters.

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \leq 1$

The probability density function (pdf) when  $r$  is an integer is

$$f(x|r,p) = \binom{r+x-1}{x} p^r q^x \quad ; \quad x = 1, 2, \dots, \infty,$$

where  $q = 1 - p$  and  $\binom{r+x-1}{x}$  is the binomial coefficient.

When  $r$  is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)},$$

where  $\Gamma(\cdot)$  is the Gamma function.

# prob.NegativeBinomialDistribution

## Examples

### Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 1
```

```
P = 0.5
```

### Create a Negative Binomial Distribution Object Using Specified Parameters

Create a negative binomial distribution object by specifying the parameter values.

```
pd = makedist('NegativeBinomial','r',5,'p',.1)
```

```
pd =
```

```
NegativeBinomialDistribution
```

```
Negative Binomial distribution
```

```
R = 5
```

```
P = 0.1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
45
```

# NeighborSearcher

---

**Purpose** Nearest neighbor search object

**Description** NeighborSearcher is an abstract class used for nearest neighbor search. You cannot create instances of this class directly. Instead, create an instance of a derived class such as ExhaustiveSearcher or KDTreeSearcher either by calling the derived class constructor or by calling the function createns.

**Construction** NeighborSearcher is an abstract class. You cannot create instances of this class directly. You can construct an object in a subclass, such as KDTreeSearcher or ExhaustiveSearcher, either by calling the subclass constructors or by using the createns function.

**Properties** **X**

A matrix used to create the object.

**Distance**

A string specifying a built-in distance metric (applies to both ExhaustiveSearcher and KDTreeSearcher) or a function handle (only applies to ExhaustiveSearcher) that you provide when you create the object. This property is the default distance metric used when you call the knnsearch method to find nearest neighbors for future query points.

**DistParameter**

Specifies the additional parameter for the chosen distance metric. The value is:

- If 'Distance' is 'minkowski': A positive scalar indicating the exponent of the Minkowski distance. (Applies for both ExhaustiveSearcher and KDTreeSearcher.)
- If 'Distance' is 'mahalanobis': A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. (Only applies for ExhaustiveSearcher.)

- If 'Distance' is 'seuclidean': A vector representing the scale value of the data when computing the 'seuclidean' distance. (Only applies for ExhaustiveSearcher.)
- Otherwise: Empty.

## See Also

`createns` | `KDTreeSearcher` | `ExhaustiveSearcher`

**Purpose**           Generate quasi-random point set

**Syntax**           `X = net(p,n)`

**Description**      `X = net(p,n)` returns the first  $n$  points  $X$  from the point set  $p$  of the `grandset` class.  $X$  is  $n$ -by- $d$ , where  $d$  is the dimension of the point set. Objects  $p$  of the `@grandset` class encapsulate properties of a specified quasi-random sequence. Values of the point set are not generated and stored in memory until  $p$  is accessed using `net` or parenthesis indexing.

**Examples**           Use `haltonset` to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : none
```

Use `scramble` to apply reverse-radix scrambling:

```
p = scramble(p,'RR2')
p =
    Halton point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : RR2
```

Use `net` to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
```

0.3013	0.6497	0.4141
0.9087	0.7883	0.2166

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11, :)
```

```
X =
```

0.0928	0.6950	0.0029
0.9087	0.7883	0.2166
0.3843	0.9840	0.9878
0.6831	0.7357	0.7923

# CompactClassificationDiscriminant.nLinearCoeffs

---

<b>Purpose</b>	Number of nonzero linear coefficients
<b>Syntax</b>	<code>ncoeffs = nLinearCoeffs(obj)</code> <code>ncoeffs = nLinearCoeffs(obj,delta)</code>
<b>Description</b>	<code>ncoeffs = nLinearCoeffs(obj)</code> returns the number of nonzero linear coefficients in the linear discriminant model <code>obj</code> . <code>ncoeffs = nLinearCoeffs(obj,delta)</code> returns the number of nonzero linear coefficients for threshold parameter <code>delta</code> .
<b>Input Arguments</b>	<b>obj</b> Discriminant analysis classifier, produced using <code>fitcdiscr</code> . <b>delta</b> Scalar or vector value of the Delta parameter. See “Gamma and Delta” on page 21-2506.
<b>Output Arguments</b>	<b>ncoeffs</b> Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model <code>obj</code> . If you call <code>nLinearCoeffs</code> with a <code>delta</code> argument, <code>ncoeffs</code> is the number of nonzero linear coefficients for threshold parameter <code>delta</code> . If <code>delta</code> is a vector, <code>ncoeffs</code> is a vector with the same number of elements. If <code>obj</code> is a quadratic discriminant model, <code>ncoeffs</code> is the number of predictors in <code>obj</code> .
<b>Definitions</b>	<b>Gamma and Delta</b> Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, $\gamma$ and $\delta$ , that control regularization as follows. <code>cvshrink</code> helps you select appropriate values of the parameters.

