Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```

PHI = repmat(beta2,1,5) + ...           % Fixed effects
      [b2(1,:);zeros(1,5);b2(2,:)];    % Random effects

colors = get(h,'Color');
tplot = 0:0.1:1600;
for I = 1:5
    fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
    PHI(3,I)));
    plot(tplot,fitted_model(tplot),'Color',colors{I}, ...
        'LineWidth',2)
end

```

# nlmefitsa

---

**Purpose** Fit nonlinear mixed-effects model with stochastic EM algorithm

**Syntax** `[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)`  
`[BETA,PSI,STATS,B] =`  
`nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',`  
`Value)`

**Description** `[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.

`[BETA,PSI,STATS,B] =`  
`nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name', Value)` accepts one or more comma-separated parameter name/value pairs. Specify *Name* inside single quotes.

## Input Arguments

### Definitions:

In the following list of arguments, the following variable definitions apply:

- *n* — number of observations
- *h* — number of predictor variables
- *m* — number of groups
- *g* — number of group-specific predictor variables

- $p$  — number of parameters
- $f$  — number of fixed effects

**X**

An  $n$ -by- $h$  matrix of  $n$  observations on  $h$  predictor variables.

**Y**

An  $n$ -by-1 vector of responses.

**GROUP**

A grouping variable indicating to which of  $m$  groups each observation belongs. GROUP can be a categorical variable, a numeric vector, a character matrix with rows for group names, or a cell array of strings.

**V**

An  $m$ -by- $g$  matrix of  $g$  group-specific predictor variables for each of the  $m$  groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of V are ordered according to GRP2IDX(GROUP). Use an  $m$ -by- $g$  cell array for V if any of the group-specific predictor values vary in size across groups. Specify [ ] for V if there are no group predictors.

**MODELFUN**

A handle to a function that accepts predictor values and model parameters, and returns fitted values. MODELFUN has the form YFIT = MODELFUN(PHI, XFUN, VFUN) with input arguments

- PHI — A 1-by- $p$  vector of model parameters.
- XFUN — An  $l$ -by- $h$  array of predictor variables where
  - $l$  is 1 if XFUN is a single row of X
  - $l$  is  $n_i$  if XFUN contains the rows of X for a single group of size  $n_i$
  - $l$  is  $n$  if XFUN contains all rows of X.

- VFUN — Either
  - A 1-by- $g$  vector of group-specific predictors for a single group, corresponding to a single row of  $V$
  - An  $n$ -by- $g$  matrix, where the  $k$ -th row of VFUN is  $V(i,:)$  if the  $k$ -th observation is in group  $i$ .

If  $V$  is empty, `nlmefitsa` calls `MODELFUN` with only two inputs.

`MODELFUN` returns an  $l$ -by-1 vector of fitted values `YFIT`. When either `PHI` or `VFUN` contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the 'Vectorization' parameter name/value pair (described below) if `MODELFUN` can compute `YFIT` for more than one vector of model parameters in one call.

## **BETA0**

An  $f$ -by-1 vector with initial estimates for the  $f$  fixed effects. By default,  $f$  is equal to the number of model parameters  $p$ . `BETA0` can also be an  $f$ -by-`REPS` matrix, and the estimation is repeated `REPS` times using each column of `BETA0` as a set of starting values.

## **Name-Value Pair Arguments**

By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an 'FE' prefix and one parameter name with an 'RE' prefix. Note that some choices change the way `nlmefitsa` calls `MODELFUN`, as described further below.

### **'FEParamsSelect'**

A vector specifying which elements of the model parameter vector `PHI` include a fixed effect, as a numeric vector with elements in  $1:p$ , or as a 1-by- $p$  logical vector. The model will include  $f$  fixed effects, where  $f$  is the specified number of elements.

### **'FEConstDesign'**

A  $p$ -by- $f$  design matrix ADESIGN, where ADESIGN\*BETA are the fixed components of the  $p$  elements of PHI.

#### **'FEGroupDesign'**

A  $p$ -by- $f$ -by- $m$  array specifying a different  $p$ -by- $f$  fixed effects design matrix for each of the  $m$  groups.

#### **'REParamsSelect'**

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in  $1:p$ , or as a 1-by- $p$  logical vector. The model will include  $r$  random effects, where  $r$  is the specified number of elements.

#### **'REConstDesign'**

A  $p$ -by- $r$  design matrix BDESIGN, where BDESIGN\*B are the random components of the  $p$  elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to  $\text{eye}(p)$ , or to setting both FEParamsSelect and REParamsSelect to  $1:p$ .

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

#### **'CovPattern'**

Specifies an  $r$ -by- $r$  logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. nlmefitsa computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. nlmefitsa constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and nlmefitsa adds non-zero elements to PAT as needed to produce such a pattern. The

default value of PAT is  $\text{eye}(r)$ , corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by- $r$  vector containing values in 1: $r$ . In this case, elements of PAT with equal values define groups of random effects, nlfitsa estimates covariances only within groups, and constrains covariances across groups to be zero.

### 'Cov0'

Initial value for the covariance matrix PSI. Must be an  $r$ -by- $r$  positive definite matrix. If empty, the default value depends on the values of BETA0.

### 'ComputeStdErrors'

true to compute standard errors for the coefficient estimates and store them in the output STATS structure, or false (default) to omit this computation.

### 'ErrorModel'

A string specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable  $e$ , the function value  $f$ , and one or two parameters  $a$  and  $b$ . Choices are

- 'constant' —  $y = f + a*e$
- 'proportional' —  $y = f + b*f*e$
- 'combined' —  $y = f + (a+b*f)*e$
- 'exponential' —  $y = f*\exp(a*e)$ , or equivalently  $\log(y) = \log(f) + a*e$

If this parameter is given, the output STATS.errorparam field has the value

- $a$  for 'constant' and 'exponential'
- $b$  for 'proportional'
- $[a\ b]$  for 'combined'

**'ErrorParameters'**

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the  $a$ ,  $b$ , or  $[a\ b]$  values depending on the `ErrorModel` parameter.

**'LogLikMethod'**

Specifies the method for approximating the loglikelihood. Choices are:

- 'is' — Importance sampling
- 'gq' — Gaussian quadrature
- 'lin' — Linearization
- 'none' — Omit the loglikelihood approximation (default)

**'NBurnIn'**

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.

**'NChains'**

Number  $c$  of "chains" simulated. Default is 1. Setting  $c > 1$  causes  $c$  simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

**'NIterations'**

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

- 1 simulated annealing
- 2 full step size
- 3 reduced step size

Default is [150 150 100]. A scalar is distributed across the three phases in the same proportions as the default.

## **'NMCIterations'**

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

- 1** full multivariate update
- 2** single coordinate update
- 3** multiple coordinate update

Default is [2 2 2]. A scalar value is treated as a three-element vector with all elements equal to the scalar.

## **'OptimFun'**

Either 'fminsearch' or 'fminunc', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

## **'Options'**

A structure created by a call to `statset`. `nlmefitsa` uses the following `statset` parameters:

- 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters  $p$ . The default is  $\text{eps}^{(1/3)}$ .
- Display — Level of display during estimation.
  - 'off' (default) — Displays no information
  - 'final' — Displays information after the final iteration of the estimation algorithm

- 'iter' — Displays information at each iteration
- FunValCheck
  - 'on' (sdefault) — Check for invalid values (such as NaN or Inf) from MODELFUN
  - 'off' — Skip this check
- OutputFcn — Function handle specified using @, a cell array with function handles or an empty array. nlmefitsa calls all output functions after each iteration. See nlmefitoutputfcn.m (the default output function for nlmefitsa) for an example of an output function.

### 'ParamTransform'

A vector of  $p$ -values specifying a transformation function  $f()$  for each of the  $p$  parameters:

$$XB = ADESIGN*BETA + BDESIGN*B$$

$$PHI = f(XB)$$

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:

- 0:  $PHI = XB$  (default for all parameters)
- 1:  $\log(PHI) = XB$
- 2:  $\text{probit}(PHI) = XB$
- 3:  $\text{logit}(PHI) = XB$

### 'Replicates'

Number REPS of estimations to perform starting from the starting values in the vector BETA0. If BETA0 is a matrix, REPS must match the number of columns in BETA0. Default is the number of columns in BETA0.

### 'Vectorization'

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. nlmefitsa calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, nlmefitsa calls MODELFUN with only two inputs.

## Output Arguments

### BETA

Estimates of the fixed effects

### PSI

An  $r$ -by- $r$  estimated covariance matrix for the random effects. By default,  $r$  is equal to the number of model parameters  $p$ .

### STATS

A structure with the following fields:

- logl — The maximized loglikelihood for the fitted model; empty if the LogLikMethod parameter has its default value of 'none'

- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion (empty if `logl` is empty), calculated as  $\text{aic} = -2 * \text{logl} + 2 * \text{numParam}$ , where
  - `logl` is the maximized loglikelihood.
  - `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- `bic` — The Bayesian information criterion (empty if `logl` is empty), calculated as  $\text{bic} = -2 * \text{logl} + \log(M) * \text{numParam}$ 
  - `M` is the number of groups.
  - `logl` and `numParam` are defined as in `aic`.  
Note that some literature suggests that the computation of `bic` should be ,  $\text{bic} = -2 * \text{logl} + \log(N) * \text{numParam}$ , where `N` is the number of observations. To adjust the value of the output you can redefine `bic` as follows:  $\text{bic} = \text{bic} - \text{numel}(\text{unique}(\text{group})) + \text{numel}(Y)$
- `sebeta` — The standard errors for BETA (empty if the `ComputeStdErrors` parameter has its default value of false)
- `covb` — The estimated covariance of the parameter estimates (empty if `ComputeStdErrors` is false)
- `dfe` — The error degrees of freedom
- `pres` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the population predicted values
- `ires` — The population residuals ( $y - y_{\text{population}}$ ), where `y_population` is the individual predicted values
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals
- `iwres` — The individual weighted residuals

## Examples

### Nonlinear Mixed-Effects Model with Stochastic EM Algorithm

Load the sample data.

```
load indomethacin
```

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

```
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t))
phi0 = [1 1 1 1];
xform = [0 1 0 1]; % log transform for 2nd and 4th parameters
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...
    subject,[],model,phi0,'ParamTransform',xform)
```

```
beta =
```

```

-0.0010	-0.0198	0.0137	-0.0757	0.0478	-0.0076

Plot the data along with an overall population fit

```
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time,concentration,subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('\bf Indomethacin Elimination')
xx = linspace(0,8);
line(xx,model(phi,xx),'linewidth',2,'color','k')
```

Plot individual curves based on random-effect estimates.

```
for j=1:6
    phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...
            beta(3)+br(3,j), exp(beta(4)+br(4,j))];
    line(xx,model(phir,xx),'color',get(h(j),'color'))
end
```

## Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

$$p(y | \beta, \sigma^2, \Sigma) = \int p(y | \beta, b, \sigma^2) p(b | \Sigma) db$$

where

- $y$  is the response data
- $\beta$  is the vector of population coefficients
- $\sigma^2$  is the residual variance
- $\Sigma$  is the covariance matrix for the random effects
- $b$  is the set of unobserved random effects

Each  $p(\cdot)$  function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

- 1 Simulation:** Generate simulated values of the random effects  $b$  from the posterior density  $p(b | \Sigma)$  given the current parameter estimates.
- 2 Stochastic approximation:** Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
- 3 Maximization step:** Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

## How To

- “Mixed-Effects Models” on page 11-22
- “Grouping Variables” on page 2-52

**Purpose** Negative of log-likelihood

**Description** The negative of the log-likelihood of the data.

---

**Note** This property applies only to `gmdistribution` objects constructed with `fitgmdist`.

---

# ProbDistParametric.NLogL property

---

<b>Purpose</b>	Read-only value specifying negative log likelihood for input data to ProbDistParametric object
<b>Description</b>	NLogL is a read-only property of the ProbDistParametric class. NLogL is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistParametric object.
<b>Values</b>	The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the <code>fitdist</code> function. This property is empty for distributions created without fitting to data, that is, by using the <code>ProbDistUnivParam.ProbDistUnivParam</code> constructor. Use this information to view and compare the negative log likelihood for input data supplied to create distributions.

# ProbDistUnivKernel.NLogL property

---

<b>Purpose</b>	Read-only value specifying negative log likelihood for input data to ProbDistUnivKernel object
<b>Description</b>	NLogL is a read-only property of the ProbDistUnivKernel class. NLogL is a value specifying the negative log likelihood for input data used to fit a distribution represented by a ProbDistUnivKernel object.
<b>Values</b>	The value is a numeric scalar for a distribution fit to input data, that is, a distribution created using the <code>fitdist</code> function. Use this information to view and compare the negative log likelihood for input data used to create distributions.

# nlparci

---

**Purpose** Nonlinear regression parameter confidence intervals

**Syntax**

```
ci = nlparci(beta,resid,'covar',sigma)
ci = nlparci(beta,resid,'jacobian',J)
ci = nlparci(...,'alpha',alpha)
```

**Description** `ci = nlparci(beta,resid,'covar',sigma)` returns the 95% confidence intervals `ci` for the nonlinear least squares parameter estimates `beta`. Before calling `nlparci`, use `nlinfit` to fit a nonlinear regression model and get the coefficient estimates `beta`, residuals `resid`, and estimated coefficient covariance matrix `sigma`.

`ci = nlparci(beta,resid,'jacobian',J)` is an alternative syntax that also computes 95% confidence intervals. `J` is the Jacobian computed by `nlinfit`. If the 'robust' option is used with `nlinfit`, use the 'covar' input rather than the 'jacobian' input so that the required `sigma` parameter takes the robust fitting into account.

`ci = nlparci(...,'alpha',alpha)` returns  $100(1-\text{alpha})\%$  confidence intervals.

`nlparci` treats NaNs in `resid` or `J` as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of `resid` exceeds the length of `beta` and `J` has full column rank. When `J` is ill-conditioned, confidence intervals may be inaccurate.

## Examples **Fit to exponential decay**

Suppose you have data, and want to fit a model of the form

$$y_i = a_1 + a_2 \exp(-a_3 x_i) + \varepsilon_i.$$

Here the  $a_i$  are the parameters you want to estimate,  $x_i$  are the data points, the  $y_i$  are the responses, and the  $\varepsilon_i$  are noise terms.

**1** Write a function handle that represents the model:

```
mdl = @(a,x)(a(1) + a(2)*exp(-a(3)*x));
```

- 2** Generate synthetic data with parameters  $a = [1;3;2]$ , with the  $x$  data points distributed exponentially with parameter 2, and normally distributed noise with standard deviation 0.1:

```
rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;
```

- 3** Fit the model to data starting from the arbitrary guess  $a_0 = [2;2;2]$ :

```
a0 = [2;2;2];
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,a0);
ahat
```

```
ahat =
    1.0153
    3.0229
    2.1070
```

- 4** Check whether  $[1;3;2]$  is in a 95% confidence interval using the Jacobian argument in `nlparci`:

```
ci = nlparci(ahat,r,'Jacobian',J)
```

```
ci =
    0.9869    1.0438
    2.9401    3.1058
    1.9963    2.2177
```

- 5** You can obtain the same result using the covariance argument:

```
ci = nlparci(ahat,r,'covar',cov)
```

```
ci =
    0.9869    1.0438
```

# nlparci

---

2.9401	3.1058
1.9963	2.2177

## See Also

[nlinfit](#) | [nlpredci](#)

**Purpose**

Nonlinear regression prediction confidence intervals

**Syntax**

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] =
nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)
```

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] =
nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)
```

**Description**

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB) returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and variance-covariance matrix, CovB.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value) uses additional options specified by one or more name-value pair arguments.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J) returns predictions, Ypred, and 95% confidence interval half-widths, delta, for the nonlinear regression model modelfun at input values X. Before calling nlpredci, use nlinfit to fit modelfun and get the estimated coefficients, beta, residuals, R, and Jacobian, J.

If you use a robust option with nlinfit, then you should use the Covar syntax rather than the Jacobian syntax. The variance-covariance matrix, CovB, is required to properly take the robust fitting into account.

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value) uses additional options specified by one or more name-value pair arguments.

## Input Arguments

### **modelfun - Nonlinear regression model function**

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array `X`—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

### **Data Types**

function\_handle

### **X - Input values for predictions**

matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of `X`. There should be a column in `X` for each coefficient in the model.

### **Data Types**

single | double

### **beta - Estimated regression coefficients**

vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

### **Data Types**

single | double

### **R - Residuals**

vector returned by `nlinfit`

Residuals for the fitted `modelfun`, specified as the vector of residuals returned by a previous call to `nlinfit`.

### **CovB - Estimated variance-covariance matrix**

matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, `beta`, specified as the variance-covariance matrix returned by a previous call to `nlinfit`.

### **J - Estimated Jacobian**

matrix returned by `nlinfit`

Estimated Jacobian of the nonlinear regression model, `modelfun`, specified as the Jacobian matrix returned by a previous call to `nlinfit`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Alpha',0.1,'PredOpt','observation'` specifies 90% prediction intervals for new observations.

### **'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). If `Alpha` has value  $a$ , then `nlpredci` returns intervals with  $100 \times (1 - a)\%$  confidence level.

The default confidence level is 95% ( $a = 0.05$ ).

**Example:** `'Alpha',0.1`

### **Data Types**

single | double

### **'ErrorModelInfo' - Information about error model fit**

structure returned by `nlinfit`

Information about the error model fit, specified as the comma-separated pair consisting of 'ErrorModelInfo' and a structure returned by a previous call to `nlinfit`.

`ErrorModelInfo` only has an effect on the returned prediction interval when `PredOpt` has the value 'observation'. If you do not use `ErrorModelInfo`, then `nlpredci` assumes the error variance model is 'constant'.

The error model structure returned by `nlinfit` has the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an $N$ -by- $p$ matrix, $X$ , and returns an $N$ -by-1 vector of error variances using the estimated error model
<code>MSE</code>	Mean squared error
<code>ScheffeSimPred</code>	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
<code>WeightFunction</code>	Logical with value true if you used a custom weight function previously in <code>nlinfit</code>
<code>FixedWeights</code>	Logical with value true if you used fixed weights previously in <code>nlinfit</code>
<code>RobustWeightFunction</code>	Logical with value true if you used robust fitting previously in

## **'MSE' - Mean squared error**

MSE returned by `nlinfit`

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to `nlinfit`.

If you use a robust option with `nlinfit`, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then `nlpredci` computes the MSE from the residuals, `R`, and does not take the robust fitting into account.

For example, if `mse` is the MSE value returned by `nlinfit`, then you can specify `'MSE',mse`.

### Data Types

single | double

### 'PredOpt' - Prediction interval to compute

'curve' (default) | 'observation'

Prediction interval to compute, specified as the comma-separated pair consisting of `'PredOpt'` and either `'curve'` or `'observation'`.

- If you specify the value `'curve'`, then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations `X`.
- If you specify the value `'observation'`, then `nlpredci` returns prediction intervals for new observations at `X`.

If you specify `'observation'` after using a robust option with `nlinfit`, then you must also specify a value for MSE to provide the robust estimate of the mean squared error.

**Example:** `'PredOpt','observation'`

### Data Types

char

### 'SimOpt' - Indicator for specifying simultaneous bounds

'off' (default) | 'on'

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of `'SimOpt'` and either `'off'` or `'on'`. Use the value `'off'` to compute nonsimultaneous bounds, and `'on'` for simultaneous bounds.

## 'Weights' - Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in X.
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W, `nlpredci` estimates the error variance at observation *i* by  $mse * (1/W(i))$ , where `mse` is the mean squared error value specified using MSE.

**Example:** 'Weights',@WFun

## Data Types

double | single | function\_handle

## Output Arguments

### Ypred - Predicted responses

vector

Predicted responses, returned as a vector with the same number of rows as X.

### delta - Confidence interval half-widths

vector

Confidence interval half-widths, returned as a vector with the same number of rows as X. By default, `delta` contains the half-widths for nonsimultaneous 95% confidence intervals for `modelfun` at the observations in X. You can compute the lower and upper bounds of the confidence intervals as `Ypred-delta` and `Ypred+delta`, respectively.

If 'PredOpt' has value 'observation', then `delta` contains the half-widths for prediction intervals of new observations at the values in X.

**Examples****Confidence Interval for Nonlinear Regression Curve**

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
```

```
ypred =
```

```
5.4622
```

```
delta =
```

```
0.1921
```

Compute the 95% confidence interval for the value of the curve.

```
[ypred-delta,ypred+delta]
```

```
ans =
```

```
5.2702    5.6543
```

**Prediction Interval for New Observation**

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels [100,100,100].

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...  
                        'PredOpt','observation')
```

```
ypred =
```

```
    1.8346
```

```
delta =
```

```
    0.5101
```

Compute the 95% prediction interval for the new observation.

```
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.3245    2.3447
```

## **Simultaneous Confidence Intervals for Robust Fit Curve**

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';  
beta0 = [2;2;2];  
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,beta0,opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = min(x):.01:max(x);  
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...  
                        'MSE',MSE,'SimOpt','on');  
lower = ypred - delta;  
upper = ypred + delta;  
  
figure()  
plot(x,y,'ko') % observed data  
hold on  
plot(xrange,ypred,'k','LineWidth',2)  
plot(xrange,[lower;upper],'r--','LineWidth',1.5)
```

## Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);  
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                        'PredOpt','observation','Weights',weights);
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.5264    2.1033
```

### Confidence Interval Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the fitted error variance model.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
                        'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]
```

```
ans =
```

```
    1.3245    2.3447
```

### Algorithms

- nlpredci treats NaN values in the residuals, R, or the Jacobian, J, as missing values, and ignores the corresponding observations.

- If the Jacobian,  $J$ , does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions, and returns NaN for those that are not.
- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:
  - 1 Define your parameter vector `beta` as the concatenation of the real and imaginary parts of the original parameter vector.
  - 2 Concatenate the real and imaginary parts of the response vector  $Y$  as a single vector.
  - 3 Modify your model function `modelfun` to accept  $X$  and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

## Definitions

### Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, `nlpredci` still tries to construct confidence intervals for any *estimable* prediction points.

For example, suppose you fit the linear function

$f(\mathbf{x}_i, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$  at the points in the design matrix

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

The estimated Jacobian at the values in  $\mathbf{X}$  is the design matrix itself,  $\mathbf{J} = \mathbf{X}$ . Thus, the Jacobian is not of full rank:

```
rng('default') % For reproducibility
y = randn(6,1);

linfun = @(b,x) x*b;
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];

[beta,R,J] = nlinfit(X,y,linfun,beta0);
```

```
Warning: The Jacobian at the solution is ill-conditioned, and
some model parameters may not be estimated well (they are not
identifiable). Use caution in making predictions.
> In nlinfit at 283
```

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

$$x_{i1} = x_{i2} + x_{i3}.$$

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns NaN for the corresponding interval half-widths:

```
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)

ypred =

    -0.0035
     0.0798
    -0.0047

delta =
```

```
      NaN  
3.8102  
3.8102
```

Here, the first element of `delta` is NaN because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.

`nlinfit` | `nlparci` | `NonLinearModel`

**Purpose** Nonnegative matrix factorization

**Syntax**

```
[W,H] = nnmf(A,k)
[W,H] = nnmf(A,k,param1,val1,param2,val2,...)
[W,H,D] = nnmf(...)
```

**Description** `[W,H] = nnmf(A,k)` factors the nonnegative  $n$ -by- $m$  matrix  $A$  into nonnegative factors  $W$  ( $n$ -by- $k$ ) and  $H$  ( $k$ -by- $m$ ). The factorization is not exact;  $W*H$  is a lower-rank approximation to  $A$ . The factors  $W$  and  $H$  are chosen to minimize the root-mean-squared residual  $D$  between  $A$  and  $W*H$ :

$$D = \text{norm}(A-W*H, 'fro') / \text{sqrt}(N*M)$$

The factorization uses an iterative method starting with random initial values for  $W$  and  $H$ . Because the root-mean-squared residual  $D$  may have local minima, repeated factorizations may yield different  $W$  and  $H$ . Sometimes the algorithm converges to a solution of lower rank than  $k$ , which may indicate that the result is not optimal.

$W$  and  $H$  are normalized so that the rows of  $H$  have unit length. The columns of  $W$  are ordered by decreasing length.

`[W,H] = nnmf(A,k,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
'algorithm'	<p>Either 'als' (the default) to use an alternating least-squares algorithm, or 'mult' to use a multiplicative update algorithm.</p> <p>In general, the 'als' algorithm converges faster and more consistently. The 'mult' algorithm is more sensitive to initial values, which makes it a</p>

Parameter	Value
	good choice when using 'replicates' to find W and H from multiple random starting values.
'w0'	An $n$ -by- $k$ matrix to be used as the initial value for W.
'h0'	A $k$ -by- $m$ matrix to be used as the initial value for H.
'options'	<p>An options structure as created by the <code>statset</code> function. <code>nnmf</code> uses the following fields of the options structure:</p> <ul style="list-style-type: none"> <li>• <b>Display</b> — Level of display. Choices: <ul style="list-style-type: none"> <li>▪ 'off' (default) — No display</li> <li>▪ 'final' — Display final result</li> <li>▪ 'iter' — Iterative display of intermediate results</li> </ul> </li> <li>• <b>MaxIter</b> — Maximum number of iterations. Default is 100. Unlike in optimization settings, reaching <code>MaxIter</code> iterations is treated as convergence.</li> <li>• <b>TolFun</b> — Termination tolerance on change in size of the residual. Default is <math>1e-4</math>.</li> <li>• <b>TolX</b> — Termination tolerance on relative change in the elements of W and H. Default is <math>1e-4</math>.</li> <li>• <b>UseParallel</b> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li>• <b>UseSubstreams</b> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code></li> </ul>

Parameter	Value
	<p>to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</p> <ul style="list-style-type: none"> <li>Streams — A RandStream object or cell array of such objects. If you do not specify Streams, nnmf uses the default stream or streams. If you choose to specify Streams, use a single object except in the case <ul style="list-style-type: none"> <li>You have an open Parallel pool</li> <li>UseParallel is true</li> <li>UseSubstreams is false</li> </ul> <p>In that case, use a cell array the same size as the Parallel pool.</p> </li> </ul>
'replicates'	<p>The number of times to repeat the factorization, using new random starting values for W and H, except at the first replication if 'w0' and 'h0' are given. This is most beneficial with the 'mult' algorithm. The default is 1.</p>

[W,H,D] = nnmf(...) also returns D, the root mean square residual.

## Examples

### Nonnegative Rank-Two Approximation and Biplot

Load the sample data.

```
load fisheriris
```

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data.

```
[W,H] = nnmf(meas,2);
H
```

```
H =  
  
    0.6943    0.2853    0.6223    0.2220  
    0.8020    0.5685    0.1830    0.0147
```

The first and third variables in `meas` (sepal length and petal length, with coefficients 0.6852 and 0.6357, respectively) provide relatively strong weights to the first column of `W`. The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8011 and 0.5740) provide relatively strong weights to the second column of `W`.

Create a biplot of the data and the variables in `meas` in the column space of `W`.

```
biplot(H', 'scores', W, 'varlabels', {'sl', 'sw', 'pl', 'pw'});  
axis([0 1.1 0 1.1])  
xlabel('Column 1')  
ylabel('Column 2')
```

### Change Algorithm

Starting from a random array  $X$  with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final');
[WO,H0] = nnmf(X,5,'replicates',10,...
               'options',opt,...
               'algorithm','mult');
```

# nnmf

---

```
rep iteration    rms resid    |delta x|
   1         5      0.560887    0.0245182
   2         5      0.66418     0.0364471
   3         5      0.609125    0.0358355
   4         5      0.608894    0.0415491
   5         5      0.619291    0.0455135
   6         5      0.621549    0.0299965
   7         5      0.640549    0.0438758
   8         5      0.673015    0.0366856
   9         5      0.606835    0.0318931
  10         5      0.633526    0.0319591
```

Final root mean square residual = 0.560887

Continue with more iterations from the best of these results using alternating least squares:

```
opt = statset('Maxiter',1000,'Display','final');
[W,H] = nnmf(X,5,'w0',W0,'h0',H0,...
             'options',opt,...
             'algorithm','als');
```

```
rep  iteration    rms resid    |delta x|
   1      24      0.257336    0.00271859
```

Final root mean square residual = 0.257336

pca | factoran | statset

**Purpose** Class values of nodes of classification tree

**Syntax** NAME=nodeclass(T)  
NAME=nodeclass(T,J)  
[NAME,ID]=nodeclass(...)

**Description** NAME=nodeclass(T) returns an  $n$ -element cell array with the names of the most probable classes in each node of the tree T, where  $n$  is the number of nodes in the tree. Every element of this array is a string equal to one of the class names returned by `classname(T)`. For regression trees, `nodeclass` returns an empty cell array.

NAME=nodeclass(T,J) takes an array J of node numbers and returns the class names for the specified nodes.

[NAME,ID]=nodeclass(...) also returns a numeric array with the class index for each node. The class index is determined by the order of classes `classname` returns.

**See Also** classregtree | classname | numnodes

# classregtree.nodeerr

---

**Purpose** Return vector of node errors

**Syntax** `e = nodeerr(t)`  
`e = nodeerr(t,nodes)`

**Description** `e = nodeerr(t)` returns an  $n$ -element vector `e` of the errors of the nodes in the tree `t`, where  $n$  is the number of nodes. For a regression tree, the error `e(i)` for node `i` is the variance of the observations assigned to node `i`. For a classification tree, `e(i)` is the misclassification probability for node `i`.

`e = nodeerr(t,nodes)` takes a vector `nodes` of node numbers and returns the errors for the specified nodes.

The error `e` is the so-called *resubstitution error* computed by applying the tree to the same data used to create the tree. This error is likely to under estimate the error you would find if you applied the tree to new data. The `test` function provides options to compute the error (or cost) using cross-validation or a test sample.

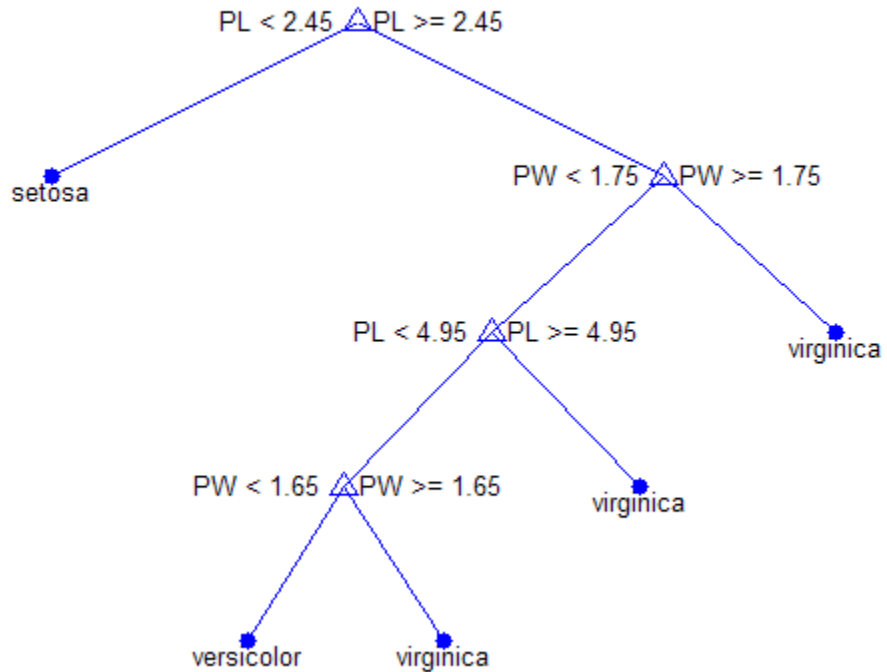

**Examples** Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
```

`classregtree` | `numnodes` | `test`

**Purpose** Mean values of nodes of regression tree

**Syntax** NM = nodemean(T)  
NM = nodemean(T,J)

**Description** NM = nodemean(T) returns an  $n$ -element numeric array with mean values in each node of the tree T, where  $n$  is the number of nodes in the tree. Every element of this array is computed by averaging true Y values over all observations in the node. For classification trees, nodemean returns an empty numeric array.

NM = nodemean(T,J) takes an array J of node numbers and returns the mean values for the specified nodes.

**See Also** classregtree | numnodes

# classregtree.nodeprob

---

**Purpose** Node probabilities

**Syntax** `p = nodeprob(t)`  
`p = nodeprob(t,nodes)`

**Description** `p = nodeprob(t)` returns an  $n$ -element vector `p` of the probabilities of the nodes in the tree `t`, where  $n$  is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. For a classification tree, this proportion is adjusted for any prior probabilities assigned to each class.

`p = nodeprob(t,nodes)` takes a vector `nodes` of node numbers and returns the probabilities for the specified nodes.

**Examples** Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

view(t)
```

# classregtree.nodeprob

classregtree | nodesize | numnodes

## Purpose

Return node size

## Syntax

```
sizes = nodesize(t)
sizes = nodesize(t,nodes)
```

## Description

`sizes = nodesize(t)` returns an  $n$ -element vector `sizes` of the sizes of the nodes in the tree `t`, where  $n$  is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

`sizes = nodesize(t,nodes)` takes a vector `nodes` of node numbers and returns the sizes for the specified nodes.

## Examples

Create a classification tree for Fisher's iris data:

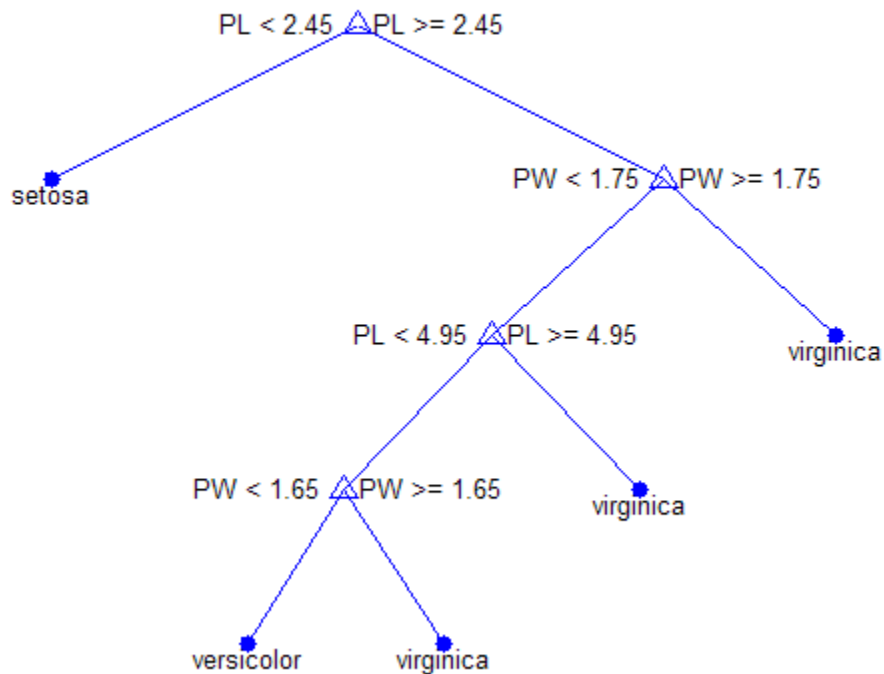

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification

# grandstream.notify

---

**Purpose** Notify listeners of event

**Syntax** `notify(h, 'eventname')`  
`notify(h, 'eventname', data)`

**Description** `notify(h, 'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a string.

`notify(h, 'eventname', data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.eventdata` class.

**See Also** `addlistener` | `event.EventData` | `events` | `grandstream`

**Superclasses** categorical

**Purpose** Arrays for nominal categorical data

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Description** Nominal arrays are used to store discrete values that are not numeric and that do not have an ordering. A nominal array provides efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values. Nominal arrays are often used as grouping variables.

You can subscript, concatenate, reshape, etc. nominal arrays much like ordinary numeric arrays. You can test equality between elements of two nominal arrays, or between a nominal array and a single string representing a nominal value.

**Construction** Use the `nominal` constructor to create a nominal array from a numeric, logical, or character array, or from a cell array of strings.

`nominal` Construct nominal categorical array

**Methods** Each nominal array carries along a list of possible values that it can store, known as its levels. The list is created when you create a nominal array, and you can access it using the `getlevels` method, or modify it using the `addlevels`, `mergelevels`, or `droplevels` methods. Assignment to the array will also add new levels automatically if the values assigned are not already levels of the array.

You can change the order of the list of levels for a nominal array using the `reorderlevels` method, however, that order has no significance for the values in the array. The order is used only for display purposes, or when you convert the nominal array to numeric values using methods such as `double` or `subsindex`, or compare two arrays using `isequal`. If

you need to work with values that have a mathematical ordering, you should use an `ordinal` array instead.

The following table lists operations available for nominal arrays.

<code>summary</code>	Summary statistics for nominal array
----------------------	--------------------------------------

## Inherited Methods

Methods in the following table are inherited from `categorical`.

<code>addlevels</code>	Add levels to categorical array
<code>cat</code>	Concatenate categorical arrays
<code>cellstr</code>	Convert categorical array to cell array of strings
<code>char</code>	Convert categorical array to character array
<code>circshift</code>	Shift categorical array circularly
<code>ctranspose</code>	Transpose categorical matrix
<code>disp</code>	Display categorical array
<code>display</code>	Display categorical array
<code>double</code>	Convert categorical array to double array
<code>droplevels</code>	Drop levels
<code>end</code>	Last index in indexing expression for categorical array
<code>flipdim</code>	Flip categorical array along specified dimension
<code>fliplr</code>	Flip categorical matrix in left/right direction

---

flipud	Flip categorical matrix in up/down direction
getlabels	Access categorical array labels
getlevels	Get categorical array levels
hist	Plot histogram of categorical data
horzcat	Horizontal concatenation for categorical arrays
int16	Convert categorical array to signed 16-bit integer array
int32	Convert categorical array to signed 32-bit integer array
int64	Convert categorical array to signed 64-bit integer array
int8	Convert categorical array to signed 8-bit integer array
intersect	Set intersection for categorical arrays
ipermute	Inverse permute dimensions of categorical array
isempty	True for empty categorical array
isequal	True if categorical arrays are equal
islevel	Test for levels
ismember	True for elements of categorical array in set
isscalar	True if categorical array is scalar
isundefined	Test for undefined elements
isvector	True if categorical array is vector

# nominal

---

length	Length of categorical array
levelcounts	Element counts by level
mergelevels	Merge levels
ndims	Number of dimensions of categorical array
numel	Number of elements in categorical array
permute	Permute dimensions of categorical array
reorderlevels	Reorder levels
repmat	Replicate and tile categorical array
reshape	Resize categorical array
rot90	Rotate categorical matrix 90 degrees
setdiff	Set difference for categorical arrays
setlabels	Label levels
setxor	Set exclusive-or for categorical arrays
shiftdim	Shift dimensions of categorical array
single	Convert categorical array to single array
size	Size of categorical array
squeeze	Squeeze singleton dimensions from categorical array
subsasgn	Subscripted assignment for categorical array

subsindex	Subscript index for categorical array
suboref	Subscripted reference for categorical array
times	Product of categorical arrays
transpose	Transpose categorical matrix
uint16	Convert categorical array to unsigned 16-bit integers
uint32	Convert categorical array to unsigned 32-bit integers
uint64	Convert categorical array to unsigned 64-bit integers
uint8	Convert categorical array to unsigned 8-bit integers
union	Set union for categorical arrays
unique	Unique values in categorical array
vertcat	Vertical concatenation for categorical arrays

## Properties

## Inherited Properties

Properties in the following table are inherited from `categorical`.

labels	Text labels for levels
undeflabel	Text label for undefined levels

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

# nominal

---

## Examples

### Create and Compare Nominal Arrays

Create a nominal array from string data in a cell array.

```
colors = nominal({'r' 'b' 'g';'g' 'r' 'b';'b' 'r' 'g'},...  
                {'blue' 'green' 'red'})
```

```
colors =
```

red	blue	green
green	red	blue
blue	red	green

Identify the elements in `colors` that are members of the level 'red'.

```
colors == 'red'
```

```
ans =
```

1	0	0
0	1	0
0	1	0

A value of 1 in the resulting array `ans` indicates that the corresponding element of `colors` is a member of 'red'.

Identify the elements of `colors` that are members of either 'red' or 'blue'.

```
ismember(colors,{'red' 'blue'})
```

```
ans =
```

1	1	0
0	1	1
1	1	0

A value of 1 in the resulting array `ans` indicates that the corresponding element of `colors` is a member of either 'red' or 'blue'.

Create a second nominal array `colors2` by flipping colors from left to right.

```
colors2 = fliplr(colors)
```

```
colors2 =
```

```
    green    blue    red  
    blue    red    green  
    green    red    blue
```

Compare the elements of `colors` and `colors2`.

```
colors == colors2
```

```
ans =
```

```
    0    1    0  
    0    1    0  
    0    1    0
```

A value of 1 in the resulting array `ans` indicates that the corresponding element of `colors` is a member of the same level as the corresponding element of `colors2`.

[histc](#) | [ordinal](#)

# nominal

---

## Purpose

Construct nominal categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
B = nominal(A)
B = nominal(A,labels)
B = nominal(A,labels,levels)
B = nominal(A,labels,[],edges)
```

## Description

`B = nominal(A)` creates a nominal array `B` from the array `A`. `A` can be numeric, logical, character, categorical, or a cell array of strings. `nominal` creates the levels of `B` from the sorted unique values in `A`, and creates default labels for them.

`B = nominal(A,labels)` labels the levels in `B` using the character array or cell array of strings `labels`. `nominal` assigns labels to levels in `B` in order according to the sorted unique values in `A`.

`B = nominal(A,labels,levels)` creates a nominal array with possible levels defined by `levels`. `levels` is a vector whose values can be compared to those in `A` using the equality operator. `nominal` assigns labels to each level from the corresponding elements of `labels`. If `A` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

`B = nominal(A,labels,[],edges)` creates a nominal array by binning the numeric array `A` with bin edges given by the numeric vector `edges`. The uppermost bin includes values equal to the right-most edge. `nominal` assigns labels to each level in `B` from the corresponding elements of `labels`. `edges` must have one more element than `labels`.

By default, an element of `B` is undefined if the corresponding element of `A` is NaN (when `A` is numeric), an empty string (when `A` is character), or undefined (when `A` is categorical). `nominal` treats such elements as “undefined” or “missing” and does not include entries for them among the possible levels for `B`. To create an explicit level for such elements

instead of treating them as undefined, you must use the `levels` input, and include `NaN`, the empty string, or an undefined element.

You may include duplicate labels in `labels` in order to merge multiple values in `A` into a single level in `B`.

## Examples

### Create and Label Nominal Arrays

Load the sample data.