Let  $\Sigma$  represent the covariance matrix of the data  $X$ , and let  $\hat{X}$  be the centered data (the data  $X$  minus the mean by class). Define

$$D = \text{diag}(\hat{X}^T * \hat{X}).$$

The regularized covariance matrix  $\tilde{\Sigma}$  is

$$\tilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever  $\gamma \geq \text{MinGamma}$ ,  $\tilde{\Sigma}$  is nonsingular.

Let  $\mu_k$  be the mean vector for those elements of  $X$  in class  $k$ , and let  $\mu_0$  be the global mean vector (the mean of the rows of  $X$ ). Let  $C$  be the correlation matrix of the data  $X$ , and let  $\tilde{C}$  be the regularized correlation matrix:

$$\tilde{C} = (1 - \gamma)C + \gamma I,$$

where  $I$  is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point  $x$  is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter  $\delta$  enters into this equation as a threshold on the final term in square brackets. Each component of the vector

$[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$  is set to zero if it is smaller in magnitude than the threshold  $\delta$ . Therefore, for class  $k$ , if component  $j$  is thresholded to zero, component  $j$  of  $x$  does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When  $\delta \geq \text{DeltaPredictor}(i)$ , all classes  $k$  have

# CompactClassificationDiscriminant.nLinearCoeffs

---

$$\left| \tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0) \right| \leq \delta.$$

Therefore, when  $\delta \geq \text{DeltaPredictor}(i)$ , the regularized classifier does not use predictor  $i$ .

## Examples

### Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various Delta values.

Create a discriminant analysis classifier from the fishseriris data.

```
load fisheriris
obj = fitcdiscr(meas,species);
```

Find the number of nonzero coefficients in obj.

```
ncoeffs = nLinearCoeffs(obj)
```

```
ncoeffs =
```

```
4
```

Find the number of nonzero coefficients for delta = 1, 2, 4, and 8.

```
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
```

```
ncoeffs =
```

```

## Concepts

- “Discriminant Analysis” on page 15-3

# nlinfit

---

## Purpose

Nonlinear regression

## Syntax

```
beta = nlinfit(X,Y,modelfun,beta0)
beta = nlinfit(X,Y,modelfun,beta0,options)
beta = nlinfit( ___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit( ___ )
```

## Description

`beta = nlinfit(X,Y,modelfun,beta0)` returns a vector of estimated coefficients for the nonlinear regression of the responses in `Y` on the predictors in `X` using the model specified by `modelfun`. The coefficients are estimated using iterative least squares estimation, with initial values specified by `beta0`.

`beta = nlinfit(X,Y,modelfun,beta0,options)` fits the nonlinear regression using the algorithm control parameters in the structure `options`. You can return any of the output arguments in the previous syntaxes.

`beta = nlinfit( ___,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

`[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit( ___ )` additionally returns the residuals, `R`, the Jacobian of `modelfun`, `J`, the estimated variance-covariance matrix for the estimated coefficients, `CovB`, an estimate of the variance of the error term, `MSE`, and a structure containing details about the error model, `ErrorModelInfo`.

## Input Arguments

### **X - Predictor variables**

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, `X` is a design matrix of predictor (independent

variable) values, with one row for each value in Y, and one column for each coefficient. However, X can be any array that `modelfun` can accept.

**Data Types**

single | double

**Y - Response values**

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

**Data Types**

single | double

**modelfun - Nonlinear regression model function**

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

**Data Types**

function\_handle

**beta0 - Initial coefficient values**

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

---

**Note** Poor starting values can lead to a solution with large residual error.

---

## Data Types

single | double

## options - Estimation algorithm options

structure created using `statset`

Estimation algorithm options, specified as a structure you create using `statset`. The following `statset` parameters are applicable to `nlinfit`.

## DerivStep - Relative difference for finite difference gradient

$\text{eps}^{(1/3)}$  (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as `beta`. Use a vector to specify a different relative difference for each coefficient.

## Display - Level of output display

'off' (default) | 'iter' | 'final'

Level of output display during estimation, specified as one of 'off', 'iter', or 'final'. If you specify 'iter', output is displayed at each iteration. If you specify 'final', output is displayed after the final iteration.

## FunValCheck - Indicator for whether to check for invalid values

'on' (default) | 'off'

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as 'on' or 'off'.

## MaxIter - Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

## RobustWgtFun - Weight function

string | function handle | []

Weight function for robust fitting, specified as a valid string or function handle.

---

**Note** RobustWgtFun must have value [] when you use observation weights, W.

---

The following table describes the possible string values. Let  $r$  denote normalized residuals and  $w$  denote robust weights. The indicator function  $I[x]$  is equal to 1 if the expression  $x$  is true, and 0 otherwise.

Weight Function	Equation	Default Tuning Constant
' ' (default)	No robust fitting	—
'andrews'	$w = I[ r  < \pi] \times \sin(r) / r$	1.339
'bisquare'	$w = I[ r  < 1] \times (1 - r^2)^2$	4.685
'cauchy'	$w = \frac{1}{(1 + r^2)}$	2.385
'fair'	$w = \frac{1}{(1 +  r )}$	1.400

Weight Function	Equation	Default Tuning Constant
'huber'	$w = \frac{1}{\max(1,  r )}$	1.345
'logistic'	$w = \frac{\tanh(r)}{r}$	1.205
'talwar'	$w = I[ r  < 1]$	2.795
'welsch'	$w = \exp\{-r^2\}$	2.985

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a `Tune` constant.

### **Tune - Tuning constant**

positive scalar value

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by `RobustWgtFun`.

If you use a function handle to specify `RobustWgtFun`, then you must specify a value for `Tune`.

### **TolFun - Termination tolerance on residual sum of squares**

1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the

convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

### **TolX - Termination tolerance on estimated coefficients**

1e-8 (default) | positive scalar value

Termination tolerance on the estimated coefficients, `beta`, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

### **Robust - Indicator for robust fitting**

'off' (default) | 'on'

Indicator for robust fitting, specified as 'off' or 'on'.

---

**Note** `Robust` will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

---

### **WgtFun - Weight function for robust fitting**

string | function handle

Weight function for robust fitting, specified as a string indicating a weight function, or a function handle. `WgtFun` is valid only when `Robust` has value 'on'.

---

**Note** `WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

---

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'ErrorModel', 'proportional', 'ErrorParameters', 0.5` specifies a proportional error model, with initial value 0.5 for the error parameter estimation

## 'ErrorModel' - Form of error term

`'constant' (default) | 'proportional' | 'combined'`

Form of the error term, specified as the comma-separated pair consisting of `'ErrorModel'` and one of the following strings indicating the error model. Each model defines the error using a standard mean-zero and unit-variance variable  $e$  in combination with independent components: the function value  $f$ , and one or two parameters  $a$  and  $b$ .

`'constant' (default)`

$$y = f + ae$$

`'proportional'`

$$y = f + bfe$$

`'combined'`

$$y = f + (a + b|f|)e$$

The only allowed error model when using `Weights` is `'constant'`.

---

**Note** `options.RobustWgtFun` must have value `[]` when using an error model other than `'constant'`.

---

## 'ErrorParameters' - Initial estimates for error model parameters

`1 or [1,1] (default) | scalar value | two-element vector`

Initial estimates for the error model parameters in the chosen `ErrorModel`, specified as the comma-separated pair consisting of `'ErrorParameters'` and a scalar value or two-element vector.

Error Model	Parameters	Default Values
'constant'	$a$	1
'proportional'	$b$	1
'combined'	$a, b$	[1, 1]

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for  $a$  and the starting value 2 for  $b$  as follows.

**Example:** 'ErrorParameters', [1,2]

You can only use the 'constant' error model when using **Weights**.

---

**Note** options.RobustWgtFun must have value [] when using an error model other than 'constant'.

---

### Data Types

double | single

### 'Weights' - Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If  $W$  is a vector, then it must be the same size as  $Y$ .
- If  $W$  is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

---

**Note** options.RobustWgtFun must have value [] when you use observation weights.

---

## Output Arguments

### Data Types

double | single | function\_handle

### **beta** - Estimated regression coefficients

vector

Estimated regression coefficients, returned as a vector. The number of elements in **beta** equals the number of elements in **beta0**.

Let  $f(X_i, \mathbf{b})$  denote the nonlinear function specified by **modelfun**, where  $\mathbf{x}_i$  are the predictors for observation  $i$ ,  $i = 1, \dots, N$ , and  $\mathbf{b}$  are the regression coefficients. The vector of coefficients returned in **beta** minimizes the weighted least squares equation,

$$\sum_{i=1}^N w_i [y_i - f(\mathbf{x}_i, \mathbf{b})]^2.$$

For unweighted nonlinear regression, all of the weight terms are equal to 1.

### **R** - Residuals

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument **Weights**, then **R** contains weighted residuals.
- If you specify an error model other than 'constant' using the name-value pair argument **ErrorModel**, then you can no longer interpret **R** as model fit residuals.

### **J** - Jacobian

matrix

Jacobian of the nonlinear regression model, **modelfun**, returned as an  $N$ -by- $p$  matrix, where  $N$  is the number of observations and  $p$  is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument `Weights`, then `J` is the weighted model function Jacobian.
- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `J` as the model function Jacobian.

### **CovB - Estimated variance-covariance matrix**

matrix

Estimated variance-covariance matrix for the fitted coefficients, `beta`, returned as a  $p$ -by- $p$  matrix, where  $p$  is the number of estimated coefficients. If the model Jacobian, `J`, has full column rank, then `CovB` =  $\text{inv}(J' * J) * \text{MSE}$ , where `MSE` is the mean squared error.

### **MSE - Mean squared error**

scalar value

Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, `J`, has full column rank, then  $\text{MSE} = (R' * R) / (N - p)$ , where  $N$  is the number of observations, and  $p$  is the number of estimated coefficients.

### **ErrorModelInfo - Information about error model fit**

structure

Information about the error model fit, returned as a structure with the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an $N$ -by- $p$ matrix, <code>X</code> , and returns an $N$ -by-1 vector of error variances using the estimated error model

MSE	Mean squared error
ScheffeSimPred	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
WeightFunction	Logical with value true if you used a custom weight function previously in nlinfit
FixedWeights	Logical with value true if you used fixed weights previously in nlinfit
RobustWeightFunction	Logical with value true if you used robust fitting previously in

## Examples

### Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
beta = nlinfit(X,y,@hougen,beta0)
```

```
beta =  
  
    1.2526  
    0.0628  
    0.0400  
    0.1124  
    1.1914
```

## Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
```

```
b = [1;3;2];
```

```
x = exprnd(2,100,1);
```

```
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
```

```
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
beta0 = [2;2;2];
```

```
beta = nlinfit(x,y,modelfun,beta0,opts)
```

```
beta =
```

```
1.0041
```

```
3.0997
```

```
2.1483
```

## Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');
```

```
X = S.reactants;
```

```
y = S.rate;
```

```
beta0 = S.beta;
```

Specify a vector of known observation weights.

```
W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';
```

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);  
beta
```

```
beta =
```

```
    2.2068  
    0.1077  
    0.0766  
    0.1818  
    0.6516
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))
```

```
ans =
```

```
    2.5721  
    0.1251  
    0.0950  
    0.2043  
    0.7735
```

## **Nonlinear Regression Using Weights Function Handle**

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;
```

```
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);  
beta
```

```
beta =  
  
    0.8308  
    0.0409  
    0.0251  
    0.0801  
    1.8261
```

Display the coefficient standard errors.

```
sqrt(diag(CovB))  
  
ans =  
  
    0.5822  
    0.0297  
    0.0197  
    0.0578  
    1.2810
```

## **Nonlinear Regression Using Nonconstant Error Model**

Load sample data.

```
S = load('reaction');
```

```
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error model.

```
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(X,y,@hougen,beta0,'ErrorModel',  
beta
```

```
beta =
```

```
    1.2526  
    0.0628  
    0.0400  
    0.1124  
    1.1914
```

Display the error model information.