```
load fisheriris;
```

Create a nominal array and display a summary of the data.

```
species = nominal(species);
summary(species)
```

```
    setosa      50
versicolor   50
 virginica    50
```

Create a nominal array from characters, and provide explicit labels.

```
colors1 = nominal({'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}, ...
                 {'blue' 'green' 'red'})
```

```
colors1 =
```

```
    red      blue      green
green      red      blue
blue       red      green
```

Create a nominal array from characters, and provide both explicit labels and an explicit order for display.

```
colors2 = nominal({'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}, ...
                 {'red' 'green' 'blue'}, {'r' 'g' 'b'})
```

```
colors2 =
```

# nominal

---

```
red      blue     green
green    red      blue
blue     red      green
```

Create a nominal array from integer data, merging odd and even values into only two nominal levels. Provide explicit labels.

```
toss = nominal(randi([1 4],5,2),{'odd' 'even' 'odd' 'even'},1:4)
```

```
toss =
```

```
even     odd
even     even
odd      odd
even     even
odd      even
```

## Change Nominal Array Levels

Load the sample data.

```
load hospital;
```

Make the {0,1}-valued variable `Smoker` nominal, and change the labels to 'No' and 'Yes'.

```
hospital.Smoker = nominal(hospital.Smoker,{'No','Yes'});
```

Add new levels to `Smoker` as placeholders for more detailed histories of smokers.

```
hospital.Smoker = addlevels(hospital.Smoker,...
                             {'0-5 Years','5-10 Years','LongTerm'});
```

Assuming the nonsmokers have never smoked, relabel the 'No' level.

```
hospital.Smoker = setlabels(hospital.Smoker,'Never','No');
```

Drop the undifferentiated 'Yes' level from `Smoker`.

```
hospital.Smoker = droplevels(hospital.Smoker, 'Yes');
```

Note that smokers now have an undefined level.

Set each smoker to one of the new levels, by observation name.

```
hospital.Smoker('YPL-320') = '5-10 Years';
```

[histc](#) | [ordinal](#)

# NonLinearModel

---

**Purpose** Nonlinear regression model class

**Description** An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the `predict` or `feval` methods.

**Construction** `nlm = fitnlm(tbl,modelfun,beta0)` or `nlm = fitnlm(X,y,modelfun,beta0)` create a nonlinear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitnlm`.

## Input Arguments

### **tbl - Input data**

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### **Data Types**

single | double | logical

### **X - Predictor variables**

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor

variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## **y** - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## **modelfun** - Functional form of the model

function handle | string of the form 'y ~  
 $f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
  - $b$  is a coefficient vector with the same number of elements as `beta0`.
  - $x$  is a matrix with the same number of columns as  $X$  or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as  $x$ . Each row of the vector is the result of evaluating `modelfun` on the corresponding row of  $x$ . In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

# NonLinearModel

---

- String of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ ', where  $f$  represents a scalar function of the scalar coefficient variables  $b_1, \dots, b_j$  and the scalar data variables  $x_1, \dots, x_k$ .

## **beta0 - Coefficients**

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. NonLinearModel starts its search for optimal coefficients from beta0.

## **Data Types**

single | double

## **Properties**

### **CoefficientCovariance**

Covariance matrix of coefficient estimates.

### **CoefficientNames**

Cell array of strings containing a label for each coefficient.

### **Coefficients**

Coefficient values stored as a table. Coefficients has one row for each coefficient and these columns:

- Estimate — Estimated coefficient value
- SE — Standard error of the estimate
- tStat —  $t$  statistic for a test that the coefficient is zero
- pValue —  $p$ -value for the  $t$  statistic

To obtain any of these columns as a vector, index into the property using dot notation. For example, in mdl the estimated coefficient vector is

```
beta = mdl.Coefficients.Estimate
```

Use coefTest to perform other tests on the coefficients.

## Diagnostics

Table with diagnostics helpful in finding outliers and influential observations. The table contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of HatMatrix	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N. An observation with Leverage larger than 2*P/N can be regarded as having high leverage.
CooksDistance	Cook's measure of scaled change in fitted values	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance larger than three times the mean Cook's distance can be an outlier.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $Fitted = HatMatrix * Y$ , where Y is the response vector and Fitted is the vector of fitted response values.

## DFE

Degrees of freedom for error (residuals), equal to the number of observations minus the number of estimated coefficients.

## Fitted

Vector of predicted values based on the training data. `fitnlm` attempts to make Fitted as close as possible to the response data.

## Formula

# NonLinearModel

---

Object that represents the mathematical form of the model.

## **Iterative**

Structure with information about the fitting process. Fields:

- `InitialCoefs` — Initial coefficient values (the `beta0` vector)
- `IterOpts` — Options included in the `Options` name-value pair argument for `fitnlm`.

## **LogLikelihood**

Log likelihood of the model distribution at the response values, with mean fitted from the model, and other parameters estimated as part of the model fit.

## **ModelCriterion**

AIC and other information criteria for comparing models. A structure with fields:

- `AIC` — Akaike information criterion
- `AICc` — Akaike information criterion corrected for sample size
- `BIC` — Bayesian information criterion
- `CAIC` — Consistent Akaike information criterion

To obtain any of these values as a scalar, index into the property using dot notation. For example, in a model `mdl`, the AIC value `aic` is:

```
aic = mdl.ModelCriterion.AIC
```

## **MSE**

Mean squared error, a scalar that is an estimate of the variance of the error term in the model.

## **NumCoefficients**

Number of coefficients in the fitted model, a scalar. `NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

## **NumEstimatedCoefficients**

Number of estimated coefficients in the fitted model, a scalar. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

## **NumPredictors**

Number of variables `fitnlm` used as predictors for fitting.

## **NumVariables**

Number of variables in the data. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector when the fit is based on those arrays. It includes variables, if any, that are not used as predictors or as the response.

## **ObservationInfo**

Table with the same number of rows as the input data (`tbl` or `X`).

<b>Field</b>	<b>Description</b>
Weights	Observation weights. Default is all 1.
Excluded	Logical value, 1 indicates an observation that you excluded from the fit with the <code>Exclude</code> name-value pair.
Missing	Logical value, 1 indicates a missing value in the input. Missing values are not used in the fit.
Subset	Logical value, 1 indicates the observation is not excluded or missing, so is used in the fit.

# NonLinearModel

---

## ObservationNames

Cell array of strings containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array

## PredictorNames

Cell array of strings, the names of the predictors used in fitting the model.

## Residuals

Table of residuals, with one row for each observation and these variables.

Field	Description
Raw	Observed minus fitted values.
Pearson	Raw residuals divided by RMSE.
Standardized	Raw residuals divided by their estimated standard deviation.
Studentized	Residual divided by an independent estimate of the residual standard deviation. The residual for observation $i$ is divided by an estimate of the error standard deviation based on all observations except for observation $i$ .

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

## **ResponseName**

String giving naming the response variable.

## **RMSE**

Root mean squared error, a scalar that is an estimate of the standard deviation of the error term in the model.

## **Robust**

Structure that is empty unless `fitnlm` constructed the model using robust regression.

<b>Field</b>	<b>Description</b>
<code>WgtFun</code>	Robust weighting function, such as 'bisquare' (see <code>robustfit</code> )
<code>Tune</code>	Value specified for tuning parameter (can be [])
<code>Weights</code>	Vector of weights used in final iteration of robust fit

## **Rsquared**

# NonLinearModel

---

Proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST}.$$

Rsquared is a structure with two fields:

- Ordinary — Ordinary (unadjusted) R-squared
- Adjusted — R-squared adjusted for the number of coefficients

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

## **SSE**

Sum of squared errors (residuals).

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

## **SSR**

Regression sum of squares, the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

## **SST**

Total sum of squares, the sum of squared deviations of  $y$  from  $\text{mean}(y)$ .

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR}.$$

## VariableInfo

Table containing metadata about `Variables`. There is one row for each term in the model, and the following columns.

Field	Description
Class	String giving variable class, such as 'double'
Range	Cell array giving variable range: <ul style="list-style-type: none"><li>• Continuous variable — Two-element vector <math>[min, max]</math>, the minimum and maximum values</li><li>• Categorical variable — Cell array of distinct variable values</li></ul>
InModel	Logical vector, where true indicates the variable is in the model
IsCategorical	Logical vector, where true indicates a categorical variable

## VariableNames

Cell array of strings containing names of the variables in the fit.

- If the fit is based on a table or dataset, this property provides the names of the variables in that table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` is the values in the `VarNames` name-value pair of the fitting method.
- Otherwise the variables have the default fitting names.

## Variables

Table containing the data, both observations and responses, that the fitting function used to construct the fit. If the fit is based

# NonLinearModel

---

on a table or dataset array, `Variables` contains all of the data from that table or dataset array. Otherwise, `Variables` is a table created from the input data matrix  $X$  and response vector  $y$ .

## Methods

<code>coefCI</code>	Confidence intervals of coefficient estimates of nonlinear regression model
<code>coefTest</code>	Linear hypothesis test on nonlinear regression model coefficients
<code>disp</code>	Display nonlinear regression model
<code>feval</code>	Evaluate nonlinear regression model prediction
<code>fit</code>	Fit nonlinear regression model
<code>plotDiagnostics</code>	Plot diagnostics of nonlinear regression model
<code>plotResiduals</code>	Plot residuals of nonlinear regression model
<code>plotSlice</code>	Plot of slices through fitted nonlinear regression surface
<code>predict</code>	Predict response of nonlinear regression model
<code>random</code>	Simulate responses for nonlinear regression model

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and the Jacobian matrix  $J$ :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here  $f$  is the nonlinear model function, and  $\beta$  is the vector of model coefficients.

The Hat Matrix  $H$  is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$
$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

## Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

# NonLinearModel

---

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $MSE$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{pMSE} \left( \frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where  $e_i$  is the  $i$ th residual.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average car.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)
```

```
mdl =
```

Nonlinear regression model:  
 $y \sim b1 + b2*x1^b3 + b4*x2^b5$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387  
Root Mean Squared Error: 3.96  
R-Squared: 0.745, Adjusted R-Squared 0.743  
F-statistic vs. constant model: 283, p-value = 1.79e-113

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using nanmean.

```
Xnew = nanmean(X)
```

```
Xnew =  
1.0e+03 *  
0.1051 2.9794
```

```
MPGnew = predict mdl, Xnew
```

```
MPGnew =  
  
21.8073
```

## **Related Examples**

- “Nonlinear Regression Workflow” on page 11-15

## **Concepts**

- “Nonlinear Regression” on page 11-2

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Normal probability distribution object

**Description** `prob.NormalDistribution` is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Normal')` creates a normal probability distribution object using the default parameter values.

`pd = makedist('Normal','mu',mu,'sigma',sigma)` creates a normal distribution object using the specified parameter values.

## Input Arguments

### **mu - Mean**

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma - Standard deviation**

1 (default) | nonnegative scalar value

Standard deviation of the normal distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

## Properties

### **mu - Mean**

scalar value

Mean of the normal distribution, stored as a scalar value.

# prob.NormalDistribution

---

## Data Types

single | double

## **sigma - Standard deviation**

nonnegative scalar value

Standard deviation of the normal distribution, stored as a nonnegative scalar value.

## Data Types

single | double

## **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated.

If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## **ParameterIsFixed - Logical flag for fixed parameters**

# prob.NormalDistribution

---

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Definitions

### Normal Distribution

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Standard deviation	$\sigma \geq 0$

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad -\infty < x < \infty.$$

## Examples

### Create a Normal Distribution Object Using Default Parameters

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

## Create a Normal Distribution Object Using Specified Parameters

Create a normal distribution object by specifying the parameter values.

```
pd = makedist('Normal','mu',75,'sigma',10)
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75
```

```
sigma = 10
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
13.4898
```

## Fit a Normal Distribution Object

Load the sample data. Create a vector containing the first column of students' exam grades data.

```
load examgrades;
```

```
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

# prob.NormalDistribution

---

```
Normal distribution
  mu = 75.0083   [73.4321, 76.5846]
  sigma =  8.7202  [7.7391, 9.98843]
```

## Concepts

- “Normal Distribution” on page B-123
- Class Attributes
- Property Attributes

**Purpose**

Normal cumulative distribution function

**Syntax**

```
p = normcdf(x)
p = normcdf(x,mu,sigma)
[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = normcdf( __ , 'upper' )
```

**Description**

`p = normcdf(x)` returns the standard normal cdf at each value in `x`. The standard normal distribution has parameters `mu = 0` and `sigma = 1`. `x` can be a vector, matrix, or multidimensional array.

`p = normcdf(x,mu,sigma)` returns the normal cdf at each value in `x` using the specified values for the mean `mu` and standard deviation `sigma`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

`[p,plo,pup] = normcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is `0.05`. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = normcdf( __ , 'upper' )` returns the complement of the normal cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

The function `normcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller

# normcdf

---

samples other methods of computing the confidence bounds might be more accurate.

The normal cdf is

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt$$

The result,  $p$ , is the probability that a single observation from a normal distribution with parameters  $\mu$  and  $\sigma$  will fall in the interval  $(-\infty, x]$ .

The *standard normal* distribution has  $\mu = 0$  and  $\sigma = 1$ .

## Examples

### Compute Normal Distribution cdf

What is the probability that an observation from a standard normal distribution will fall on the interval  $[-1, 1]$ ?

```
p = normcdf([-1 1]);  
p(2) - p(1)
```

```
ans =  
    0.6827
```

More generally, about 68% of the observations from a normal distribution fall within one standard deviation,  $\sigma$ , of the mean,  $\mu$ .

## How To

- “Normal Distribution” on page B-123

**Purpose**

Normal parameter estimates

**Syntax**

```
[muhat,sigmahat] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data)
[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)
[...] = normfit(data,alpha,censoring)
[...] = normfit(data,alpha,censoring,freq)
[...] = normfit(data,alpha,censoring,freq,options)
```

**Description**

`[muhat,sigmahat] = normfit(data)` returns an estimate of the mean  $\mu$  in `muhat`, and an estimate of the standard deviation  $\sigma$  in `sigmahat`, of the normal distribution given the data in `data`.

`[muhat,sigmahat,muci,sigmaci] = normfit(data)` returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays `muci` and `sigmaci`, respectively. The first row of `muci` contains the lower bounds of the confidence intervals for  $\mu$  the second row contains the upper bounds. The first row of `sigmaci` contains the lower bounds of the confidence intervals for  $\sigma$ , and the second row contains the upper bounds.

`[muhat,sigmahat,muci,sigmaci] = normfit(data,alpha)` returns  $100(1 - \alpha)$  % confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is 0.05, which corresponds to 95% confidence intervals.

`[...] = normfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = normfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

# normfit

---

[...] = normfit(data,alpha,censoring,freq,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates when there is censoring. The normal fit function accepts an options structure which you can create using the function statset. Enter statset('normfit') to see the names and default values of the parameters that normfit accepts in the options structure. See the reference page for statset for more information about these options.

---

**Note** With no censoring, normfit computes muhat using the sample mean and sigmahat using the square root of the unbiased estimator of the variance. With censoring, both muhat and sigmahat are the maximum likelihood estimates.

---

## Examples

In this example the data is a two-column random normal matrix. Both columns have  $\mu = 10$  and  $\sigma = 2$ . Note that the confidence intervals below contain the "true values."

```
data = normrnd(10,2,100,2);
[mu,sigma,muci,sigmaci] = normfit(data)
mu =
    10.1455    10.0527
sigma =
    1.9072    2.1256
muci =
    9.7652    9.6288
    10.5258    10.4766
sigmaci =
    1.6745    1.8663
    2.2155    2.4693
```

## See Also

## How To

- “Normal Distribution” on page B-123

**Purpose**

Normal inverse cumulative distribution function

**Syntax**

```
X = norminv(P,mu,sigma)
[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)
```

**Description**

`X = norminv(P,mu,sigma)` computes the inverse of the normal cdf using the corresponding mean `mu` and standard deviation `sigma` at the corresponding probabilities in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive, and the values in `P` must lie in the interval `[0 1]`.

`[X,XLO,XUP] = norminv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` specifies `100(1 - alpha)%` confidence bounds. The default value of `alpha` is `0.05`. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `norminv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where  $q$  is the  $P$ th quantile from a normal distribution with mean 0 and standard deviation 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds may be more accurate.

The normal inverse function is defined in terms of the normal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x : F(x | \mu, \sigma) = p\}$$

where

# norminv

---

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt$$

The result,  $x$ , is the solution of the integral equation above where you supply the desired probability,  $p$ .

## Examples

Find an interval that contains 95% of the values from a standard normal distribution.

```
x = norminv([0.025 0.975],0,1)
x =
-1.9600  1.9600
```

Note that the interval  $x$  is not the only such interval, but it is the shortest.

```
x1 = norminv([0.01 0.96],0,1)
x1 =
-2.3263  1.7507
```

The interval  $x1$  also contains 95% of the probability, but it is longer than  $x$ .

<b>How To</b>	<ul style="list-style-type: none"><li>• “Normal Distribution” on page B-123</li></ul>

# normpdf

---

**Purpose** Normal probability density function

**Syntax**  
`Y = normpdf(X,mu,sigma)`  
`Y = normpdf(X)`  
`Y = normpdf(X,mu)`

**Description** `Y = normpdf(X,mu,sigma)` computes the pdf at each of the values in `X` using the normal distribution with mean `mu` and standard deviation `sigma`. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `sigma` must be positive.

The normal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

The *likelihood function* is the pdf viewed as a function of the parameters. Maximum likelihood estimators (MLEs) are the values of the parameters that maximize the likelihood function for a fixed value of `x`.

The *standard normal* distribution has  $\mu = 0$  and  $\sigma = 1$ .

If `x` is standard normal, then `xσ + μ` is also normal with mean  $\mu$  and standard deviation  $\sigma$ . Conversely, if `y` is normal with mean  $\mu$  and standard deviation  $\sigma$ , then `x = (y-μ) / σ` is standard normal.

`Y = normpdf(X)` uses the standard normal distribution (`mu = 0`, `sigma = 1`).

`Y = normpdf(X,mu)` uses the normal distribution with unit standard deviation (`sigma = 1`).

## Examples

```
mu = [0:0.1:2];  
[y i] = max(normpdf(1.5,mu,1));  
MLE = mu(i)  
MLE =
```

1.5000

pdf | normcdf | norminv | normstat | normfit | normlike | normrnd  
| mvnpdf

**How To**

- “Normal Distribution” on page B-123

# normplot

---

**Purpose** Normal probability plot

**Syntax** `h = normplot(X)`

**Description** `h = normplot(X)` displays a normal probability plot of the data in `X`. For matrix `X`, `normplot` displays a line for each column of `X`. `h` is a handle to the plotted lines.

The plot has the sample data displayed with the plot symbol '+' . Superimposed on the plot is a line joining the first and third quartiles of each column of `X` (a robust linear fit of the sample order statistics.) This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

The purpose of a normal probability plot is to graphically assess whether the data in `X` could come from a normal distribution. If the data are normal the plot will be linear. Other distribution types will introduce curvature in the plot. `normplot` uses midpoint probability plotting positions. Use `probplot` when the data included censored observations.

## Examples **Generate a Normal Probability Plot**

Generate random sample data from a normal distribution with `mu = 10` and `sigma = 1`.

```
rng('default'); % For reproducibility
x = normrnd(10,1,25,1);
```

Create a normal probability plot of the sample data.

```
figure;
normplot(x)
```

The plot indicates that the data follows a normal distribution.

### How To

- “Normal Distribution” on page B-123

# normrnd

---

**Purpose** Normal random numbers

**Syntax**  
`R = normrnd(mu,sigma)`  
`R = normrnd(mu,sigma,m,n,...)`  
`R = normrnd(mu,sigma,[m,n,...])`

**Description** `R = normrnd(mu,sigma)` generates random numbers from the normal distribution with mean parameter `mu` and standard deviation parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = normrnd(mu,sigma,m,n,...)` or `R = normrnd(mu,sigma,[m,n,...])` generates an `m`-by-`n`-by-... array. The `mu`, `sigma` parameters can each be scalars or arrays of the same size as `R`.

**Examples**

```
n1 = normrnd(1:6,1./(1:6))
n1 =
    2.1650    2.3134    3.0250    4.0879    4.8607    6.2827

n2 = normrnd(0,1,[1 5])
n2 =
    0.0591    1.7971    0.2641    0.8717   -1.4462

n3 = normrnd([1 2 3;4 5 6],0.1,2,3)
n3 =
    0.9299    1.9361    2.9640
    4.1246    5.0577    5.9864
```

**See Also** `random` | `normpdf` | `normcdf` | `norminv` | `normstat` | `normfit` | `normlike` | `mvnrnd` | `lognrnd`

**How To** • “Normal Distribution” on page B-123

**Purpose** Normal density plot between specifications

**Syntax**

```
normspec(specs)
normspec(specs,mu,sigma)
normspec(specs,mu,sigma,region)
p = normspec(...)
[p,h] = normspec(...)
```

**Description**

`normspec(specs)` plots the standard normal density, shading the portion inside the specification limits given by the two-element vector `specs`. Set `specs(1)` to `-Inf` if there is no lower limit; set `specs(2)` to `Inf` if there is no upper limit.

`normspec(specs,mu,sigma)` shades the portion inside the specification limits of a normal density with parameters `mu` and `sigma`. The defaults are `mu = 0` and `sigma = 1`.

`normspec(specs,mu,sigma,region)` shades the `region` either 'inside' or 'outside' the specification limits. The default is 'inside'.

`p = normspec(...)` also returns the probability, `p`, of the shaded area.

`[p,h] = normspec(...)` also returns a handle `h` to the line objects.

## Examples

### Create a Normal Density Plot

This example shows how to create a normal density plot.

A production process fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces (2/128 gallons). What is the probability that the cans will be filled under specification by 3 or more ounces?

```
p = normspec([1-3/128,Inf],1,2/128,'outside')
```

```
p =
```

## How To

- “Normal Distribution” on page B-123

**Purpose** Normal mean and variance

**Syntax** `[M,V] = normstat(mu,sigma)`

**Description** `[M,V] = normstat(mu,sigma)` returns the mean of and variance for the normal distribution using the corresponding mean `mu` and standard deviation `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

The mean of the normal distribution with parameters  $\mu$  and  $\sigma$  is  $\mu$ , and the variance is  $\sigma^2$ .

**Examples**

```
n = 1:5;
[m,v] = normstat(n'*n,n'*n)
m =
     1     2     3     4     5
     2     4     6     8    10
     3     6     9    12    15
     4     8    12    16    20
     5    10    15    20    25

v =
     1     4     9    16    25
     4    16    36    64   100
     9    36    81   144   225
    16    64   144   256   400
    25   100   225   400   625
```

**How To** • “Normal Distribution” on page B-123

# piecewisedistribution.nsegments

---

**Purpose**            Number of segments

**Syntax**            `n = nsegments(obj)`

**Description**        `n = nsegments(obj)` returns the number of segments `n` in the piecewise distribution object `obj`.

**Examples**            Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
n = nsegments(obj)  
n =  
    3
```

**See Also**            `paretotails` | `boundary` | `segment`

# TreeBagger.NTrees property

---

<b>Purpose</b>	Number of decision trees in ensemble
<b>Description</b>	The NTrees property is a scalar equal to the number of decision trees in the ensemble.
<b>See Also</b>	Trees

# ProbDistParametric.NumParams property

---

<b>Purpose</b>	Read-only value specifying number of parameters of ProbDistParametric object
<b>Description</b>	NumParams is a read-only property of the ProbDistParametric class. NumParams is a value specifying the number of parameters of a distribution represented by a ProbDistParametric object.
<b>Values</b>	This value is an integer that counts both the specified parameters and parameters that are fit to the data. Use this information to view and compare the number of parameters supplied to create distributions.

**Purpose**

Number of elements in dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
n = numel(A)
n = numel(A, varargin)
```

**Description**

`n = numel(A)` returns 1. To find the number of elements, `n`, in the dataset array `A`, use `prod(size(A))` or `numel(A, ':', ':')`.

`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`, where `varargin` is a cell array whose elements are `index1, index2, ... indexn`.

**See Also**

`length` | `size`

# categorical.numel

---

## **Purpose**

Number of elements in categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

```
n = numel(A)
n = numel(A, varargin)
```

## **Description**

`n = numel(A)` returns the number of elements in the categorical array `A`.

`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexN)`, where `varargin` is a cell array whose elements are `index1, index2, ..., indexN`.

classregtree

## cvpartition.NumTestSets property

---

**Purpose**

Number of test sets

**Description**

Value is the number of folds in partitions of type 'kfold' and 'leaveout'.

Value is 1 in partitions of type 'holdout' and 'resubstitution'.

# TreeBagger.NVarToSample property

---

**Purpose** Number of variables for random feature selection

**Description** The `NVarToSample` property specifies the number of predictor or feature variables to select at random for each decision split. By default, it is set to the square root of the total number of variables for classification and one third of the total number of variables for regression. Setting this argument to any valid value except 'all' invokes Breiman's "random forest" algorithm.

**See Also** `classregtree`

## **Purpose**

Cell array of nonempty, distinct strings giving names of observations in data set

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Description**

A cell array of nonempty, distinct strings giving the names of the observations in the data set. This property may be empty, but if not empty, the number of strings must equal the number of observations.

# optimalleaforder

---

**Purpose** Optimal leaf ordering for hierarchical clustering

**Syntax**  
`leafOrder = optimalleaforder(tree,D)`  
`leafOrder = optimalleaforder(tree,D,Name,Value)`

**Description** `leafOrder = optimalleaforder(tree,D)` returns an optimal leaf ordering for the hierarchical binary cluster tree, `tree`, using the distances, `D`. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

`leafOrder = optimalleaforder(tree,D,Name,Value)` returns the optimal leaf ordering using one or more name-value pair arguments.

## Input Arguments

### **tree - Hierarchical binary cluster tree**

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an  $(M - 1)$ -by-3 matrix that you generate using `linkage`, where  $M$  is the number of leaves.

### **D - Distances**

matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using `pdist`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Criteria', 'group', 'Transformation', 'inverse'` specifies that the sum of similarities be maximized between every leaf

and all other leaves in adjacent clusters, using an inverse similarity transformation.

## 'Criteria' - Optimization criterion

'adjacent' (default) | 'group'

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of 'criteria' and one of these strings:

'adjacent'	Maximize the sum of similarities between adjacent leaves.
'group'	Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

**Example:** 'Criteria', 'group'

## Data Types

char

## 'Transformation' - Method for transforming distances to similarities

'linear' (default) | 'inverse' | function handle

Method for transforming distances to similarities, specified as the comma-separated pair consisting of 'Transformation' and one of 'linear', 'inverse', or a function handle.

Let  $d_{i,j}$  and  $Sim_{i,j}$  denote the distance and similarity between leaves  $i$  and  $j$ , respectively. The included similarity transformations are:

'linear'	$Sim_{i,j} = \max_{i,j} (d_{i,j}) - d_{i,j}$
'inverse'	$Sim_{i,j} = 1/d_{i,j}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, D, and returns a matrix of similarities, S. The function should be monotonic decreasing in the

# optimalleaforder

---

range of distance values.  $S$  must have the same size as  $D$ , with  $S(i, j)$  being the similarity computed based on  $D(i, j)$ .

**Example:** 'Transformation',@myTransform

## Data Types

char | function\_handle

## Output Arguments

### leafOrder - Optimal leaf order

vector

Optimal leaf order, returned as a length- $M$  vector, where  $M$  is the number of leaves. `leafOrder` is a permutation of the vector  $1:M$ , giving an optimal leaf ordering based on the specified distances and similarity transformation.

## Examples

### Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using `linkage`. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.

```
D = pdist(X);
tree = linkage(D, 'average');
leafOrder = optimalleaforder(tree,D);
```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

```
figure()
subplot(2,1,1)
dendrogram(tree)
```

```

title('Default Leaf Order')

subplot(2,1,2)
dendrogram(tree,'reorder',leafOrder)
title('Optimal Leaf Order')

```

The order of the leaves in the bottom figure corresponds to the elements in `leafOrder`.

`leafOrder`

# optimalleaforder

---

```
leafOrder =  
    1     4     9    10     2     5     8     3     7     6
```

## Optimal Leaf Order Using Inverse Distance Similarity

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree.

```
D = pdist(X);  
tree = linkage(D,'average');
```

Use the inverse distance similarity transformation to determine an optimal leaf order.

```
leafOrder = optimalleaforder(tree,D,'Transformation','inverse')
```

```
leafOrder =  
    1     4     9    10     2     5     8     3     7     6
```

**Purpose** Out-of-bag classification edge

**Syntax**  
edge = oobEdge(ens)  
edge = oobEdge(ens,Name,Value)

**Description**  
edge = oobEdge(ens) returns out-of-bag classification edge for ens.  
edge = oobEdge(ens,Name,Value) computes classification edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

**Input Arguments**  
**ens**  
A classification bagged ensemble, constructed with fitensemble.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

#### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. oobEdge uses only these learners for calculating loss.

**Default:** 1:NumTrained

#### **'mode'**

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.

# ClassificationBaggedEnsemble.oobEdge

---

- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

### edge

Classification edge, a weighted average of the classification margin.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed

prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Examples

Find the out-of-bag edge for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
edge = oobEdge(ens)

edge =
    0.8730
```

## See Also

[oobMargin](#) | [oobPredict](#) | [oobLoss](#)

# TreeBagger.oobError

---

**Purpose** Out-of-bag error

**Syntax**  
`err = oobError(B)`  
`err = oobError(B, 'param1', val1, 'param2', val2, ...)`

**Description** `err = oobError(B)` computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger `B`. `err` is a vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`err = oobError(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'mode' String indicating how `oobError` computes errors. If set to 'cumulative' (default), the method computes cumulative errors and `err` is a vector of length `NTrees`, where the first element gives error from `trees(1)`, second element gives error from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to 'individual', `err` is a vector of length `NTrees`, where each element is an error from each tree in the ensemble. If set to 'ensemble', `err` is a scalar showing the cumulative error for the entire ensemble.

'trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the

first element gives error from `trees(1)`, the second element gives error from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobError` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

## See Also

`CompactTreeBagger.error`

# TreeBagger.OOBIndices property

---

**Purpose** Indicator matrix for out-of-bag observations

**Description** The `OOBIndices` property is a logical array of size `Nobs-by-NTrees` where `Nobs` is the number of observations in the training data and `NTrees` is the number of trees in the ensemble. The  $(I, J)$  element is true if observation `I` is out-of-bag for tree `J` and false otherwise. In other words, a true value means observation `I` was not selected for the training data used to grow tree `J`.

**See Also** `classregtree`

# TreeBagger.OOBInstanceWeight property

---

**Purpose**

Count of out-of-bag trees for each observation

**Description**

The `OOBInstanceWeight` property is a numeric array of size `Nobs-by-1` containing the number of trees used for computing out-of-bag response for each observation. `Nobs` is the number of observations in the training data used to create the ensemble.

# ClassificationBaggedEnsemble.oobLoss

---

**Purpose** Out-of-bag classification error

**Syntax**  
L = oobloss(ens)  
L = oobloss(ens,Name,Value)

**Description** L = oobloss(ens) returns the classification error for ens computed for out-of-bag data.

L = oobloss(ens,Name,Value) computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**ens**  
A classification bagged ensemble, constructed with fitensemble.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to NumTrained. oobLoss uses only these learners for calculating loss.

**Default:** 1:NumTrained

### 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-2674
- 'classiferror' — Fraction of misclassified data

- 'exponential' — See “Loss Functions” on page 21-2674

You can write your own loss function in the syntax described in “Loss Functions” on page 21-2674.

**Default:** 'classiferror'

## 'mode'

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

**L**

Classification error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

# ClassificationBaggedEnsemble.oobLoss

---

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .
- $K$  is the number of classes in `tree`, represented in `tree.ClassNames`.
- $C$  is an  $N$ -by- $K$  logical matrix, with one true per row for the true class. The index for each class is its position in `tree.ClassNames`.

# ClassificationBaggedEnsemble.oobLoss

---

- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. The default `'classiferror'` cost function uses a cost of 0 for correct classification, and 1 for misclassification. In other words, `'classiferror'` uses  $COST = \text{ones}(K) - \text{eye}(K)$ .
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Find the out-of-bag error for a bagged ensemble from the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
L = oobLoss(ens)

L =
    0.0467
```

## See Also

`loss` | `oobEdge` | `oobMargin` | `oobPredict`

# RegressionBaggedEnsemble.oobLoss

---

**Purpose** Out-of-bag regression error

**Syntax**  
L = oobLoss(ens)  
L = oobLoss(ens,Name,Value)

**Description** L = oobLoss(ens) returns the mean squared error for ens computed for out-of-bag data.

L = oobLoss(ens,Name,Value) computes error with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**ens**  
A regression bagged ensemble, constructed with fitensemble.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to NumTrained. oobLoss uses only these learners for calculating loss.

**Default:** 1:NumTrained

### 'lossfun'

Function handle for loss function, or the string 'mse', meaning mean squared error. If you pass a function handle fun, oobLoss calls it as

FUN(Y,Yfit,W)

where  $Y$ ,  $Y_{fit}$ , and  $W$  are numeric vectors of the same length.  $Y$  is the observed response,  $Y_{fit}$  is the predicted response, and  $W$  is the observation weights.

**Default:** 'mse'

## 'mode'

String representing the meaning of the output  $L$ :

- 'ensemble' —  $L$  is a scalar value, the loss for the entire ensemble.
- 'individual' —  $L$  is a vector with one element per trained learner.
- 'cumulative' —  $L$  is a vector in which element  $J$  is obtained by using learners  $1:J$  from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

### $L$

Mean squared error of the out-of-bag observations, a scalar.  $L$  can be a vector, or can represent a different quantity, depending on the name-value settings.

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting  $N$  observations out of  $N$  with replacement, where  $N$  is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag"

# RegressionBaggedEnsemble.oobLoss

---

observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Examples

Compute the out-of-bag error for the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
L = oobLoss(ens)

L =
    17.0665
```

<b>Description</b>	<code>margin = oobMargin(ens)</code> returns out-of-bag classification margins. <code>margin = oobMargin(ens,Name,Value)</code> calculates margins with additional options specified by one or more <code>Name,Value</code> pair arguments.
<b>Input Arguments</b>	<b>ens</b> A classification bagged ensemble, constructed with <code>fitensemble</code> . <b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code> . <b>'learners'</b> Indices of weak learners in the ensemble ranging from 1 to <code>ens.NumTrained</code> . <code>oobEdge</code> uses only these learners for calculating loss. <b>Default:</b> <code>1:NumTrained</code>
<b>Output Arguments</b>	<b>margin</b> A numeric column vector of length <code>size(ens.X,1)</code> .
<b>Definitions</b>	<b>Out of Bag</b> <i>Bagging</i> , which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, <code>fitensemble</code> generates many bootstrap replicas of the dataset and

# ClassificationBaggedEnsemble.oobMargin

---

grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting  $N$  observations out of  $N$  with replacement, where  $N$  is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

## Examples

Find the out-of-bag margin for a bagged ensemble from the Fisher iris data: Find how many elements of margin are equal to 1.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
margin = oobMargin(ens);
sum(margin == 1)

ans =
    108
```

## See Also

`oobPredict` | `oobLoss` | `oobEdge` | `margin`

## Purpose

Out-of-bag margins

## Syntax

```
mar = oobMargin(B)
mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)
```

## Description

`mar = oobMargin(B)` computes an Nobs-by-NTrees matrix of classification margins for out-of-bag observations in the training data, using the trained bagger B.

`mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'mode'	String indicating how <code>oobMargin</code> computes errors. If set to 'cumulative' (default), the method computes cumulative margins and <code>mar</code> is an Nobs-by-NTrees matrix, where the first column gives margins from <code>trees(1)</code> , second column gives margins from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is an Nobs-by-NTrees matrix, where each column gives margins from each tree in the ensemble. If set to 'ensemble', <code>mar</code> is a single column of length Nobs showing the cumulative margins for the entire ensemble.
'trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns an Nobs-by-NTrees matrix for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a single column for 'ensemble' mode. For example, in the 'cumulative' mode, the first column gives

# TreeBagger.oobMargin

---

margins from `trees(1)`, the second column gives margins from `trees(1:2)` etc.

'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

## See Also

`CompactTreeBagger.margin`

## Purpose

Out-of-bag mean margins

## Syntax

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)
```

## Description

`mar = oobMeanMargin(B)` computes average classification margins for out-of-bag observations in the training data, using the trained bagger `B`. `oobMeanMargin` averages the margins over all out-of-bag observations. `mar` is a row-vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

- 'mode' String indicating how `oobMargin` computes errors. If set to 'cumulative' (default), is a vector of length `NTrees` where the first element gives mean margin from `trees(1)`, second column gives mean margins from `trees(1:2)` etc, up to `trees(1:NTrees)`. If set to 'individual', `mar` is a vector of length `NTrees`, where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', `mar` is a scalar showing the cumulative mean margin for the entire ensemble.
- 'trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.
- 'treeweights' Vector of tree weights. This vector must have the same length as the 'trees' vector. `oobMeanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

# TreeBagger.OOBPermutedVarCountRaiseMargin property

---

**Purpose** Variable importance for raising margin

**Description** The OOBPermutedVarCountRaiseMargin property is a numeric array of size 1-by-Nvars containing a measure of variable importance for each predictor. For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

# TreeBagger.OOBPermutedVarDeltaError property

---

**Purpose** Variable importance for prediction error

**Description** The `OOBPermutedVarDeltaError` property is a numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

# TreeBagger.OOBPermutedVarDeltaMeanMargin property

---

**Purpose** Variable importance for classification margin

**Description** The `OOBPermutedVarDeltaMeanMargin` property is a numeric array of size 1-by-Nvars containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

# ClassificationBaggedEnsemble.oobPredict

---

<b>Purpose</b>	Predict out-of-bag response of ensemble
<b>Syntax</b>	<pre>[label,score] = oobPredict(ens) [label,score] = oobPredict(ens,Name,Value)</pre>

The label is the class with the highest score. In case of a tie, the label is earliest in ens.ClassNames.</p> <p><b>score</b></p>

An N-by-K numeric matrix for N observations and K classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1.

## Definitions

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

# ClassificationBaggedEnsemble.oobPredict

---

## Examples

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores in the range (0.2,0.8); these are the scores where there is notable uncertainty in the resulting classifications.

```
load fisheriris
ens = fitensemble(meas,species,'Bag',100,...
    'Tree','type','classification');
[label score] = oobPredict(ens);
unsure = ( (score > .2) & (score < .8));
sum(sum(unsure)) % How many uncertain predictions?

ans =
    16
```

### Out of Bag

*Bagging*, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitensemble` obtains each bootstrap replica by randomly selecting  $N$  observations out of  $N$  with replacement, where  $N$  is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing  $N$  out of  $N$  observations with replacement omits on average 37% ( $1/e$ ) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

## Examples

Compute out-of-bag predictions for the `carsmall` data. Look at the first three terms of the fit:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression');
Yfit = oobPredict(ens);
Yfit(1:3) % first three terms

ans =
    15.7964
    14.7162
    14.8062
```

## See Also

`oobLoss` | `predict`

**Purpose** Ensemble predictions for out-of-bag observations

**Syntax**  
`Y = oobPredict(B)`  
`Y = oobPredict(B, 'param1', val1, 'param2', val2, ...)`

**Description** `Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned `Y` is a cell array of strings for classification and a numeric array for regression.

`Y = oobPredict(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

`'trees'` Array of tree indices to use for computation of responses. Default is `'all'`.

`'treeweights'` Array of `Ntrees` weights for weighting votes from the specified trees.

# ordinal

---

**Superclasses**    categorical

**Purpose**    Arrays for ordinal categorical data

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Description**    Ordinal arrays are used to store discrete values that have an ordering but are not numeric. An ordinal array provides efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values. Ordinal arrays are often used as grouping variables.

Like a numerical array, an ordinal array can have any size or dimension. You can subscript, concatenate, reshape, sort, etc. ordinal arrays, much like ordinary numeric arrays. You can make comparisons between elements of two ordinal arrays, or between an ordinal array and a single string representing a ordinal value.

**Construction**    Use the `ordinal` constructor to create an ordinal array from a numeric, logical, or character array, or from a cell array of strings.

<code>ordinal</code>	Construct ordinal categorical array
----------------------	-------------------------------------

**Methods**    Each ordinal array carries along a list of possible values that it can store, known as its levels. The list is created when you create an ordinal array, and you can access it using the `getlevels` method, or modify it using the `addlevels`, `mergelevels`, or `droplevels` methods. Assignment to the array will also add new levels automatically if the values assigned are not already levels of the array. The ordering on values stored in an ordinal array is defined by the order of the list of levels. You can change that order using the `reorderlevels` method.

The following table lists operations available for ordinal arrays.

sort	Sort elements of ordinal array
sortrows	Sort rows
summary	Summary statistics for ordinal array

### Inherited Methods

Methods in the following table are inherited from categorical.

addlevels	Add levels to categorical array
cat	Concatenate categorical arrays
cellstr	Convert categorical array to cell array of strings
char	Convert categorical array to character array
circshift	Shift categorical array circularly
ctranspose	Transpose categorical matrix
disp	Display categorical array
display	Display categorical array
double	Convert categorical array to double array
droplevels	Drop levels
end	Last index in indexing expression for categorical array
flipdim	Flip categorical array along specified dimension
fliplr	Flip categorical matrix in left/right direction
flipud	Flip categorical matrix in up/down direction

<code>getlabels</code>	Access categorical array labels
<code>getlevels</code>	Get categorical array levels
<code>hist</code>	Plot histogram of categorical data
<code>horzcat</code>	Horizontal concatenation for categorical arrays
<code>int16</code>	Convert categorical array to signed 16-bit integer array
<code>int32</code>	Convert categorical array to signed 32-bit integer array
<code>int64</code>	Convert categorical array to signed 64-bit integer array
<code>int8</code>	Convert categorical array to signed 8-bit integer array
<code>intersect</code>	Set intersection for categorical arrays
<code>ipermute</code>	Inverse permute dimensions of categorical array
<code>isempty</code>	True for empty categorical array
<code>isequal</code>	True if categorical arrays are equal
<code>islevel</code>	Test for levels
<code>ismember</code>	True for elements of categorical array in set
<code>isscalar</code>	True if categorical array is scalar
<code>isundefined</code>	Test for undefined elements
<code>isvector</code>	True if categorical array is vector
<code>length</code>	Length of categorical array
<code>levelcounts</code>	Element counts by level

---

<code>mergelevels</code>	Merge levels
<code>ndims</code>	Number of dimensions of categorical array
<code>numel</code>	Number of elements in categorical array
<code>permute</code>	Permute dimensions of categorical array
<code>reorderlevels</code>	Reorder levels
<code>repmat</code>	Replicate and tile categorical array
<code>reshape</code>	Resize categorical array
<code>rot90</code>	Rotate categorical matrix 90 degrees
<code>setdiff</code>	Set difference for categorical arrays
<code>setlabels</code>	Label levels
<code>setxor</code>	Set exclusive-or for categorical arrays
<code>shiftdim</code>	Shift dimensions of categorical array
<code>single</code>	Convert categorical array to single array
<code>size</code>	Size of categorical array
<code>squeeze</code>	Squeeze singleton dimensions from categorical array
<code>subsasgn</code>	Subscripted assignment for categorical array
<code>subsindex</code>	Subscript index for categorical array

# ordinal

---

suboref	Subscripted reference for categorical array
times	Product of categorical arrays
transpose	Transpose categorical matrix
uint16	Convert categorical array to unsigned 16-bit integers
uint32	Convert categorical array to unsigned 32-bit integers
uint64	Convert categorical array to unsigned 64-bit integers
uint8	Convert categorical array to unsigned 8-bit integers
union	Set union for categorical arrays
unique	Unique values in categorical array
vertcat	Vertical concatenation for categorical arrays

## Properties

## Inherited Properties

Properties in the following table are inherited from `categorical`.

labels	Text labels for levels
undeflabel	Text label for undefined levels

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## Examples

### Create and Compare Ordinal Arrays

Create an ordinal array from integer data.