```
ErrorModelInfo
```

```
ErrorModelInfo =
```

```
    ErrorModel: 'combined'  
    ErrorParameters: [0.1517 5.6783e-08]  
    ErrorVariance: @(x)mse*(errorparam(1)+errorparam(2)*abs(model(x)))  
                MSE: 1.6245  
    ScheffeSimPred: 6  
    WeightFunction: 0  
    FixedWeights: 0  
    RobustWeightFunction: 0
```

## Tips

- To produce error estimates on predictions, use the optional output arguments R, J, CovB, or MSE as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, `beta`, use the optional output arguments R, J, CovB, or MSE as inputs to `nlparci`.

- If you use the robust fitting option, `RobustWgtFun`, you must use `CovB`—and might need `MSE`—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.

## Algorithms

- `nlinfit` treats NaN values in `Y` or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlinfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlinfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation's residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlinfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.

## Definitions

### Weighted Residuals

A *weighted residual* is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients,  $\mathbf{b}$ , the residual for observation  $i$  is

$$r_i = y_i - f(\mathbf{x}_i, \mathbf{b}),$$

where  $y_i$  is the observed response and  $f(\mathbf{x}_i, \mathbf{b})$  is the fitted response at predictors  $\mathbf{x}_i$ .

When you fit a weighted nonlinear regression with weights  $w_i$ ,  $i = 1, \dots, N$ , `nlinfit` returns the weighted residuals,

$$r_i^* = \sqrt{w_i} (y_i - f(\mathbf{x}_i, \mathbf{b})).$$

## Weighted Model Function Jacobian

The *weighted model function Jacobian* is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients,  $\mathbf{b}$ , the estimated model Jacobian,  $\mathbf{J}$ , for the nonlinear function  $f(\mathbf{x}_i, \mathbf{b})$  has elements

$$\mathbf{J}_{ij} = \frac{\partial f(\mathbf{x}_i, \mathbf{b})}{\partial b_j},$$

where  $b_j$  is the  $j$ th element of  $\mathbf{b}$ .

When you fit a weighted nonlinear regression with diagonal weights matrix  $\mathbf{W}$ , `nlinfit` returns the weighted Jacobian matrix,

$$\mathbf{J}^* = \mathbf{W}^{1/2}\mathbf{J}.$$

**Concepts**

- “Nonlinear Regression” on page 11-2

# nlintool

---

**Purpose** Interactive nonlinear regression

**Syntax**

```
nlintool(X,y,fun,beta0)
nlintool(X,y,fun,beta0,alpha)
nlintool(X,y,fun,beta0,alpha,'xname','yname')
```

**Description** `nlintool(X,y,fun,beta0)` is a graphical user interface to the `nlinfit` function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.

`nlintool(X,y,fun,beta0,alpha)` shows  $100(1-\alpha)\%$  confidence bands. These are simultaneous confidence bounds for the function value. Using the **Bounds** menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.

`nlintool(X,y,fun,beta0,alpha,'xname','yname')` labels the plots using the string matrix 'xname' for the predictors and the string 'yname' for the response.

**Examples** The data in `reaction.mat` are partial pressures of three chemical reactants and the corresponding reaction rates. The function `hougen` implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:

```
load reaction
nlintool(reactants,rate,@hougen,beta,0.01,xn,yn)
```

**See Also** [nlinfit](#) | [polytool](#) | [rstool](#)

# nlmefit

---

**Purpose** Nonlinear mixed-effects estimation

**Syntax**

```
beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] =
nlmefit(X,y,group,V,fun,beta0,'Name',value)
```

**Description** `beta = nlmefit(X,y,group,V,fun,beta0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `beta`. By default, `nlmefit` fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

`X` is an  $n$ -by- $h$  matrix of  $n$  observations on  $h$  predictors.

`y` is an  $n$ -by-1 vector of responses.

`group` is a grouping variable indicating  $m$  groups in the observations. `group` is a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings. For more information on grouping variables, see “Grouping Variables” on page 2-52.

`V` is an  $m$ -by- $g$  matrix or cell array of  $g$  group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of `V` are assigned to groups using `grp2idx`, according to the order specified by `grp2idx(group)`. Use a cell array for `V` if group predictors vary in size across groups. Use `[]` for `V` if there are no group-specific predictors.

`fun` is a handle to a function that accepts predictor values and model parameters and returns fitted values. `fun` has the form

```
yfit = modelfun(PHI,XFUN,VFUN)
```

The arguments are:

- `PHI` — A 1-by- $p$  vector of model parameters.

- XFUN — A  $k$ -by- $h$  array of predictors, where:
  - $k = 1$  if XFUN is a single row of X.
  - $k = n_i$  if XFUN contains the rows of X for a single group of size  $n_i$ .
  - $k = n$  if XFUN contains all rows of X.
- VFUN — Group-specific predictors given by one of:
  - A 1-by- $g$  vector corresponding to a single group and a single row of V.
  - An  $n$ -by- $g$  array, where the  $j$ th row is  $V(I,:)$  if the  $j$ th observation is in group I.

If V is empty, nlmefit calls modelfun with only two inputs.
- yfit — A  $k$ -by-1 vector of fitted values

When either PHI or VFUN contains a single row, it corresponds to all rows in the other two input arguments.

---

**Note** If modelfun can compute yfit for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.

---

beta0 is a  $q$ -by-1 vector with initial estimates for  $q$  fixed effects. By default,  $q$  is the number of model parameters  $p$ .

nlmefit fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

`[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)` also returns `PSI`, an  $r$ -by- $r$  estimated covariance matrix for the random effects. By default,  $r$  is equal to the number of model parameters  $p$ .

`[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)` also returns `stats`, a structure with fields:

- `dfc` — The error degrees of freedom for the model
- `logl` — The maximized loglikelihood for the fitted model
- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion, calculated as  $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$ , where `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and `logl` is a field in the `stats` structure
- `bic` — The Bayesian information criterion, calculated as  $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$ 
  - `M` is the number of groups.
  - `numParam` and `logl` are defined as in `aic`.Note that some literature suggests that the computation of `bic` should be ,  $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$ , where `N` is the number of observations.
- `covb` — The estimated covariance matrix of the parameter estimates
- `sebeta` — The standard errors for `beta`
- `ires` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the individual predicted values
- `pres` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the population predicted values
- `iwres` — The individual weighted residuals

- pwres — The population weighted residuals
- cwres — The conditional weighted residuals

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)` also returns `B`, an  $r$ -by- $m$  matrix of estimated random effects for the  $m$  groups. By default,  $r$  is equal to the number of model parameters  $p$ .

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)` specifies one or more optional parameter name/value pairs. Specify *Name* inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both `FEConstDesign` and `REConstDesign` to `eye(p)`, or by setting both `FEPARAMSSelect` and `REPARAMSSelect` to `1:p`.) Use at most one parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The `nlmefit` function requires you to specify at least one fixed effect and one random effect.

Parameter	Value
<code>FEPARAMSSelect</code>	A vector specifying which elements of the parameter vector <code>PHI</code> include a fixed effect, given as a numeric vector of indices from 1 to $p$ or as a 1-by- $p$ logical vector. If $q$ is the specified number of elements, then the model includes $q$ fixed effects.
<code>FEConstDesign</code>	A $p$ -by- $q$ design matrix <code>ADESIGN</code> , where <code>ADESIGN*beta</code> are the fixed components of the $p$ elements of <code>PHI</code> .
<code>FEGroupDesign</code>	A $p$ -by- $q$ -by- $m$ array specifying a different $p$ -by- $q$ fixed-effects design matrix for each of the $m$ groups.
<code>FEObsDesign</code>	A $p$ -by- $q$ -by- $n$ array specifying a different $p$ -by- $q$ fixed-effects design matrix for each of the $n$ observations.

Parameter	Value
REParamsSelect	A vector specifying which elements of the parameter vector PHI include a random effect, given as a numeric vector of indices from 1 to $p$ or as a 1-by- $p$ logical vector. The model includes $r$ random effects, where $r$ is the specified number of elements.
REConstDesign	A $p$ -by- $r$ design matrix BDESIGN, where BDESIGN*B are the random components of the $p$ elements of PHI.
REGroupDesign	A $p$ -by- $r$ -by- $m$ array specifying a different $p$ -by- $r$ random-effects design matrix for each of $m$ groups.
REObsDesign	A $p$ -by- $r$ -by- $n$ array specifying a different $p$ -by- $r$ random-effects design matrix for each of $n$ observations.

Use the following parameters to control the iterative algorithm for maximizing the likelihood:

Parameter	Value
RefineBeta0	Determines whether nlmefit makes an initial refinement of beta0 by first fitting modelfun without random effects and replacing beta0 with beta. Choices are 'on' and 'off'. The default value is 'on'.
ErrorModel	A string specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable $e$ , the function value $f$ , and one or two parameters $a$ and $b$ . Choices are: <ul style="list-style-type: none"> <li>'constant': <math>y = f + a*e</math></li> </ul>

Parameter	Value