```
quality = ordinal([1 2 3; 3 2 1; 2 1 3],{'low' 'medium' 'high'})
```

```
quality =
```

```
    low    medium    high
    high    medium    low
    medium    low    high
```

Identify the elements in `quality` that are members of a level that is greater than or equal to `'medium'`.

```
quality >= 'medium'
```

```
ans =
```

```
    0    1    1
    1    1    0
    1    0    1
```

A value of 1 in the resulting array `ans` indicates that the corresponding element of `quality` is a member of a level that is greater than or equal to `'medium'`.

Identify the elements of `quality` that are members of either `'low'` or `'high'`.

```
ismember(quality,{'low' 'high'})
```

```
ans =
```

```
    1    0    1
    1    0    1
    0    1    1
```

A value of 1 in the resulting array `ans` indicates that the corresponding element of `quality` is a member of either `'low'` or `'high'`.

Create a second nominal array `quality2` by flipping `quality` from left to right.

# ordinal

---

```
quality2 = fliplr(quality)

quality2 =

    high    medium    low
    low     medium    high
    high     low      medium
```

Compare the elements of `quality` and `quality2`.

```
quality == quality2
```

```
ans =

    0     1     0
    0     1     0
    0     1     0
```

A value of 1 in the resulting array `ans` indicates that the corresponding element of `quality` is a member of the same level as the corresponding element of `quality2`.

`histc` | `nominal`

**Purpose**

Construct ordinal categorical array

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
B = ordinal(A)
B = ordinal(A,labels)
B = ordinal(A,labels,levels)
B = ordinal(A,labels,[],edges)
```

**Description**

`B = ordinal(A)` creates an ordinal array `B` from the array `A`. `A` can be numeric, logical, character, categorical, or a cell array of strings. `ordinal` creates the levels of `B` from the sorted unique values in `A`, and creates default labels for them.

`B = ordinal(A,labels)` labels the levels in `B` using the character array or cell array of strings `labels`. `ordinal` assigns labels to levels in `B` in order according to the sorted unique values in `A`.

`B = ordinal(A,labels,levels)` creates an ordinal array with possible levels defined by `levels`. `levels` is a vector whose values can be compared to those in `A` using the equality operator. `ordinal` assigns labels to each level from the corresponding elements of `labels`. If `A` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined. Use `[]` for `labels` to allow `ordinal` to create default labels.

`B = ordinal(A,labels,[],edges)` creates an ordinal array by binning the numeric array `A`, with bin edges given by the numeric vector `edges`. The uppermost bin includes values equal to the right-most edge. `ordinal` assigns labels to each level in `B` from the corresponding elements of `labels`. `edges` must have one more element than `labels`.

By default, an element of `B` is undefined if the corresponding element of `A` is NaN (when `A` is numeric), an empty string (when `A` is character), or undefined (when `A` is categorical). `ordinal` treats such elements as “undefined” or “missing” and does not include entries for them among the possible levels for `B`. To create an explicit level for such elements

# ordinal

---

instead of treating them as undefined, you must use the `levels` input, and include `NaN`, the empty string, or an undefined element.

You may include duplicate labels in `labels` in order to merge multiple values in `A` into a single level in `B`.

## Examples

### Create and Label Ordinal Arrays

Create an ordinal array from integer data, and provide explicit labels.

```
quality1 = ordinal([1 2 3; 3 2 1; 2 1 3],...  
                  {'low' 'medium' 'high'})
```

```
quality1 =
```

low	medium	high
high	medium	low
medium	low	high

Create an ordinal array from integer data, and provide both explicit labels and an explicit order.

```
quality2 = ordinal([1 2 3; 3 2 1; 2 1 3],...  
                  {'high' 'medium' 'low'},[3 2 1])
```

```
quality2 =
```

low	medium	high
high	medium	low
medium	low	high

Create an ordinal array by binning floating point values.

```
size = ordinal(rand(5,2),{'small' 'medium' 'large'},...  
               [],[0 1/3 2/3 1])
```

```
size =
```

small	small
-------	-------

```
large      medium
large      large
medium     large
large      large
```

### Create Ordinal Array Using Sample Data

Load the sample data.

```
load fisheriris;
```

Create an ordinal array from the measurements in Fisher's iris data, ignoring decimal lengths.

```
m = floor(min(meas(:)));
M = floor(max(meas(:)));
labels = num2str((m:M)');
edges = m:M+1;
cms = ordinal(meas,labels,[],edges);
```

Display the first five rows of `meas`, which contains actual flower measurements.

```
meas(1:5,:)
```

```
ans =
```

```
5.1000    3.5000    1.4000    0.2000
4.9000    3.0000    1.4000    0.2000
4.7000    3.2000    1.3000    0.2000
4.6000    3.1000    1.5000    0.2000
5.0000    3.6000    1.4000    0.2000
```

Display the first five rows of the ordinal array `cms`.

```
cms(1:5,:)
```

```
ans =
```

# ordinal

---

```
5     3     1     0
4     3     1     0
4     3     1     0
4     3     1     0
5     3     1     0
```

## Create Groups in Ordinal Array

Load the sample data.

```
load hospital;
```

Create an age group ordinal array from the patients' age data.

```
edges = 0:10:100;
labels = strcat(num2str((0:10:90)', '%d'), {'s'});
AgeGroup = ordinal(hospital.Age, labels, [], edges);
```

Display the first five elements of the ordinal array AgeGroup.

```
AgeGroup(1:5)
```

```
ans =
```

```
30s
40s
30s
40s
40s
```

## Purpose

Outlier measure for data

## Syntax

```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)
```

## Description

`out = outlierMeasure(B,X)` computes outlier measures for predictors `X` using trees in the ensemble `B`. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. `outlierMeasure` then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the `'data'` parameter.

`out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

<code>'data'</code>	Flag indicating how to treat the <code>X</code> input argument. If set to <code>'predictors'</code> (default), the method assumes <code>X</code> is a matrix of predictors and uses it for computation of the proximity matrix. If set to <code>'proximity'</code> , the method treats <code>X</code> as a proximity matrix returned by the <code>proximity</code> method. If you do not supply the proximity matrix, <code>outlierMeasure</code> computes it internally. If you use the <code>proximity</code> method to compute a proximity matrix, supplying it as input to <code>outlierMeasure</code> reduces computing time.
<code>'labels'</code>	Vector of true class labels. True class labels can be either a numeric vector, character matrix, or cell array of strings. When you supply this parameter, the method performs the outlier calculation for any observations using only other observations from the same class. This parameter must specify one label for each observation (row) in <code>X</code> .

# CompactTreeBagger.outlierMeasure

---

## See Also

`proximity`

# TreeBagger.OutlierMeasure property

---

**Purpose** Measure for determining outliers

**Description** The OutlierMeasure property is a numeric array of size Nobs-by-1, where Nobs is the number of observations in the training data, containing outlier measures for each observation.

**See Also** CompactTreeBagger.outlierMeasure

# parallelcoords

---

**Purpose** Parallel coordinates plot

**Syntax**

```
parallelcoords(X)
parallelcoords(X,...,'Standardize','on')
parallelcoords(X,...,'Standardize','PCA')
parallelcoords(X,...,'Standardize','PCAStd')
parallelcoords(X,...,'Quantile',alpha)
parallelcoords(X,...,'Group',group)
parallelcoords(X,...,'Labels',labels)
parallelcoords(X,...,PropertyName,PropertyValue,...)
h = parallelcoords(X,...)
parallelcoords(axes,...)
```

**Description** `parallelcoords(X)` creates a parallel coordinates plot of the multivariate data in the  $n$ -by- $p$  matrix  $X$ . Rows of  $X$  correspond to observations, columns to variables. A parallel coordinates plot is a tool for visualizing high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices. `parallelcoords` treats NaNs in  $X$  as missing values and does not plot those coordinate values.

`parallelcoords(X,...,'Standardize','on')` scales each column of  $X$  to have mean 0 and standard deviation 1 before making the plot.

`parallelcoords(X,...,'Standardize','PCA')` creates a parallel coordinates plot from the principal component scores of  $X$ , in order of decreasing eigenvalues. `parallelcoords` removes rows of  $X$  containing missing values (NaNs) for principal components analysis (PCA) standardization.

`parallelcoords(X,...,'Standardize','PCAStd')` creates a parallel coordinates plot using the standardized principal component scores.

`parallelcoords(X,...,'Quantile',alpha)` plots only the median and the  $\alpha$  and  $1-\alpha$  quantiles of  $f(t)$  at each value of  $t$ . This is useful if  $X$  contains many observations.

`parallelcoords(X,...,'Group',group)` plots the data in different groups with different colors. Groups are defined by `group`, a numeric

array containing a group index for each observation. `group` can also be a categorical variable, character matrix, or cell array of strings, containing a group name for each observation.

`parallelcoords(X,...,'Labels',labels)` labels the coordinate tick marks along the horizontal axis using `labels`, a character array or cell array of strings.

`parallelcoords(X,...,PropertyName,PropertyValue,...)` sets properties to the specified property values for all line graphics objects created by `parallelcoords`.

`h = parallelcoords(X,...)` returns a column vector of handles to the line objects created by `parallelcoords`, one handle per row of `X`. If you use the `'Quantile'` input argument, `h` contains one handle for each of the three lines objects created. If you use both the `'Quantile'` and the `'Group'` input arguments, `h` contains three handles for each group.

`parallelcoords(axes,...)` plots into the axes with handle axes.

## Examples

```
% Make a grouped plot of the raw data
load fisheriris
labels = {'Sepal Length','Sepal Width',...
         'Petal Length','Petal Width'};
parallelcoords(meas,'group',species,'labels',labels);
```

```
% Plot only the median and quartiles of each group
parallelcoords(meas,'group',species,'labels',labels,...
              'quantile',.25);
```

## How To

- “Grouping Variables” on page 2-52

# ProbDistUnivParam.paramci

---

**Purpose** Return parameter confidence intervals of ProbDistUnivParam object

**Syntax** CI = paramci(PD)  
CI = paramci(PD, Alpha)

**Description** CI = paramci(PD) returns CI, a 2-by-N array containing 95% confidence intervals for the parameters of the ProbDistUnivParam object PD. N is the number of parameters in the distribution. When you create PD by specifying parameters (such as using the ProbDistUnivParam.ProbDistUnivParam constructor or using the fitdist function and specifying a 'binomial' or 'generalized pareto' distribution) rather than by fitting to data, the confidence intervals have a width of 0 because the parameters are viewed as estimates of an unknown parameter.

CI = paramci(PD, Alpha) returns 100\*(1 - Alpha)% confidence intervals. Default Alpha is 0.05, which specifies 95% confidence intervals.

---

**Note** If you create PD with a distribution that does not support confidence intervals, then CI contains NaN values.

---

**Input Arguments**

PD	An object of the class ProbDistUnivParam.
Alpha	A value between 0 and 1 that specifies a confidence interval. Default is 0.05, which specifies 95% confidence intervals.

**Output Arguments**

CI	A 2-by-N array containing 100*(1 - Alpha)% confidence intervals for the parameters of the ProbDistUnivParam object PD. N is the number of parameters in the distribution.
----	---

**See Also**     `fitdist`

# prob.ToolboxFittableParametricDistribution.paramci

---

**Purpose** Confidence intervals for probability distribution parameters

**Syntax**  
`ci = paramci(pd)`  
`ci = paramci(pd,Name,Value)`

**Description**  
`ci = paramci(pd)` returns the array `ci` containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution `pd`.  
`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

## Input Arguments

**pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Alpha',0.01` specifies a 99% confidence interval.

## 'Alpha' - Alpha level

0.05 (default) | scalar value in the range (0,1)

Alpha level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value

in the range (0,1). The default value 0.05 corresponds to a 95% confidence interval.

**Example:** 'Alpha',0.01

## Data Types

single | double

## 'Parameter' - Parameter list

vector | cell array of strings

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of 'Parameter' and a vector or a cell array of strings containing the parameter names. By default, paramci computes confidence intervals for all distribution parameters.

**Example:** 'Parameter', 'mu'

## Data Types

char

## 'Type' - Computation method

'exact' | 'Wald' | 'lr'

Computation method for the confidence intervals, specified as the comma-separated pair consisting of 'Type' and 'exact', 'Wald', or 'lr'.

'exact' computes the confidence intervals using an exact method, and is available for the following distributions.

Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.

# prob.ToolboxFittableParametricDistribution.paramci

---

Normal	Computation method based on $t$ and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Lognormal	Computation method based on $t$ and chi-square distributions for uncensored samples provides exact coverage. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

'exact' is the default when it is available. Alternatively, you can specify 'Wald' to compute the confidence intervals using the Wald method, or 'lr' to compute the confidence intervals using the likelihood ratio method.

**Example:** 'Type', 'Wald'

## 'LogFlag' - Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of 'LogFlag' and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

**Example:** 'LogFlag', [0, 1]

## Data Types

logical

## Output Arguments

### ci - Confidence interval

array

Confidence interval, returned as a  $p$ -by-2 array containing the lower and upper bounds of the  $(1 - \text{Alpha})\%$  confidence interval for each distribution parameter.  $p$  is the number of distribution parameters.

## Examples

### Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the 95% confidence interval for the distribution parameters.

```
ci = paramci(pd)
```

```
ci =
```

```
73.4321 7.7391  
76.5846 9.9884
```

# prob.ToolboxFittableParametricDistribution.paramci

---

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

## Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')  
  
pd =  
  
NormalDistribution  
  
Normal distribution  
    mu = 75.0083    [73.4321, 76.5846]  
    sigma =  8.7202    [7.7391, 9.98843]
```

Compute the 99% confidence interval for the distribution parameters.

```
ci = paramci(pd,'Alpha',.01)  
  
ci =  
  
    72.9245    7.4627  
    77.0922   10.4403
```

Column 1 of `ci` contains the lower and upper 99% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

# ProbDistParametric.ParamCov property

---

<b>Purpose</b>	Read-only covariance matrix of parameter estimates of ProbDistParametric object
<b>Description</b>	ParamCov is a read-only property of the ProbDistParametric class. ParamCov is a covariance matrix containing the parameter estimates of a distribution represented by a ProbDistParametric object. ParamCov has a size of NumParams-by-NumParams.
<b>Values</b>	This covariance matrix includes estimates for both the specified parameters and parameters that are fit to the data. For specified parameters, the covariance is 0, indicating the parameter is known exactly. Use this information to view and compare the descriptions of parameters supplied to create distributions.

# ProbDistParametric.ParamDescription property

---

<b>Purpose</b>	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
<b>Description</b>	ParamDescription is a read-only property of the ProbDistParametric class. ParamDescription is a cell array of strings specifying the descriptions or meanings of the parameters of a distribution represented by a ProbDistParametric object. ParamDescription has a length of NumParams.
<b>Values</b>	This cell array includes a brief description of the meaning of both the specified parameters and parameters that are fit to the data. The description is the same as the parameter name when no further description information is available. Use this information to view and compare the descriptions of parameters used to create distributions.

# ProbDistParametric.ParamIsFixed property

---

<b>Purpose</b>	Read-only logical array specifying fixed parameters of ProbDistParametric object
<b>Description</b>	ParamIsFixed is a read-only property of the ProbDistParametric class. ParamIsFixed is a logical array specifying the fixed parameters of a distribution represented by a ProbDistParametric object. ParamIsFixed has a length of NumParams.
<b>Values</b>	This array specifies a 1 (true) for fixed parameters, and a 0 (false) for parameters that are estimated from the input data. Use this information to view and compare the fixed parameters used to create distributions.

# ProbDistParametric.ParamNames property

---

<b>Purpose</b>	Read-only cell array specifying names of parameters of ProbDistParametric object
<b>Description</b>	ParamNames is a read-only property of the ProbDistParametric class. ParamNames is a cell array of strings specifying the names of the parameters of a distribution represented by a ProbDistParametric object. ParamNames has a length of NumParams.
<b>Values</b>	This cell array includes the names of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the names of parameters used to create distributions.

## Purpose

Parameter estimates

## Description

The Params property is an NClasses-by-NDims cell array containing the parameter estimates, excluding the class priors. Params(i, j) contains the parameter estimates for the jth feature in the ith class. Params(i, j) is an empty cell if the ith class is empty.

The entry in Params(i, j) depends on the distribution type used for the jth feature, as follows:

'normal'	A vector of length two. The first element is the mean, and the second element is standard deviation.
'kernel'	A ProbDistUnivKernel object
'mvmn'	A vector containing the probability for each possible value of the jth feature in the ith class. The order of the probabilities is decided by the sorted order of all the unique values of the jth feature.
'mn'	A scalar representing the probability the jth token appearing in the ith class, Prob(token j   class i). It is estimated as $(1 + \text{the number of occurrence of token J in class I}) / (\text{NDims} + \text{the total number of token occurrence in class I})$ .

# ProbDistParametric.Params property

---

<b>Purpose</b>	Read-only array specifying values of parameters of ProbDistParametric object
<b>Description</b>	Params is a read-only property of the ProbDistParametric class. Params is an array of values specifying the values of the parameters of a distribution represented by a ProbDistParametric object. Params has a length of NumParams.
<b>Values</b>	This array includes the values of both the specified parameters and parameters that are fit to the data. Use this information to view and compare the values of parameters used to create distributions.

# prob.ParametricTruncatableDistribution

---

<b>Superclasses</b>	TruncatableDistribution	
<b>Purpose</b>	Parametric truncatable probability distribution object	
<b>Description</b>	Create a probability distribution object with specified parameter values using <code>makedist</code> .	
<b>Methods</b>	<code>mean</code>	Mean of probability distribution object
	<code>std</code>	Standard deviation of probability distribution object
	<code>var</code>	Variance of probability distribution object
	<b>Inherited Methods</b>	
	<code>cdf</code>	Cumulative distribution function of probability distribution object
	<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
	<code>iqr</code>	Interquartile range of probability distribution object
	<code>median</code>	Median of probability distribution object
	<code>pdf</code>	Probability density function of probability distribution object
	<code>random</code>	Generate random numbers from probability distribution object
	<code>truncate</code>	Truncate probability distribution object

---

<b>Superclasses</b>	piecewisedistribution	
<b>Purpose</b>	Empirical distributions with Pareto tails	
<b>Construction</b>	paretotails	Construct Pareto tails object
<b>Methods</b>	lowerparams upperparams	Lower Pareto tails parameters Upper Pareto tails parameters

## Inherited Methods

Methods in the following table are inherited from piecewisedistribution.

boundary	Piecewise distribution boundaries
cdf	Cumulative distribution function for piecewise distribution
disp	Display piecewisedistribution object
display	Display piecewisedistribution object
icdf	Inverse cumulative distribution function for piecewise distribution
nsegments	Number of segments
pdf	Probability density function for piecewise distribution
random	Random numbers from piecewise distribution
segment	Segments containing values

## **Properties**

Objects of the `paretotails` class have no properties accessible by dot indexing, `get` methods, or `set` methods. To obtain information about a `paretotails` object, use the appropriate method.

## **Copy Semantics**

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## **How To**

- “Generalized Pareto Distribution” on page B-60

# paretotails

---

**Purpose** Construct Pareto tails object

**Syntax**  
`obj = paretotails(x,p1,pu)`  
`obj = paretotails(x,p1,pu,cdffun)`

**Description** `obj = paretotails(x,p1,pu)` creates an object `obj` defining a distribution consisting of the empirical distribution of `x` in the center and Pareto distributions in the tails. `x` is a real-valued vector of data values whose extreme observations are fit to generalized Pareto distributions (GPDs). `p1` and `pu` identify the lower- and upper-tail cumulative probabilities such that  $100 \cdot p1$  and  $100 \cdot (1 - pu)$  percent of the observations in `x` are, respectively, fit to a GPD by maximum likelihood. If `p1` is 0, or if there are not at least two distinct observations in the lower tail, then no lower Pareto tail is fit. If `pu` is 1, or if there are not at least two distinct observations in the upper tail, then no upper Pareto tail is fit.

`obj = paretotails(x,p1,pu,cdffun)` uses `cdffun` to estimate the cdf of `x` between the lower and upper tail probabilities. `cdffun` may be any of the following:

- 'ecdf' — Uses an interpolated empirical cdf, with data values as the midpoints in the vertical steps in the empirical cdf, and computed by linear interpolation between data values. This is the default.
- 'kernel' — Uses a kernel-smoothing estimate of the cdf.
- @fun — Uses a handle to a function of the form `[p,xi] = fun(x)` that accepts the input data vector `x` and returns a vector `p` of cdf values and a vector `xi` of evaluation points. Values in `xi` must be sorted and distinct but need not equal the values in `x`.

`cdffun` is used to compute the quantiles corresponding to `p1` and `pu` by inverse interpolation, and to define the fitted distribution between these quantiles.

The output object `obj` is a Pareto tails object with methods to evaluate the cdf, inverse cdf, and other functions of the fitted distribution. These methods are well-suited to copula and other Monte Carlo simulations.

The pdf method in the tails is the GPD density, but in the center it is computed as the slope of the interpolated cdf.

The `paretotails` class is a subclass of the `piecewisedistribution` class, and many of its methods are derived from that class.

## Examples

### Fit Pareto Tails to a Probability Distribution

Generate sample data containing 100 random numbers from a  $t$  distribution with 3 degrees of freedom.

```
rng('default'); % For reproducibility
t = trnd(3,100,1);
```

Fit pareto tails to the distribution at cumulative probabilities 0.1 and 0.9.

```
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj);
```

Plot the cdf of the Pareto tails and the cdf of the fitted  $t$  distribution on the same figure.

```
x = linspace(-5,5);
plot(x,cdf(obj,x),'b-','LineWidth',2)
hold on;
plot(x,tcdf(x,3),'r:','LineWidth',2)
plot(q,p,'bo','LineWidth',2,'MarkerSize',5)
legend('Pareto Tails Object','t Distribution',...
      'Location','NW')
hold off;
```

# paretotails

---

## See Also

[cdf](#) | [ecdf](#) | [gpfitt](#) | [icdf](#) | [ksdensity](#)

**Purpose** Linear or rank partial correlation coefficients

**Syntax**

```
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr( ___,Name,Value)
[rho,pval] = partialcorr( __ )
```

**Description** `rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the remaining variables in `x`.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the variables in `z`.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x` and `y`, controlling for the variables in `z`.

`rho = partialcorr( ___,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr( __ )` also returns a matrix `pval` of  $p$ -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

## Input Arguments

### **x - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_x$  matrix. The rows of  $x$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

### **y - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_y$  matrix. The rows of  $y$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

### **z - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_z$  matrix. The rows of  $z$  correspond to observations, and columns correspond to variables.

### **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** 'Type', 'Spearman', 'Rows', 'complete' computes Spearman partial correlations using only the data in rows that contain no missing values.

### **'Type' - Type of partial correlations**

'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and one of the following.

'Pearson'	Compute Pearson (linear) partial correlations.
'Spearman'	Compute Spearman (rank) partial correlations.

**Example:** 'Type', 'Spearman'

**'Rows' - Rows to use in computation**

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

'all'	Use all rows regardless of missing (NaN) values.
'complete'	Use only rows with no missing values.
'pairwise'	Compute $\rho(i, j)$ using rows with no missing values in column $i$ or $j$ .

Using 'pairwise' can produce a  $\rho$  that is not positive definite. 'complete' always produces a positive definite  $\rho$ , but when data is missing, the estimates are generally based on fewer observations.

**Example:** 'Rows', 'complete'

**'Tail' - Alternative hypothesis**

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the correlation is not 0.
'right'	Test the alternative hypothesis that the correlation is greater than 0.
'left'	Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

## Output Arguments

### **rho** - Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an  $\mathbf{x}$  matrix,  $\mathbf{rho}$  is a symmetric  $p_x$ -by- $p_x$  matrix. The  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ -th and  $j$ -th columns in  $\mathbf{x}$ .
- If you input  $\mathbf{x}$  and  $\mathbf{z}$  matrices,  $\mathbf{rho}$  is a symmetric  $p_x$ -by- $p_x$  matrix. The  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th and  $j$ th columns in  $\mathbf{x}$ , controlled for the variables in  $\mathbf{z}$ .
- If you input  $\mathbf{x}$ ,  $\mathbf{y}$ , and  $\mathbf{z}$  matrices,  $\mathbf{rho}$  is a  $p_x$ -by- $p_y$  matrix, where the  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th column in  $\mathbf{x}$  and the  $j$ th column in  $\mathbf{y}$ , controlled for the variables in  $\mathbf{z}$ .

If the covariance matrix of  $[\mathbf{x}, \mathbf{z}]$  is

$$S = \begin{pmatrix} S_{xx} & S_{xz} \\ S_{xz}^T & S_{zz} \end{pmatrix},$$

then the partial correlation matrix of  $\mathbf{x}$ , controlling for  $\mathbf{z}$ , can be defined formally as a normalized version of the covariance matrix  $S_{xy} = S_{xx} - (S_{xz} S_{zz}^{-1} S_{xz}^T)$

### **pval** - p-values

matrix

$p$ -values, returned as a matrix. Each element of `pval` is the  $p$ -value for the corresponding element of `rho`.

If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from 0.

`partialcorr` computes  $p$ -values for linear and rank partial correlations using a Student's  $t$  distribution for a transformation of the correlation. This is exact for linear partial correlation when  $x$  and  $z$  are normal, but is a large-sample approximation otherwise.

## Examples

### Compute Partial Correlation Coefficients

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient's gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```
rho = partialcorr(x)
```

```
rho =
```

```

    1.0000    -0.0105    0.0273    0.9421
   -0.0105     1.0000    0.0419    0.0369
    0.0273     0.0419     1.0000    0.0451
    0.9421     0.0369     0.0451     1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the  $p$ -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames', {'SexID', 'Age', 'Smoker', 'Weight'}, ...  
    'RowNames', {'SexID', 'Age', 'Smoker', 'Weight'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)
```

```
Partial Correlation Coefficients  
                SexID      Age      Smoker      Weight  
-----  
SexID           1      -0.01052    0.027324    0.9421  
Age      -0.01052           1      0.041945    0.036873  
Smoker    0.027324    0.041945           1      0.045106  
Weight    0.9421      0.036873    0.045106           1
```

## Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```
x = [hospital.Age hospital.BloodPressure];  
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The `x` matrix contains the variables to test for partial correlation. The `z` matrix contains the variables to control for. The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,z)
```

```
rho =
```

```
    1.0000    0.1300    0.0462
    0.1300    1.0000    0.0012
    0.0462    0.0012    1.0000
```

```
pval =
```

```
    0    0.2044    0.6532
    0.2044    0    0.9903
    0.6532    0.9903    0
```

The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{ 'Age', 'BPTop', 'BPBottom'},...
    'RowNames',{ 'SexID', 'Smoker', 'Weight'});
```

```
pval = array2table(pval, ...
```

```
'VariableNames',{ 'Age', 'BPTop', 'BPBottom'}, ...  
'RowNames',{ 'SexID', 'Smoker', 'Weight'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)  
disp('p-values')  
disp(pval)
```

```
Partial Correlation Coefficients
```

	Age	BPTop	BPBottom
SexID	1	0.13	0.046202
Smoker	0.13	1	0.0012475
Weight	0.046202	0.0012475	1

```
p-values
```

	Age	BPTop	BPBottom
SexID	0	0.20438	0.65316
Smoker	0.20438	0	0.99032
Weight	0.65316	0.99032	0

## Test for Paired Partial Correlation Coefficients

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];  
y = [hospital.Weight hospital.Age];  
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x` and `y`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,y,z)
```

```
rho =
```

```
   -0.0257    0.1289  
    0.0292    0.0472
```

```
pval =
```

```
    0.8018    0.2058  
    0.7756    0.6442
```

The results in `pval` indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient's blood pressure measurements and that patient's weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames',{'BPTop','BPBottom'},...  
    'RowNames',{'Weight','Age'});
```

```
pval = array2table(pval, ...  
    'VariableNames',{'BPTop','BPBottom'},...
```

```
'RowNames',{'Weight','Age'});  
  
disp('Partial Correlation Coefficients')  
disp(rho)  
disp('p-values')  
disp(pval)
```

```
Partial Correlation Coefficients  
                BPTop      BPBottom  
-----  
Weight          -0.02568      0.12893  
Age             0.029168      0.047226
```

```
p-values  
                BPTop      BPBottom  
-----  
Weight          0.80182      0.2058  
Age             0.77556      0.64424
```

## One-Tailed Partial Correlation Test

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.

Load the sample data. Convert the strings in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];  
y = [hospital.Weight hospital.Age];  
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender

and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```
[rho,pval] = partialcorr(x,y,z,'Tail','right')
```

```
rho =
```

```
   -0.0257    0.1289  
    0.0292    0.0472
```

```
pval =
```

```
   0.5991    0.1029  
   0.3878    0.3221
```

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames',{'BPTop','BPBottom'},...  
    'RowNames',{'Weight','Age'});
```

```
pval = array2table(pval, ...  
    'VariableNames',{'BPTop','BPBottom'},...  
    'RowNames',{'Weight','Age'});
```

```
disp('Partial Correlation Coefficients')  
disp(rho)
```

# partialcorr

## See Also

[corr](#) | [tiedrank](#) | [corrcoef](#) | [partialcorri](#)

## Purpose

Partial correlation coefficients adjusted for internal variables

## Syntax

```
rho = partialcorri(y,x)
rho = partialcorri(y,x,z)
rho = partialcorri( ___,Name,Value)
[rho,pval] = partialcorri( ___)
```

## Description

`rho = partialcorri(y,x)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`.

`rho = partialcorri(y,x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`, after first controlling both `x` and `y` for the variables in `z`.

`rho = partialcorri( ___,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorri( ___)` also returns a matrix `pval` of  $p$ -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

## Input Arguments

### **x** - Data matrix

matrix

Data matrix, specified as an  $n$ -by- $p_x$  matrix. The rows of `x` correspond to observations, and the columns correspond to variables.

### Data Types

single | double

## **y - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_y$  matrix. The rows of  $y$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

## **z - Data matrix**

matrix

Data matrix, specified as an  $n$ -by- $p_z$  matrix. The rows of  $z$  correspond to observations, and the columns correspond to variables.

### **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

**Example:** 'Type', 'Spearman', 'Rows', 'complete' computes Spearman partial correlations using only the data in rows that contain no missing values.

## **'Type' - Type of partial correlations**

'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and either 'Pearson' or 'Spearman'. Pearson computes the Pearson (linear) partial correlations. Spearman computes the Spearman (rank) partial correlations.

**Example:** 'Type', 'Spearman'

**'Rows' - Rows to use in computation**

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

- 'all' Use all rows regardless of missing (NaN) values.
- 'complete' Use only rows with no missing values.
- 'pairwise' Use all available values in each column of **y** when computing the partial correlation coefficients and *p*-values corresponding to that column. For each column of **y**, rows will be dropped corresponding to missing values in **x** (and/or **z**, if supplied). However, remaining rows with valid values in that column of **y** are used, even if there are missing values in other columns of **y**.

Example: 'Rows', 'complete'

**'Tail' - Alternative hypothesis**

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- 'both' Test the alternative hypothesis that the correlation is not zero.
- 'right' Test the alternative hypothesis that the correlation is greater than 0.
- 'left' Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

## Output Arguments

### **rho - Sample linear partial correlation coefficients**

matrix

Sample linear partial correlation coefficients, returned as a  $p_y$ -by- $p_x$  matrix.

- If you input  $x$  and  $y$  matrices, the  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th column in  $y$  and the  $j$ th column in  $x$ , controlled for all the columns of  $x$  except column  $j$ .
- If you input  $x$ ,  $y$ , and  $z$  matrices, the  $(i,j)$ th entry is the sample linear partial correlation between the  $i$ th column in  $y$  and the  $j$ th column in  $x$ , adjusted for all the columns of  $x$  except column  $j$ , after first controlling both  $x$  and  $y$  for the variables in  $z$ .

### **pval - p-values**

matrix

$p$ -values, returned as a matrix. Each element of `pval` is the  $p$ -value for the corresponding element of `rho`. If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from zero.

`partialcorri` computes  $p$ -values for linear and rank partial correlations using a Student's  $t$  distribution for a transformation of the correlation. This is exact for linear partial correlation when  $x$  and  $z$  are normal, but is a large-sample approximation otherwise.

## Examples

### **Compute Partial Correlation Coefficients**

Compute partial correlation coefficients for each pair of variables in the  $x$  and  $y$  input matrices, while controlling for the effects of the remaining variables in  $x$ .

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design

variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```
rho = partialcorri(y,x,'Rows','complete')
```

```
rho =
```

```
-0.0537   -0.1520   -0.4856
-0.3994   -0.4008    0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the *p*-values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
disp('Partial Correlation Coefficients')
disp(rho)
```

```
Partial Correlation Coefficients
                Displacement   Horsepower   Weight
                -----
```

MPG	-0.053684	-0.15199	-0.48563
Acceleration	-0.39941	-0.40075	0.49123

## Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x plus additional variables in matrix z.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Create a new variable Headwind, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

```
rng('default'); % For reproducibility  
Headwind = (10:-0.2:-9.8)' + 5*randn(100,1);
```

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables. The z matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];  
x = [Displacement,Horsepower,Weight];
```

```
z = Headwind;
```

Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

```
[rho,pval] = partialcorri(y,x,z,'Rows','complete')
```

```
rho =
```

```
    0.0572   -0.1055   -0.5736
   -0.3845   -0.3966    0.4674
```

```
pval =
```

```
    0.5923    0.3221    0.0000
    0.0002    0.0001    0.0000
```

The small returned *p*-value of 0.001 in *pval* indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
pval = array2table(pval, ...
    'VariableNames',{'Displacement','Horsepower','Weight'}, ...
    'RowNames',{'MPG','Acceleration'});
```

```
disp('Partial Correlation Coefficients, Accounting for Headwind')
disp(rho)
disp('p-values, Accounting for Headwind')
disp(pval)
```

```
Partial Correlation Coefficients, Accounting for Headwind
```

## See Also

[partialcorr](#) | [corr](#)

**Purpose**

Principal component analysis of raw data

**Syntax**

```
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca( ___ )
[coeff,score,latent,tsquared] = pca( ___ )
[coeff,score,latent,tsquared,explained,mu] = pca( ___ )
```

**Description**

`coeff = pca(X)` returns the principal component coefficients for the  $n$ -by- $p$  data matrix  $X$ . Rows of  $X$  correspond to observations and columns correspond to variables. The coefficient matrix is  $p$ -by- $p$ . Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

`[coeff,score,latent] = pca( ___ )` also returns the principal component scores in `score` and the principal component variances in `latent`. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of  $X$  in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of  $X$ .

`[coeff,score,latent,tsquared] = pca( ___ )` also returns the Hotelling's T-squared statistic for each observation in *X*.

`[coeff,score,latent,tsquared,explained,mu] = pca( ___ )` also returns `explained`, the percentage of the total variance explained by each principal component and `mu`, the estimated mean of each variable in *X*.

## Input Arguments

### **X - Input data**

matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of *X* correspond to observations and columns to variables.

### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

### **Example:**

`'Algorithm','eig','Centered',false,'Rows','all','NumComponents',3` specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

### **'Algorithm' - Principal component algorithm**

`'svd' (default) | 'eig' | 'als'`

Principal component algorithm that `pca` uses to perform the principal component analysis, specified as the comma-separated pair consisting of `'Algorithm'` and one of the following.

'svd'	Default. Singular value decomposition (SVD) of $X$ .
'eig'	Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, $n$ , exceeds the number of variables, $p$ , but is less accurate because the condition number of the covariance is the square of the condition number of $X$ .
'als'	Alternating least squares (ALS) algorithm. This algorithm finds the best rank- $k$ approximation by factoring $X$ into a $n$ -by- $k$ left factor matrix, $L$ , and a $p$ -by- $k$ right factor matrix, $R$ , where $k$ is the number of principal components. The factorization uses an iterative method starting with random initial values. ALS is designed to better handle missing values. It is preferable to pairwise deletion ('Rows', 'pairwise') and deals with missing values without listwise deletion ('Rows', 'complete'). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.

Example: 'Algorithm', 'eig'

### Data Types

char

### 'Centered' - Indicator for centering columns

true (default) | false

Indicator for centering the columns, specified as the comma-separated pair consisting of 'Centered' and one of these logical expressions.

true	Default. <code>pca</code> centers $X$ by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If $X$ contains NaN missing values, <code>nanmean</code> is used to find the mean with any available data. You can reconstruct the centered data using <code>score*coeff</code> .
false	In this case <code>pca</code> does not center the data. You can reconstruct the original data using <code>score*coeff</code> .

**Example:** 'Centered', false

### Data Types

logical

### 'Economy' - Indicator for economy size output

true (default) | false

Indicator for the economy size output when the degrees of freedom,  $d$ , is smaller than the number of variables,  $p$ , specified as the comma-separated pair consisting of 'Economy' and one of these logical expressions.

true	Default. <code>pca</code> returns only the first $d$ elements of latent and the corresponding columns of <code>coeff</code> and <code>score</code> .  This option can be significantly faster when the number of variables $p$ is much larger than $d$ .
false	<code>pca</code> returns all elements of latent. The columns of <code>coeff</code> and <code>score</code> corresponding to zero elements in latent are zeros.

Note that when  $d < p$ , `score(:, d+1:p)` and `latent(d+1:p)` are necessarily zero, and the columns of `coeff(:, d+1:p)` define directions that are orthogonal to  $X$ .

**Example:** 'Economy', false

### Data Types

logical

### 'NumComponents' - Number of components requested

number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer  $k$  satisfying  $0 < k \leq p$ , where  $p$  is the number of original variables in  $X$ . When specified, `pca` returns the first  $k$  columns of `coeff` and `score`.

**Example:** 'NumComponents', 3

**Data Types**

single | double

**'Rows' - Action to take for NaN values**

'complete' (default) | 'pairwise' | 'all'

Action to take for NaN values in the data matrix  $X$ , specified as the comma-separated pair consisting of 'Rows' and one of the following.

'complete'	Default. Observations with NaN values are removed before calculation. Rows of NaNs are reinserted into score and tsquared at the corresponding locations.
'pairwise'	<p>This option only applies when the algorithm is 'eig'. If you don't specify the algorithm along with 'pairwise', then <code>pca</code> sets it to 'eig'. If you specify 'svd' as the algorithm, along with the option 'Rows', 'pairwise', then <code>pca</code> returns a warning message, sets the algorithm to 'eig' and continues.</p> <p>When you specify the 'Rows', 'pairwise' option, <code>pca</code> computes the <math>(i,j)</math> element of the covariance matrix using the rows with no NaN values in the columns <math>i</math> or <math>j</math> of <math>X</math>.</p> <p>Note that the resulting covariance matrix might not be positive definite. In that case, <code>pca</code> terminates with an error message.</p>
'all'	$X$ is expected to have no missing values. <code>pca</code> uses all of the data and terminates if any NaN value is found.

**Example:** 'Rows', 'pairwise'

**Data Types**

char

**'Weights' - Observation weights**

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length  $n$  containing all positive elements.

**Data Types**

single | double

**'VariableWeights' - Variable weights**

row vector | 'variance'

Variable weights, specified as the comma-separated pair consisting of 'VariableWeights' and one of the following.

---

Vector of length  $p$  containing all positive elements.

The string 'variance'. The variable weights are the inverse of sample variance. If you also assign weights to observations using 'Weights', then the variable weights become the inverse of weighted sample variance.

If 'Centered' is set to true at the same time, the data matrix  $X$  is centered and standardized. In this case, pca returns the principal components based on the correlation matrix.

---

**Example:** 'VariableWeights', 'variance'

**Data Types**

single | double | char

**'Coeff0' - Initial value for coefficients**

matrix of random values (default) |  $p$ -by- $k$  matrix

Initial value for the coefficient matrix `coeff`, specified as the comma-separated pair consisting of 'Coeff0' and a  $p$ -by- $k$  matrix, where  $p$  is the number of variables, and  $k$  is the number of principal components requested.

---

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

---

**Data Types**

single | double

**'Score0' - Initial value for scores**matrix of random values (default) |  $k$ -by- $m$  matrix

Initial value for scores matrix `score`, specified as a comma-separated pair consisting of 'Score0' and an  $n$ -by- $k$  matrix, where  $n$  is the number of observations and  $k$  is the number of principal components requested.

---

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

---

**Data Types**

single | double

**'Options' - Options for iterations**

structure

Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the `statset` function. `pca` uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number steps allowed. The default is 100. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.
'TolFun'	Positive number giving the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.

---

**Note** You can use this name-value pair only when 'algorithm' is 'als'.

---

You can change the values of these fields and specify the new structure in `pca` using the 'Options' name-value pair argument.

**Example:** `opt = statset('pca'); opt.MaxIter = 2000; coeff = pca(X,'Options',opt);`

### Data Types

struct

## Output Arguments

### **coeff** - Principal component coefficients

matrix

Principal component coefficients, returned as a  $p$ -by- $p$  matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `latent`.

### **score** - Principal component scores

matrix

Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

### **latent** - Principal component variances

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of `X`, returned as a column vector.

### **tsquared** - Hotelling's T-squared statistic

column vector

"Hotelling's T-Squared Statistic" on page 21-2774, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

**explained - Percentage of total variance explained**

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

**mu - Estimated means**

row vector

Estimated means of the variables in X, returned as a row vector. When 'algorithm' is 'als', this is estimated by ALS algorithm. When 'algorithm' is not 'als', mu is equal to the sample mean of X.

**Examples****Principal Components of a Data Set**

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

```
coeff = pca(ingredients)
```

```
coeff =
```

```

-0.0678   -0.6460    0.5673    0.5062
-0.6785   -0.0200   -0.5440    0.4933
 0.0290    0.7553    0.4036    0.5156
 0.7309   -0.1085   -0.4684    0.4844
```

The rows of `coeff` contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

**PCA in the Presence of Missing Data**

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

```
load imports-85
```

Data matrix  $X$  has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform principal component analysis.

```
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the 'Rows', 'complete' name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use 'pairwise' to perform the principal component analysis.

```
coeff = pca(X(:,3:15), 'Rows', 'pairwise');
```

In this case, `pca` computes the  $(i,j)$  element of the covariance matrix using the rows with no NaN values in the columns  $i$  or  $j$  of  $X$ . Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to 'eig'. If you require 'svd' as the algorithm, with the 'pairwise' option, then `pca` returns a warning message, sets the algorithm to 'eig' and continues.

If you use the 'Rows', 'all' name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```
coeff = pca(X(:,3:15), 'Rows', 'all');
```

---

```
Error using pca (line 180)
Raw data contains NaN missing value while 'Rows' option is set to 'all'
```

## Weighted PCA

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```
load hald
```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```
[wcoeff,~,latent,~,explained] = pca(ingredients,...
'VariableWeights','variance')
```

```
wcoeff =
```

```
   -2.7998    2.9940   -3.9736    1.4180
   -8.7743   -6.4411    4.8927    9.9863
    2.5240   -3.8749   -4.0845    1.7196
    9.1714    7.5529    3.2710   11.3273
```

```
latent =
```

```
    2.2357
    1.5761
    0.1866
    0.0016
```

```
explained =
```

```
    55.8926
    39.4017
     4.6652
     0.0406
```

Note that the coefficient matrix, `wcoeff`, is not orthonormal.

Calculate the orthonormal coefficient matrix.

```
coefforth = inv(diag(std(ingredients))) * wcoeff
```

```
coefforth =
```

```
-0.4760    0.5090   -0.6755    0.2411  
-0.5639   -0.4139    0.3144    0.6418  
 0.3941   -0.6050   -0.6377    0.2685  
 0.5479    0.4512    0.1954    0.6767
```

Check orthonormality of the new coefficient matrix, `coefforth`.

```
coefforth*coefforth'
```

```
ans =
```

```
 1.0000    0.0000   -0.0000   -0.0000  
 0.0000    1.0000   -0.0000   -0.0000  
-0.0000   -0.0000    1.0000    0  
-0.0000   -0.0000    0    1.0000
```

### PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff,score,latent,tsquared,explained] = pca(ingredients);  
coeff
```

```
coeff =
    -0.0678    -0.6460     0.5673     0.5062
    -0.6785    -0.0200    -0.5440     0.4933
     0.0290     0.7553     0.4036     0.5156
     0.7309    -0.1085    -0.4684     0.4844
```

Introduce missing values randomly.

```
y = ingredients;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.30;
y(ix) = NaN
```

```
y =
     7     26     6  NaN
     1     29    15   52
    NaN  NaN     8   20
    11    31  NaN   47
     7    52     6   33
    NaN   55  NaN  NaN
    NaN   71  NaN    6
     1    31  NaN   44
     2  NaN  NaN   22
    21   47     4   26
    NaN   40   23   34
    11   66     9  NaN
    10   68     8   12
```

Approximately 30% of the data has missing values now, indicated by NaN.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...
'algorithm','als');
```

coeff1

coeff1 =

-0.0362	0.8215	-0.5252	0.2190
-0.6831	-0.0998	0.1828	0.6999
0.0169	0.5575	0.8215	-0.1185
0.7292	-0.0657	0.1261	0.6694

Display the estimated mean.

mu1

mu1 =

8.9956	47.9088	9.0451	28.5515
--------	---------	--------	---------

Reconstruct the observed data.

t = score1\*coeff1' + repmat(mu1,13,1)

t =

7.0000	26.0000	6.0000	51.5250
1.0000	29.0000	15.0000	52.0000
10.7819	53.0230	8.0000	20.0000
11.0000	31.0000	13.5500	47.0000
7.0000	52.0000	6.0000	33.0000
10.4818	55.0000	7.8328	17.9362
3.0982	71.0000	11.9491	6.0000
1.0000	31.0000	-0.5161	44.0000
2.0000	53.7914	5.7710	22.0000
21.0000	47.0000	4.0000	26.0000
21.5809	40.0000	23.0000	34.0000
11.0000	66.0000	9.0000	5.7078
10.0000	68.0000	8.0000	12.0000

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```
subspace(coeff,coeff1)
```

```
ans =
```

```
2.2925e-16
```

This is a small value. It indicates that the results if you use `pca` with `'Rows','complete'` name-value pair argument when there is no missing data and if you use `pca` with `'algorithm','als'` name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using `'Rows','complete'` name-value pair argument and display the component coefficients.

```
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2
```

```
coeff2 =
```

```
-0.2054    0.8587    0.0492
-0.6694   -0.3720    0.5510
 0.1474   -0.3513   -0.5187
 0.6986   -0.0298    0.6518
```

In this case, `pca` removes the rows with missing values, and `y` has only four rows with no missing values. `pca` returns only three principal components. You cannot use the `'Rows','pairwise'` option because the covariance matrix is not positive semidefinite and `pca` returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when `'Rows','complete'`).

```
subspace(coeff(:,1:3),coeff2)
```

```
ans =
```

```
0.3576
```

The angle between the two spaces is substantially larger. This indicates that these two results are different.

Display the estimated mean.

```
mu2
```

```
mu2 =
```

```
7.8889 46.9091 9.8750 29.6000
```

In this case, the mean is just the sample mean of y.

Reconstruct the observed data.

```
score2*coeff2'
```

```
ans =
```

```
NaN NaN NaN NaN
-7.5162 -18.3545 4.0968 22.0056
NaN NaN NaN NaN
NaN NaN NaN NaN
-0.5644 5.3213 -3.3432 3.6040
NaN NaN NaN NaN
NaN NaN NaN NaN
NaN NaN NaN NaN
NaN NaN NaN NaN
12.8315 -0.1076 -6.3333 -3.7758
NaN NaN NaN NaN
NaN NaN NaN NaN
1.4680 20.6342 -2.9292 -18.0043
```

This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

### Principal Component Coefficients, Scores, and Variances

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```
[coeff,score,latent] = pca(ingredients)
```

```
coeff =
```

-0.0678	-0.6460	0.5673	0.5062
-0.6785	-0.0200	-0.5440	0.4933
0.0290	0.7553	0.4036	0.5156
0.7309	-0.1085	-0.4684	0.4844

```
score =
```

36.8218	-6.8709	-4.5909	0.3967
29.6073	4.6109	-2.2476	-0.3958
-12.9818	-4.2049	0.9022	-1.1261
23.7147	-6.6341	1.8547	-0.3786
-0.5532	-4.4617	-6.0874	0.1424
-10.8125	-3.6466	0.9130	-0.1350
-32.5882	8.9798	-1.6063	0.0818
22.6064	10.7259	3.2365	0.3243
-9.2626	8.9854	-0.0169	-0.5437
-3.2840	-14.1573	7.0465	0.3405

```
    9.2200    12.3861    3.4283    0.4352
  -25.5849   -2.7817   -0.3867    0.4468
  -26.9032   -2.9310   -2.4455    0.4116
```

latent =

```
517.7969
 67.4964
 12.4054
  0.2372
```

Each column of `score` corresponds to one principal component. The vector, `latent`, stores the variances of the four principal components.

Reconstruct the centered ingredients data.

```
Xcentered = score*coeff'
```

Xcentered =

```
-0.4615  -22.1538  -5.7692  30.0000
-6.4615  -19.1538   3.2308  22.0000
 3.5385   7.8462  -3.7692 -10.0000
 3.5385  -17.1538  -3.7692  17.0000
-0.4615   3.8462  -5.7692   3.0000
 3.5385   6.8462  -2.7692  -8.0000
-4.4615  22.8462   5.2308 -24.0000
-6.4615  -17.1538  10.2308  14.0000
-5.4615   5.8462   6.2308  -8.0000
13.5385  -1.1538  -7.7692  -4.0000
-6.4615  -8.1538  11.2308   4.0000
 3.5385  17.8462  -2.7692 -18.0000
 2.5385  19.8462  -3.7692 -18.0000
```

The new data in `Xcentered` is the original ingredients data centered by subtracting the column means from corresponding columns.

## T-Squared Statistic

Find the Hotelling's T-squared statistic values.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

```
[coeff,score,latent,tsquared] = pca(ingredients);  
tsquared
```

```
tsquared =
```

```
    5.6803  
    3.0758  
    6.0002  
    2.6198  
    3.3681  
    0.5668  
    3.4818  
    3.9794  
    2.6086  
    7.4818  
    4.1830  
    2.2327  
    2.7216
```

Request only the first two principal components and compute the T-squared values in the reduced space of requested principal components.

```
[coeff,score,latent,tsquared] = pca(ingredients,'NumComponents',2);  
tsquared
```

```
tsquared =  
  
    5.6803  
    3.0758  
    6.0002  
    2.6198  
    3.3681  
    0.5668  
    3.4818  
    3.9794  
    2.6086  
    7.4818  
    4.1830  
    2.2327  
    2.7216
```

Note that even when you specify a reduced component space, `pca` computes the T-squared values in the full space, using all four components.

The T-squared value in the reduced space corresponds to the Mahalanobis distance in the reduced space.

```
tsqreduced = mahal(score, score)
```

```
tsqreduced =  
  
    3.3179  
    2.0079  
    0.5874  
    1.7382  
    0.2955  
    0.4228  
    3.2457  
    2.6914  
    1.3619  
    2.9903
```

```
2.4371
1.3788
1.5251
```

Calculate the T-squared values in the discarded space by taking the difference of the T-squared values in the full space and Mahalanobis distance in the reduced space.

```
tsqdiscarded = tsquared - tsqreduced
```

```
tsqdiscarded =
```

```
2.3624
1.0679
5.4128
0.8816
3.0726
0.1440
0.2362
1.2880
1.2467
4.4915
1.7459
0.8539
1.1965
```

### **Percent Variability Explained by Principal Components**

Find the percent variability explained by the principal components.

Load the sample data set.

```
load imports-85
```

Data matrix  $X$  has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
```

```
explained
```

```
explained =
```

```
64.3429
35.4484
0.1550
0.0379
0.0078
0.0048
0.0013
0.0011
0.0005
0.0002
0.0002
0.0000
0.0000
```

The first two components explain 99.79% of all variability.

To skip any of the outputs, you can use ~ instead in the corresponding element. For example, if you don't want to get the T-squared values, specify

```
[coeff,score,latent,~,explained] = pca(X(:,3:15));
```

## **Definitions**

### **Hotelling's T-Squared Statistic**

Hotelling's T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic

(computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:

- For the T-squared statistic in the reduced space, use `mahal(score, score)`.
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using `[coeff, score, latent, tsquared] = pca(X, 'NumComponents', k, ...)`, compute the T-squared statistic in the reduced space using `tsqreduced = mahal(score, score)`, and then take the difference: `tsquared - tsqreduced`.

### Degrees of Freedom

The degrees of freedom,  $d$ , is equal to  $n - 1$ , if data is centered and  $n$  otherwise, where:

- $n$  is the number of rows without any NaNs if you use `'Rows', 'complete'`.
- $n$  is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use `'Rows', 'pairwise'`.

### Variable Weights

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called `varwei`, and the principal component coefficients vector `pca` returned is `wcoeff`. You can then calculate the orthonormal coefficients using the transformation `diag(sqrt(varwei))*wcoeff`.

**Purpose**

Residuals from principal component analysis

**Syntax**

```
residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)
```

**Description**

`residuals = pcares(X,ndim)` returns the residuals obtained by retaining `ndim` principal components of the `n`-by-`p` matrix `X`. Rows of `X` correspond to observations, columns to variables. `ndim` is a scalar and must be less than or equal to `p`. `residuals` is a matrix of the same size as `X`. Use the data matrix, *not* the covariance matrix, with this function.

`pcares` does not normalize the columns of `X`. To perform the principal components analysis based on standardized variables, that is, based on correlations, use `pcares(zscore(X), ndim)`. You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using `pcacov`.

`[residuals,reconstructed] = pcares(X,ndim)` returns the reconstructed observations; that is, the approximation to `X` obtained by retaining its first `ndim` principal components.

**Examples**

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

```
load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);

r11 = r1(1,:)
r11 =
    2.0350    2.8304   -6.8378    3.0879

r21 = r2(1,:)
r21 =
   -2.4037    2.6930   -1.6482    2.3425
```

```
r31 = r3(1,:)
r31 =
    0.2008    0.1957    0.2045    0.1921
```

**Purpose**

Probabilistic principal component analysis

**Syntax**

```
[coeff,score,pcvar] = ppca(Y,K)
[coeff,score,pcvar] = ppca(Y,K,Name,Value)
[coeff,score,pcvar,mu] = ppca(____)
[coeff,score,pcvar,mu,v,S] = ppca(____)
```

**Description**

`[coeff,score,pcvar] = ppca(Y,K)` returns the principal component coefficients for the  $n$ -by- $p$  data matrix  $Y$  based on a probabilistic principal component analysis (PPCA). It also returns the principal component scores, which are the representations of  $Y$  in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of  $Y$ , in `pcvar`.

Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of `score` correspond to observations, and columns correspond to components. Rows of  $Y$  correspond to observations and columns correspond to variables.

Probabilistic principal component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

`[coeff,score,pcvar] = ppca(Y,K,Name,Value)` returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can introduce initial values for the residual variance, `v`, or change the termination criteria.

[coeff, score, pcvar, mu] = ppca( \_\_\_ ) also returns the estimated mean of each variable in  $Y$ . You can use any of the input arguments in the previous syntaxes.

[coeff, score, pcvar, mu, v, S] = ppca( \_\_\_ ) also returns the isotropic residual variance in  $v$  and the final results at convergence in structure  $S$ .

## Input Arguments

### **Y - Input data**

*n*-by-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of  $Y$  correspond to observations and columns correspond to variables.

### **Data Types**

single | double

### **K - Number of principal components**

positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is  $\min(n,p)$ , where  $n$  is the number of observations and  $p$  is the number of variables. However, if the data is correlated, the rank might be smaller than  $\min(n,p)$ .

ppca orders the components based on their variance.

If  $K$  is  $\min(n,p)$ , ppca sets  $K$  equal to  $\min(n,p) - 1$ , and 'W0' is truncated to  $\min(p,n) - 1$  columns if you specify a *p*-by-*p*  $W0$  matrix.

For example, you can request only the first three components, based on the component variance as follows.

**Example:** coeff = ppca(Y,3)

### **Data Types**

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'W0', init, 'Options', opt` specifies that the initial values for `'W0'` are in matrix `init` and `ppca` uses the options defined by `opt`.

### 'W0' - Initial value of $W$

matrix of random values (default) |  $p$ -by- $k$  matrix

Initial value of  $W$  in the probabilistic principal component analysis algorithm, specified as a comma-separated pair consisting of `'W0'` and a  $p$ -by- $k$  matrix.

#### Data Types

single | double

### 'v0' - Initial value of residual variance

random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of `'v0'` and a positive scalar value.

#### Data Types

single | double

### 'Options' - Options for iterations

structure

Options for the iterations, specified as a comma-separated pair `'Options'` and a structure created by the `statset` function. `ppca` uses the following fields in the options structure.

'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the MaxIter value is regarded as convergence.
'TolFun'	Positive integer stating the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive integer stating the convergence threshold for the relative change in the elements of $W$ . The default is 1e-6.

You can change the values of these fields and specify the new structure in ppca using the 'Options' name-value pair argument.

**Example:** `opt = statset('ppca'); opt.MaxIter = 2000; coeff = ppca(Y,3,'Options',opt);`

**Data Types**

struct

**Output Arguments**

**coeff - Principal component coefficients**

*p*-by-*k* matrix

Principal component coefficients, returned as a *p*-by-*k* matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `pcvar`.

**score - Principal component scores**

*n*-by-*k* matrix

Principal component scores, returned as an *n*-by-*k* matrix. Rows of `score` correspond to observations, and columns correspond to components.

**pcvar - Principal component variances**

column vector

Principal component variances, which are the eigenvalues of the covariance matrix of  $Y$ , returned as a column vector.

### **$\mu$ - Estimated mean**

row vector

Estimated mean of each variable in  $Y$ , returned as a row vector.

### **$v$ - Isotropic residual variance**

scalar value

Isotropic residual variance, returned as a scalar value.

### **$S$ - Final results at convergence**

structure

Final results at convergence, returned as a structure containing the following fields.

$W$	$W$ at convergence.
Xexp	Conditional expectation of the estimated latent variable $x$ .
Recon	Reconstructed observations using $k$ principal components. This is a low dimension approximation of the input data $Y$ , and is equal to $\mu + \text{score} * \text{coeff}'$ .
$v$	Residual variance.
RMSResid	Root mean square of residuals.
NumIter	Number of iteration counts.
nloglk	Negative loglikelihood function value.

## Examples

### Perform Probabilistic Principal Component Analysis

Load the sample data.

```
load fisheriris
```

The double matrix `meas` consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

```
y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;
```

Now, approximately 20% of the data is missing, indicated by NaN.

Perform probabilistic principal component analysis and request the component coefficients and variances.

```
[coeff,score,pcvar,mu] = ppca(y,3);
coeff
```

```
coeff =
```

```
    0.3562    0.6709   -0.5518
   -0.0765    0.7121    0.6332
    0.8592   -0.1596    0.0596
    0.3592   -0.1318    0.5395
```

```
pcvar
```

```
pcvar =
```

```
    4.0912
    0.2126
    0.0617
```

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

```
[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...
```

```
'NumComponents',3);  
coeff2  
  
coeff2 =  
  
    0.3376    0.4955    0.7404  
   -0.0731    0.8607   -0.4479  
    0.8657   -0.1169   -0.1231  
    0.3623   -0.0087   -0.4859
```

```
pcvar2
```

```
pcvar2 =  
  
    4.0734  
    0.2651  
    0.1221
```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

```
subspace(coeff,coeff2)
```

```
ans =  
  
    0.0881
```

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

### **Change the Termination Criteria for Probabilistic Principal Component Analysis**

Load the sample data set.

```
load imports-85
```

Data matrix  $X$  has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3);
```

```
Warning: Maximum number of iterations 1000 reached'.  
> In ppca at 249
```

Change the termination tolerance for the cost function to 0.01.

```
opt = statset('ppca');  
opt.TolFun = 0.01;
```

Perform probabilistic principal component analysis.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
```

ppca now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

## Reconstruct Observations

Load the sample data.

```
load hald  
y = ingredients;
```

The ingredients data has 13 observations for 4 variables.

Introduce missing values to the data.

```
y(2:16:end) = NaN;
```

Every 16th value is NaN. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

```
[coeff,score,pcvar,mu,v,S] = ppca(y,3);
S.Recon
```

```
ans =
```

```

    6.8533    25.8675    5.8388    59.8755
    1.0431    28.9690   14.9652    51.9758
   11.5770   56.5080    8.6352   20.5062
   11.0833   31.0707    8.0920   47.0764
    7.0684   52.2539    6.0753   33.0597
   11.0486   55.0442    9.0534   22.0410
    2.8494   70.8719   16.8338    5.8624
    1.0331   31.0267   19.6906   44.0321
    2.0401   54.0364   18.0440   22.0337
   20.7823   46.8096    3.7603   25.8075
    0.9540   39.9590   22.9495   31.1540
   10.8251   65.8498    8.8072   11.8420
    9.9174   67.9309    7.9087   11.9230
```

You can also reconstruct the observations using the principal components and the estimated mean.

```
t = score*coeff' + repmat(mu,13,1);
```

## Results at Convergence

Load the sample data.

```
load hald
```

Here, `ingredients` is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.

```
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);  
coeff
```

```
coeff =
```

```
   -0.0693   -0.6459    0.5673  
   -0.6786   -0.0184   -0.5440  
    0.0308    0.7552    0.4036  
    0.7306   -0.1102   -0.4684
```

Display the algorithm results at convergence of the PPCA.

```
S
```

```
S =
```

```
      W: [4x3 double]  
     Xexp: [13x3 double]  
    Recon: [13x4 double]  
         v: 0.2372  
   NumIter: 1000  
  RMSResid: 0.2340  
   nloglk: 149.3388
```

Display the matrix W.

```
S.W
```

```
ans =
```

```
    0.5624    2.0279    5.4075  
    4.8320   -10.3894    5.9202  
   -3.7521   -3.0555   -4.1552  
   -1.5144   11.7122   -7.2564
```

Orthogonalizing W recovers the coefficients.

```

orth(S.W)

ans =

    -0.0693    0.6459    0.5673
    -0.6786    0.0184   -0.5440
     0.0308   -0.7552    0.4036
     0.7306    0.1102   -0.4684

```

## Definitions

### Probabilistic Principal Component Analysis

Probabilistic principal component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a  $p$ -dimensional observation vector  $y$  to a corresponding  $k$ -dimensional vector of latent (or unobserved) variable  $x$ , which is normal with mean zero and covariance  $I(k)$ . The relationship is

$$y^T = W * x^T + \mu + \varepsilon,$$

where  $y$  is the row vector of observed variable,  $x$  is the row vector of latent variables, and  $\varepsilon$  is the isotropic error term.  $\varepsilon$  is Gaussian with mean zero and covariance of  $v * I(k)$ , where  $v$  is the residual variance. Here,  $k$  needs to be smaller than the rank for the residual variance to be greater than 0 ( $v > 0$ ). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables,  $y$ , are conditionally independent given the values of the latent variables,  $x$ . So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular  $y_i$ . The  $p$ -by- $k$  matrix  $W$  relates the latent and observation variables, and the vector  $\mu$  permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,

$$y \sim N\left(\mu, W * W^T + v * I(k)\right).$$

There is no closed-form analytical solution for  $W$  and  $v$ , so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of  $W$  spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coeff`, for the components by orthogonalization of  $W$ .

# gmdistribution.PComponents property

---

**Purpose** Input vector of mixing proportions

**Description** Optional input vector of mixing proportions  $p$ , or its default value.

**Purpose** Probability density functions

**Syntax**  
 $Y = \text{pdf}(\text{name}, X, A)$   
 $Y = \text{pdf}(\text{name}, X, A, B)$   
 $Y = \text{pdf}(\text{name}, X, A, B, C)$

**Description**  $Y = \text{pdf}(\text{name}, X, A)$  computes the probability density function for the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`. Densities are evaluated at the values in `X` and returned in `Y`.

If `X` and `A` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`. If `A` is a scalar, it is expanded to a constant matrix the same size as `X`.

`Y` is the common size of `X` and `A` after any necessary scalar expansion.

$Y = \text{pdf}(\text{name}, X, A, B)$  computes the probability density function for two-parameter families of distributions, where parameter values are given in `A` and `B`.

If `X`, `A`, and `B` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A` and `B`. If either `A` or `B` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, and `B` after any necessary scalar expansion.

$Y = \text{pdf}(\text{name}, X, A, B, C)$  computes the probability density function for three-parameter families of distributions, where parameter values are given in `A`, `B`, and `C`.

If `X`, `A`, `B`, and `C` are arrays, they must be the same size. If `X` is a scalar, it is expanded to a constant matrix the same size as `A`, `B`, and `C`. If any of `A`, `B` or `C` are scalars, they are expanded to constant matrices the same size as `X`.

`Y` is the common size of `X`, `A`, `B` and `C` after any necessary scalar expansion.

## Examples

Compute the pdf of the normal distribution with mean 0 and standard deviation 1 at inputs  $-2, -1, 0, 1, 2$ :

```
p1 = pdf('Normal', -2:2, 0, 1)
p1 =
    0.0540    0.2420    0.3989    0.2420    0.0540
```

The order of the parameters is the same as for `normpdf`.

Compute the pdfs of Poisson distributions with rate parameters 0, 1, ..., 4 at inputs 1, 2, ..., 5, respectively:

```
p2 = pdf('Poisson', 0:4, 1:5)
```

---

```
p2 =  
  0.3679  0.2707  0.2240  0.1954  0.1755
```

The order of the parameters is the same as for `poisspdf`.

# gmdistribution.pdf

---

**Purpose** Probability density function for Gaussian mixture distribution

**Syntax** `y = pdf(obj,X)`

**Description** `y = pdf(obj,X)` returns a vector  $y$  of length  $n$  containing the values of the probability density function (pdf) for the `gmdistribution` object `obj`, evaluated at the  $n$ -by- $d$  data matrix  $X$ , where  $n$  is the number of observations and  $d$  is the dimension of the data. `obj` is an object created by `gmdistribution` or `fitgmdist`. `y(I)` is the pdf of observation  $I$ .

## **Examples**      **Construct a Gaussian Mixture Distribution**

Create a `gmdistribution` distribution defining a two-component mixture of bivariate Gaussian distributions.

```
mu = [1 2;-3 -5];  
sigma = cat(3,[2 0;0 .5],[1 0;0 1]);  
p = ones(1,2)/2;  
obj = gmdistribution(mu,sigma,p);  
  
ezsurf(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])
```

**See Also** [gmdistribution](#) | [fitgmdist](#) | [cdf](#) | [mvnpdf](#)

# piecewisedistribution.pdf

---

**Purpose** Probability density function for piecewise distribution

**Syntax** `P = pdf(obj,X)`

**Description** `P = pdf(obj,X)` returns an array `P` of values of the probability density function for the piecewise distribution object `obj`, evaluated at the values in the array `X`.

---

**Note** For a Pareto tails object, the pdf is computed using the generalized Pareto distribution in the tails. In the center, the pdf is computed using the slopes of the cdf, which are interpolated between a set of discrete values. Therefore the pdf in the center is piecewise constant. It is noisy for a *cdf* specified in *paretotails* via the 'ecdf' option, and somewhat smoother for the 'kernel' option, but generally not a good estimate of the underlying density of the original data.

---

## Examples

Fit Pareto tails to a *t* distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);
[p,q] = boundary(obj)
p =
    0.1000
    0.9000
q =
   -1.7766
    1.8432

pdf(obj,q)
ans =
    0.2367
    0.1960
```

# pdist

---

**Purpose** Pairwise distance between pairs of objects

**Syntax**  
`D = pdist(X)`  
`D = pdist(X, distance)`

**Description** `D = pdist(X)` computes the Euclidean distance between pairs of objects in  $m$ -by- $n$  data matrix  $X$ . Rows of  $X$  correspond to observations, and columns correspond to variables.  $D$  is a row vector of length  $m(m-1)/2$ , corresponding to pairs of observations in  $X$ . The distances are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1).  $D$  is commonly used as a dissimilarity matrix in clustering or multidimensional scaling.

To save space and computation time,  $D$  is formatted as a vector. However, you can convert this vector into a square matrix using the `squareform` function so that element  $i, j$  in the matrix, where  $i < j$ , corresponds to the distance between objects  $i$  and  $j$  in the original data set.

`D = pdist(X, distance)` computes the distance between objects in the data matrix,  $X$ , using the method specified by `distance`, which can be any of the following character strings.

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in $X$ is scaled by dividing by the corresponding element of the standard deviation <code>S=nanstd(X)</code> . To specify another value for $S$ , use <code>D=pdist(X, 'seuclidean', S)</code> .
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use <code>D = pdist(X, 'minkowski', P)</code> , where $P$ is a scalar positive value of the exponent.

<b>Metric</b>	<b>Description</b>
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of X as computed by nancov. To compute the distance with a different covariance, use <code>D = pdist(X, 'mahalanobis', C)</code> , where the matrix C is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
custom distance function	<p>A distance function specified using @:  <code>D = pdist(X,@distfun)</code></p> <p>A distance function must be of form</p> $d2 = \text{distfun}(XI, XJ)$ <p>taking as arguments a 1-by-<i>n</i> vector XI, corresponding to a single row of X, and an <i>m2</i>-by-<i>n</i> matrix XJ, corresponding to multiple rows of X. <code>distfun</code> must accept a matrix XJ with an arbitrary number of rows. <code>distfun</code> must return an <i>m2</i>-by-1 vector of distances d2, whose <i>k</i>th element is the distance between XI and XJ(<i>k</i>, :).</p>

The output  $D$  is arranged in the order of  $((2,1),(3,1),\dots,(m,1),(3,2),\dots(m,2),\dots(m,m-1))$ , i.e. the lower left triangle of the full  $m$ -by- $m$  distance matrix in column order. To get the distance between the  $i$ th and  $j$ th observations ( $i < j$ ), either use the formula  $D((i-1)*(m-i/2)+j-i)$ , or use the helper function  $Z = \text{squareform}(D)$ , which returns an  $m$ -by- $m$  square symmetric matrix, with the  $(i,j)$  entry equal to distance between observation  $i$  and observation  $j$ .

## Metrics

Given an  $m$ -by- $n$  data matrix  $X$ , which is treated as  $m$  (1-by- $n$ ) row vectors  $x_1, x_2, \dots, x_m$ , the various distances between the vector  $x_s$  and  $x_t$  are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - x_t)(x_s - x_t)'$$

Notice that the Euclidean distance is a special case of the Minkowski metric, where  $p = 2$ .

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)'$$

where  $V$  is the  $n$ -by- $n$  diagonal matrix whose  $j$ th diagonal element is  $S(j)^2$ , where  $S$  is the vector of standard deviations.

- Mahalanobis distance

$$d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)'$$

where  $C$  is the covariance matrix.

- City block metric

$$d_{st} = \sum_{j=1}^n |x_{sj} - x_{tj}|$$

Notice that the city block distance is a special case of the Minkowski metric, where  $p=1$ .

- Minkowski metric

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - x_{tj}|^p}$$

Notice that for the special case of  $p = 1$ , the Minkowski metric gives the city block metric, for the special case of  $p = 2$ , the Minkowski metric gives the Euclidean distance, and for the special case of  $p = \infty$ , the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - x_{tj}|\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where  $p = \infty$ .

- Cosine distance

$$d_{st} = 1 - \frac{x_s x_t'}{\sqrt{(x_s x_s')(x_t x_t')}}}$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)' (x_t - \bar{x}_t)(x_t - \bar{x}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \quad \text{and} \quad \bar{x}_t = \frac{1}{n} \sum_j x_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq x_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq x_{tj}) \cap ((x_{sj} \neq 0) \cup (x_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (x_{tj} \neq 0)]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'} \sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- $r_{sj}$  is the rank of  $x_{sj}$  taken over  $x_{1j}, x_{2j}, \dots, x_{mj}$ , as computed by `tiedrank`
- $r_s$  and  $r_t$  are the coordinate-wise rank vectors of  $x_s$  and  $x_t$ , i.e.,  
 $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$

$$\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$$

$$\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$$

## Examples

Generate random data and find the unweighted Euclidean distance and then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance.
X = randn(100, 5);
D = pdist(X, 'euclidean'); % euclidean distance
```

```
% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation.
```

```
Dstd = pdist(X,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];      % coordinate weights
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist(X, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

**See Also**

# pdist2

---

**Purpose** Pairwise distance between two sets of observations

**Syntax**

```
D = pdist2(X,Y)
D = pdist2(X,Y,distance)
D = pdist2(X,Y,'minkowski',P)
D = pdist2(X,Y,'mahalanobis',C)
D = pdist2(X,Y,distance,'Smallest',K)
D = pdist2(X,Y,distance,'Largest',K)
[D,I] = pdist2(X,Y,distance,'Smallest',K)
[D,I] = pdist2(X,Y,distance,'Largest',K)
```

**Description** `D = pdist2(X,Y)` returns a matrix `D` containing the Euclidean distances between each pair of observations in the  $mx$ -by- $n$  data matrix `X` and  $my$ -by- $n$  data matrix `Y`. Rows of `X` and `Y` correspond to observations, columns correspond to variables. `D` is an  $mx$ -by- $my$  matrix, with the  $(i,j)$  entry equal to distance between observation  $i$  in `X` and observation  $j$  in `Y`. The  $(i,j)$  entry will be NaN if observation  $i$  in `X` or observation  $j$  in `Y` contain NaNs.

`D = pdist2(X,Y,distance)` computes `D` using `distance`. Choices are:

Metric	Description
'euclidean'	Euclidean distance (default).
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>X</code> and <code>Y</code> is scaled by dividing by the corresponding element of the standard deviation computed from <code>X</code> , <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use <code>D = PDIST2(X,Y,'seuclidean',S)</code> .
'cityblock'	City block metric.
'minkowski'	Minkowski distance. The default exponent is 2. To compute the distance with a different exponent, use <code>D = pdist2(X,Y,'minkowski',P)</code> , where the exponent <code>P</code> is a scalar positive value.

<b>Metric</b>	<b>Description</b>
'chebychev'	Chebychev distance (maximum coordinate difference).
'mahalanobis'	Mahalanobis distance, using the sample covariance of X as computed by nancov. To compute the distance with a different covariance, use $D = \text{pdist2}(X, Y, \text{'mahalanobis'}, C)$ where the matrix C is symmetric and positive definite.
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations, treated as sequences of values.
'hamming'	Hamming distance, the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
function	<p>A distance function specified using @:  <math>D = \text{pdist2}(X, Y, @\text{distfun})</math>.</p> <p>A distance function must be of the form</p> <pre>function D2 = distfun(ZI, ZJ)</pre> <p>taking as arguments a 1-by-n vector ZI containing a single observation from X or Y, an m2-by-n matrix ZJ containing multiple observations from X or Y, and returning an m2-by-1 vector of distances D2, whose Jth element is the distance between the observations ZI and ZJ(J, :).</p>

Metric	Description
	If your data is not sparse, generally it is faster to use a built-in distance than to use a function handle.

$D = \text{pdist2}(X,Y,\text{distance},\text{'Smallest'},K)$  returns a  $K$ -by- $m_y$  matrix  $D$  containing the  $K$  smallest pairwise distances to observations in  $X$  for each observation in  $Y$ .  $\text{pdist2}$  sorts the distances in each column of  $D$  in ascending order.  $D = \text{pdist2}(X,Y,\text{distance},\text{'Largest'},K)$  returns the  $K$  largest pairwise distances sorted in descending order. If  $K$  is greater than  $m_x$ ,  $\text{pdist2}$  returns an  $m_x$ -by- $m_y$  distance matrix. For each observation in  $Y$ ,  $\text{pdist2}$  finds the  $K$  smallest or largest distances by computing and comparing the distance values to all the observations in  $X$ .

$[D,I] = \text{pdist2}(X,Y,\text{distance},\text{'Smallest'},K)$  returns a  $K$ -by- $m_y$  matrix  $I$  containing indices of the observations in  $X$  corresponding to the  $K$  smallest pairwise distances in  $D$ .  $[D,I] = \text{pdist2}(X,Y,\text{distance},\text{'Largest'},K)$  returns indices corresponding to the  $K$  largest pairwise distances.

## Metrics

Given an  $m_x$ -by- $n$  data matrix  $X$ , which is treated as  $m_x$  (1-by- $n$ ) row vectors  $x_1, x_2, \dots, x_{m_x}$ , and  $m_y$ -by- $n$  data matrix  $Y$ , which is treated as  $m_y$  (1-by- $n$ ) row vectors  $y_1, y_2, \dots, y_{m_y}$ , the various distances between the vector  $x_s$  and  $y_t$  are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - y_t)(x_s - y_t)'$$

Notice that the Euclidean distance is a special case of the Minkowski metric, where  $p=2$ .

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)'$$

where  $V$  is the  $n$ -by- $n$  diagonal matrix whose  $j$ th diagonal element is  $S(j)^2$ , where  $S$  is the vector of standard deviations.

- Mahalanobis distance

$$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)'$$

where  $C$  is the covariance matrix.

- City block metric

$$d_{st} = \sum_{j=1}^n |x_{sj} - y_{tj}|$$

Notice that the city block distance is a special case of the Minkowski metric, where  $p=1$ .

- Minkowski metric

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - y_{tj}|^p}$$

Notice that for the special case of  $p = 1$ , the Minkowski metric gives the City Block metric, for the special case of  $p = 2$ , the Minkowski metric gives the Euclidean distance, and for the special case of  $p=\infty$ , the Minkowski metric gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - y_{tj}|\}$$

Notice that the Chebychev distance is a special case of the Minkowski metric, where  $p=\infty$ .

- Cosine distance

$$d_{st} = \left( 1 - \frac{x_s y_t'}{\sqrt{(x_s x_s')(y_t y_t')}} \right)$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \quad \text{and}$$
$$\bar{y}_t = \frac{1}{n} \sum_j y_{tj}$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq y_{tj}) / n)$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq y_{tj}) \cap ((x_{sj} \neq 0) \cup (y_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (y_{tj} \neq 0)]}$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- $r_{sj}$  is the rank of  $x_{sj}$  taken over  $x_{1j}, x_{2j}, \dots, x_{mx,j}$ , as computed by `tiedrank`
- $r_{tj}$  is the rank of  $y_{tj}$  taken over  $y_{1j}, y_{2j}, \dots, y_{my,j}$ , as computed by `tiedrank`
- $r_s$  and  $r_t$  are the coordinate-wise rank vectors of  $x_s$  and  $y_t$ , i.e.  $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$  and  $r_t = (r_{t1}, r_{t2}, \dots, r_{tn})$

$$\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$$

$$\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$$

## Examples

Generate random data and find the unweighted Euclidean distance, then find the weighted distance using two different methods:

```
% Compute the ordinary Euclidean distance
X = randn(100, 5);
Y = randn(25, 5);
D = pdist2(X,Y,'euclidean'); % euclidean distance

% Compute the Euclidean distance with each coordinate
% difference scaled by the standard deviation
Dstd = pdist2(X,Y,'seuclidean');

% Use a function handle to compute a distance that weights
% each coordinate contribution differently.
Wgts = [.1 .3 .3 .2 .1];
weuc = @(XI,XJ,W)(sqrt(bsxfun(@minus,XI,XJ).^2 * W'));
Dwgt = pdist2(X,Y, @(Xi,Xj) weuc(Xi,Xj,Wgts));
```

## See Also

`pdist` | `createns` | `knnsearch` | `KDTreeSearcher` | `ExhaustiveSearcher`

# pearsrnd

---

## Purpose

Pearson system random numbers

## Syntax

```
r = pearsrnd(mu,sigma,skew,kurt,m,n)
r = pearsrnd(mu,sigma,skew,kurt)
r = pearsrnd(mu,sigma,skew,kurt,m,n,...)
r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])
[r,type] = pearsrnd(...)
[r,type,coefs] = pearsrnd(...)
```

## Description

`r = pearsrnd(mu,sigma,skew,kurt,m,n)` returns an  $m$ -by- $n$  matrix of random numbers drawn from the distribution in the Pearson system with mean `mu`, standard deviation `sigma`, skewness `skew`, and kurtosis `kurt`. The parameters `mu`, `sigma`, `skew`, and `kurt` must be scalars.

---

**Note** Because `r` is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

`pearsrnd` uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The `pearsrnd` function does not use this convention.

---

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

`r = pearsrnd(mu,sigma,skew,kurt)` returns a scalar value.

`r = pearsrnd(mu,sigma,skew,kurt,m,n,...)` or `r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])` returns an  $m$ -by- $n$ -by-... array.

`[r,type] = pearsrnd(...)` returns the type of the specified distribution within the Pearson system. `type` is a scalar integer from 0

to 7. Set `m` and `n` to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- 0 — Normal distribution
- 1 — Four-parameter beta distribution
- 2 — Symmetric four-parameter beta distribution
- 3 — Three-parameter gamma distribution
- 4 — Not related to any standard distribution. The density is proportional to:

$$(1 + ((x - a)/b)^2)^{-c} \exp(-d \arctan((x - a)/b)).$$

- 5 — Inverse gamma location-scale distribution
- 6 —  $F$  location-scale distribution
- 7 — Student's  $t$  location-scale distribution

`[r,type,coefs] = pearsrnd(...)` returns the coefficients `coefs` of the quadratic polynomial that defines the distribution via the differential equation

$$\frac{d}{dx} \log(p(x)) = \frac{-(a+x)}{c(0) + c(1)x + c(2)x^2}.$$

## Examples

Generate random values from the standard normal distribution:

```
r = pearsrnd(0,1,0,3,100,1); % Equivalent to randn(100,1)
```

Determine the distribution type:

```
[r,type] = pearsrnd(0,1,1,4,0,0);
r =
    []
```

# pearsrnd

---

type =  
1

## Purpose

Compute Receiver Operating Characteristic (ROC) curve or other performance curve for classifier output

## Syntax