	<ul style="list-style-type: none"> <li>• 'proportional': <math>y = f + b \cdot f^a \cdot e</math></li> <li>• 'combined': <math>y = f + (a + b \cdot f)^a \cdot e</math></li> <li>• 'exponential': <math>y = f \cdot \exp(a \cdot e)</math>, or equivalently <math>\log(y) = \log(f) + a \cdot e</math></li> </ul> <p>If this parameter is given, the output <code>stats.errorparam</code> field has the value</p> <ul style="list-style-type: none"> <li>• <math>a</math> for 'constant' and 'exponential'</li> <li>• <math>b</math> for 'proportional'</li> <li>• <math>[a \ b]</math> for 'combined'</li> </ul>
ApproximationType	<p>The method used to approximate the likelihood of the model. Choices are:</p> <ul style="list-style-type: none"> <li>• 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of beta and B. This is the default.</li> <li>• 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of beta and B.</li> <li>• 'FO' — First-order Laplacian approximation without random effects.</li> <li>• 'FOCE' — First-order Laplacian approximation at the conditional estimates of B.</li> </ul>

Parameter	Value
Vectorization	<p data-bbox="753 317 1283 407">Indicates acceptable sizes for the PHI, XFUN, and VFUN input arguments to <code>modelfun</code>. Choices are:</p> <ul data-bbox="753 442 1283 1397" style="list-style-type: none"><li data-bbox="753 442 1283 789">• 'SinglePhi' — <code>modelfun</code> can only accept a single set of model parameters at a time, so PHI must be a single row vector in each call. <code>nlfmfit</code> calls <code>modelfun</code> in a loop, if necessary, with a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. This is the default.</li><li data-bbox="753 807 1283 1067">• 'SingleGroup' — <code>modelfun</code> can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row.</li><li data-bbox="753 1085 1283 1397">• 'Full' — <code>modelfun</code> can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to <code>modelfun</code>, but may require <code>modelfun</code> to perform singleton expansion on PHI or V.</li></ul>

Parameter	Value
CovParameterization	Specifies the parameterization used internally for the scaled covariance matrix. Choices are 'chol' for the Cholesky factorization or 'logm' the matrix logarithm. The default is 'logm'.
CovPattern	<p>Specifies an <math>r</math>-by-<math>r</math> logical or numeric matrix <math>P</math> that defines the pattern of the random-effects covariance matrix <math>\Psi</math>. <code>nlmefit</code> estimates the variances along the diagonal of <math>\Psi</math> and the covariances specified by nonzeros in the off-diagonal elements of <math>P</math>. Covariances corresponding to zero off-diagonal elements in <math>P</math> are constrained to be zero. If <math>P</math> does not specify a row-column permutation of a block diagonal matrix, <code>nlmefit</code> adds nonzero elements to <math>P</math> as needed. The default value of <math>P</math> is <math>\text{eye}(r)</math>, corresponding to uncorrelated random effects.</p> <p>Alternatively, <math>P</math> may be a 1-by-<math>r</math> vector containing values in <math>1:r</math>, with equal values specifying groups of random effects. In this case, <code>nlmefit</code> estimates covariances only within groups, and constrains covariances across groups to be zero.</p>

Parameter	Value
ParamTransform	<p>A vector of <math>p</math>-values specifying a transformation function <math>f()</math> for each of the <math>P</math> parameters: <math>XB = ADESIGN*BETA + BDESIGN*B</math> <math>PHI = f(XB)</math>. Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of <math>PHI</math>:</p> <ul style="list-style-type: none"> <li>• 0: <math>PHI = XB</math> (default for all parameters)</li> <li>• 1: <math>\log(PHI) = XB</math></li> <li>• 2: <math>\text{probit}(PHI) = XB</math></li> <li>• 3: <math>\text{logit}(PHI) = XB</math></li> </ul>
Options	<p>A structure of the form returned by <code>statset</code>. <code>nlmefit</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"> <li>• 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters <math>p</math>. The default is <math>\text{eps}^{(1/3)}</math>.</li> <li>• 'Display' — Level of iterative display during estimation. Choices are: <ul style="list-style-type: none"> <li>▪ 'off' (default) — Displays no information</li> <li>▪ 'final' — Displays information after the final iteration</li> <li>▪ 'iter' — Displays information at each iteration</li> </ul> </li> <li>• 'FunValCheck' — Check for invalid values, such as NaN or Inf, from</li> </ul>

Parameter	Value
	<p>modelfun. Choices are 'on' and 'off'. The default is 'on'.</p> <ul style="list-style-type: none"> <li>• 'MaxIter' — Maximum number of iterations allowed. The default is 200.</li> <li>• 'OutputFcn' — Function handle specified using @, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration.</li> <li>• 'TolFun' — Termination tolerance on the loglikelihood function. The default is 1e-4.</li> <li>• 'TolX' — Termination tolerance on the estimated fixed and random effects. The default is 1e-4.</li> </ul>
OptimFun	<p>Specifies the optimization function used in maximizing the likelihood. Choices are 'fminsearch' to use fminsearch or 'fminunc' to use fminunc. The default is 'fminsearch'. You can specify 'fminunc' only if Optimization Toolbox software is installed.</p>

## Examples

### Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