```
[X,Y] = perfcurve(labels,scores,posclass)
[X,Y] = perfcurve(labels,scores,posclass,'Name',value)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,
    posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
```

## Description

`[X,Y] = perfcurve(labels,scores,posclass)` computes a ROC curve for a vector of classifier predictions `scores` given true class labels, `labels`. `labels` can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector. `scores` is a numeric vector of scores returned by a classifier for some data. `posclass` is the positive class label (scalar), either numeric (for numeric labels), logical (for logical labels), or char. The returned values `X` and `Y` are coordinates for the performance curve and can be visualized with `plot(X,Y)`. For more information on `labels`, `scores`, and `posclass`, see “Input Arguments” on page 21-2827. For more information on `X` and `Y`, see “Output Arguments” on page 21-2832.

`[X,Y] = perfcurve(labels,scores,posclass,'Name',value)` specifies one or more optional parameter name/value pairs, with `Name` in single quotes. See “Input Arguments” on page 21-2827 for a list of inputs, parameter name/value pairs, and respective explanations.

See “Grouping Variables” on page 2-52 for more information on grouping variables.

`[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores, posclass)` returns:

- An array of thresholds on classifier scores for the computed values of `X` and `Y` (`T`).
- The area under curve (AUC) for the computed values of `X` and `Y`.
- The optimal operating point of the ROC curve (`OPTROCPT`).
- An array of `Y` values for negative subclasses (`SUBY`).

- A cell array of negative class names (SUBYNAMES).

For more information on each output, see “Output Arguments” on page 21-2832.

`[X,Y,T,AUC] = perfcurve(labels,scores,posclass)` also returns pointwise confidence bounds for the computed values X, Y, T, and AUC if you supply cell arrays for `labels` and `scores` or set `NBoot` (see “Input Arguments” on page 21-2827) to a positive integer. To compute the confidence bounds, `perfcurve` uses either vertical averaging (VA) or threshold averaging (TA). The returned values Y are an  $m$ -by-3 array in which the 1st element in every row gives the mean value, the 2nd element gives the lower bound and the 3rd element gives the upper bound. The returned AUC is a row-vector with 3 elements following the same convention. For VA, the returned values T are an  $m$ -by-3 array and X is a column-vector. For TA, the returned values X are an  $m$ -by-3 matrix and T is a column-vector.

`perfcurve` computes confidence bounds using either cross validation or bootstrap. If you supply cell arrays for `labels` and `scores`, `perfcurve` uses cross validation and treats elements in the cell arrays as cross validation folds. `labels` can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of strings or categorical vectors. All elements in `labels` must have the same type. `scores` is a cell array of numeric vectors. The cell arrays for `labels` and `scores` must have the same number of elements, and the number of labels in cell  $k$  must be equal to the number of scores in cell  $k$  for any  $k$  in the range from 1 to the number of elements in `scores`.

If you set `NBoot` to a positive integer, `perfcurve` generates `nboot` bootstrap replicas to compute pointwise confidence bounds. You cannot supply cell arrays for `labels` and `scores` and set `NBoot` to a positive integer at the same time.

`perfcurve` returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

If you use 'XCrit' or 'YCrit' options described below to set the criterion for X or Y to an anonymous function, `perfcurve` can only compute confidence bounds by bootstrap.

**Input Arguments**

labels	labels can be a numeric vector, logical vector, character matrix, cell array of strings or categorical vector.
scores	scores is a numeric vector of scores returned by a classifier for some data. This vector must have as many elements as labels does.
posclass	posclass is the positive class label. If labels is a: <ul style="list-style-type: none"> <li>• Numeric vector, then posclass is a numeric scalar</li> <li>• Logical vector, then posclass is a logical scalar</li> <li>• Character matrix, then posclass is a character string</li> <li>• Cell array of strings, then posclass is a character string or cell containing a character string</li> <li>• Categorical vector, then posclass is a categorical scalar</li> </ul> <p>posclass must be a member of labels.</p>

**Name-Value Pair Arguments**

<b>Name</b>	<b>Value and Description</b>
negClass	List of negative classes. Can be either a numeric array or an array of chars or a cell array of strings. By default, negClass is set to 'all' and all classes found in the input array of labels that are not the positive class are considered negative. If negClass is a subset of the classes found in the input array of

Name	Value and Description
xCrit	<p data-bbox="486 309 1288 371">labels, instances with labels that do not belong to either positive or negative classes are discarded.</p> <p data-bbox="486 388 1288 482">Criterion to compute for X. This criterion must be a monotone function of the positive class score. <code>perfcurve</code> supports the following criteria:</p> <ul data-bbox="486 517 1288 1364" style="list-style-type: none"><li data-bbox="486 517 1020 545">• TP — Number of true positive instances.</li><li data-bbox="486 562 1035 590">• FN — Number of false negative instances.</li><li data-bbox="486 607 1028 635">• FP — Number of false positive instances.</li><li data-bbox="486 652 1028 680">• TN — Number of true negative instances.</li><li data-bbox="486 697 865 725">• TP+FP — Sum of TP and FP.</li><li data-bbox="486 743 980 822">• RPP — Rate of positive predictions. <math>RPP = (TP+FP) / (TP+FN+FP+TN)</math></li><li data-bbox="486 840 988 902">• RNP — Rate of negative predictions. <math>RNP = (TN+FN) / (TP+FN+FP+TN)</math></li><li data-bbox="486 920 1161 947">• <code>accu</code> — Accuracy. <math>accu = (TP+TN) / (TP+FN+FP+TN)</math></li><li data-bbox="486 965 1288 1027">• TPR, <code>sens</code>, <code>reca</code> — True positive rate, sensitivity, recall. <math>TPR, sens, reca = TP / (TP+FN)</math></li><li data-bbox="486 1045 1288 1072">• FNR, <code>miss</code> — False negative rate, miss. <math>FNR, miss = FN / (TP+FN)</math></li><li data-bbox="486 1090 1043 1152">• FPR, <code>fall</code> — False positive rate, fallout. <math>FPR, fall = FP / (TN+FP)</math></li><li data-bbox="486 1170 1080 1232">• TNR, <code>spec</code> — True negative rate, specificity. <math>TNR, spec = TN / (TN+FP)</math></li><li data-bbox="486 1249 1136 1312">• PPV, <code>prec</code> — Positive predictive value, precision. <math>PPV, prec = TP / (TP+FP)</math></li><li data-bbox="486 1329 1147 1357">• NPV — Negative predictive value. <math>NPV = TN / (TN+FN)</math></li></ul>

**Name**

**Value and Description**

- `ecost` — Expected cost.  

$$\text{ecost} = (\text{TP} * \text{COST}(P|P) + \text{FN} * \text{COST}(N|P) + \text{FP} * \text{COST}(P|N) + \text{TN} * \text{COST}(N|N)) / (\text{TP} + \text{FN} + \text{FP} + \text{TN})$$

In addition, you can define an arbitrary criterion by supplying an anonymous function of three arguments, `(C, scale, cost)`, where `C` is a 2-by-2 confusion matrix, `scale` is a 2-by-1 array of class scales, and `cost` is a 2-by-2 misclassification cost matrix.

---

**Caution** Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.

---

`yCrit`

Criterion to compute for Y. `perfcurve` supports the same criteria as for X. This criterion does not have to be a monotone function of the positive class score.

`XVals`

Values for the X criterion. The default value for `xVals` is 'all' and `perfcurve` computes X and Y values for all scores. If the value for `xVals` is not 'all', it must be a numeric array. In this case, `perfcurve` computes X and Y only for the specified `xVals`.

`TVals`

Thresholds for the positive class score. By default, `TVals` is unset and `perfcurve` computes X, Y, and T values for all scores. You can set `TVals` to either 'all' or a numeric array. If `TVals` is set to 'all' or unset and `XVals` is unset, `perfcurve` returns X, Y, and T values for all scores and computes pointwise confidence bounds for Y and X using threshold averaging. If `TVals` is set to a numeric array, `perfcurve` returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for Y and X at these thresholds using threshold averaging. You cannot set `XVals` and `TVals` at the same time.

Name	Value and Description
UseNearest	'on' to use nearest values found in the data instead of the specified numeric XVals or TVals and 'off' otherwise. If you specify numeric XVals and set UseNearest to 'on', perfcurve returns nearest unique values X found in the data, as well as corresponding values of Y and T. If you specify numeric XVals and set UseNearest to 'off', perfcurve returns these XVals sorted. By default this parameter is set to 'on'. If you compute confidence bounds by cross validation or bootstrap, this parameter is always 'off'.
ProcessNaN	Specifies how perfcurve processes NaN scores. The default value is 'ignore' and perfcurve removes observations with NaN scores from the data. If you set the parameter to 'addtofalse', perfcurve adds instances with NaN scores to false classification counts in the respective class. That is, perfcurve always counts instances from the positive class as false negative (FN), and always counts instances from the negative class as false positive (FP).
Prior	Either string or array with two elements. It represents prior probabilities for the positive and negative class, respectively. Default is 'empirical', that is, perfcurve derives prior probabilities from class frequencies. If set to 'uniform', perfcurve sets all prior probabilities equal.
Cost	A 2-by-2 matrix of misclassification costs [C(P P) C(N P); C(P N) C(N N)] where C(I J) is the cost of misclassifying class J as class I. By default set to [0 0.5; 0.5 0].
Alpha	A numeric value between 0 and 1. perfcurve returns $100 \cdot (1 - \text{Alpha})$ percent pointwise confidence bounds for X, Y, T and AUC. By default set to 0.05 for 95% confidence interval.

<b>Name</b>	<b>Value and Description</b>
Weights	A numeric vector of nonnegative observation weights. This vector must have as many elements as <code>scores</code> or <code>labels</code> do. If you supply cell arrays for <code>scores</code> and <code>labels</code> and you need to supply <code>weights</code> , you must supply them as a cell array too. In this case, every element in <code>weights</code> must be a numeric vector with as many elements as the corresponding element in <code>scores</code> : <code>numel(weights{1})==numel(scores{1})</code> etc. To compute <code>X</code> , <code>Y</code> and <code>T</code> or to compute confidence bounds by cross validation, <code>perfcurve</code> uses these observation weights instead of observation counts. To compute confidence bounds by bootstrap, <code>perfcurve</code> samples $N$ out of $N$ with replacement using these weights as multinomial sampling probabilities.
NBoot	Number of bootstrap replicas for computation of confidence bounds. Must be a positive integer. By default this parameter is set to zero, and bootstrap confidence bounds are not computed. If you supply cell arrays for <code>labels</code> and <code>scores</code> , this parameter must be set to zero because <code>perfcurve</code> cannot use both cross validation and bootstrap to compute confidence bounds.
BootType	Confidence interval type <code>bootci</code> uses to compute confidence bounds. You can specify any type supported by <code>bootci</code> . By default set to <code>'bca'</code> .
BootArg	Optional input arguments for <code>bootci</code> used to compute confidence bounds. You can specify all arguments <code>bootci</code> supports. Empty by default.

## Output Arguments

- X *x*-coordinates for the performance curve. By default, X is false positive rate, FPR, (equivalently, fallout, or 1-specificity). To change this output, use the 'xCrit' name/value input. For accepted criterion, see 'xCrit' in “Input Arguments” on page 21-2827 for more information.
- Y *y*-coordinates for the performance curve. By default, Y is true positive rate, TPR, (equivalently, recall, or sensitivity). To change this output, use the 'yCrit' input. For accepted criterion, see 'xCrit' in “Input Arguments” on page 21-2827 for more information.
- T An array of thresholds on classifier scores for the computed values of X and Y. It has the same number of rows as X and Y. For each threshold, TP is the count of true positive observations with scores greater or equal to this threshold, and FP is the count of false positive observations with scores greater or equal to this threshold. `perfcurve` defines negative counts, TN and FN, in a similar way then sorts the thresholds in the descending order which corresponds to the ascending order of positive counts.
- For the M distinct thresholds found in the array of scores, `perfcurve` returns the X, Y and T arrays with M+1 rows. `perfcurve` sets elements T(2:M+1) to the distinct thresholds, and T(1) replicates T(2). By convention, T(1) represents the highest 'reject all' threshold and `perfcurve` computes the corresponding values of X and Y for TP=0 and FP=0. T(end) is the lowest 'accept all' threshold for which TN=0 and FN=0.

**AUC** The area under curve (AUC) for the computed values of X and Y. If you set xVals to 'all' (the default), perfcurve computes AUC using the returned X and Y values. If xVals is a numeric array, perfcurve computes AUC using X and Y values found from all distinct scores in the interval specified by the smallest and largest elements of xVals. More precisely, perfcurve finds X values for all distinct thresholds as if xVals were set to 'all', then uses a subset of these (with corresponding Y values) between min(xVals) and max(xVals) to compute AUC. The function uses trapezoidal approximation to estimate the area. If the first or last value of X or Y are NaNs, perfcurve removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

**OPTROCP** The optimal operating point of the ROC curve as an array of size 1-by-2 with FPR and TPR values for the optimal ROC operating point. perfcurve computes optrocp only for the standard ROC curve and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, perfcurve first finds the slope, S, using

$$S = \frac{\text{cost}(P | N) - \text{cost}(N | N) * N}{\text{cost}(N | P) - \text{cost}(P | P) * P}$$

where  $\text{cost}(I | J)$  is the cost of assigning an instance of class J to class I, and  $P=TP+FN$  and  $N=TN+FP$  are the total instance counts in the positive and negative class, respectively. perfcurve then finds the optimal operating point by moving the straight line with slope S from the upper left corner of the ROC plot (FPR=0, TPR=1) down and to the right until it intersects the ROC curve.

- SUBY** An array of Y values for negative subclasses. If you only specify one negative class, SUBY is identical to Y. Otherwise SUBY is a matrix of size M-by-K, where M is the number of returned values for X and Y, and K is the number of negative classes. `perfcurve` computes Y values by summing counts over all negative classes. SUBY gives values of the Y criterion for each negative class separately. For each negative class, `perfcurve` places a new column in SUBY and fills it with Y values for TN and FP counted just for this class.
- SUBYNAMES** A cell array of negative class names. If you provide an input array, `negClass`, of negative class names, `perfcurve` copies it into SUBYNAMES. If you do not provide `negClass`, `perfcurve` extracts SUBYNAMES from input labels. The order of SUBYNAMES is the same as the order of columns in SUBY, that is, `SUBY(:,1)` is for negative class `SUBYNAMES{1}` etc.

**Examples****Plot a ROC Curve for Classification Algorithms**

Plot the ROC curve for classification by logistic regression.

```
load fisheriris
x = meas(51:end,1:2);
% Iris data, 2 classes and 2 features
y = (1:100) '>50';
% Versicolor = 0, virginica = 1
b = glmfit(x,y,'binomial');
% Logistic regression
p = glmval(b,x,'logit');
% Fit probabilities for scores
[X,Y,T,AUC] = perfcurve(species(51:end,:),p,'virginica');
plot(X,Y)
xlabel('False positive rate'); ylabel('True positive rate')
title('ROC for classification by logistic regression')
```

# perfcurve

Obtain errors on TPR by vertical averaging.

```
[X,Y] = perfcurve(species(51:end,:),p,'virginica',...  
    'NBoot',1000,'XVals','All');  
% Plot errors  
errorbar(X,Y(:,1),Y(:,2)-Y(:,1),Y(:,3)-Y(:,1));
```

## How To

- “Grouping Variables” on page 2-52
- “Performance Curves” on page 15-41

**Purpose** Enumeration of permutations

**Syntax** `P = perms(v)`

**Description** `P = perms(v)`, where `v` is a row vector of length `n`, creates a matrix whose rows consist of all possible permutations of the `n` elements of `v`. The matrix `P` contains `n!` rows and `n` columns.

`perms` is only practical when `n` is less than about 11 (for `n = 11`, the output takes over 3 gigabytes).

**Examples** `perms([2 4 6])`

`ans =`

```
6 4 2
6 2 4
4 6 2
4 2 6
2 4 6
2 6 4
```

`combnk`

# categorical.permute

---

## **Purpose**

Permute dimensions of categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`B = permute(A,order)`

## **Description**

`B = permute(A,order)` rearranges the dimensions of the categorical array `A` so that they are in the order specified by the vector `order`. The array produced has the same values as `A` but the order of the subscripts needed to access any particular element are rearranged as specified by `order`. The elements of `order` must be a rearrangement of the numbers from 1 to `n`.

<b>Properties</b>	<p><b>x - Data values</b> vector of scalar values</p>

# prob.PiecewiseLinearDistribution

---

Data values at which the cumulative distribution function (cdf) changes slope, stored as a vector of scalar values.

## Data Types

single | double

## Fx - cdf value

vector of scalar values

cdf value at each value in x, stored as a vector of scalar values.

## Data Types

single | double

## DistributionName - Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

# prob.PiecewiseLinearDistribution

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Piecewise Linear Distribution

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

## Examples

### Create a Piecewise Linear Distribution Object Using Default Parameters

Create a piecewise linear distribution object using the default parameter values.

```
pd = makedist('PiecewiseLinear')
```

```
pd =
```

```
  PiecewiseLinearDistribution
```

```
F(0) = 0
```

```
F(1) = 1
```

### Create a Piecewise Linear Distribution Object Using Specified Parameters

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital;  
hist(hospital.Weight)
```

# prob.PiecewiseLinearDistribution

---

The histogram shows that the data has two modes, one for female patients and one for male patients.

Compute the empirical cumulative distribution function (ecdf) for the data.

```
[f,x] = ecdf(hospital.Weight);
```

Construct a piecewise linear approximation to the ecdf and plot both functions.

# prob.PiecewiseLinearDistribution

```
f = f(1:5:end); % keep a less dense grid of points  
x = x(1:5:end);
```

```
figure;  
ecdf(hospital.Weight)  
hold on  
plot(x,f,'ro','MarkerFace','r') % overlay grid  
plot(x,f,'k') % show interpolation
```

# prob.PiecewiseLinearDistribution

---

Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.

```
pd = makedist('PiecewiseLinear','x',x,'Fx',f)
```

```
pd =
```

```
    PiecewiseLinearDistribution
```

```
F(111) = 0
F(118) = 0.05
F(124) = 0.13
F(130) = 0.25
F(135) = 0.37
F(142) = 0.5
F(163) = 0.55
F(171) = 0.61
F(178) = 0.7
F(183) = 0.82
F(189) = 0.94
F(202) = 1
```

Generate 100 random numbers from the distribution.

```
rw = random(pd,100,1);
```

Plot the random numbers to visually compare their distribution to the original data.

```
figure;
hist(rw)
```

The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

# clustering.evaluation.ClusterCriterion.plot

---

**Purpose** Plot clustering evaluation object criterion values

**Syntax** `plot(eva)`  
`h = plot(eva)`

**Description** `plot(eva)` displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object `eva`.

`h = plot(eva)` returns a handle to the plot line.

**Input Arguments** **eva - Clustering evaluation data**  
clustering evaluation object  
Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

**Output Arguments** **h - Handle to plot line**  
scalar value  
Handle to the plot line, returned as a scalar value.

## Examples **Plot the Clustering Evaluation Criterion Values**

Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
rng('default'); % For reproducibility
```

# clustering.evaluation.ClusterCriterion.plot

```
eva = evalclusters(meas, 'kmeans', 'CalinskiHarabasz', 'KList', [1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;  
plot(eva);
```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

# clustering.evaluation.ClusterCriterion.plot

---

## See Also

`evalclusters`

**Purpose**

Scatter plot or added variable plot of linear model

**Syntax**

```
plot mdl
h = plot mdl
```

**Description**

`plot(mdl)` creates a plot of the fitted linear model. The plot type depends on the number of predictor variables.

- If there is just one predictor variable, `plot` creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If there are multiple predictor variables, `plot` creates an added variable plot.
- If there are no predictors, `plot` creates a histogram of the residuals.

`h = plot(mdl)` returns handles to the lines in the plot.

**Input Arguments****mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

**Output Arguments****h**

Vector of handles to lines or patches in the plot.

**Definitions****Added Variable Plot, Adjusted Response**

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

**Examples****Create an Added Variable Plot**

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

# LinearModel.plot

Create a linear model of mileage from the carsmall data.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plot(mdl)
```

The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

**Alternatives**     Use `plotAdded` to select particular predictors for an added variable plot.

**See Also**         `LinearModel` | `plotAdded`

**How To**            • “Linear Regression” on page 9-12

# RepeatedMeasuresModel.plot

---

**Purpose** Plot data with optional grouping

**Syntax**

```
plot(rm)
plot(rm,Name,Value)
H = plot( ___ )
```

**Description** `plot(rm)` plots the measurements in the repeated measures model `rm` for each subject as a function of time. If there is a single numeric within-subjects factor, `plot` uses the values of that factor as the time values. Otherwise, `plot` uses the discrete values 1 through  $r$  as the time values, where  $r$  is the number of repeated measurements.

`plot(rm,Name,Value)` also plots the measurements in the repeated measures model `rm`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plot( ___ )` returns handles, `H`, to the plotted lines.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **'Group' - Name of between-subject factor or factors**

string | cell array of strings

Name of between-subject factor or factors, specified as the comma-separated pair consisting of 'Group' and a string or cell array of strings. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

**Example:** 'Group', {'Drug', 'Sex'}

## **Data Types**

char | cell

## **'Marker' - Marker to use for each group**

cell array of strings

Marker to use for each group, specified as the comma-separated pair consisting of 'Marker' and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify o as the marker for the groups of drug and x as the marker for the groups of sex as follows.

**Example:** 'Marker', {'o', 'o', 'x', 'x'}

## **Data Types**

cell

## **'Color' - Color for each group**

string | cell array of strings | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a string, cell array of strings, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color

# RepeatedMeasuresModel.plot

---

for the groups of drug and blue as the color for the groups of sex as follows.

**Example:** 'Color', 'rbbb'

## Data Types

single | double | cell

## 'LineStyle' - Line style for each group

cell array of strings

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

**Example:** 'LineStyle', {'-' ':' '-' ':' }

## Data Types

cell

## Output Arguments

### H - Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

## Examples

### Plot Data by Group

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Plot data grouped by the factor species.

```
plot(rm,'group','species')
```

# RepeatedMeasuresModel.plot

Change the line style for each group.

```
plot(rm,'group','species','LineStyle',{'-','-',':'})
```

## Plot Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

# RepeatedMeasuresModel.plot

---

Fit a repeated measures model, where the repeated measures  $y_1$  through  $y_8$  are the responses, and age, IQ, group, gender, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', withi
```

Plot data with Group coded by color and Gender coded by line type.

```
plot(R, 'group', {'Group' 'Gender'}, 'Color', 'rrbbgg', ...  
      'LineStyle', {'-' ':' '-' ':' '-' ':''}, 'Marker', '.')
```

# RepeatedMeasuresModel.plot

**See Also**

[plotprofile](#) | [fitrm](#) | [multcompare](#)

# LinearModel.plotAdded

---

**Purpose** Added variable plot or leverage plot for linear model

**Syntax**

```
plotAdded mdl
plotAdded mdl,coef
h = plotAdded mdl,...
h = plotAdded mdl,coef,Name,Value
```

**Description**

`plotAdded(mdl)` produces a generalized added variable plot for all terms in `mdl` except the constant term.

`plotAdded(mdl,coef)` produces an added variable plot for the `coef` terms in `mdl`, after adjusting for all other terms.

`h = plotAdded(mdl,...)` returns handles to the lines in the plot.

`h = plotAdded(mdl,coef,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **coef**

Coefficients in `mdl`. Represent as:

- String giving a single coefficient name
- Vector of coefficient numbers in the `mdl.CoefficientNames` property

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

**'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

**'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

**'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

**'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

**'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

**'MarkerSize'**

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

# LinearModel.plotAdded

---

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Added Variable Plot, Adjusted Response

An added variable plot illustrates the incremental effect on the response of specified terms by removing the effects of all other terms. The slope of the fitted line is the coefficient of the linear combination of the specified terms projected onto the best-fitting direction. The adjusted response includes the constant (intercept) terms, and averages out all other terms.

## Examples

### Create an Added Variable Plot

Create a model of car mileage as a function of weight and model year. Then create a plot to see the significance of the model.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Create an added variable plot.

```
plotAdded(mdl)
```

The plot illustrates that the model is significant—a horizontal line does not fit between the confidence bounds.

## Create an Added Variable Plot for Particular Variables

Create a model of car mileage as a function of weight and model year. Then create a plot to see the effect of the weight terms (Weight and Weight<sup>2</sup>).

Create a linear model of mileage from the carsmall data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

# LinearModel.plotAdded

Find the terms in the model corresponding to the `Weight` and `Weight^2`.

```
mdl.CoefficientNames
```

```
ans =
```

```
'(Intercept)' 'Weight' 'Year_76' 'Year_82' 'Weight^2'
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```
coef = [2 5];  
plotAdded(mdl,coef)
```

The plot illustrates that the weight terms are significant—a horizontal line does not fit between the confidence bounds.

**'MarkerSize'**

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

**Output Arguments**

**h**

Vector of handles to lines or patches in the plot.

# LinearModel.plotAdjustedResponse

---

## Definitions **Adjusted Response Plot**

The adjusted response plot shows the fitted response as a function of var, with the other predictors averaged out by averaging the fitted values over the data used in the fit. Adjusted data points are computed by adding the residual to the adjusted fitted value for each observation.

## Examples **Plot Adjusted Responses**

Plot the adjusted responses of a fitted linear model.

Load the carsmall data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the effect of 'Weight' averaged over Year values.

```
plotAdjustedResponse(mdl,'Weight')
```

# LinearModel.plotAdjustedResponse

Plot the effect of Year averaged over 'Weight' values. Include the h output.

```
h = plotAdjustedResponse(md1, 'Year');
```

# LinearModel.plotAdjustedResponse

Change the adjusted data to black x instead of red o.

```
set(h(1), 'Marker', 'x', 'Color', 'k')
```

# LinearModel.plotAdjustedResponse

## How To

- “Linear Regression” on page 9-12

# GeneralizedLinearModel.plotDiagnostics

---

**Purpose** Plot diagnostics of generalized linear regression model

**Syntax**

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value
```

**Description**

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics from the `mdl` generalized linear model in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### **plottype**

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

**Default:** 'leverage'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### 'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### 'LineStyle'

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### 'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### 'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### 'MarkerFaceColor'

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### 'MarkerSize'

# GeneralizedLinearModel.plotDiagnostics

---

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and a diagonal weight matrix  $W$ :

$$H = X(X^T W X)^{-1} X^T W^T.$$

$W$  has diagonal elements  $w_i$ :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- $g$  is the link function mapping  $y_i$  to  $x_i b$ .
- $g'$  is the derivative of the link function  $g$ .
- $V$  is the variance function.
- $\mu_i$  is the  $i$ th mean.

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

## Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = w_i \frac{e_i^2}{p\hat{\phi}} \frac{h_{ii}}{(1-h_{ii})^2},$$

where

- $\hat{\phi}$  is the dispersion parameter (estimated or theoretical).
- $e_i$  is the linear predictor residual,  $g(y_i) - x_i\hat{\beta}$ , where
  - $g$  is the link function.
  - $y_i$  is the observed response.
  - $x_i$  is the observation.
  - $\hat{\beta}$  is the estimated coefficient vector.
- $p$  is the number of coefficients in the regression model.
- $h_{ii}$  is the  $i$ th diagonal element of the Hat Matrix  $H$ .

## Examples

### Diagnostic Plots for Generalized Linear Models

Create leverage and Cook's distance plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

# GeneralizedLinearModel.plotDiagnostics

---

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,...
    'y ~ x1 + x2','distr','poisson');
```

Create a leverage plot.

```
plotDiagnostics(mdl)
```

# GeneralizedLinearModel.plotDiagnostics

Create a contour plot with Cook's distance.

```
plotDiagnostics(md1, 'contour')
```

## References

## Related Examples

- “Diagnostic Plots” on page 10-26

## Concepts

- “Generalized Linear Models” on page 10-12

# LinearModel.plotDiagnostics

---

**Purpose** Plot diagnostics of linear regression model

**Syntax**

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value)
```

**Description**

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using scaled delete-1 fitted values.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **plottype**

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'covratio'	Delete-1 ratio of determinant of covariance
'dfbetas'	Scaled delete-1 coefficient estimates

'dffits'	Scaled delete-1 fitted values
'leverage'	Leverage
's2_i'	Delete-1 variance estimate

Delete-1 means compute a new model without the current observation. If the delete-1 calculation differs significantly from the model using all observations, then the observation is influential.

**Default:** 'leverage'

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### 'Color'

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### 'LineStyle'

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### 'LineWidth'

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

# LinearModel.plotDiagnostics

---

Default: 0.5

## 'MarkerEdgeColor'

Color of the marker or edge color for filled markers, a string or ColorSpec specification. For details, see linespec.

## 'MarkerFaceColor'

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see linespec.

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$ :

$$H = X(X^T X)^{-1} X^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

### Leverage

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the

number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

Cook's distance is the scaled change in fitted values. Each element in `CooksDistance` is the normalized change in the vector of coefficients due to the deletion of an observation. The Cook's distance,  $D_i$ , of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{pMSE},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $MSE$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{pMSE} \left( \frac{h_{ii}}{(1-h_{ii})^2} \right),$$

where  $r_i$  is the  $i$ th residual, and  $h_{ii}$  is the  $i$ th leverage value.

`CooksDistance` is an  $n$ -by-1 column vector in the `Diagnostics` table of the `LinearModel` object.

# LinearModel.plotDiagnostics

---

## Examples

### Leverage Plot of Linear Model

Plot the leverage values of observations in a fitted model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
mdl = fitlm(ds,'MPG ~ Year + Weight^2');
```

Plot the leverage values.

```
plotDiagnostics(mdl)
```

Plot the Cook's distance.

```
plotDiagnostics(md1, 'cookd')
```

# LinearModel.plotDiagnostics

---

The two diagnostic plots give different results.

## References

[1] Neter, J., M. H. Kutner, C. J. Nachtsheim, and W. Wasserman. *Applied Linear Statistical Models*, Fourth Edition. Irwin, Chicago, 1996.

## Alternatives

The `mdl.Diagnostics` property contains the information that `plotDiagnostics` uses to create plots.

## See Also

`LinearModel`

## Tutorials

- “Diagnostic Plots” on page 9-24

## How To

- “Linear Regression” on page 9-12

# NonLinearModel.plotDiagnostics

---

**Purpose** Plot diagnostics of nonlinear regression model

**Syntax**

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics mdl,plottype,Name,Value
```

**Description**

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the *x* and *y* values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **plottype**

String specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

**Default:** 'leverage'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerSize'**

# NonLinearModel.plotDiagnostics

---

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Hat Matrix

The *hat matrix*  $H$  is defined in terms of the data matrix  $X$  and the Jacobian matrix  $J$ :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here  $f$  is the nonlinear model function, and  $\beta$  is the vector of model coefficients.

The Hat Matrix  $H$  is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements  $H_{ii}$  satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where  $n$  is the number of observations (rows of  $X$ ), and  $p$  is the number of coefficients in the regression model.

The *leverage* of observation  $i$  is the value of the  $i$ th diagonal term,  $h_{ii}$ , of the hat matrix  $H$ . Because the sum of the leverage values is  $p$  (the number of coefficients in the regression model), an observation  $i$  can be considered to be an outlier if its leverage substantially exceeds  $p/n$ , where  $n$  is the number of observations.

## Cook's Distance

The Cook's distance  $D_i$  of observation  $i$  is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- $\hat{y}_j$  is the  $j$ th fitted response value.
- $\hat{y}_{j(i)}$  is the  $j$ th fitted response value, where the fit does not include observation  $i$ .
- $\text{MSE}$  is the mean squared error.
- $p$  is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left( \frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where  $e_i$  is the  $i$ th residual.

## Examples

### Nonlinear Model Leverage Plot

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

# NonLinearModel.plotDiagnostics

Create a leverage plot of the fitted model.

```
plotDiagnostics(md1)
```

To examine the observation with high leverage, activate the Data Cursor and click the observation.

# NonLinearModel.plotDiagnostics

Alternatively, find the high-leverage observation at the command line.

```
find(md1.Diagnostics.Leverage > 0.8)
```

```
ans =
```

```
6
```

<b>Purpose</b>	Plot main effects of each predictor in linear regression model
<b>Syntax</b>	<pre>plotEffects(md1) h = plotEffects(md1)</pre>
<b>Description</b>	<p><code>plotEffects(md1)</code> produces an effects plot for the predictors in the <code>md1</code> regression model. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. <code>plotEffects</code> chooses values to produce a relatively large effect on the response.</p> <p><code>h = plotEffects(md1)</code> returns handles to the lines in the plot.</p>
<b>Tips</b>	<ul style="list-style-type: none"><li>• For many plots, the Data Cursor tool in the figure window displays the <math>x</math> and <math>y</math> values for any data point, along with the observation name or number.</li></ul>
<b>Input Arguments</b>	<p><b>md1</b></p> <p>Linear model, as constructed by <code>fitlm</code> or <code>stepwiselm</code>.</p>
<b>Output Arguments</b>	<p><b>h</b></p> <p>Vector of handles to lines or patches in plot. <code>h(1)</code> is a handle to the circles that represent the main effect estimates. <code>h(j+1)</code> is a handle to the line that defines the confidence interval for the effect of predictor <math>j</math>.</p>
<b>Examples</b>	<p><b>Effects Plot</b></p> <p>Plot the effects of two predictors in a fitted linear model.</p> <p>Load the <code>carsmall</code> data and fit a linear model of the mileage as a function of model year, weight, and weight squared.</p> <pre>load carsmall ds = dataset(MPG,Weight); ds.Year = ordinal(Model_Year);</pre>

# LinearModel.plotEffects

---

```
mdl = fitlm(ds, 'MPG ~ Year + Weight^2');
```

Create an effects plot.

```
plotEffects(mdl)
```

The width of each horizontal line in the figure shows a confidence interval for the effect on the response of the listed change in each predictor. The estimated effect of changing Year from 70 to 82 is an increase of about 8, and is between 6 and 10 with 95% confidence.

## Alternatives

Use `plotInteraction` for an effects plot of the interactions of two specified variables.

**See Also**

[LinearModel](#) | [plotAdjustedResponse](#) | [plotInteraction](#)

**Tutorials**

- “Plots to Understand Predictor Effects” on page 9-31

**How To**

- “Linear Regression” on page 9-12

# LinearModel.plotInteraction

---

**Purpose** Plot interaction effects of two predictors in linear regression model

**Syntax**

```
plotInteraction mdl, var1, var2)
plotInteraction mdl, var1, var2, ptype)
h = plotInteraction(...)
```

**Description** `plotInteraction(mdl, var1, var2)` creates a plot of the interaction effects of the predictors `var1` and `var2` in `mdl`. The plot shows the estimated effect on the response from changing each predictor value, averaging out the effects of the other predictors. The plot also shows the estimated effect with the other predictor fixed at certain values. `plotInteraction` chooses values to produce a relatively large effect on the response. The plot lets you examine whether the effect of one predictor depends on the value of the other predictor.

`plotInteraction(mdl, var1, var2, ptype)` returns a plot of the type specified in `ptype`.

`h = plotInteraction(...)` returns handles to the lines in the plot.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **var1**

String naming the variable for plot. `plotInteraction` chooses values of `var1` to create relatively large changes in the response. When you set `ptype = 'predictions'`, the plot shows curves as a function of `var2` with various fixed values of `var1`.

### **var2**

String naming the variable for plot. `plotInteraction` chooses values of `var2` to create relatively large changes in the response.

When you set `pctype = 'predictions'`, the plot shows curves as a function of `var2` various fixed values of `var1`.

## **pctype**

String naming the plot type.

- `'effects'` — The plot shows each effect as a circle, with a horizontal bar showing the confidence interval for the estimated effect. `plotInteraction` computes the effect values from the adjusted response curve, as shown by the `plotAdjustedResponse` function.
- `'predictions'` — The plot shows the adjusted response curve as a function of `var2`, with `var1` fixed at certain values.

**Default:** `'effects'`

## **Output Arguments**

### **h**

Vector of handles to lines or patches in the plot.

## **Examples**

### **Interaction Plot**

Create a model of car mileage as a function of weight and model year. Then create a plot to see if the predictors have interactions.

Create a linear model of mileage from the `carsmall` data.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
var1 = 'Year';
var2 = 'Weight';
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot.

```
plotInteraction(mdl,var1,var2)
```

# LinearModel.plotInteraction

The plot might show an interaction, because the groups of points are not perfectly vertical. But the error bars seem large enough that a vertical line could pass within all of the confidence intervals for each group, possibly indicating no interaction.

## Prediction Curve Interaction Plot

Create a model of car mileage as a function of weight and model year. Then create an interaction curve plot to see if the predictors have interactions.

Create a linear model of mileage from the carsmall data.

```
load carsmall
```

# LinearModel.plotInteraction

```
ds = dataset(MPG,Weight);  
ds.Year = ordinal(Model_Year);  
var1 = 'Year';  
var2 = 'Weight';  
mdl = fitlm(ds,'MPG ~ Year * Weight^2');
```

Create an interaction plot with type 'predictions'.

```
plotInteraction(mdl,var1,var2,'predictions')
```

The curves are not parallel. This indicates interactions between the predictors. The effect is subtle enough not to definitively indicate a interaction.

# LinearModel.plotInteraction

---

**Alternatives**    Use `plotEffects` for an effects plot showing separate effects for all predictors.

**See Also**        `LinearModel` | `plotAdjustedResponse` | `plotEffects`

**How To**            • “Linear Regression” on page 9-12

## Purpose

Plot expected marginal means with optional grouping

## Syntax

```
plotprofile(rm,X)
plotprofile(rm,Name,Value)
H = plotprofile( ___ )
```

## Description

`plotprofile(rm,X)` plots the expected marginal means computed from the repeated measures model `rm` as a function of the variable `X`.

`plotprofile(rm,Name,Value)` plots the expected marginal means computed from the repeated measures model `rm` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plotprofile( ___ )` returns handles, `H`, to the plotted lines.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **X - Name of between-subjects or within-subjects factor**

string

Name of a between-subjects or within-subjects factor, specified as a string.

For example, if you want to plot the marginal means as a function of the groups of a between-subjects variable `drug`, you can specify it as follows.

**Example:** 'Drug'

# RepeatedMeasuresModel.plotprofile

---

## Data Types

char

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'Group' - Name of between-subject factor or factors

string | cell array of strings

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a string or cell array of strings. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, `drug` and `sex`, and you want to group the lines in the plot according to them, you can specify these factors as follows.

**Example:** `'Group',{ 'Drug', 'Sex' }`

## Data Types

char | cell

## 'Marker' - Marker to use for each group

cell array of strings

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a cell array of strings.

For example, if you have two between-subject factors, `drug` and `sex`, with each having two groups, you can specify `o` as the marker for the groups of `drug` and `x` as the marker for the groups of `sex` as follows.

**Example:** `'Marker',{ 'o', 'o', 'x', 'x' }`

## Data Types

cell

### 'Color' - Color for each group

string | cell array of strings | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a string, cell array of strings, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

**Example:** 'Color', 'rbbb'

## Data Types

single | double | cell

### 'LineStyle' - Line style for each group

cell array of strings

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a cell array of strings.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

**Example:** 'LineStyle', {'-' ':' '-' ':' }

## Data Types

cell

## Output Arguments

### H - Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

# RepeatedMeasuresModel.plotprofile

---

## Examples

### Plot Expected Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform data grouped by the factor species.

```
plotprofile(rm,'species')
```

The estimated marginal means seem to differ with group. You can compute the standard error and the 95% confidence intervals for the marginal means using the `margmean` method.

### **Plot Marginal Means for Two Groups**

Load the sample data.

```
load repeatedmeas
```

# RepeatedMeasuresModel.plotprofile

---

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within)
```

Plot the estimated marginal means based on the factors `Group` and `Gender`.

```
ax1 = subplot(1,2,1);  
plotprofile(R, 'Group')  
ax2 = subplot(1,2,2);  
plotprofile(R, 'Gender')  
linkaxes([ax1 ax2], 'y')
```

# RepeatedMeasuresModel.plotprofile

Plot the estimated marginal means based on the factor Group and grouped by Gender.

```
figure()  
plotprofile(R, 'Group', 'Group', 'Gender')
```

# RepeatedMeasuresModel.plotprofile

**See Also** `plot` | `fitrm` | `margmean`

# GeneralizedLinearModel.plotResiduals

## Purpose

Plot residuals of generalized linear regression model

## Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
h = plotResiduals(...)
h = plotResiduals(mdl, plottype, Name, Value)
```

## Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl, plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

## Tips

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### **plottype**

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ( $r(t)$ vs. $r(t-1)$ )

# GeneralizedLinearModel.plotResiduals

---

'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Default:** 'histogram'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as **Name1**, **Value1**, ..., **NameN**, **ValueN**.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

# GeneralizedLinearModel.plotResiduals

## 'MarkerFaceColor'

Color of the marker face for filled markers, a string or ColorSpec specification. For details, see `linespec`.

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## 'ResidualType'

String giving type of residual used in the plot.

'Raw'	Observed minus fitted values
'LinearPredictor'	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
'Pearson'	Raw residuals divided by RMSE
'Anscombe'	Residuals defined on transformed data with the transformation chosen to remove skewness
'Deviance'	Residuals based on the contribution of each observation to the deviance

**Default:** 'Raw'

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Definitions

### Deviance

*Deviance* is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.

# GeneralizedLinearModel.plotResiduals

---

## Examples

### Residual Plots for Generalized Linear Models

Create residual plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a default residuals plot.

```
plotResiduals(mdl)
```

# GeneralizedLinearModel.plotResiduals

---

Create a probability plot.

```
plotResiduals mdl, 'probability'
```

# GeneralizedLinearModel.plotResiduals

The residuals do not match a normal distribution in the tails—they are more spread out.

Create a plot of the fitted residuals of Anscombe type.

# GeneralizedLinearModel.plotResiduals

**See Also** `GeneralizedLinearModel`

## Related Examples

## Concepts

- “Generalized Linear Models” on page 10-12

# LinearModel.plotResiduals

---

**Purpose** Plot residuals of linear regression model

**Syntax**

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals mdl,plottype,Name,Value)
```

**Description**

`plotResiduals mdl` gives a histogram plot of the residuals of the `mdl` linear model.

`plotResiduals mdl,plottype` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals mdl,plottype,Name,Value` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **plottype**

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ( $r(t)$ vs. $r(t-1)$ )
'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Default:** 'histogram'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

# LinearModel.plotResiduals

---

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## 'ResidualType'

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

**Default:** 'Raw'

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Examples

### Linear Residuals Plot

Plot the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the raw residuals.

```
plotResiduals(mdl)
```

## Residual Probability Plot

Create a normal probability plot of the residuals of a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

# LinearModel.plotResiduals

---

**Alternatives** The `mdl.Residuals` table contains the information in residual plots.

# LinearMixedModel.plotResiduals

---

**Purpose** Plot residuals of linear mixed-effects model

**Syntax** `plotResiduals(lme,plottype)`  
`plotResiduals(lme,plottype,Name,Value)`

`h = plotResiduals( ___ )`

**Description** `plotResiduals(lme,plottype)` plots the raw conditional residuals of the linear mixed-effects model `lme` in a plot of the type specified by `plottype`.

`plotResiduals(lme,plottype,Name,Value)` also plots the residuals of the linear mixed-effects model `lme` with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

`plotResiduals` also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see `plot`.

`h = plotResiduals( ___ )` returns a handle, `h`, to the lines or patches in the plot of residuals.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **plottype - Type of residual plot**

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following strings.

# LinearMixedModel.plotResiduals

---

'histogram'	Default. Histogram of residuals
'caseorder'	Residuals versus case (row) order
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ( $r(t)$ versus $r(t - 1)$ )
'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Example:** `plotResiduals(lme, 'lagged')`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'Conditional' - Indicator for conditional residuals

True (default) | False

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

**Example:** `'Conditional', 'False'`

## 'ResidualType' - Residual type

# LinearMixedModel.plotResiduals

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Zb]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\text{Var}_{y,b}(y - X\hat{\beta} - Zb)]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\text{Var}_y(y - X\hat{\beta})]_{ii}}}$
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\text{Var}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\text{Var}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see [Definitions](#) at the end of this page.

**Example:** 'ResidualType', 'Standardized'

## Output Arguments

### h - Handle to residual plot

handle

Handle to the residual plot, returned as a handle.

## Examples

### Examine Residuals

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

# LinearMixedModel.plotResiduals

---

load weight

weight contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define Subject and Program as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Plot the histogram of the raw residuals.

```
plotResiduals(lme)
```

# LinearMixedModel.plotResiduals

Plot the residuals versus the fitted values.

```
figure();  
plotResiduals(lme, 'fitted')
```

# LinearMixedModel.plotResiduals

---

There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```
figure();  
plotResiduals(lme,'probability')
```

Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```
find(residuals(lme)>0.25)
```

```
ans =
```

```
101
```

# LinearMixedModel.plotResiduals

---

Create a box plot of the raw, Pearson, and standardized residuals.

```
r = residuals(lme);  
pr = residuals(lme, 'ResidualType', 'Pearson');  
st = residuals(lme, 'ResidualType', 'Standardized');  
X = [r pr st];  
boxplot(X, 'labels', {'Raw', 'Pearson', 'Standardized'});
```

All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point

out a second possible outlier on the left tail. Find the corresponding observation number.

```
find(pr<-2)
```

```
ans =
```

```
    10
```

Plot the raw residuals versus lagged residuals.

```
plotResiduals(lme, 'lagged')
```

# LinearMixedModel.plotResiduals

There is no obvious pattern in the graph. The residuals do not appear to be correlated.

## Definitions

### Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also,

suppose the  $p$ -by-1 estimated fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\hat{\beta} - Z\hat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\hat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

## See Also

`LinearMixedModel` | `residuals` | `fitted`

# NonLinearModel.plotResiduals

---

**Purpose** Plot residuals of nonlinear regression model

**Syntax**

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals mdl,plottype,Name,Value)
```

**Description**

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For many plots, the Data Cursor tool in the figure window displays the  $x$  and  $y$  values for any data point, along with the observation name or number.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **plottype**

String specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ( $r(t)$ vs. $r(t-1)$ )
'probability'	Normal probability plot
'symmetry'	Symmetry plot

**Default:** 'histogram'

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

---

**Note** The plot property name-value pairs apply to the first returned handle `h(1)`.

---

### **'Color'**

Color of the line or marker, a string or `ColorSpec` specification. For details, see `linespec`.

### **'LineStyle'**

Type of line, a string or `lineseriesproperties` specification. For details, see `linespec`.

### **'LineWidth'**

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

**Default:** 0.5

### **'MarkerEdgeColor'**

Color of the marker or edge color for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

### **'MarkerFaceColor'**

Color of the marker face for filled markers, a string or `ColorSpec` specification. For details, see `linespec`.

# NonLinearModel.plotResiduals

---

## 'MarkerSize'

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

## 'ResidualType'

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

**Default:** 'Raw'

## Output Arguments

**h**

Vector of handles to lines or patches in the plot.

## Examples

### Residual Plot

Plot the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Plot the residuals of the fitted model.

```
plotResiduals(mdl)
```

## Residual Probability Plot

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

# LinearModel.plotSlice

---

**Purpose** Plot of slices through fitted linear regression surface

**Syntax** `plotSlice mdl`  
`h = plotSlice(mdl)`

**Description** `plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

- Tips**
- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
  - The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

**Input Arguments** **mdl**  
Linear model, as constructed by `fitlm` or `stepwiselm`.

**Output Arguments** **h**  
Vector of handles to lines or patches in the plot.

## Examples

### Slice Plot

Plot the slices through a fitted linear model.

Load the `carsmall` data and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = ordinal(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a slice plot.

```
plotSlice mdl
```

Drag the Weight prediction line to the right and observe the change in the predicted MPG and the response curve for Year.

## Purpose

Partial least-squares regression

## Syntax

```
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = PLSREGRESS(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] =
plsregress(...,param1,val1,param2,
            val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = PLSREGRESS(X,Y,ncomp,...)
```

## Description

[XL,YL] = plsregress(X,Y,ncomp) computes a partial least-squares (PLS) regression of Y on X, using ncomp PLS components, and returns the predictor and response loadings in XL and YL, respectively. X is an  $n$ -by- $p$  matrix of predictor variables, with rows corresponding to observations and columns to variables. Y is an  $n$ -by- $m$  response matrix. XL is a  $p$ -by- $ncomp$  matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. YL is an  $m$ -by- $ncomp$  matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

[XL,YL,XS] = plsregress(X,Y,ncomp) returns the predictor scores XS, that is, the PLS components that are linear combinations of the variables in X. XS is an  $n$ -by- $ncomp$  orthonormal matrix with rows corresponding to observations and columns to components.

[XL,YL,XS,YS] = plsregress(X,Y,ncomp) returns the response scores YS, that is, the linear combinations of the responses with which the PLS components XS have maximum covariance. YS is an  $n$ -by- $ncomp$  matrix with rows corresponding to observations and columns to components. YS is neither orthogonal nor normalized.

plsregress uses the SIMPLS algorithm, first centering X and Y by subtracting off column means to get centered variables X0 and Y0.

However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize `X` and `Y`.

If `ncomp` is omitted, its default value is `min(size(X,1)-1,size(X,2))`.

The relationships between the scores, loadings, and centered variables `X0` and `Y0` are:

$$XL = (XS \setminus X0)' = X0' * XS,$$

$$YL = (XS \setminus Y0)' = Y0' * XS,$$

`XL` and `YL` are the coefficients from regressing `X0` and `Y0` on `XS`, and `XS*XL'` and `XS*YL'` are the PLS approximations to `X0` and `Y0`.

`plsregress` initially computes `YS` as:

$$YS = Y0 * YL = Y0 * Y0' * XS,$$

By convention, however, `plsregress` then orthogonalizes each column of `YS` with respect to preceding columns of `XS`, so that `XS' * YS` is lower triangular.

`[XL, YL, XS, YS, BETA] = PLSREGRESS(X, Y, ncomp, ...)` returns the PLS regression coefficients `BETA`. `BETA` is a  $(p+1)$ -by- $m$  matrix, containing intercept terms in the first row:

$$Y = [\text{ones}(n,1), X] * BETA + Y_{\text{residuals}},$$

`Y0 = X0 * BETA(2:end, :) + Y_{\text{residuals}}`. Here `Y_{\text{residuals}}` is the vector of response residuals.

`[XL, YL, XS, YS, BETA, PCTVAR] = plsregress(X, Y, ncomp)` returns a 2-by-`ncomp` matrix `PCTVAR` containing the percentage of variance explained by the model. The first row of `PCTVAR` contains the percentage of variance explained in `X` by each PLS component, and the second row contains the percentage of variance explained in `Y`.

`[XL, YL, XS, YS, BETA, PCTVAR, MSE] = plsregress(X, Y, ncomp)` returns a 2-by- $(ncomp+1)$  matrix `MSE` containing estimated mean-squared errors for PLS models with 0:`ncomp` components. The first row of `MSE` contains mean-squared errors for the predictor variables in `X`, and the second row contains mean-squared errors for the response variable(s) in `Y`.

# plsregress

[XL,YL,XS,YS,BETA,PCTVAR,MSE] =  
 plsregress(...,param1,val1,param2, val2,...) specifies optional parameter name/value pairs from the following table to control the calculation of MSE.

Parameter	Value
'cv'	<p>The method used to compute MSE.</p> <ul style="list-style-type: none"> <li>• When the value is a positive integer <i>k</i>, plsregress uses <i>k</i>-fold cross-validation.</li> <li>• When the value is an object of the <code>cvpartition</code> class, other forms of cross-validation can be specified.</li> <li>• When the value is 'resubstitution', plsregress uses <i>X</i> and <i>Y</i> both to fit the model and to estimate the mean-squared errors, without cross-validation.</li> </ul> <p>The default is 'resubstitution'.</p>
'mcreps'	<p>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution'.</p>
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> <li>• <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li>• <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</li> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, plsregress uses the default stream.</li> </ul>

```
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] =  
PLSREGRESS(X,Y,ncomp,...) returns a structure stats with the  
following fields:
```

- **W** — A  $p$ -by- $ncomp$  matrix of PLS weights so that  $XS = X0*W$ .
- **T2** — The  $T^2$  statistic for each point in  $XS$ .
- **Xresiduals** — The predictor residuals, that is,  $X0-XS*XL'$ .
- **Yresiduals** — The response residuals, that is,  $Y0-XS*YL'$ .

## Examples

### Perform Partial Least-Squares Regression

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings.

```
load spectra  
X = NIR;  
y = octane;
```

Perform PLS regression with ten components.

```
[XL,y1,XS,YS,beta,PCTVAR] = plsregress(X,y,10);
```

Plot the percent of variance explained in the response variable as a function of the number of components.

```
plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');  
xlabel('Number of PLS components');  
ylabel('Percent Variance Explained in y');
```

# plsregress

---

Compute the fitted response and display the residuals.

```
yfit = [ones(size(X,1),1) X]*beta;  
residuals = y - yfit;  
stem(residuals)  
xlabel('Observation');  
ylabel('Residual');
```

# plsregress

---

## See Also

[regress](#) | [sequentialfs](#)

**Purpose**

Point generation method

**Description**

The `PointOrder` property contains a string that specifies the order in which the Sobol sequence points are produced. The property value must be one of 'standard' or 'graycode'. When set to 'standard' the points produced match the original Sobol sequence implementation. When set to 'graycode', the sequence is generated using an implementation that uses the Gray code of the index instead of the index itself.

# grandstream.PointSet property

---

**Purpose** Point set from which stream is drawn

**Description** The PointSet property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

## Examples

```
Q = grandstream('sobol', 5, 'Skip', 8);  
% Create a new stream based on the same sequence as that in Q  
Q2 = grandstream(Q.PointSet);  
u1 = qrnd(Q, 10)  
u2 = qrnd(Q2, 10) % contains exactly the same values as u1
```

**Purpose** Poisson cumulative distribution function

**Syntax**  
`p = poisscdf(x,lambda)`  
`p = poisscdf(x,lambda,'upper')`

**Description** `p = poisscdf(x,lambda)` returns the Poisson cdf at each value in `x` using the corresponding mean parameters in `lambda`. `x` and `lambda` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must be positive.

`p = poisscdf(x,lambda,'upper')` returns the complement of the Poisson cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Poisson cdf is

$$p = F(x | \lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!}$$

## Examples **Compute Poisson Distribution cdf**

For example, consider a Quality Assurance department that performs random tests of individual hard disks. Their policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. What is the probability of shutting down the process if the mean number of bad sectors ( $\lambda$ ) is two?

```
probability = 1-poisscdf(4,2)
```

```
probability =  
0.0527
```

About 5% of the time, a normally functioning manufacturing process produces more than four flaws on a hard disk.

# poisscdf

---

Suppose the average number of flaws ( $\lambda$ ) increases to four. What is the probability of finding fewer than five flaws on a hard drive?

```
probability = poisscdf(4,4)
```

```
probability =  
    0.6288
```

This means that this faulty manufacturing process continues to operate after this first inspection almost 63% of the time.

## How To

- “Poisson Distribution” on page B-130

**Purpose**

Poisson parameter estimates

**Syntax**

```
lambdahat = poissfit(data)
[lambdahat,lambdaci] = poissfit(data)
[lambdahat,lambdaci] = poissfit(data,alpha)
```

**Description**

`lambdahat = poissfit(data)` returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution,  $\lambda$ , given the data `data`.

`[lambdahat,lambdaci] = poissfit(data)` also gives 95% confidence intervals in `lambdaci`.

`[lambdahat,lambdaci] = poissfit(data,alpha)` gives  $100(1 - \alpha)\%$  confidence intervals. For example `alpha = 0.001` yields 99.9% confidence intervals.

The sample mean is the MLE of  $\lambda$ .

$$\hat{\lambda} = \frac{1}{n} \sum_{i=1}^n x_i$$

**Examples**

```
r = poissrnd(5,10,2);
[l,lci] = poissfit(r)
l =
    7.4000    6.3000
lci =
    5.8000    4.8000
    9.1000    7.9000
```

**See Also**

`mle` | `poisspdf` | `poisscdf` | `poissinv` | `poisstat` | `poissrnd`

**How To**

- “Poisson Distribution” on page B-130

# poissinv

---

**Purpose** Poisson inverse cumulative distribution function

**Syntax** `X = poissinv(P,lambda)`

**Description** `X = poissinv(P,lambda)` returns the smallest value  $X$  such that the Poisson cdf evaluated at  $X$  equals or exceeds  $P$ , using mean parameters in `lambda`.  $P$  and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

**Examples** If the average number of defects ( $\lambda$ ) is two, what is the 95th percentile of the number of defects?

```
poissinv(0.95,2)
ans =
     5
```

What is the median number of defects?

```
median_defects = poissinv(0.50,2)
median_defects =
     2
```

**How To** • “Poisson Distribution” on page B-130

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Poisson probability distribution object

**Description** `prob.PoissonDistribution` is an object consisting of parameters, a model description, and sample data for a Poisson probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Poisson')` creates a Poisson probability distribution object using the default parameter values.

`pd = makedist('Poisson','lambda',lambda)` creates a Poisson distribution object using the specified parameter value.

## Input Arguments

### lambda - Mean

1 (default) | nonnegative scalar value

Mean of the Poisson distribution, specified as a nonnegative scalar value.

### Data Types

single | double

## Properties

### lambda - Mean

nonnegative scalar value

Mean of the Poisson distribution, stored as a nonnegative scalar value.

### Data Types

single | double

### DistributionName - Probability distribution name

probability distribution name string

# prob.PoissonDistribution

---

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

### **Data Types**

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

### **Data Types**

char

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

# prob.PoissonDistribution

---

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object

random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Poisson Distribution

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.

Parameter	Description	Support
lambda	Mean	$\lambda \geq 0$

The probability density function of the Poisson distribution is

# prob.PoissonDistribution

---

$$f(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda} \quad ; \quad x = 0, 1, 2, \dots, \infty.$$

## Examples

### Create a Poisson Distribution Object Using Default Parameters

Create a Poisson distribution object using the default parameter values.

```
pd = makedist('Poisson')
```

```
pd =
```

```
PoissonDistribution
```

```
Poisson distribution  
lambda = 1
```

### Create a Poisson Distribution Object Using Specified Parameters

Create a Poisson distribution object by specifying the parameter values.

```
pd = makedist('Poisson','lambda',5)
```

```
pd =
```

```
PoissonDistribution
```

```
Poisson distribution  
lambda = 5
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =
```

```
5
```

For the Poisson distribution, both the mean and variance are equal to the parameter lambda.

- Class Attributes
- Property Attributes

# poisspdf

---

**Purpose** Poisson probability density function

**Syntax** `Y = poisspdf(X,lambda)`

**Description** `Y = poisspdf(X,lambda)` computes the Poisson pdf at each of the values in `X` using mean parameters in `lambda`. `X` and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `lambda` must all be positive.

The Poisson pdf is

$$f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty.$$

The density function is zero unless  $x$  is an integer.

## Examples

A computer hard disk manufacturer has observed that flaws occur randomly in the manufacturing process at the average rate of two flaws in a 4 GB hard disk and has found this rate to be acceptable. What is the probability that a disk will be manufactured with no defects?

In this problem,  $\lambda = 2$  and  $x = 0$ .

```
p = poisspdf(0,2)
p =
    0.1353
```

<b>How To</b>	• “Poisson Distribution” on page B-130

# poisstat

---

**Purpose** Poisson mean and variance

**Syntax** `M = poisstat(lambda)`  
`[M,V] = poisstat(lambda)`

**Description** `M = poisstat(lambda)` returns the mean of the Poisson distribution using mean parameters in `lambda`. The size of `M` is the size of `lambda`.  
`[M,V] = poisstat(lambda)` also returns the variance `V` of the Poisson distribution.  
For the Poisson distribution with parameter  $\lambda$ , both the mean and variance are equal to  $\lambda$ .

**Examples** Find the mean and variance for the Poisson distribution with  $\lambda = 2$ .

```
[m,v] = poisstat([1 2; 3 4])  
m =  
    1    2  
    3    4  
v =  
    1    2  
    3    4
```

**See Also** `poisspdf` | `poisscdf` | `poissinv` | `poissfit` | `poissrnd`

**How To** • “Poisson Distribution” on page B-130

**Purpose** Polynomial confidence intervals

**Syntax**

```
Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)
```

**Description**

`Y = polyconf(p,X)` evaluates the polynomial `p` at the values in `X`. `p` is a vector of coefficients in descending powers.

`[Y,DELTA] = polyconf(p,X,S)` takes outputs `p` and `S` from `polyfit` and generates 95% prediction intervals `Y - DELTA` for new observations at the values in `X`.

`[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs chosen from the following list.

Parameter	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 * (1 - \text{alpha})\%$ . The default is 0.05.
'mu'	A two-element vector containing centering and scaling parameters. With this option, <code>polyconf</code> uses $(X - \text{mu}(1)) / \text{mu}(2)$ in place of <code>X</code> .
'predopt'	Either 'observation' (the default) to compute prediction intervals for new observations at the values in <code>X</code> , or 'curve' to compute confidence intervals for the fit evaluated at the values in <code>X</code> . See below.
'simopt'	Either 'off' (the default) for nonsimultaneous bounds, or 'on' for simultaneous bounds. See below.

The 'predopt' and 'simopt' parameters can be understood in terms of the following functions:

- $p(x)$  — the unknown mean function estimated by the fit
- $l(x)$  — the lower confidence bound

- $u(x)$  — the upper confidence bound

Suppose you make a new observation  $y_{n+1}$  at  $x_{n+1}$ , so that

$$y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}$$

By default, the interval  $[l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]$  is a 95% confidence bound on  $y_{n+1}(x_{n+1})$ .

The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.

'simopt'	'predopt'	Bounded Quantity
'off'	'observation'	$y_{n+1}(x_{n+1})$ (default)
'off'	'curve'	$p(x_{n+1})$
'on'	'observation'	$y_{n+1}(x)$ , for all $x$
'on'	'curve'	$p(x)$ , for all $x$

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors  $x$ .

## Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector `p` into a string for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

---

**Note** Statistics Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder (`matlabroot`). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add the subdirectory to the MATLAB path (`addpath`) or make the subdirectory your current working folder (`cd`).

---

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```
xdata = -5:5;
ydata = xdata.^2 - 5*xdata - 3 + 5*randn(size(xdata));

degree = 2; % Degree of the fit
alpha = 0.05; % Significance level

% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the
% data.
r = roots(p)'; % Roots as a row vector.
real_r = r(imag(r) == 0); % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);
```

```

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
    'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
hroots = plot(real_r,zeros(size(real_r)),...
    'bo','MarkerSize',5,...
    'LineWidth',2,...
    'MarkerFaceColor','b');

grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])

% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')

% Display the polynomial fit and the real roots.
approx_p = round(100*p)/100; % Round for display.
htitle = title(['{\bf Fit:   }',...
    texlabel(polystr(approx_p))]);
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100; % Round for display.
hxlabel = xlabel(['{\bf Real Roots:   }',...
    num2str(approx_real_r)]);
set(hxlabel,'Color','b')

% Add a legend.
legend([hdata,hfit,hroots,hconf],...
    'Data','Fit','Real Roots of Fit',...

```

# polyconf

'95% Prediction Intervals')

Fit:  $0.81x^2 - 4.51x - 1.19$

## See Also

[polyfit](#) | [polyval](#) | [polytool](#)

**Purpose** Interactive polynomial fitting

**Syntax**

```
polytool
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)
```

**Description**

`polytool`

`polytool(x,y)` fits a line to the vectors `x` and `y` and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

`polytool(x,y,n)` initially fits a polynomial of degree `n`. The default is 1, which produces a linear fit.

`polytool(x,y,n,alpha)` initially plots  $100(1 - \alpha)\%$  confidence intervals on the predicted values. The default is 0.05 which results in 95% confidence intervals.

`polytool(x,y,n,alpha,xname,yname)` labels the `x` and `y` values on the graphical interface using the strings `xname` and `yname`. Specify `n` and `alpha` as `[]` to use their default values.

`h = polytool(...)` outputs a vector of handles, `h`, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

## Examples **Interactive polynomial fitting**

This example shows how to start an interactive fitting session with `polytool`.

Generate data from a quadratic curve with added noise.

```
rng('default') % for reproducibility
x = -5:5;
```

# polytool

```
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with 0.90 confidence intervals.

```
n = 2;  
alpha = 0.1;  
polytool(x,y,n,alpha)
```

**See Also** [polyfit](#) | [polyval](#) | [polyconf](#) | [invpred](#)

## Purpose

Posterior probabilities of components

## Syntax

```
P = posterior(obj,X)
[P,nlogl] = posterior(obj,X)
```

## Description

`P = posterior(obj,X)` returns the posterior probabilities of each of the  $k$  components in the Gaussian mixture distribution defined by `obj` for each observation in the data matrix `X`. `X` is  $n$ -by- $d$ , where  $n$  is the number of observations and  $d$  is the dimension of the data. `obj` is an object created by `gmdistribution` or `fitgmdist`. `P` is  $n$ -by- $k$ , with `P(I,J)` the probability of component `J` given observation `I`.

`posterior` treats NaN values as missing data. Rows of `X` with NaN values are excluded from the computation.

`[P,nlogl] = posterior(obj,X)` also returns `nlogl`, the negative log-likelihood of the data.

## Examples

### Compute Posterior Probabilities for Gaussian Mixture Variates

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function.

```
MU1 = [2 2];
SIGMA1 = [2 0; 0 1];
MU2 = [-2 -1];
SIGMA2 = [1 0; 0 1];
rng(1); % For reproducibility
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];

scatter(X(:,1),X(:,2),10,'.')
hold on
```

# gmdistribution.posterior

---

Fit a two-component Gaussian mixture model.

```
obj = fitgmdist(X,2);  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Compute posterior probabilities of the components.

```
P = posterior(obj,X);  
  
delete(h)  
scatter(X(:,1),X(:,2),10,P(:,1))  
hb = colorbar;  
ylabel(hb,'Component 1 Probability')
```

# gmdistribution.posterior

**See Also** `gmdistribution` | `fitgmdist` | `cluster` | `mahal`

## Purpose

Compute posterior probability of each class for test data

## Syntax

```
post = posterior(nb,test)
[post,cpre] = posterior(nb,test)
[post,cpre,logp] = posterior(nb,test)
[...] = posterior(..., 'HandleMissing',val)
```

## Description

`post = posterior(nb,test)` returns the posterior probability of the observations in `test` according to the `NaiveBayes` object `nb`. `test` is a `N-by-nb.ndims` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `post` is a `N-by-nb.nclasses` matrix containing the posterior probability of each observation for each class. `post(i,j)` is the posterior probability of point `I` belonging to class `j`. Classes are ordered the same as `nb.clevels`, i.e., column `j` of `post` corresponds to the `j`th class in `nb.clevels`. The posterior probabilities corresponding to any empty classes are `NaN`.

`[post,cpre] = posterior(nb,test)` returns `cpre`, an `N-by-1` vector, containing the class to which each row of `test` has been assigned. `cpre` has the same type as `nb.CLevels`.

`[post,cpre,logp] = posterior(nb,test)` returns `logp`, an `N-by-1` vector containing estimates of the log of the probability density function (PDF). `logp(i)` is the log of the PDF of point `i`. The PDF value of point `i` is the sum of  $\text{Prob}(\text{point } I \mid \text{class } J) * \text{Pr}\{\text{class } J\}$  taken over all classes.

`[...] = posterior(..., 'HandleMissing',val)` specifies how `posterior` treats `NaN` (missing values). `val` can be one of the following:

# NaiveBayes.posterior

---

'off' (default)	Observations with NaN in any of the columns are not classified into any class. The corresponding rows in <code>post</code> and <code>logp</code> are NaN. The corresponding rows in <code>cpre</code> are NaN (if <code>obj.clevels</code> is numeric or logical), empty strings (if <code>obj.clevels</code> is char or cell array of strings) or (if <code>obj.clevels</code> is categorical).
'on'	For observations having NaN in some (but not all) columns, <code>post</code> and <code>cpre</code> are computed using the columns with non-NaN values. Corresponding <code>logp</code> values are NaN.

## Data Types

double | single

## dim - Dimension

1 (default) | positive integer

Dimension along which the percentiles of  $X$  are required, specified as a positive integer. For example, for a matrix  $X$ , when  $\text{dim} = 1$ , `prctile` returns the quantile(s) of the columns of  $X$  and when  $\text{dim} = 2$ , `prctile` returns the quantile(s) of the rows of  $X$ . For a multidimensional array  $X$ , the length of the  $\text{dim}$ th dimension of  $Y$  is equal to the length of  $p$ .

## Data Types

double

## Output Arguments

### Y - Percentiles

scalar | array

Percentiles of a data vector or array, specified as a scalar or array for one or more percentage values.

- If  $X$  is a vector, then  $Y$  is a scalar or a vector with the same length as the number of percentiles required (`length(p)`).  $Y(i)$  contains the  $p(i)$ th percentile.
- If  $X$  is a matrix, then  $Y$  is a vector or a matrix with the length of the  $\text{dim}$ th dimension equal to the number percentiles required (`length(p)`). When  $\text{dim} = 1$ , for example, the  $i$ th row of  $Y$  contains the  $p(i)$ th percentiles of columns of  $X$ .
- If  $X$  is an array of dimension  $d$ , then  $Y$  is an array with the length of the  $\text{dim}$ th dimension equal to the number of percentiles required (`length(p)`).

## Definitions

### Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if  $X$  is a 1-by-3-by-4 array, then  $X$  is a 3-D array.

## Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X.

## Linear Interpolation

Linear interpolation uses linear polynomials to find  $y_i = f(x_i)$ , the values of the underlying function  $Y = f(X)$  at the points in the vector or array  $x$ . Given the data points  $(x_1, y_1)$  and  $(x_2, y_2)$ , where  $y_1 = f(x_1)$  and  $y_2 = f(x_2)$ , linear interpolation finds  $y = f(x)$  for a given  $x$  between  $x_1$  and  $x_2$  as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the  $100(1.5/n)$ th percentile is  $y_{1.5/n}$  and the  $100(2.5/n)$ th percentile is  $y_{2.5/n}$ , then linear interpolation finds the  $100(2.3/n)$ th percentile,  $y_{2.3/n}$  as:

$$\frac{y_{2.3}}{n} = \frac{y_{1.5}}{n} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)} \left(\frac{y_{2.5}}{n} - \frac{y_{1.5}}{n}\right).$$

## Algorithms

For an  $n$ -element vector X, prctile returns percentiles as follows:

- 1 The sorted values in X are taken as the  $100(0.5/n)$ th,  $100(1.5/n)$ th, ...,  $100([n - 0.5]/n)$ th percentiles. For example:
  - For a data vector of five elements such as {6, 3, 2, 10, 1}, the sorted elements {1, 2, 3, 6, 10} respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
  - For a data vector of six elements such as {6, 3, 2, 10, 8, 1}, the sorted elements {1, 2, 3, 6, 8, 10} respectively correspond to the

(50/6)th, (150/6)th, (250/6)th, (350/6)th, (450/6)th, and (550/6)th percentiles.

- 2** `prctile` uses linear interpolation to compute percentiles for percentages between  $100(0.5/n)$  and  $100([n - 0.5]/n)$ .
- 3** `prctile` assigns the minimum or maximum values in `X` to the percentiles corresponding to the percentages outside that range.

`prctile` treats NaNs as missing values and removes them.

## Examples

### Percentiles of a Data Vector

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x =
    6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328
```

Calculate the 42nd percentile.

```
Y = prctile(X,42)
```

```
Y =
    5.6709
```

### Percentiles of a Data Matrix

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

```
X = (1:5)'*(2:6)
```

```
X =
```

2	3	4	5	6
4	6	8	10	12
6	9	12	15	18
8	12	16	20	24
10	15	20	25	30

Calculate the 25th, 50th, and 75th percentiles along the columns of X.

```
Y = prctile(X,[25 50 75],1)
```

```
Y =
    3.5000    5.2500    7.0000    8.7500   10.5000
    6.0000    9.0000   12.0000   15.0000   18.0000
    8.5000   12.7500   17.0000   21.2500   25.5000
```

The rows of Y correspond to the percentiles of columns of X. For example, the 25th, 50th, and 75th percentiles of the third column of X with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. `Y = prctile(X,[25 50 75])` returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of X.

```
Y = prctile(X,[25 50 75],2)
```

```
Y =
    2.7500    4.0000    5.2500
    5.5000    8.0000   10.5000
    8.2500   12.0000   15.7500
   11.0000   16.0000   21.0000
   13.7500   20.0000   26.2500
```

The rows of Y correspond to the percentiles of rows of X. For example, the 25th, 50th, and 75th percentiles of the first row of X with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

---

## **Concepts**

- “Quantiles and Percentiles” on page 3-7

## Purpose

Predict  $k$ -nearest neighbor classification

## Syntax

```
label = predict(md1,Xnew)
[label,score] = predict(md1,Xnew)
[label,score,cost] = predict(md1,Xnew)
```

## Description

`label = predict(md1,Xnew)` returns a vector of predicted class labels for a matrix `Xnew`, based on `md1`, a `ClassificationKNN` model.

`[label,score] = predict(md1,Xnew)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label,score,cost] = predict(md1,Xnew)` returns a matrix of costs; `label` is the vector of minimal costs for each row of `cost`

## Input Arguments

### **md1 - Classifier model**

classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `md1` is of class `ClassificationKNN`, and you can use the `predict` method to make predictions.

### **Xnew - Prediction points**

matrix

Points at which `md1` predicts classifications. Each row of `Xnew` is one point. The number of columns in `Xnew` must equal the number of predictors in `md1`.

# ClassificationKNN.predict

---

## Output Arguments

### label

Predicted class labels for the points in  $X_{\text{new}}$ , a vector with length equal to the number of rows of  $X_{\text{new}}$ . The label is the class with minimal expected cost. See “Predicted Class Label” on page 21-2996.

### score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in  $X_{\text{new}}$ , and K is the number of classes (in `mdl.ClassNames`). `score(i, j)` is the posterior probability that row  $i$  of  $X_{\text{new}}$  is of class  $j$ . See “Posterior Probability” on page 21-2997.

### cost

Matrix of expected costs of size N-by-K, where N is the number of observations (rows) in  $X_{\text{new}}$ , and K is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row  $i$  of  $X$  as class  $j$ . See “Expected Cost” on page 21-2998.

## Definitions

### Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k | x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y | k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

## Posterior Probability

For a vector (single query point)  $X_{\text{new}}$  and model  $\text{mdl}$ , let:

- $K$  be the number of nearest neighbors used in prediction,  $\text{mdl.NumNeighbors}$
- $\text{nbrd}(\text{mdl}, X_{\text{new}})$  be the  $K$  nearest neighbors to  $X_{\text{new}}$  in  $\text{mdl.X}$
- $Y(\text{nbrd})$  be the classifications of the points in  $\text{nbrd}(\text{mdl}, X_{\text{new}})$ , namely  $\text{mdl.Y}(\text{nbrd})$
- $W(\text{nbrd})$  be the weights of the points in  $\text{nbrd}(\text{mdl}, X_{\text{new}})$
- $\text{prior}$  be the priors of the classes in  $\text{mdl.Y}$

If there is a vector of prior probabilities, then the observation weights  $W$  are normalized by class to sum to the priors. This might involve a calculation for the point  $X_{\text{new}}$ , because weights can depend on the distance from  $X_{\text{new}}$  to the points in  $\text{mdl.X}$ .

The posterior probability  $p(j | X_{\text{new}})$  is

$$p(j | X_{\text{new}}) = \frac{\sum_{i \in \text{nbrd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \text{nbrd}} W(i)}.$$

Here,  $1_{Y(X(i)=j)}$  means 1 when  $\text{mdl.Y}(i) = j$ , and 0 otherwise.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i, j)` is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default, `Cost(i, j)=1` if  $i \neq j$ , and `Cost(i, j)=0` if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

# ClassificationKNN.predict

---

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs`-by-`K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### KNN Classification Predictions

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ . Evaluate some model predictions on new data.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.

```
Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)
```

```
label =
    'setosa'
    'versicolor'
    'virginica'
```

```
score =
    1     0     0
    0     1     0
    0     0     1
```

```
cost =
    0     1     1
    1     0     1
    1     1     0
```

The classifications have binary values for the score and cost matrices, meaning all five nearest neighbors of each of the three points have identical classifications.

# CompactClassificationDiscriminant.predict

---

obj.ClassNames). score(i, j) is the posterior probability that row i of X is of class j; see “Posterior Probability” on page 21-3002.

## cost

Matrix of expected costs of size N-by-K. cost(i, j) is the cost of classifying row i of X as class j. See “Cost” on page 21-3003.

## Definitions

### Posterior Probability

The posterior probability that a point  $z$  belongs to class  $j$  is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean  $\mu_j$  and covariance  $\Sigma_j$  at a point  $z$  is

$$P(x | k) = \frac{1}{(2\pi |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

Let  $P(k)$  represent the prior probability of class  $k$ . Then the posterior probability that an observation  $x$  is of class  $k$  is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where  $P(x)$  is a normalization constant, the sum over  $k$  of  $P(x | k)P(k)$ .

### Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class  $k$  is one over the total number of classes.
- 'empirical' — The prior probability of class  $k$  is the number of training samples of class  $k$  divided by the total number of training samples.

- Custom — The prior probability of class  $k$  is the  $k$ th element of the prior vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

## Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k|x) C(y|k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k|x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y|k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

## Examples

Examine predictions for a few rows in the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
X = meas(99:102,:); % take four rows
```

# CompactClassificationDiscriminant.predict

---

```
[label score cost] = predict(obj,X)

label =
    'versicolor'
    'versicolor'
    'virginica'
    'virginica'

score =
    0.0000    1.0000    0.0000
    0.0000    0.9999    0.0001
    0.0000    0.0000    1.0000
    0.0000    0.0011    0.9989

cost =
    1.0000    0.0000    1.0000
    1.0000    0.0001    0.9999
    1.0000    1.0000    0.0000
    1.0000    0.9989    0.0011
```

## How To

- “Discriminant Analysis” on page 15-3

# CompactClassificationEnsemble.predict

---

## Purpose

Predict classification

## Syntax

```
labels = predict(ens,X)
[labels,score] = predict(ens,X)
[labels,...] = predict(ens,X,Name,Value)
```

## Description

`labels = predict(ens,X)` returns a vector of predicted class labels for a matrix `X`, based on `ens`, a trained full or compact classification ensemble.

`[labels,score] = predict(ens,X)` also returns scores for all classes.

`[labels,...] = predict(ens,X,Name,Value)` predicts classifications with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A classification ensemble created by `fitensemble`, or a compact classification ensemble created by `compact`.

### **X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `ens`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners `predict` uses for computation of responses, a numeric vector.

# CompactClassificationEnsemble.predict

---

**Default:**  $1:T$ , where  $T$  is the number of weak learners in `ens`

## 'UseObsForLearner'

A logical matrix of size  $N$ -by- $T$ , where:

- $N$  is the number of rows of  $X$ .
- $T$  is the number of weak learners in `ens`.

When `UseObsForLearner(i, j)` is `true`, learner  $j$  is used in predicting the class of row  $i$  of  $X$ .

**Default:** `true(N, T)`

## Output Arguments

### labels

Vector of classification labels. `labels` has the same data type as the labels used in training `ens`.

### score

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

## Definitions

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Train a boosting ensemble for the ionosphere data, and predict the classification of the mean of the data:

```
load ionosphere;
ada = fitensemble(X,Y,'AdaBoostM1',100,'tree');
Xbar = mean(X);
[ypredict score] = predict(ada,Xbar)

ypredict =
    'g'

score =
    -2.9460    2.9460
```

## See Also

[margin](#) | [edge](#) | [loss](#)

# CompactClassificationSVM.predict

---

**Purpose** Predict classification

**Syntax** `label = predict(SVMModel,X)`  
`[label,Score] = predict(SVMModel,X)`

**Description** `label = predict(SVMModel,X)` returns a vector of predicted class labels for predictor data X, based on the trained, full, or compact SVM classifier SVMModel.

`[label,Score] = predict(SVMModel,X)` additionally returns class likelihood measures, i.e., either scores or posterior probabilities.

## Input Arguments

### **SVMModel - SVM classifier**

ClassificationSVM classifier | CompactClassificationSVM classifier

SVM classifier that was trained using `fitcsvm`, specified as a ClassificationSVM or CompactClassificationSVM classifier.

### **X - Predictor data**

matrix of numeric values

Predictor data, specified as a matrix of numeric values.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of X should be the same as the variables that trained the SVMModel classifier.

The length of Y and the number of rows of X must be equal.

If you set 'Standardize', true in `fitcsvm` to train SVMModel, then the software standardizes the columns of X using the corresponding means in SVMModel.Mu and standard deviations in SVMModel.Sigma.

### **Data Types**

double | single

## Output Arguments

### label - Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of strings

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of strings.

label:

- Is the same data type as the observed class labels (Y) that trained `SVMModel`
- Has length equal to the number of rows of X

### Score - Predicted class likelihoods

numeric matrix

Predicted class likelihoods, returned as a numeric matrix.

If the `ScoreTransform` property of `SVMModel` is `none`, then `Score` is a matrix of scores indicating the likelihood that an observation comes from a particular class.

- For one-class learning, `Score` has the same number of rows as X, and one column. The elements are the positive class scores for the corresponding observations.
- For two-class learning, `Score` has the same number of rows as X, and two columns. The elements of the first column of `Score` correspond to the negative class (`SVMModel.ClassNames{1}`) scores. The elements of the second column correspond to the positive class (`SVMModel.ClassNames{2}`) scores for the corresponding observations. If the `ScoreTransform` property of `SVMModel` is not `none`, then `Score` is a matrix of posterior probabilities that an observation comes from a particular class.

### Data Types

double | single

# CompactClassificationSVM.predict

---

## Definitions

### Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

### Posterior Probability

The probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score,  $P(s)$ , that observation  $j$  is in class  $k = \{-1, 1\}$ .

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- $s_j$  is the score of observation  $j$ .
- $+1$  and  $-1$  denote the positive and negative classes, respectively.
- $\pi$  is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters  $A$  and  $B$  are the slope and intercept parameters.

- For one-class learning, the posterior probability is 1 or 0. A posterior probability of 1 indicates that the observation is from the positive class, and 0 indicates that it is not from the positive class.

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population, for each class.

## Examples

### Label Test Sample Observations of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order and standardize the data.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact C
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Label the test sample observations. Display the results for the first 10 observations in the test sample.

# CompactClassificationSVM.predict

---

```
[label,score] = predict(CompactSVMModel,XTest);  
table(YTest(1:10),label(1:10),score(1:10,2), 'VariableNames',...  
      {'TrueLabel','PredictedLabel','Score'})
```

```
ans =
```

TrueLabel	PredictedLabel	Score
'b'	'b'	-1.7177
'g'	'g'	2.0003
'b'	'b'	-9.6841
'g'	'g'	2.5618
'b'	'b'	-1.548
'g'	'g'	2.0984
'b'	'b'	-2.7018
'b'	'b'	-0.66291
'g'	'g'	1.6046
'g'	'g'	1.7731

## Predict Labels and Posterior Probabilities of SVM Classifiers

A goal of classification is to predict labels of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently label new observations using an SVM classifier.

Load the ionosphere data set. Suppose that the last 10 observations become available after training the SVM classifier.

```
load ionosphere
```

```
n = size(X,1);      % Training sample size  
isInds = 1:(n-10); % In-sample indices
```

# CompactClassificationSVM.predict

```
oosInds = (n-9):n; % Out-of-sample indices
```

Train an SVM classifier. It is good practice to standardize the predictors and specify the order of the classes. Conserve memory by reducing the size of the trained SVM classifier.

```
SVMMModel = fitcsvm(X(isInds,:),Y(isInds),'Standardize',true,...  
    'ClassNames',{'b','g'});  
CompactSVMMModel = compact(SVMMModel);  
whos('SVMMModel','CompactSVMMModel')
```

Name	Size	Bytes	Class
CompactSVMMModel	1x1	29562	classreg.learning.classif.CompactClassificationSVM
SVMMModel	1x1	137539	ClassificationSVM

The positive class is 'g'. The CompactClassificationSVM classifier (CompactSVMMModel) uses less space than the ClassificationSVM classifier (SVMMModel) because the latter stores the data.

Estimate the optimal score-to-posterior-probability-transformation function.

```
CompactSVMMModel = fitPosterior(CompactSVMMModel,...  
    X(isInds,:),Y(isInds))
```

```
CompactSVMMModel =
```

```
classreg.learning.classif.CompactClassificationSVM  
    PredictorNames: {1x34 cell}  
    ResponseName: 'Y'  
    ClassNames: {'b' 'g'}  
    ScoreTransform: '@(S)sigmoid(S,-1.968452e+00,3.121267e-01)'  
    Alpha: [88x1 double]  
    Bias: -0.2143  
    KernelParameters: [1x1 struct]
```

# CompactClassificationSVM.predict

---

```
        Mu: [1x34 double]
        Sigma: [1x34 double]
    SupportVectors: [88x34 double]
SupportVectorLabels: [88x1 double]
```

The optimal score transformation function (CompactSVMModel.ScoreTransform) is the sigmoid function because the classes are inseparable.

Predict the out-of-sample labels and positive class posterior probabilities. Since true labels are available, compare them with the predicted labels.

```
[labels,postProbs] = predict(CompactSVMModel,X(oosInds,:));
table(labels,Y(oosInds),postProbs(:,2),'VariableNames',...
      {'TrueLabels','PredictedLabels','PosteriorProbabilities'})
```

ans =

TrueLabels	PredictedLabels	PosteriorProbabilities
'g'	'g'	0.98419
'g'	'g'	0.95545
'g'	'g'	0.67792
'g'	'g'	0.94448
'g'	'g'	0.98744
'g'	'g'	0.92482
'g'	'g'	0.97111
'g'	'g'	0.96986
'g'	'g'	0.97803
'g'	'g'	0.94361

posterior is a 10-by-2 matrix; its first column is the negative class posterior probabilities, and second column is the positive class posterior probabilities corresponding to the new observations.

## Plot Posterior Probability Regions for SVM Classifiers

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species, 'virginica');
X = meas(classKeep,3:4);
y = species(classKeep);
```

Train an SVM classifier using the data. It is good practice to specify the order of the classes.

```
SVMModel = fitcsvm(X,y, 'ClassNames', {'setosa', 'versicolor'});
```

Estimate the optimal score transformation function.

```
rng(1); % For reproducibility
[SVMModel, ScoreParameters] = fitPosterior(SVMModel);
ScoreParameters
```

```
Warning: Classes are perfectly separated. The optimal score-to-posterior
transformation is a step function.
```

```
ScoreParameters =
```

```
                Type: 'step'
        LowerBound: -0.8431
        UpperBound:  0.6897
PositiveClassProbability: 0.5000
```

The optimal score transformation function is the step function because the classes are separable. The fields LowerBound and UpperBound

# CompactClassificationSVM.predict

---

of `ScoreParameters` indicate the lower and upper end points of the interval of scores corresponding to observations within the class-separating hyperplanes (the margin). No training observation falls within the margin. If a new score is in the interval, then the software assigns the corresponding observation a positive class posterior probability, i.e., the value in the `PositiveClassProbability` field of `ScoreParameters`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
h = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):h:xMax(1),xMin(2):h:xMax(2));

[~,PosteriorRegion] = predict(SVMModel,[x1Grid(:),x2Grid(:)]);
```

Plot the positive class posterior probability region and the training data.