```
CIRC = [30 58 87 115 120 142 145;
        33 69 111 156 172 203 203;
        30 51 75 108 115 139 140;
        32 62 112 167 179 209 214;
        30 49 81 125 142 174 177];
time = [118 484 664 1004 1231 1372 1582];
```

```
h = plot(time,CIRC','o','LineWidth',2);  
xlabel('Time (days)')  
ylabel('Circumference (mm)')  
title('\bf Orange Tree Growth')  
legend([repmat('Tree ',5,1),num2str((1:5)')],...  
       'Location','NW')  
grid on  
hold on
```

Use an anonymous function to specify a logistic growth model.

```
model = @(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3))));
```

Fit the model using `nlmefit` with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

```
TIME = repmat(time,5,1);
NUMS = repmat((1:5)',size(time));

beta0 = [100 100 100];
[beta1,PSI1,stats1] = nlmefit(TIME(:),CIRC(:),NUMS(:),...
                             [],model,beta0)
```

```
beta1 =
```

```
191.3189
723.7608
346.2517
```

```
PSI1 =
```

```
962.1533    0    0
    0    0.0000    0
    0    0    297.9882
```

```
stats1 =
```

```
    dfe: 28
    logl: -131.5457
    mse: 59.7882
    rmse: 7.9016
    errorparam: 7.7323
```

# nlmefit

---

```
    aic: 277.0913
    bic: 274.3574
   covb: [3x3 double]
 sebeta: [15.2249 33.1579 26.8235]
   ires: [35x1 double]
   pres: [35x1 double]
  iwres: [35x1 double]
 pwres: [35x1 double]
 cwres: [35x1 double]
```

The negligible variance of the second random effect,  $\text{PSI1}(2,2)$ , suggests that it can be removed to simplify the model.

```
[beta2,PSI2,stats2,b2] = nlmefit(TIME(:),CIRC(:),...
    NUMS(:),[],model,beta0,'REParamsSelect',[1 3])
```

```
beta2 =
```

```
    191.3190
    723.7617
    346.2507
```

```
PSI2 =
```

```
    962.5701         0
         0    297.5714
```

```
stats2 =
```

```
    dfe: 29
   logl: -131.5457
    mse: 59.7863
   rmse: 7.7644
```

```

errorparam: 7.7322
      aic: 275.0913
      bic: 272.7479
      covb: [3x3 double]
sebeta: [15.2276 33.1578 26.8216]
      ires: [35x1 double]
      pres: [35x1 double]
      iwres: [35x1 double]
      pwres: [35x1 double]
      cwres: [35x1 double]

```

```
b2 =
```

```

-28.5273   31.6066  -36.5085   39.0760   -5.6468
   9.9858   -0.7610    5.9971   -9.4468   -5.7751

```

The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria ( `aic` and `bic` ) are reduced, supporting the decision to drop the second random effect from the model.