```
contourf(x1Grid,x2Grid,...
         reshape(PosteriorRegion(:,2),size(x1Grid,1),size(x1Grid,2)));
h(1) = colorbar;
set(get(h(1),'YLabel'),'String','P({\it versicolor})','FontSize',16);
hold on
gscatter(X(:,1),X(:,2),y,'mc','x',[15,10])
sv = X(SVMModel.IsSupportVector,:);
plot(sv(:,1),sv(:,2),'ro','MarkerSize',15,'LineWidth',2);
axis tight
hold off
```

In two-class learning, if the classes are separable, then there are three regions: one where observations have positive class posterior probability 0, one where it is 1, and the other where it is the positive class prior probability.

## Algorithms

- By default, the software computes optimal posterior probabilities using Platt's method [1]:
  - 1 Performing 10-fold cross validation

# CompactClassificationSVM.predict

---

- 2 Fitting the sigmoid function parameters to the scores returned from the cross validation
  - 3 Estimating the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function
- The software incorporates prior probabilities in the SVM objective function during training.
  - For SVM, `predict` classifies observations into the class yielding the largest score (i.e., the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector  $P$ , misclassification cost matrix  $C$ , and observation weight vector  $w$ , the software defines a new vector of observation weights ( $W$ ) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

## Purpose

Predict classification

## Syntax

```
label = predict(tree,X)
[label,score] = predict(tree,X)
[label,score,node] = predict(tree,X)
[label,score,node,cnum] = predict(tree,X)
[label,...] = predict(tree,X,Name,Value)
```

## Description

`label = predict(tree,X)` returns a vector of predicted class labels for a matrix `X`, based on `tree`, a trained full or compact classification tree.

`[label,score] = predict(tree,X)` returns a matrix of scores, indicating the likelihood that a label comes from a particular class.

`[label,score,node] = predict(tree,X)` returns a vector of predicted node numbers for the classification, based on `tree`.

`[label,score,node,cnum] = predict(tree,X)` returns a vector of predicted class number for the classification, based on `tree`.

`[label,...] = predict(tree,X,Name,Value)` returns labels with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A classification tree created by `fitctree`, or a compact classification tree created by `compact`.

### **X**

A matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `tree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# CompactClassificationTree.predict

---

specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## **'subtrees'**

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the `subtrees` name-value pair, `tree` must include a pruning sequence as created by the `fitctree` or `prune` methods. If `subtrees` has  $T$  elements, and  $X$  has  $N$  rows, then `labels` is an  $N$ -by- $T$  matrix. The  $i$ th column of `labels` contains the fitted values produced by the `subtrees(I)` subtree. Similarly, `score` is an  $N$ -by- $K$ -by- $T$  array, and `node` and `cnum` are  $N$ -by- $T$  matrices. `subtrees` must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use `prune` to prune the tree.)

**Default:** 0

## **Output Arguments**

### **label**

Vector of class labels of the same type as the response data used in training `tree`. Each entry of `label` corresponds to the class with minimal expected cost for the corresponding row of  $X$ . See “Predicted Class Label” on page 21-3021.

### **score**

Numeric matrix of size  $N$ -by- $K$ , where  $N$  is the number of observations (rows) in  $X$ , and  $K$  is the number of classes (in `tree.ClassNames`). `score(i, j)` is the posterior probability that row  $i$  of  $X$  is of class  $j$ .

### **node**

Numeric vector of node numbers for the predicted classes. Each entry corresponds to the predicted node in `tree` for the corresponding row of  $X$ .

### **cnum**

Numeric vector of class numbers corresponding to the predicted labels. Each entry of `cnum` corresponds to a predicted class number for the corresponding row of `X`.

## Definitions

### Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \arg \min_{y=1,\dots,K} \sum_{k=1}^K \hat{P}(k | x) C(y | k),$$

where

- $\hat{y}$  is the predicted classification.
- $K$  is the number of classes.
- $\hat{P}(k | x)$  is the posterior probability of class  $k$  for observation  $x$ .
- $C(y | k)$  is the cost of classifying an observation as  $y$  when its true class is  $k$ .

### Score (tree)

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

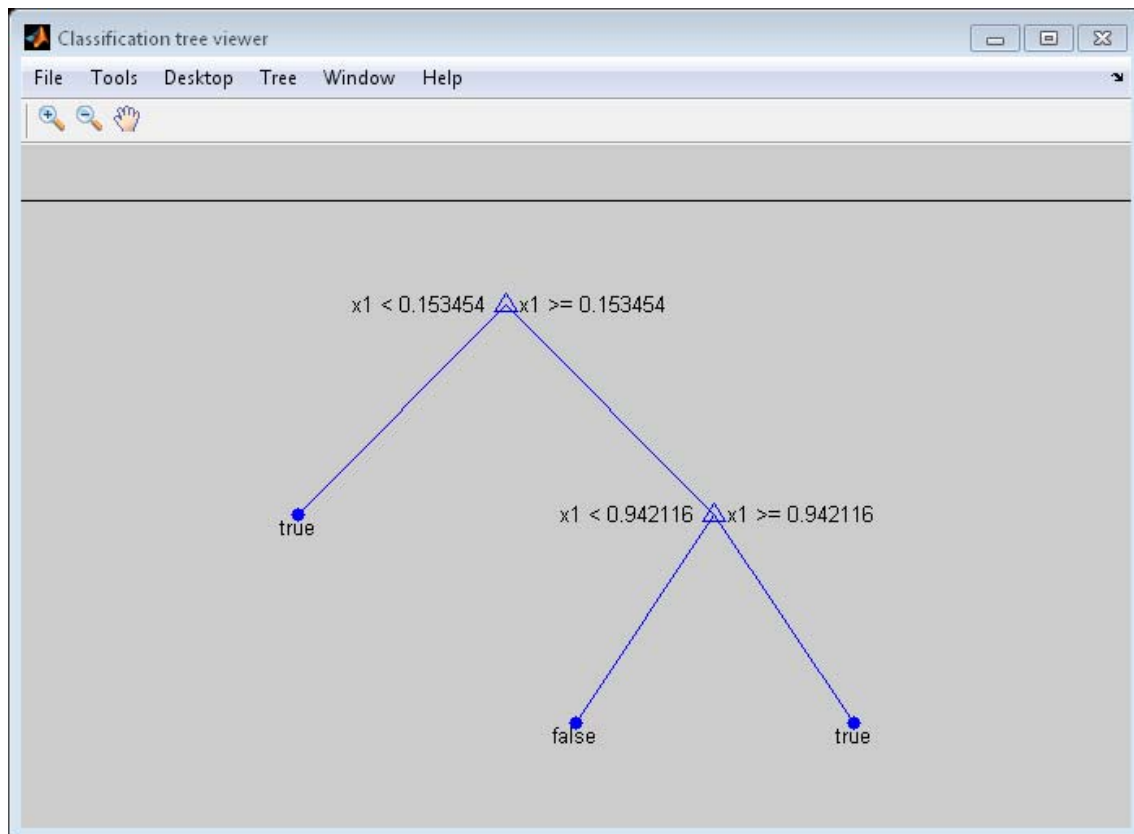

For example, consider classifying a predictor `X` as true when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
```

# CompactClassificationTree.predict

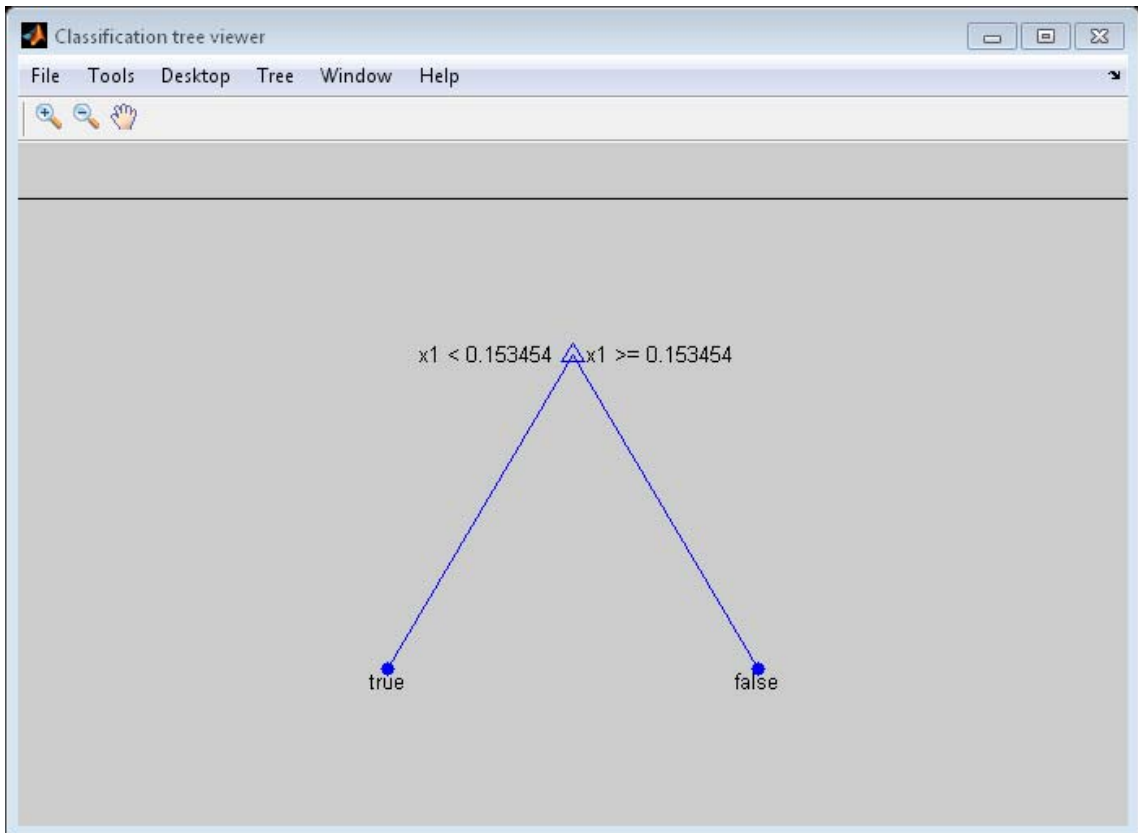

```
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

# CompactClassificationTree.predict

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

# CompactClassificationTree.predict

---

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range (.95, 1) instead of the expected 5 observations.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default, `Cost(i, j)=1` if  $i \neq j$ , and `Cost(i, j)=0` if  $i=j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have  $N_{\text{obs}}$  observations that you want to classify with a trained classifier. Suppose you have  $K$  classes. You place the observations into a matrix  $X_{\text{new}}$  with one observation per row.

The expected cost matrix  $CE$  has size  $N_{\text{obs}}\text{-by-}K$ . Each row of  $CE$  contains the expected (average) cost of classifying the observation into each of the  $K$  classes.  $CE(n, k)$  is

$$\sum_{i=1}^K \hat{P}(i | X_{\text{new}}(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X_{\text{new}}(n))$  is the posterior probability of class  $i$  for observation  $X_{\text{new}}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Predictive Measure of Association

The predictive measure of association between the optimal split on variable  $i$  and a surrogate split on variable  $j$  is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

# CompactClassificationTree.predict

---

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L,L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R,R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

## Examples

Examine predictions for a few rows in the Fisher iris data.

```
load fisheriris
tree = fitctree(meas,species);
X = meas(99:102,:); % take four rows
[label score node cnum] = predict(tree,X)

label =
    'versicolor'
    'versicolor'
    'virginica'
    'virginica'

score =
    0    1.0000         0
    0    1.0000         0
    0    0.0217    0.9783
    0    0.0217    0.9783

node =
    8
    8
    5
    5
```

# CompactClassificationTree.predict

---

```
cnum =  
    2  
    2  
    3  
    3
```

---

Examine predictions from pruned trees for the Fisher iris model.

```
load fisheriris  
tree = fitctree(meas,species);  
X = meas(99:102,:); % taking four rows  
[label score node cnum] = predict(tree,X,'subtrees',[2 3 4])
```

```
label =  
    'versicolor'    'versicolor'    'setosa'  
    'versicolor'    'versicolor'    'setosa'  
    'virginica'     'versicolor'    'setosa'  
    'virginica'     'versicolor'    'setosa'
```

```
score(:,:,1) =  
    0    0.9074    0.0926  
    0    0.9074    0.0926  
    0    0.0217    0.9783  
    0    0.0217    0.9783
```

```
score(:,:,2) =  
    0    0.5000    0.5000  
    0    0.5000    0.5000  
    0    0.5000    0.5000  
    0    0.5000    0.5000
```

```
score(:,:,3) =  
    0.3333    0.3333    0.3333  
    0.3333    0.3333    0.3333  
    0.3333    0.3333    0.3333  
    0.3333    0.3333    0.3333
```

# CompactClassificationTree.predict

---

```
node =
  4   3   1
  4   3   1
  5   3   1
  5   3   1

cnum =
  2   2   1
  2   2   1
  3   2   1
  3   2   1
```

## Algorithms

`predict` generates predictions by following the branches of tree until it reaches a leaf node or a missing value. If `predict` reaches a leaf node, it returns the classification of that node.

If `predict` reaches a node with a missing value for a predictor, its behavior depends on the setting of the `Surrogate` name-value pair when `fitctree` constructs `tree`.

- **Surrogate = 'off'** (default) — `predict` returns the label with the largest number of training samples that reach the node.
- **Surrogate = 'on'** — `predict` uses the best surrogate split at the node. If all surrogate split variables with positive *predictive measure of association* are missing, `predict` returns the label with the largest number of training samples that reach the node. For a definition, see “Predictive Measure of Association” on page 21-3025.

# CompactRegressionEnsemble.predict

---

## Purpose

Predict response of ensemble

## Syntax

```
Yfit = predict(ens,Xdata)
Yfit = predict(ens,Xdata,Name,Value)
```

## Description

`Yfit = predict(ens,Xdata)` returns predicted responses to the data in `Xdata`, based on the `ens` regression ensemble model.

`Yfit = predict(ens,Xdata,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

Regression ensemble created by `fitensemble`, or by the compact method.

### **Xdata**

Numeric array with the same number of columns as the array used for creating `ens`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

**Default:** `1:NumTrained`

### **'UseObsForLearner'**

# CompactRegressionEnsemble.predict

---

A logical matrix of size N-by-NumTrained, where N is the number of observations in `ens.X`, and NumTrained is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner J in predicting observation I.

**Default:** `true(N,NumTrained)`

## Output Arguments

### Yfit

A numeric column vector with the same number of rows as `Xdata`. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the `ens` regression model.

## Examples

Find the predicted mileage for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the `carsmall` data:

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
rens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Mileage = predict(rens,[4 200 150 3000])
```

```
Mileage =
    20.4982
```

## See Also

`loss` | `fitensemble`

## Purpose

Predict response of regression tree

## Syntax

```
Yfit = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata)
[Yfit,node] = predict(tree,Xdata,Name,Value)
```

## Description

`Yfit = predict(tree,Xdata)` returns predicted responses to the data in `Xdata`, based on the tree regression tree.

`[Yfit,node] = predict(tree,Xdata)` returns the predicted node numbers of tree in response to `Xdata`.

`[Yfit,node] = predict(tree,Xdata,Name,Value)` predicts response with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

Regression tree created by `fitrtree`, or by the compact method.

### **Xdata**

Numeric array with the same number of columns as the array used for creating `tree`. Each row of `Xdata` corresponds to one data point, and each column corresponds to one predictor.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'subtrees'**

Numeric vector of pruning levels, with 0 representing the full, unpruned tree. To use the `subtrees` name-value pair, `tree` must include a pruning sequence as created by the `fitrtree` or `prune` methods. If `subtrees` has `T` elements, and `X` has `N` rows, then

# CompactRegressionTree.predict

---

`Yfit` is an N-by-T matrix. The *i*th column of `Yfit` contains the fitted values produced by the `subtrees(I)` subtree. Similarly, `node` is an N-by-T matrix. `subtrees` must be sorted in ascending order. (To compute fitted values for a tree that is not part of the optimal pruning sequence, first use `prune` to prune the tree.)

**Default:** 0

## Output Arguments

### `Yfit`

A numeric column vector with the same number of rows as `Xdata`. Each row of `Yfit` gives the predicted response to the corresponding row of `Xdata`, based on the `tree` regression model.

### `node`

Numeric vector of node numbers for the predictions. Each entry corresponds to the predicted leaf node in `tree` for the corresponding row of `Xdata`.

## Examples

Find the predicted mileage for a car with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs, based on the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
Mileage = predict(tree,[200 150 3000])
```

```
Mileage =
    21.9375
```

## See Also

`fitrtree` | `compact` | `loss`

**Purpose** Predict response

**Syntax**

```
YFIT = predict(B,X)
[YFIT,stdevs] = predict(B,X)
[YFIT,scores] = predict(B,X)
[YFIT,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)
```

**Description**

`YFIT = predict(B,X)` computes the predicted response of the trained ensemble `B` for predictors `X`. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble. In `X`, rows represent observations and columns represent variables. `YFIT` is a cell array of strings for classification and a numeric array for regression.

For regression, `[YFIT,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[YFIT,scores] = predict(B,X)` returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[YFIT,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

# CompactTreeBagger.predict

---

'trees'	Array of tree indices to use for computation of responses. Default is 'all'.
'treeweights'	Array of NTrees weights for weighting votes from the specified trees.
'useifort'	Logical matrix of size Nobs-by-NTrees indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

[ClassificationTree.predict](#) | [RegressionTree.predict](#) | [TreeBagger.predict](#)

## Purpose

Predict response of generalized linear regression model

## Syntax

```
ypred = predict mdl, Xnew
[ypred, yci] = predict mdl, Xnew
[ypred, yci] = predict mdl, Xnew, Name, Value
```

## Description

`ypred = predict(mdl, Xnew)` returns the predicted response of the `mdl` generalized linear regression model to the points in `Xnew`.

`[ypred, yci] = predict(mdl, Xnew)` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict(mdl, Xnew, Name, Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

## Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from dataset arrays, try `feval`.

## Input Arguments

### `mdl`

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### `Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding

# GeneralizedLinearModel.predict

---

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'alpha'

Positive scalar from 0 to 1. Confidence level of  $y_{ci}$  is  $100(1 - \alpha)\%$ .

**Default:** 0.05, meaning a 95% confidence interval.

## 'BinomialSize'

Value of the binomial  $n$  parameter for each row in the training data. BinomialSize can be a vector the same length as  $X_{new}$ , or a scalar that applies to each row. The default value 1 produces  $y_{pred}$  values that are predicted proportions. Use BinomialSize only if `mdl` is fit to a binomial distribution.

**Default:** 1

## 'Offset'

Value of the offset for each row in  $X_{new}$ . Offset can be a vector the same length as  $X_{new}$ , or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1. In other words, if  $\mathbf{b}$  is the fitted coefficient vector, and  $\text{link}$  is the link function,

$$\text{link}(y_{pred}) = \text{Offset} + X_{new} * \mathbf{b}.$$

**Default:** `zeros(size(Xnew,1))`

## 'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the

entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

**Default:** `false`

## Output Arguments

### **ypred**

Vector of predicted mean values at `Xnew`.

### **yci**

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

## Examples

### **Generalized Linear Model Predictions**

Create a generalized linear model, and predict its response to new data.

Generate artificial data for the model using Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create points for prediction.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Xnew = [Xtest1(:),Xtest2(:)];
```

Predict responses at the new points.

# GeneralizedLinearModel.predict

---

```
ypred = predict mdl, Xnew;
```

Plot the predictions.

```
surf(Xtest1, Xtest2, reshape(ypred, 9, 9))
```

Create confidence intervals on the predictions.

```
[ypred yci] = predict(mdl, Xnew);
```

## Alternatives

`feval` gives the same predictions, but uses separate input arrays for each predictor, instead of one input array containing all predictors.

`random` predicts with added noise.

GeneralizedLinearModel | random

**Related Examples**

- “predict” on page 10-37
- “Generalized Linear Model Workflow” on page 10-42

**Concepts**

- “Generalized Linear Models” on page 10-12

# LinearModel.predict

---

**Purpose** Predict response of linear regression model

**Syntax**

```
y_pred = predict mdl, X_new
[y_pred, y_ci] = predict mdl, X_new
[y_pred, y_ci] = predict mdl, X_new, Name, Value
```

**Description** `y_pred = predict mdl, X_new` returns the predicted response of the `mdl` linear regression model to the points in `X_new`.

`[y_pred, y_ci] = predict mdl, X_new` returns confidence intervals for the true mean responses.

`[y_pred, y_ci] = predict mdl, X_new, Name, Value` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

**Tips**

- For predictions with added noise, use `random`.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'alpha'

Positive scalar from 0 to 1. Confidence level of  $y_{ci}$  is  $100(1 - \alpha)\%$ .

**Default:** 0.05, meaning a 95% confidence interval.

## 'Prediction'

String specifying the type of prediction:

- 'curve' — predict predicts confidence bounds for the fitted mean values.
- 'observation' — predict predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

**Default:** 'curve'

## 'Simultaneous'

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

**Default:** `false`

## Output Arguments

### `ypred`

Vector of predicted mean values at `Xnew`.

# LinearModel.predict

---

**yci**

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

## Examples

### Predict Response to Data

Create a model of car mileage as a function of weight, and predict the response.

Create a quadratic model of car mileage as a function of weight from the `carsmall` data.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create predicted responses to the data.

```
Xnew = X;
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',Xnew,ypred,'x')
legend('Data','Predictions')
```

## Alternatives

`feval` gives the same predictions, but uses multiple input arrays with one component in each input argument. `feval` can be simpler to use with a model created from a table or dataset array `tbl`. `feval` does not give confidence intervals on its predictions.

`random` predicts with added noise.

- “Linear Regression Workflow” on page 9-45

# LinearModel.predict

---

## How To

- “Linear Regression” on page 9-12

**Purpose** Predict response of linear mixed-effects model

**Syntax**

```
ypred = predict(lme)
ypred = predict(lme,tblnew)
ypred = predict(lme,Xnew,Znew)
ypred = predict(lme,Xnew,Znew,Gnew)
ypred = predict( __ ,Name,Value)
[ypred,ypredCI] = predict( __ )
[ypred,ypredCI,DF] = predict( __ )
```

**Description** `ypred = predict(lme)` returns a vector of conditional predicted responses `ypred` at the original predictors used to fit the linear mixed-effects model `lme`.

`ypred = predict(lme,tblnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `predict` if you use a table or dataset array for fitting the model `lme`.

If a particular grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`ypred = predict(lme,Xnew,Znew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. In this case, the grouping variable `G` is `ones(n,1)`, where  $n$  is the number of observations used in the fit.

Use the matrix format for `predict` if using design matrices for fitting the model `lme`.

# LinearMixedModel.predict

---

`ypred = predict(lme, Xnew, Znew, Gnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

`ypred = predict(___, Name, Value)` returns a vector of predicted responses `ypred` from the fitted linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects.

`[ypred, ypredCI] = predict(___)` also returns confidence intervals `ypredCI` for the predictions `ypred` for any of the input arguments in the previous syntaxes.

`[ypred, ypredCI, DF] = predict(___)` also returns the degrees of freedom `DF` used in computing the confidence intervals for any of the input arguments in the previous syntaxes.

## Input Arguments

### **lme** - Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

### **tblnew** - New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset

array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

## Data Types

single | double | logical | char

## **Xnew - New fixed-effects design matrix**

*n*-by-*p* matrix

New fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of fixed predictor variables. Each row of *X* corresponds to one observation and each column of *X* corresponds to one variable.

## Data Types

single | double

## **Znew - New random-effects design**

*n*-by-*q* matrix | cell array of length *R*

New random-effects design, specified as an *n*-by-*q* matrix or a cell array of *R* design matrices  $Z\{r\}$ , where  $r = 1, 2, \dots, R$ . If *Znew* is a cell array, then each  $Z\{r\}$  is an *n*-by- $q(r)$  matrix, where *n* is the number of observations, and  $q(r)$  is the number of random predictor variables.

## Data Types

single | double | logical | char | cell

## **Gnew - New grouping variable or variables**

vector | cell array of grouping variables of length *R*

New grouping variable or variables, specified as a vector or a cell array, of length *R*, of grouping variables with the same levels or groups as the original grouping variables used to fit the linear mixed-effects model `lme`.

## Data Types

single | double | logical | char | cell

# LinearMixedModel.predict

---

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'Alpha' - Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value  $\alpha$ , the confidence level is  $100*(1-\alpha)\%$ .

For example, for 99% confidence intervals, you can specify the confidence level as follows.

**Example:** `'Alpha', 0.01`

## Data Types

single | double

## 'Conditional' - Indicator for conditional predictions

True (default) | False

Indicator for conditional predictions, specified as the comma-separated pair consisting of `'Conditional'` and one of the following.

True	Contributions from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

**Example:** `'Conditional', 'False'`

## 'DFMethod' - Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom to use in the confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'Residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$ , where $n$ is the number of observations and $p$ is the number of fixed effects.
'Satterthwaite'	Satterthwaite approximation.
'None'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

**Example:** 'DFMethod', 'Satterthwaite'

## 'Simultaneous' - Type of confidence bounds

false (default) | true

Type of confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and one of the following.

false	Default. Nonsimultaneous bounds.
true	Simultaneous bounds.

**Example:** 'Simultaneous', true

## 'Prediction' - Type of prediction

'curve' (default) | 'observation'

Type of prediction, specified as the comma-separated pair consisting of 'Prediction' and one of the following.

# LinearMixedModel.predict

---

'curve'	Default. Confidence bounds apply to the fitted function and do not include any variability associated with a new observation.
'observation'	Variability due to observation error for the new observations is included in the confidence bound calculations.

**Example:** 'Prediction', 'observation'

## Output Arguments

### **ypred - Predicted responses**

vector

Predicted responses, returned as a vector. `ypred` can contain the conditional or marginal responses, depending on the value choice of the 'Conditional' name-value pair argument. Conditional predictions include contributions from both fixed and random effects.

### **ypredCI - Point-wise confidence intervals**

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `yCI` contains the lower bounds, and the second column contains the upper bound. By default, `yCI` contains the 95% confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair argument, make them simultaneous using the `Simultaneous` name-value pair argument, and also make them for a new observation rather than for the curve using the `Prediction` name-value pair argument.

### **DF - Degrees of freedom**

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If the 'Simultaneous' name-value pair argument is false, then DF is a vector.
- If the 'Simultaneous' name-value pair argument is true, then DF is a scalar value.

## Examples

### Predict Responses at the Original Design Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

# LinearMixedModel.predict

---

Predict the response values at the original design values. Display the first five predictions with the observed response values.

```
yhat = predict(lme);  
[yhat(1:5) ds.Yield(1:5)]
```

```
ans =
```

```
    115.4788    104.0000  
    135.1455    136.0000  
    152.8121    158.0000  
    160.4788    174.0000  
     58.0839     57.0000
```

## Plot Predictions vs. Observed Responses

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed effect for Weight, and a random intercept grouped by Model\_Year. First, store the data in a table.

```
tbl = table(MPG,Weight,Model_Year);  
lme = fitlme(tbl,'MPG ~ Weight + (1|Model_Year)');
```

Create predicted responses to the data.

```
yhat = predict(lme,tbl);
```

Plot the original responses and the predicted responses to see how they differ. Group them by model year.

```
figure()  
gscatter(Weight,MPG,Model_Year)  
hold on  
gscatter(Weight,yhat,Model_Year,[],'o+x')  
legend('70-data','76-data','82-data','70-pred','76-pred','82-pred')
```

## Predict Responses at Values in a New Dataset Array

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

# LinearMixedModel.predict

---

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();  
dsnew.Soil = nominal({'Sandy'; 'Silty'});  
dsnew.Tomato = nominal({'Cherry'; 'Vine'});  
dsnew.Fertilizer = nominal([2; 2]);
```

Predict the conditional and marginal responses at the original design points.

```
yhatC = predict(lme, dsnew);  
yhatM = predict(lme, dsnew, 'Conditional', false);
```

```
[yhatC yhatM]
```

```
ans =
```

```
    92.7505    111.6667  
    87.5891     82.6667
```

## Predict Responses at the Values in New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];  
Z = [ones(406,1) Acceleration];  
Model_Year = nominal(Model_Year);  
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...  
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...  
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original

# LinearMixedModel.predict

---

grouping variable in G is the model year. So, Gnew must contain values for the model year. Note that Gnew must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];  
Znew = [1,13.5; 1,17; 1,21.2];  
Gnew = nominal([73 77 82]);
```

Predict the responses for the data in the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat =
```

```
8.7063  
5.4423  
12.5384
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, refit the model.

```
Z = {ones(406,1),Acceleration};  
G = {Model_Year,Model_Year};
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....  
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...  
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, Znew, and the grouping variable design, Gnew, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};  
MY = nominal([73 77 82]);  
Gnew = {MY,MY};
```

Predict the responses using the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat =  
  
    8.6365  
    5.9199  
   12.1247
```

## Compute Confidence Intervals for Predictions

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the variables in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Model_Year);
```

Now, fit the model using `fitlme` with the defined design matrices and grouping variables.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Create the new data and store it in a new table.

```
tblnew = table();  
tblnew.Acceleration = linspace(8,25)';  
tblnew.Horsepower = linspace(nanmin(Horsepower),nanmax(Horsepower))';  
tblnew.Model_Year = repmat(70,100,1);
```

`linspace` creates 100 equally distanced values between the lower and the upper input limits. `Model_Year` is fixed at 70. You can repeat this for any model year.

Compute and plot the predicted values and 95% confidence limits (nonsimultaneous).

```
[ypred,yCI,DF] = predict(lme,tblnew);  
figure();
```

# LinearMixedModel.predict

---

```
h1 = line(tblnew.Acceleration,ypred);
hold on;
h2 = plot(tblnew.Acceleration,yCI,'g-');
```

Display the degrees of freedom.

```
DF(1)
```

```
ans =
```

```
389
```

Compute and plot the simultaneous confidence bounds.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true);
h3 = plot(tblnew.Acceleration,yCI,'r--');
```

Display the degrees of freedom.

```
DF
```

```
DF =
```

```
389
```

Compute the simultaneous confidence bounds using the Satterthwaite method to compute the degrees of freedom.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true,'DFMethod','Satterthwaite');
h4 = plot(tblnew.Acceleration,yCI,'k:');
hold off
xlabel('Acceleration')
ylabel('Response')
ylim([-50,60])
xlim([8,25])
legend([h1,h2(1),h3(1),h4(1)],'Predicted response','95%','95% Sim',...
'95% Sim-Satt','Location','Best')
```

Display the degrees of freedom.

DF

DF =

3.6001

## Definitions

### Conditional and Marginal Predictions

A conditional prediction includes contributions from both fixed and random effects, whereas a marginal model includes contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also, suppose the estimated  $p$ -by-1 fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The predicted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

which corresponds to the 'Conditional', 'true' and 'Prediction', 'curve' name-value pair arguments. The predicted conditional response that also includes observation error is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

which corresponds to the 'Conditional', 'true' and 'Prediction', 'observation' name-value pair arguments.

The predicted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

This corresponds to the 'Conditional', 'false' and 'Prediction', 'curve' name-value pair arguments. The marginal conditional response that also includes observation error is

$$\hat{y}_{Mar} = X\hat{\beta} + \varepsilon,$$

which corresponds to the 'Conditional', 'false' and 'Prediction', 'observation' name-value pair arguments.

When making predictions, if a particular grouping variable has new levels (1s that were not in the original data), then the random effects

for the grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

## See Also

`LinearMixedModel` | `fitted` | `random`

# NaiveBayes.predict

---

**Purpose** Predict class label for test data

**Syntax**  
`cpre = predict(nb,test)`  
`cpre = predict(...,'HandleMissing',val)`

**Description** `cpre = predict(nb,test)` classifies each row of data in `test` into one of the classes according to the `NaiveBayes` classifier `nb`, and returns the predicted class level `cpre`. `test` is an `N`-by-`nb.ndims` matrix, where `N` is the number of observations in the test data. Rows of `test` correspond to points, columns of `test` correspond to features. `cpre` is an `N`-by-1 vector of the same type as `nb.CLevels`, and it indicates the class to which each row of `test` has been assigned.

`cpre = predict(...,'HandleMissing',val)` specifies how `predict` treats NaN (missing values). `val` can be one of the following:

'off'  
(default) Observations with NaN in any of the columns are not classified into any class. The corresponding rows in `post` and `logp` are NaN. The corresponding rows in `cpre` are NaN (if `obj.clevels` is numeric or logical), empty strings (if `obj.clevels` is char or cell array of strings) or `<undefined>` (if `obj.clevels` is categorical).

'on' For observations having NaN in some (but not all) columns, `post` and `predict` computes `cpre` using the columns with non-NaN values. Corresponding `logp` values are NaN.

**See Also** `NaiveBayes` | `fitNaiveBayes` | `posterior`

## Purpose

Predict response of nonlinear regression model

## Syntax

```
ypred = predict mdl,Xnew
[ypred,yci] = predict(mdl,Xnew)
[ypred,yci] = predict(mdl,Xnew,Name,Value)
```

## Description

`ypred = predict(mdl,Xnew)` returns the predicted response of the `mdl` nonlinear regression model to the points in `Xnew`.

`[ypred,yci] = predict(mdl,Xnew)` returns confidence intervals for the true mean responses.

`[ypred,yci] = predict(mdl,Xnew,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

## Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from tables or dataset arrays, try `feval`.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments.

`Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

# NonLinearModel.predict

---

specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## **'alpha'**

Positive scalar from 0 to 1. Confidence level of  $y_{ci}$  is  $100(1 - \text{alpha})\%$ .

**Default:** 0.05, meaning a 95% confidence interval.

## **'Prediction'**

String specifying the type of prediction:

- 'curve' — predict predicts confidence bounds for the fitted mean values.
- 'observation' — predict predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

**Default:** 'curve'

## **'Simultaneous'**

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

**Default:** `false`

## 'Weights'

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in  $X_{new}$ .
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights,  $W$ , `predict` estimates the error variance at observation  $i$  by  $MSE * (1/W(i))$ , where  $MSE$  is the mean squared error.

**Default:** No weights

## Output Arguments

### `ypred`

Vector of predicted mean values at  $X_{new}$ .

### `yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

## Examples

### Predict Responses

Create a nonlinear model of car mileage as a function of weight, and predict the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
```

# NonLinearModel.predict

---

```
beta0 = [1 1 1];  
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the data.

```
Xnew = X;  
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',X,ypred,'x')  
legend('Data','Predicted')
```

## Confidence Intervals for Predictions

Create a nonlinear model of car mileage as a function of weight, and examine confidence intervals of some responses.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the smallest, mean, and largest data points.

```
Xnew = [min(X);mean(X);max(X)];
[ypred,yci] = predict(mdl,Xnew)
```

```
ypred =
    34.9469
    22.6868
    10.0617
```

```
yci =
    32.5212    37.3726
    21.4061    23.9674
    7.0148    13.1086
```

## Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp\{-b_3 x\} + \varepsilon,$$

# NonLinearModel.predict

---

where  $b_1$ ,  $b_2$ , and  $b_3$  are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';  
b0 = [2;2;2];  
mdl = fitnlm(x,y,modelfun,b0,'Options',opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = [min(x):.01:max(x)]';  
[ypred,yci] = predict(mdl,xrange,'Simultaneous',true);
```

```
figure()  
plot(x,y,'ko') % observed data  
hold on  
plot(xrange,ypred,'k','LineWidth',2)  
plot(xrange,yci,'r--','LineWidth',1.5)
```

## Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);  
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights);
```

# NonLinearModel.predict

---

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,yci] = predict mdl,[100,100,100], 'Prediction', 'observation', ...  
                    'Weights', weights)
```

```
ypred =
```

```
    1.8149
```

```
yci =
```

```
    1.5264    2.1033
```

## Purpose

Compute predicted values given predictor values

## Syntax

```
ypred = predict(rm,tnew)
ypred = predict(rm,tnew,Name,Value)
[ypred,yci] = predict( __ )
```

## Description

`ypred = predict(rm,tnew)` returns the predicted values from the repeated measures model `rm` using the predictor values from the table `t`.

`ypred = predict(rm,tnew,Name,Value)` returns the predicted values from the repeated measures model `rm` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the within-subjects design matrix.

`[ypred,yci] = predict( __ )` also returns the 95% confidence interval for the predicted values.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **tnew - New data**

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding

# RepeatedMeasuresModel.predict

---

value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## 'Alpha' - Confidence level

0.05 (default) | scalar value in the range of 0 through 1

Confidence level of the confidence intervals for the predicted values, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range of 0 to 1. The confidence level is  $100 \cdot (1 - \alpha)\%$ .

**Example:** 'alpha', 0.01

## Data Types

double | single

## 'WithinModel' - Model for within-subject factors

'separatemeans' | 'orthogonalcontrasts' | text string

Model for the within-subject factors, specified as the comma-separated pair consisting of 'WithinModel' and one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- 'orthogonalcontrasts' — Valid when the within-subject design consists of a single numeric factor  $T$ . This specifies a model consisting of orthogonal polynomials up to order  $T^{(r-1)}$ , where  $r$  is the number of repeated measures.
- A string that defines a model specification in the within-subject factors.

**Example:** 'WithinModel', 'orthogonalcontrasts'

## 'WithinDesign' - Design for within-subject factors

vector | matrix | table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and a vector,

matrix, or a table. It provides the values of the within-subject factors in the same form as the `RM.WithinDesign` property.

**Example:** `'WithinDesign','Time'`

## Data Types

single | double | table

## Output Arguments

### **ypred - Predicted values**

*n*-by-*r* matrix

Predicted values from the repeated measures model `rm`, returned as an *n*-by-*r* matrix, where *n* is the number of rows in `tnew` and *r* is the number of repeated measures in `rm`.

### **yci - Confidence intervals for predicted values**

*n*-by-*r*-by-2 matrix

Confidence intervals for predicted values from the repeated measures model `rm`, returned as an *n*-by-*r*-by-2 matrix.

These are nonsimultaneous intervals for predicting the mean response at the specified predictor values. For predicted value `ypred(i,j)`, the lower limit of the interval is `yci(i,j,1)` and the upper limit is `yci(i,j,2)`.

## Examples

### **Predict Response Values**

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
```

# RepeatedMeasuresModel.predict

---

```
Meas = dataset([1 2 3 4]', 'VarNames', {'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Predict responses for the three species.

```
Y = predict(rm, t([1 51 101], :))
```

Y =

5.0060	3.4280	1.4620	0.2460
5.9360	2.7700	4.2600	1.3260
6.5880	2.9740	5.5520	2.0260

## Predict Response Values and Plot Predictions

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M']
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...  
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';  
Y = predict(rm,t([1 5 8 12],:), ...  
'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions along with the estimated marginal means.

```
plotprofile(rm,'Time','Group',{'Gender'})  
hold on;  
plot(time,Y,'Color','r','LineStyle',':');  
hold off
```

# RepeatedMeasuresModel.predict

## Compute and Plot Confidence Intervals

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

# RepeatedMeasuresModel.predict

The matrix `Y` contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of `Y` corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions and the confidence intervals for predictions along with the estimated marginal means.

```
plotprofile(rm,'Time','Group',{'Gender'})  
hold on;  
plot(time,ypred,'Color','r','LineStyle',':');  
plot(time,ypredci(:, :, 1))  
plot(time,ypredci(:, :, 2))
```

# RepeatedMeasuresModel.predict

## See Also

`fitrm` | `random`

**Purpose** Predict response

**Syntax**

```
Y = predict(B,X)
[Y,stdevs] = predict(B,X)
[Y,scores] = predict(B,X)
[Y,scores,stdevs] = predict(B,X)
Y = predict(B,X,'param1',val1,'param2',val2,...)
```

**Description** `Y = predict(B,X)` computes predicted response of the trained ensemble `B` for data `X`. The output has one prediction for each row of `X`. The returned `Y` is a cell array of strings for classification and a numeric array for regression.

For regression, `[Y,stdevs] = predict(B,X)` also returns standard deviations of the computed responses over the ensemble of the grown trees.

For classification, `[Y,scores] = predict(B,X)` returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[Y,scores,stdevs] = predict(B,X)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

`Y = predict(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

# TreeBagger.predict

---

'trees'	Array of tree indices to use for computation of responses. Default is 'all'.
'treeweights'	Array of NTrees weights for weighting votes from the specified trees.
'useifort'	Logical matrix of size Nobs-by-NTrees indicating which trees to use to make predictions for each observation. By default all trees are used for all observations.

# CompactClassificationEnsemble.predictorImportance

## Definitions

### Predictor Importance

`predictorImportance` computes estimates of predictor importance for `ens` by summing changes in the *risk* due to splits on every predictor and dividing the sum by the number of branch nodes. If `ens` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `ens` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `ens`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

### Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*. Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes  $i$  at the node, and  $p(i)$  is the observed fraction of classes with class  $i$  that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With  $p(i)$  defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('`twoing`') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let  $L(i)$

denote the fraction of members of class  $i$  in the left child node after a split, and  $R(i)$  denote the fraction of members of class  $i$  in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where  $P(L)$  and  $P(R)$  are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If  $j$  is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

## Predictive Measure of Association

The predictive measure of association between the optimal split on variable  $i$  and a surrogate split on variable  $j$  is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.

# CompactClassificationEnsemble.predictorImportance

---

- $P_{R,R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

Element  $\text{ma}(i, j)$  is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

## Examples

Estimate the predictor importance for all variables in the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
imp = predictorImportance(ens)

imp =
    0.0001    0.0005    0.0384    0.0146
```

The first two predictors are not very important in ens.

---

Estimate the predictor importance for all variables in the Fisher iris data for an ensemble where the trees contain surrogate splits:

```
load fisheriris
surrtree = templateTree('Surrogate','on');
ens2 = fitensemble(meas,species,'AdaBoostM2',100,surrtree);
[imp2,ma] = predictorImportance(ens2)

imp2 =
    0.0224    0.0142    0.0525    0.0508
```

# CompactClassificationEnsemble.predictorImportance

---

```
ma =
  1.0000      0    0.0001    0.0001
  0.0115    1.0000    0.0023    0.0054
  0.2810    0.1747    1.0000    0.5372
  0.0789    0.0463    0.2339    1.0000
```

The first two predictors show much more importance than in the previous example.

---

<b>Purpose</b>	Estimates of predictor importance
<b>Syntax</b>	<code>imp = predictorImportance(tree)</code>
<b>Description</b>	<code>imp = predictorImportance(tree)</code> computes estimates of predictor importance for <code>tree</code> by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes.
<b>Input Arguments</b>	<b>tree</b> A classification tree created by <code>fitctree</code> , or by the compact method.
<b>Output Arguments</b>	<b>imp</b> A row vector with the same number of elements as the number of predictors (columns) in <code>tree.X</code> . The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

## Definitions **Predictor Importance**

`predictorImportance` computes estimates of predictor importance for `tree` by summing changes in the *risk* due to splits on every predictor and dividing the sum by the number of branch nodes. If `tree` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `tree` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `tree`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not

use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

## Impurity and Node Error

`ClassificationTree` splits nodes based on either *impurity* or *node error*. Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes  $i$  at the node, and  $p(i)$  is the observed fraction of classes with class  $i$  that reach the node. A node with just one class (a *pure* node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With  $p(i)$  defined the same as for the Gini index, the deviance of a node is

$$-\sum_i p(i) \log p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('`twoing`') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let  $L(i)$  denote the fraction of members of class  $i$  in the left child node after a split, and  $R(i)$  denote the fraction of members of class  $i$  in the right child node after a split. Choose the split criterion to maximize

# CompactClassificationTree.predictorImportance

---

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where  $P(L)$  and  $P(R)$  are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and hence similar to the parent node, and so the split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If  $j$  is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

## Examples

Estimate the predictor importance for all variables in the Fisher iris data:

```
load fisheriris
tree = fitctree(meas,species);
imp = predictorImportance(tree)

imp =
      0      0  0.0403  0.0303
```

The first two elements of `imp` are zero. Therefore, the first two predictors do not enter into tree calculations for classifying irises.

---

Estimate the predictor importance for all variables in the Fisher iris data for a tree grown with surrogate splits:

```
tree2 = fitctree(meas,species,...
    'Surrogate','on');
imp2 = predictorImportance(tree2)

imp2 =
```

# CompactClassificationTree.predictorImportance

---

```
0.0287    0.0136    0.0560    0.0556
```

In this case, all predictors have some importance. As you expect by comparing to the first example, the first two predictors are less important than the final two.

---

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits. For example, permute the order of the data columns in the previous example:

```
load fisheriris
meas3 = meas(:, [4 1 3 2]);
tree3 = fitctree(meas3, species);
imp3 = predictorImportance(tree2)
```

```
imp3 =
    0.0674         0    0.0033         0
```

The estimates of predictor importance are not a permutation of `imp` from the first example.

Estimate the predictor importance using surrogate splits.

```
tree4 = fitctree(meas3, species, ...
    'Surrogate', 'on');
imp4 = predictorImportance(tree4)
```

```
imp4 =
    0.0556    0.0287    0.0560    0.0136
```

`imp4` is a permutation of `imp2`, demonstrating that estimates of predictor importance do not depend on the order of predictors with surrogate splits.

# CompactRegressionEnsemble.predictorImportance

---

<b>Purpose</b>	Estimates of predictor importance
<b>Syntax</b>	<code>imp = predictorImportance(ens)</code> <code>[imp,ma] = predictorImportance(ens)</code>
<b>Description</b>	<p><code>imp = predictorImportance(ens)</code> computes estimates of predictor importance for <code>ens</code> by summing these estimates over all weak learners in the ensemble. <code>imp</code> has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for <code>ens</code>.</p> <p><code>[imp,ma] = predictorImportance(ens)</code> returns a P-by-P matrix with predictive measures of association for P predictors.</p>
<b>Input Arguments</b>	<p><b>ens</b></p> <p>A regression ensemble created by <code>fitensemble</code>, or by the <code>compact</code> method.</p>
<b>Output Arguments</b>	<p><b>imp</b></p> <p>A row vector with the same number of elements as the number of predictors (columns) in <code>ens.X</code>. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.</p> <p><b>ma</b></p> <p>A P-by-P matrix of predictive measures of association for P predictors. Element <code>ma(I,J)</code> is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. <code>predictorImportance</code> averages this predictive measure of association over all trees in the ensemble.</p>
<b>Definitions</b>	<p><b>Predictor Importance</b></p> <p><code>predictorImportance</code> computes estimates of predictor importance for tree by summing changes in the mean squared error (MSE) due to</p>

splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

## Predictive Measure of Association

The predictive measure of association between the optimal split on variable  $i$  and a surrogate split on variable  $j$  is:

$$\lambda_{i,j} = \frac{\min(P_L, P_R) - (1 - P_{L_i L_j} - P_{R_i R_j})}{\min(P_L, P_R)}.$$

Here

- $P_L$  and  $P_R$  are the node probabilities for the optimal split of node  $i$  into Left and Right nodes respectively.
- $P_{L_i L_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Left.
- $P_{R_i R_j}$  is the probability that both (optimal) node  $i$  and (surrogate) node  $j$  send an observation to the Right.

Clearly,  $\lambda_{i,j}$  lies from  $-\infty$  to 1. Variable  $j$  is a worthwhile surrogate split for variable  $i$  if  $\lambda_{i,j} > 0$ .

Element `ma(i, j)` is the predictive measure of association averaged over surrogate splits on predictor  $j$  for which predictor  $i$  is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor  $i$  and surrogate splits on predictor  $j$  and dividing by the total number of

# CompactRegressionEnsemble.predictorImportance

---

optimal splits on predictor  $i$ , including splits for which the predictive measure of association between predictors  $i$  and  $j$  is negative.

## Examples

Estimate the predictor importance for all numeric variables in the `carsmall` data:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
imp = predictorImportance(ens)

imp =
    0.0082         0    0.0049    0.0133    0.0142    0.1737
```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0; this means the number of cylinders has no impact on predictions made with `ens`.

---

Estimate the predictor importance for all variables in the `carsmall` data for an ensemble where the trees contain surrogate splits:

```
load carsmall
surrtree = templateTree('Surrogate','on');
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
ens2 = fitensemble(X,MPG,'LSBoost',100,surrtree);
[imp2,ma] = predictorImportance(ens2)

imp2 =
    0.0725    0.1342    0.1425    0.1397    0.1380    0.1855

ma =
    1.0000    0.0414    0.0607    0.0782    0.0102    0.0322
         0    1.0000         0         0         0         0
    0.0441    0.0704    1.0000    0.0883    0.0175    0.0913
    0.0944    0.1166    0.1400    1.0000    0.0390    0.1308
```

# CompactRegressionEnsemble.predictorImportance

---

0.0121	0.0139	0.0127	0.0127	1.0000	0.0113
0.0818	0.1317	0.2072	0.1878	0.0340	1.0000

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) is essentially tied for third most important predictor.

# CompactRegressionTree.predictorImportance

---

<b>Purpose</b>	Estimates of predictor importance
<b>Syntax</b>	<code>imp = predictorImportance(tree)</code>
<b>Description</b>	<code>imp = predictorImportance(tree)</code> computes estimates of predictor importance for <code>tree</code> by summing changes in the mean squared error due to splits on every predictor and dividing the sum by the number of branch nodes.
<b>Input Arguments</b>	<b>tree</b> A regression tree created by <code>fitrtree</code> , or by the <code>compact</code> method.
<b>Output Arguments</b>	<b>imp</b> A row vector with the same number of elements as the number of predictors (columns) in <code>tree.X</code> . The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.
<b>Definitions</b>	<b>Predictor Importance</b> <p><code>predictorImportance</code> computes estimates of predictor importance for <code>tree</code> by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. <code>imp</code> has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.</p> <p>Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.</p>

# CompactRegressionTree.predictorImportance

---

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

## Examples

Find predictor importance for the `carsmall` data. Use just the numeric predictors:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
tree = fitrtree(X,MPG);
imp = predictorImportance(tree)

imp =
    0.0315         0    0.1082    0.0686    0.1629    1.2924
```

The weight (last predictor) has the most impact on mileage (MPG). The second predictor has importance 0; this means the number of cylinders has no impact on predictions made with `tree`.

---

Estimate the predictor importance for all variables in the `carsmall` data for a tree grown with surrogate splits:

```
load carsmall
X = [Acceleration Cylinders Displacement ...
     Horsepower Model_Year Weight];
tree2 = fitrtree(X,MPG,...
                'Surrogate','on');
imp2 = predictorImportance(tree2)

imp2 =
    0.5287    1.1977    1.2400    0.7059    1.0677    1.4106
```

# CompactRegressionTree.predictorImportance

---

While weight (last predictor) still has the most impact on mileage (MPG), this estimate has the second predictor (number of cylinders) as the third most important predictor.

## See Also

`predictorImportance` | `fitrtree`

**Purpose** Principal component analysis (PCA) on data

**Syntax**

```
[COEFF,SCORE] = princomp(X)
[COEFF,SCORE,latent] = princomp(X)
[COEFF,SCORE,latent,tsquare] = princomp(X)
[...] = princomp(X,'econ')
```

**Description** `COEFF = princomp(X)` performs principal components analysis (PCA) on the  $n$ -by- $p$  data matrix  $X$ , and returns the principal component coefficients, also known as loadings. Rows of  $X$  correspond to observations, columns to variables. `COEFF` is a  $p$ -by- $p$  matrix, each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`princomp` centers  $X$  by subtracting off column means, but does not rescale the columns of  $X$ . To perform principal components analysis with standardized variables, that is, based on correlations, use `princomp(zscore(X))`. To perform principal components analysis directly on a covariance or correlation matrix, use `pcacov`.

`[COEFF,SCORE] = princomp(X)` returns `SCORE`, the principal component scores; that is, the representation of  $X$  in the principal component space. Rows of `SCORE` correspond to observations, columns to components.

`[COEFF,SCORE,latent] = princomp(X)` returns `latent`, a vector containing the eigenvalues of the covariance matrix of  $X$ .

`[COEFF,SCORE,latent,tsquare] = princomp(X)` returns `tsquare`, which contains Hotelling's  $T^2$  statistic for each data point.

The scores are the data formed by transforming the original data into the space of the principal components. The values of the vector `latent` are the variance of the columns of `SCORE`. Hotelling's  $T^2$  is a measure of the multivariate distance of each observation from the center of the data set.

When  $n \leq p$ , `SCORE(:,n:p)` and `latent(n:p)` are necessarily zero, and the columns of `COEFF(:,n:p)` define directions that are orthogonal to  $X$ .

[...] = princomp(X, 'econ') returns only the elements of latent that are not necessarily zero, and the corresponding columns of COEFF and SCORE, that is, when  $n \leq p$ , only the first  $n-1$ . This can be significantly faster when  $p$  is much larger than  $n$ .

## Examples

Compute principal components for the ingredients data in the Hald data set, and the variance accounted for by each component.

```
load hald;
[pc,score,latent,tsquare] = princomp(ingredients);
pc,latent
```

```
pc =
```

```
   -0.0678   -0.6460    0.5673    0.5062
   -0.6785   -0.0200   -0.5440    0.4933
    0.0290    0.7553    0.4036    0.5156
    0.7309   -0.1085   -0.4684    0.4844
```

```
latent =
```

```
517.7969
 67.4964
 12.4054
  0.2372
```

The following command and plot show that two components account for 98% of the variance:

```
cumsum(latent)./sum(latent)
ans =
    0.86597
    0.97886
    0.9996
     1
biplot(pc(:,1:2), 'Scores', score(:,1:2), 'VarLabels', ...
```

```
{'X1' 'X2' 'X3' 'X4'}
```

For a more detailed example and explanation of this analysis method, see “Principal Component Analysis (PCA)” on page 13-80.

# ProbDistUnivKernel

---

**Purpose** Construct ProbDistUnivKernel object

**Syntax**  $PD = \text{ProbDistUnivKernel}(X)$   
 $PD = \text{ProbDistUnivKernel}(X, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \dots)$

## Description

---

**Tip** Although you can use this constructor function to create a ProbDistUnivKernel object, using the `fitdist` function is an easier way to create the ProbDistUnivKernel object.

---

$PD = \text{ProbDistUnivKernel}(X)$  creates  $PD$ , a ProbDistUnivKernel object, which represents a nonparametric probability distribution, based on a normal kernel smoothing function.

$PD = \text{ProbDistUnivKernel}(X, \text{param1}, \text{val1}, \text{param2}, \text{val2}, \dots)$  specifies optional parameter name/value pairs, as described in the Parameter/Values table. Parameter and value names are case insensitive.

**Input Arguments**  $X$  A column vector of data.

---

**Note** Any NaN values in  $X$  are ignored by the fitting calculations.

---

Parameter	Values
'censoring'	<p>A Boolean vector the same size as <math>X</math>, containing 1s when the corresponding elements in <math>X</math> are right-censored observations and 0s when the corresponding elements are exact observations. Default is a vector of 0s.</p> <hr/> <p><b>Note</b> Any NaN values in this censoring vector are ignored by the fitting calculations.</p> <hr/>
'frequency'	<p>A vector the same size as <math>X</math>, containing nonnegative integers specifying the frequencies for the corresponding elements in <math>X</math>. Default is a vector of 1s.</p> <hr/> <p><b>Note</b> Any NaN values in this frequency vector are ignored by the fitting calculations.</p> <hr/>
'kernel'	<p>A string specifying the type of kernel smoother to use. Choices are:</p> <ul style="list-style-type: none"><li>• 'normal' (default)</li><li>• 'box'</li><li>• 'triangle'</li><li>• 'epanechnikov'</li></ul>

# ProbDistUnivKernel

---

Parameter	Values
'support'	Any of the following to specify the support: <ul style="list-style-type: none"><li>• 'unbounded' — Default. If the density can extend over the whole real line.</li><li>• 'positive' — To restrict it to positive values.</li><li>• A two-element vector giving finite lower and upper limits for the support of the density.</li></ul>
'width'	A value specifying the bandwidth of the kernel smoothing window. The default is optimal for estimating normal densities, but you may want to choose a smaller value to reveal features such as multiple modes.

## Output Arguments

*PD*

An object in the ProbDistUnivKernel class, which is derived from the ProbDist class. It represents a nonparametric probability distribution.

## References

[1] Bowman, A. W., and A. Azzalini. *Applied Smoothing Techniques for Data Analysis*. New York: Oxford University Press, 1997.

<b>Superclasses</b>	ProbDistParametric	
<b>Purpose</b>	Object representing univariate parametric probability distribution	
<b>Description</b>	A ProbDistUnivParam object represents a univariate parametric probability distribution. You create this object by using the constructor ( <code>ProbDistUnivParam.ProbDistUnivParam</code> ) and supplying parameter values, or by using the <code>fitdist</code> function to fit the distribution to data.	
<b>Construction</b>	ProbDistUnivParam	Construct ProbDistUnivParam object
<b>Methods</b>	<code>cdf</code>	Return cumulative distribution function (CDF) for ProbDist object
	<code>icdf</code>	Return inverse cumulative distribution function (ICDF) for ProbDistUnivParam object
	<code>iqr</code>	Return interquartile range (IQR) for ProbDistUnivParam object
	<code>mean</code>	Return mean of ProbDistUnivParam object
	<code>median</code>	Return median of ProbDistUnivParam object
	<code>paramci</code>	Return parameter confidence intervals of ProbDistUnivParam object
	<code>pdf</code>	Return probability density function (PDF) for ProbDist object
	<code>random</code>	Generate random number drawn from ProbDist object

# ProbDistUnivParam

---

std	Return standard deviation of ProbDistUnivParam object
var	Return variance of ProbDistUnivParam object

---

**Note** Some of the above methods are inherited from the ProbDistParametric class.

---

## Properties

DistName	Read-only string containing probability distribution name of ProbDist object
InputData	Read-only structure containing information about input data to ProbDist object
NLogL	Read-only value specifying negative log likelihood for input data to ProbDistParametric object
NumParams	Read-only value specifying number of parameters of ProbDistParametric object
ParamCov	Read-only covariance matrix of parameter estimates of ProbDistParametric object
ParamDescription	Read-only cell array specifying descriptions of parameters of ProbDistParametric object
ParamIsFixed	Read-only logical array specifying fixed parameters of ProbDistParametric object

ParamNames	Read-only cell array specifying names of parameters of ProbDistParametric object
Params	Read-only array specifying values of parameters of ProbDistParametric object
Support	Read-only structure containing information about support of ProbDist object

---

**Note** The above properties are inherited from the ProbDistParametric class.

---

---

**Note** Parameter values are also properties. For example, if you create PD, a univariate parametric probability distribution object that represents a normal distribution, then PD.mu and PD.sigma are properties that give the values of the mu and sigma parameters.

---

## Copy Semantics

**Purpose** Construct ProbDistUnivParam object

**Syntax** `PD = ProbDistUnivParam(DistName, Params)`

**Description** `PD = ProbDistUnivParam(DistName, Params)` creates *PD*, a ProbDistUnivParam object, which represents a probability distribution. This distribution is defined by the parametric distribution specified by *DistName*, with parameters specified by the numeric vector *Params*.

**Input Arguments**

*DistName* A string specifying a distribution. Choices are:

- 'beta'
- 'binomial'
- 'birnbaumsaunders'
- 'exponential'
- 'extreme value' or 'ev'
- 'gamma'
- 'generalized extreme value' or 'gev'
- 'generalized pareto' or 'gp'
- 'inversegaussian'
- 'logistic'
- 'loglogistic'
- 'lognormal'
- 'nakagami'
- 'negative binomial' or 'nbin'
- 'normal'
- 'poisson'

# ProbDistUnivParam

---

- 'rayleigh'
- 'rician'
- 'tlocationscale'
- 'weibull' or 'wbl'

For more information on these parametric distributions, see Appendix B, “Distribution Reference”.

*Params*

Numeric vector of distribution parameters. The number and type of parameters depends on the distribution you specify with *DistName*. For information on parameters for each distribution type, see Appendix B, “Distribution Reference”.

## Output Arguments

*PD*

An object in the ProbDistUnivParam class, which is derived from the ProbDist class. It represents a parametric probability distribution.

## Examples

- 1 Create an object representing a normal distribution with a mean of 100 and a standard deviation of 10.

```
pd = ProbDistUnivParam('normal',[100 10])
```

```
pd =
```

```
normal distribution
```

```
mu = 100  
sigma = 10
```

**2** Generate a 4-by-5 matrix of random values from this distribution.

```
random(pd, 4, 5)
```

```
ans =
```

```
105.3767  103.1877  135.7840  107.2540  98.7586  
118.3389   86.9231  127.6944   99.3695  114.8970  
 77.4115   95.6641   86.5011  107.1474  114.0903  
108.6217  103.4262  130.3492   97.9503  114.1719
```

## How To

- Appendix B, “Distribution Reference”

# probplot

---

## Purpose

Probability plots

## Syntax

```
probplot(Y)
probplot(distribution,Y)
probplot(Y,cens,freq)
probplot(ax,Y)
probplot(...,'noref')
probplot(ax,PD)
probplot(ax,fun,params)
h = probplot(...)
```

## Description

`probplot(Y)` produces a normal probability plot comparing the distribution of the data `Y` to the normal distribution. `Y` can be a single vector, or a matrix with a separate sample in each column. The plot includes a reference line useful for judging whether the data follow a normal distribution.

`probplot` uses midpoint probability plotting positions. The  $i^{\text{th}}$  sorted value from a sample of size  $N$  is plotted against the midpoint in the jump of the empirical CDF on the  $y$  axis. With uncensored data, that midpoint is  $(i-0.5)/N$ . With censored data (see below), the  $y$  value is more complicated to compute.

`probplot(distribution,Y)` creates a probability plot for the distribution specified by *distribution*. Acceptable strings for *distribution* are:

- 'exponential' — Exponential probability plot (nonnegative values)
- 'extreme value' — Extreme value probability plot (all values)
- 'lognormal' — Lognormal probability plot (positive values)
- 'normal' — Normal probability plot (all values)
- 'rayleigh' — Rayleigh probability plot (positive values)
- 'weibull' — Weibull probability plot (positive values)

The  $y$  axis scale is based on the selected distribution. The  $x$  axis has a log scale for the Weibull and lognormal distributions, and a linear scale for the others.

Not all distributions are appropriate for all data sets, and `probplot` will error when asked to create a plot with a data set that is inappropriate for a specified distribution. Appropriate data ranges for each distribution are given parenthetically in the list above.

`probplot(Y,cens,freq)` or `probplot(distname,Y,cens,freq)` requires a vector  $Y$ . `cens` is a vector of the same size as  $Y$  and contains 1 for observations that are right-censored and 0 for observations that are observed exactly. `freq` is a vector of the same size as  $Y$ , containing integer frequencies for the corresponding elements in  $Y$ .

`probplot(ax,Y)` takes a handle `ax` to an existing probability plot, and adds additional lines for the samples in  $Y$ . `ax` is a handle for a set of axes.

`probplot(..., 'noref')` omits the reference line.

`probplot(ax,PD)` takes a probability distribution object, `PD`, and adds a fitted line to the axes specified by `ax` to represent the probability distribution specified by `PD`. `PD` is a `ProbDist` object of the `ProbDistUnivParam` class or `ProbDistUnivKernel` class.

`probplot(ax,fun,params)` takes a function `fun` and a set of parameters, `params`, and adds fitted lines to the axes of an existing probability plot specified by `ax`. `fun` is a function handle to a cdf function, specified with `@` (for example, `@wblcdf`). `params` is the set of parameters required to evaluate `fun`, and is specified as a cell array or vector. The function must accept a vector of  $X$  values as its first argument, then the optional parameters, and must return a vector of cdf values evaluated at  $X$ .

`h = probplot(...)` returns handles to the plotted lines.

## Examples

### Test Data for Weibull Distribution Using `probplot`

Generate sample data. The sample `x1` contains 100 random numbers from a Weibull distribution with scale parameter  $A = 3$  and shape

# probplot

---

parameter  $B = 3$ . The sample  $x_2$  contains 100 random numbers from a Rayleigh distribution with scale parameter  $B = 3$ .

```
rng('default'); % For reproducibility
x1 = wblrnd(3,3,100,1);
x2 = raylrnd(3,100,1);
```

Create a probability plot to assess whether the data in  $x_1$  and  $x_2$  comes from a Weibull distribution.

```
figure;
probplot('weibull',[x1 x2])
legend('Weibull Sample','Rayleigh Sample','Location','NW')
```

The probability plot shows that the data in x1 comes from a Weibull distribution, while the data in x2 does not.

### Test Data for Normal Distribution Using probplot

Generate sample data containing about 20% outliers in the tails. The left tail of the sample data contains 10 values randomly generated from an exponential distribution with parameter  $\mu = 1$ . The right tail contains 10 values randomly generated from an exponential distribution

with parameter  $\mu = 5$ . The center of the sample data contains 80 values randomly generated from a standard normal distribution.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,10,1);
right_tail = exprnd(5,10,1);
center = randn(80,1);
data = [left_tail;center;right_tail];
```

Create a probability plot to assess whether the data in `data` comes from a normal distribution. Plot a  $t$  location-scale curve on the same figure to compare with data.

```
figure;
probplot(data);
p = mle(data,'dist','tlo');
t = @(data,mu,sig,df)cdf('tlocationscale',data,mu,sig,df);
h = probplot(gca,t,p);
set(h,'color','r','linestyle','-');
title('\bf Probability Plot')
legend('Data','Normal','t','Location','NW')
```

The plot shows that neither the normal line nor the  $t$  location-scale curve fit the tails very well because of the outliers.

**See Also**

`normplot` | `ecdf` | `wblplot`

**Purpose** Procrustes analysis

**Syntax**

```
d = procrustes(X,Y)
[d,Z] = procrustes(X,Y)
[d,Z,transform] = procrustes(X,Y)
[...] = procrustes(...,'scaling',flag)
[...] = procrustes(...,'reflection',flag)
```

**Description** `d = procrustes(X,Y)` determines a linear transformation (translation, reflection, orthogonal rotation, and scaling) of the points in matrix `Y` to best conform them to the points in matrix `X`. The goodness-of-fit criterion is the sum of squared errors. `procrustes` returns the minimized value of this dissimilarity measure in `d`. `d` is standardized by a measure of the scale of `X`, given by:

```
sum(sum((X-repmat(mean(X,1),size(X,1),1)).^2,1))
```

That is, the sum of squared elements of a centered version of `X`. However, if `X` comprises repetitions of the same point, the sum of squared errors is not standardized.

`X` and `Y` must have the same number of points (rows), and `procrustes` matches `Y(i)` to `X(i)`. Points in `Y` can have smaller dimension (number of columns) than those in `X`. In this case, `procrustes` adds columns of zeros to `Y` as necessary.

`[d,Z] = procrustes(X,Y)` also returns the transformed `Y` values.

`[d,Z,transform] = procrustes(X,Y)` also returns the transformation that maps `Y` to `Z`. `transform` is a structure array with fields:

- `c` — Translation component
- `T` — Orthogonal rotation and reflection component
- `b` — Scale component

That is:

```
c = transform.c;
T = transform.T;
```

```
b = transform.b;
```

```
Z = b*Y*T + c;
```

[...] = `procrustes(..., 'scaling', flag)`, when `flag` is `false`, allows you to compute the transformation without a scale component (that is, with `b` equal to 1). The default `flag` is `true`.

[...] = `procrustes(..., 'reflection', flag)`, when `flag` is `false`, allows you to compute the transformation without a reflection component (that is, with `det(T)` equal to 1). The default `flag` is `'best'`, which computes the best-fitting transformation, whether or not it includes a reflection component. A `flag` of `true` forces the transformation to be computed with a reflection component (that is, with `det(T)` equal to -1)

## Examples

### Procrustes Analysis

Generate the sample data in two dimensions.

```
rng('default')
n = 10;
X = normrnd(0,1,[n 2]);
```

Rotate, scale, translate, and add some noise to sample points.

```
S = [0.5 -sqrt(3)/2; sqrt(3)/2 0.5];
Y = normrnd(0.5*X*S+2,0.05,n,2);
```

Conform `Y` to `X` using procrustes analysis.

```
[d,Z,tr] = procrustes(X,Y);
```

Plot the original `X` and `Y` with the transformed `Y`.

```
plot(X(:,1),X(:,2), 'rx', Y(:,1), Y(:,2), 'b.', Z(:,1), Z(:,2), 'bx');
```

# prob.ToolboxFittableParametricDistribution.proflik

---

**Purpose** Profile likelihood function for probability distribution object

**Syntax**

```
[ll,param] = proflik(pd,pnum)
[ll,param] = proflik(pd,pnum,'Display',display)
[ll,param] = proflik(pd,pnum,setparam)
[ll,param] = proflik(pd,pnum,setparam,'Display',display)
[ll,param,other] = proflik( ___ )
```

**Description**

[ll,param] = proflik(pd,pnum) returns a vector ll of loglikelihood values and a vector param of corresponding parameter values for the parameter in the position indicated by pnum.

[ll,param] = proflik(pd,pnum,'Display',display) returns the loglikelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

[ll,param] = proflik(pd,pnum,setparam) returns the loglikelihood values and corresponding parameter values as specified by setparam.

[ll,param] = proflik(pd,pnum,setparam,'Display',display) returns the loglikelihood values and corresponding parameter values as specified by setparam, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

[ll,param,other] = proflik( \_\_\_ ) also returns a matrix other containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

## Input Arguments

### **pd - Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

### **pnum - Parameter number**

positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector { 'A' , 'B' }, so specify `pnum` as 2 to compute the profile likelihood for B.

## Data Types

single | double

## setparam - Parameter value restriction

scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `profilik` chooses the values for output vector `param` based on the default confidence interval method for the probability distribution `pd`. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

**Example:** [3,3.5,4]

## display - Display toggle

'off' (default) | 'on'

Display toggle, specified as either 'on' or 'off'. Specify 'on' to display a plot of the profile loglikelihood overlaid on an approximation of the loglikelihood. Specify 'off' to omit the display. The approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position `pnum` or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

## Output Arguments

### ll - Loglikelihood values

vector

Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position `pnum` set to the values in `param`, maximized over the remaining parameters.

### param - Parameter values

vector

Parameter values corresponding to the loglikelihood values in `ll`, returned as a vector. If you specify parameter values using `setparam`, then `param` is equal to `setparam`.

### other - Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of `other` contains the values for all parameters except the parameter in position `pnum`.

## Examples

### Profile Likelihood of a Distribution Parameter

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'Weibull')

pd =

WeibullDistribution

Weibull distribution
A = 26.5079    [24.8333, 28.2954]
B = 3.27193   [2.79441, 3.83104]
```

View the parameter names for the distribution.

```
pd.ParameterNames
```

```
ans =
```

```
    'A'    'B'
```

For the Weibull distribution, A is in position 1, and B is in position 2.

Compute the profile likelihood for B, which is in position `pnum = 2`.

```
[ll,param] = proflik(pd,2);
```

Display the loglikelihood values for the estimated values of B.

```
[ll',param']
```

```
ans =
```

```
-329.9688    2.7132  
-329.4312    2.7748  
-328.9645    2.8365  
-328.5661    2.8981  
-328.2340    2.9597  
-327.9658    3.0213  
-327.7596    3.0830  
-327.6135    3.1446  
-327.5256    3.2062  
-327.4943    3.2678  
-327.5178    3.3295  
-327.5946    3.3911  
-327.7233    3.4527  
-327.9023    3.5143  
-328.1303    3.5760  
-328.4060    3.6376  
-328.7281    3.6992  
-329.0956    3.7608  
-329.5071    3.8224  
-329.9617    3.8841  
-330.4583    3.9457
```

# prob.ToolboxFittableParametricDistribution.proflik

---

These results show that the profile loglikelihood is maximized between the estimated B values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of B is 3.27193, which is in this interval as expected.

## Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG,'GeneralizedExtremeValue')

pd =

    GeneralizedExtremeValueDistribution

    Generalized Extreme Value distribution
         k = -0.207765    [-0.381674, -0.0338564]
    sigma =    7.49674    [6.31755, 8.89603]
         mu =    20.6233    [18.8859, 22.3606]
```

View the parameter names for the distribution.

```
pd.ParameterNames

ans =

    'k'    'sigma'    'mu'
```

For the generalized extreme value distribution, k is in position 1, sigma is in position 2, and mu is in position 3.

Compute the profile likelihood for mu, which is in position `pnum = 3`. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');
```

The plot shows the estimated value for the parameter  $\mu$  that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of  $\mu$ , and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]
```

```
ans =
```

# prob.ToolboxFittableParametricDistribution.proflk

---

makedist | fitdist | dfittool

**Purpose** Proximity matrix for data

**Syntax** `prox = proximity(B,X)`

**Description** `prox = proximity(B,X)` computes a numeric matrix of size Nobs-by-Nobs of proximities for data X, where Nobs is the number of observations (rows) in X. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble B for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1.

# TreeBagger.Proximity property

---

**Purpose** Proximity matrix for observations

**Description** The Proximity property is a numeric matrix of size Nobs-by-Nobs, where Nobs is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

**See Also** `CompactTreeBagger.proximity` | `classregtree.varimportance`

**Purpose** Produce sequence of subtrees by pruning

**Syntax**

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

**Description** `tree1 = prune(tree)` creates a copy of the classification tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

**Tips**

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned tree, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using the `fitctree` function with pruning set 'off'. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

## Input Arguments

**tree**

A classification tree created with `fitctree`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

#### 'Alpha'

A numeric scalar. `prune` prunes `tree` to the specified value of the pruning cost.

#### 'Level'

# ClassificationTree.prune

---

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

## 'Nodes'

A numeric vector with elements from 1 to `tree.NumNodes`. Any `tree` branch nodes listed in `nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

## Output Arguments

### `tree1`

A classification tree.

## Examples

### Prune and Display a Classification Tree

Construct and display a full classification tree for Fisher's iris data.

```
load fisheriris;
varnames = {'SL' 'SW' 'PL' 'PW'};
t1 = fitctree(meas,species,...
    'minparent',5,'predictorNames',varnames);
view(t1,'mode','graph');
```

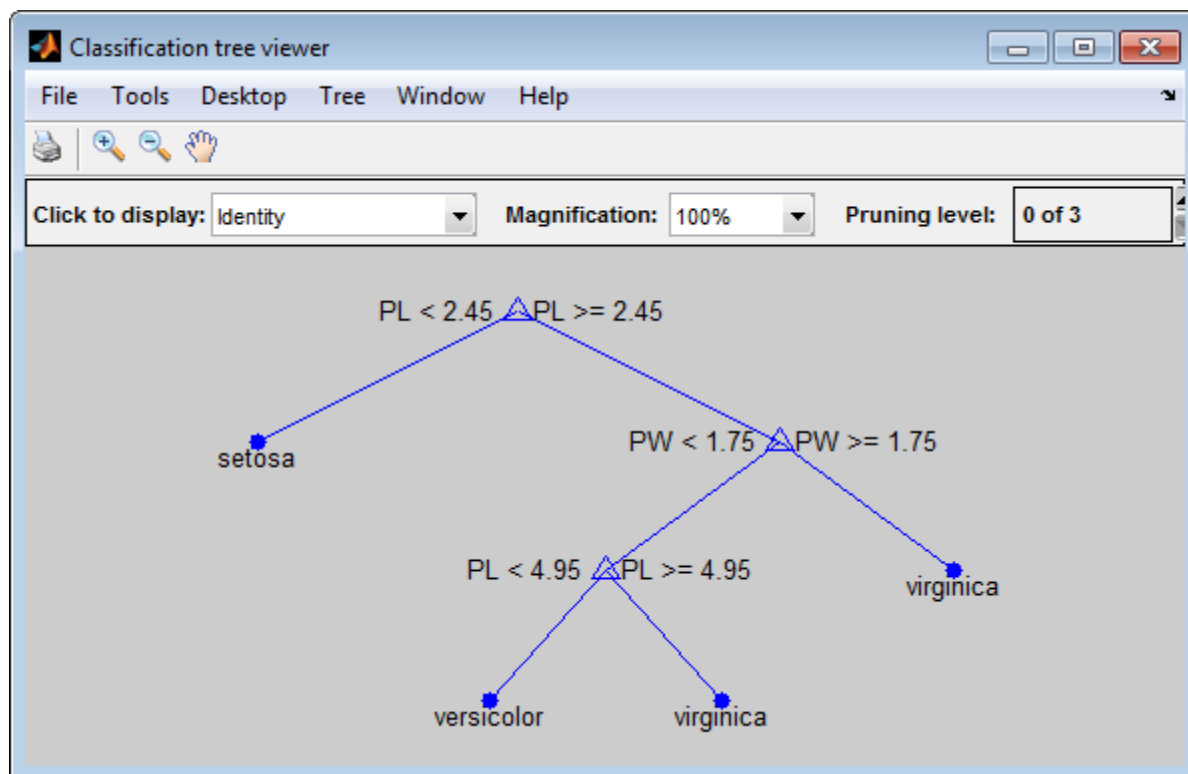

# ClassificationTree.prune

Construct and display the next largest tree from the optimal pruning sequence.

```
t2 = prune(t1,'level',1);  
view(t2,'mode','graph');
```

# ClassificationTree.prune

**See Also**

`fitctree`

## Purpose

Prune tree

## Syntax

```
t2 = prune(t1, 'level', level)
t2 = prune(t1, 'nodes', nodes)
t2 = prune(t1)
```

## Description

`t2 = prune(t1, 'level', level)` takes a decision tree `t1` and a pruning level `level`, and returns the decision tree `t2` pruned to that level. If `level` is 0, there is no pruning. Trees are pruned based on an optimal pruning scheme that first prunes branches giving less improvement in error cost.

`t2 = prune(t1, 'nodes', nodes)` prunes the nodes listed in the `nodes` vector from the tree. Any `t1` branch nodes listed in `nodes` become leaf nodes in `t2`, unless their parent nodes are also pruned. Use `view` to display the node numbers for any node you select.

`t2 = prune(t1)` returns the decision tree `t2` that is the full, unpruned `t1`, but with optimal pruning information added. This is useful only if `t1` is created by pruning another tree, or by using the `classregtree` function with the `'prune'` parameter set to `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

Pruning is the process of reducing a tree by turning some branch nodes into leaf nodes and removing the leaf nodes under the original branch.

## Examples

Display the full tree for Fisher's iris data:

```
load fisheriris;

t1 = classregtree(meas, species, ...
                 'names', {'SL' 'SW' 'PL' 'PW'}, ...
                 'splitmin', 5)

t1 =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
```

# classregtree.prune

```
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5 class = virginica
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

view(t1)
```

Click to display:  Magnification:  Pruning level:

Display the next largest tree from the optimal pruning sequence:

```
t2 = prune(t1, 'level', 1)
t2 =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  class = versicolor
7  class = virginica

view(t2)
```

# classregtree.prune

## Purpose

Produce sequence of subtrees by pruning

## Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

## Description

`tree1 = prune(tree)` creates a copy of the regression tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name, Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1, ,NameN,ValueN`.

## Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned tree, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using `fitrtree` with pruning set 'off'. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

## Input Arguments

### **tree**

A regression tree created with `fitrtree`.

### **Name-Value Pair Arguments**

Optional comma-separated pair of `Name, Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify only one name-value pair argument.

#### **'alpha'**

A numeric scalar from 0 (no pruning) to 1 (prune to one node). Prunes to minimize the sum of (`alpha` times the number of leaf nodes) and a cost (mean squared error).

#### **'level'**

# RegressionTree.prune

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

## 'nodes'

A numeric vector with elements from 1 to `tree.NumNodes`. Any `tree` branch nodes listed in `nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

## Output Arguments

### `tree1`

A regression tree.

## Examples

Display a full tree for the `carsmall` data, as well as the tree pruned to level 10:

```
load carsmall;
varnames = {'Weight' 'Horsepower'};
t1 = fitrtree([Weight Horsepower],MPG,...
    'predictorNames',varnames)
view(t1,'mode','graph');
```

```
t2 = prune(t1,'level',10);
```

```
view(t2,'mode','graph');
```

# TreeBagger.Prune property

---

**Purpose** Flag to prune trees

**Description** The Prune property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

**See Also** `classregtree.prune`

**Purpose**

Pruning levels for decision tree nodes

**Syntax**

`P = pruneList(T)`  
`P = pruneList(T,J)`

**Description**

`P = pruneList(T)` returns an  $n$ -element numeric vector with the pruning levels in each node of the tree `T`, where  $n$  is the number of nodes. When you call `prune(T, 'level', level)`, nodes with the pruning levels below `level` are pruned, and nodes with the pruning levels greater or equal to `level` are not pruned.

`P = pruneList(T,J)` takes an array `J` of node numbers and returns the pruning levels for the specified nodes.

**See Also**

`classregtree` | `numnodes`

# grandstream.grand

---

**Purpose** Generate quasi-random points from stream

**Syntax**  
`x = grand(q)`  
`X = grand(q,n)`

**Description** `x = grand(q)` returns the next value  $x$  in the quasi-random number stream  $q$  of the `grandstream` class.  $x$  is a 1-by- $d$  vector, where  $d$  is the dimension of the stream. The command sets `q.State` to the index in the underlying point set of the next value to be returned.

`X = grand(q,n)` returns the next  $n$  values  $X$  in an  $n$ -by- $d$  matrix.

Objects  $q$  of the `grandstream` class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until  $q$  is accessed using `grand`.

## Examples

Use `grandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
    Halton quasi-random stream in 3 dimensions
    Point set properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
     1
```

Use `grand` to generate two samples of size four:

```
X1 = grand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
```

```
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
    5

X2 = grand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
    9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
    1

X = grand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

# grandset

---

<b>Purpose</b>	Quasi-random point sets	
<b>Description</b>	grandset is a base class that encapsulates a sequence of multi-dimensional quasi-random numbers. This base class is abstract and cannot be instantiated directly. Concrete subclasses include sobolset and haltonset.	
<b>Construction</b>	grandset	Abstract quasi-random point set class
<b>Methods</b>	disp	Display grandset object
	end	Last index in indexing expression for point set
	length	Length of point set
	ndims	Number of dimensions in matrix
	net	Generate quasi-random point set
	scramble	Scramble quasi-random point set
	size	Number of dimensions in matrix
	suboref	Subscripted reference for grandset
<b>Properties</b>	Dimensions	Number of dimensions
	Leap	Interval between points
	ScrambleMethod	Settings that control scrambling

Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

# grandset

---

**Purpose** Abstract quasi-random point set class

**Description** `grandset` is an abstract class, and you cannot create instances of it directly. You must use `haltonset` or `sobolset` to create a `grandset` object.

**See Also** `haltonset` | `sobolset`

<b>Purpose</b>	Quasi-random number streams	
<b>Construction</b>	grandstream	Construct quasi-random number stream
<b>Methods</b>	addlistener	Add listener for event
	delete	Delete handle object
	disp	Display grandstream object
	eq	Test handle equality
	findobj	Find objects matching specified conditions
	findprop	Find property of MATLAB handle object
	ge	Greater than or equal relation for handles
	gt	Greater than relation for handles
	isvalid	Test handle validity
	le	Less than or equal relation for handles
	lt	Less than relation for handles
	ne	Not equal relation for handles
	notify	Notify listeners of event
	grand	Generate quasi-random points from stream
	rand	Generate quasi-random points from stream
	reset	Reset state

# grandstream

---

## Properties

PointSet

Point set from which stream is drawn

State

Current state of the stream

## Copy Semantics

Handle. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

**Purpose** Construct quasi-random number stream

**Syntax**

```
q = grandstream(type,d)
q = grandstream(type,d,prop1,val1,prop2,val2,...)
q = grandstream(p)
```

**Description** `q = grandstream(type,d)` constructs a *d*-dimensional quasi-random number stream *q* of the `grandstream` class, of type specified by the string *type*. *type* is either 'halton' or 'sobol', and *q* is based on a point set from either the `haltonset` class or `sobolset` class, respectively, with default property settings.

`q = grandstream(type,d,prop1,val1,prop2,val2,...)` specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on *type*.

`q = grandstream(p)` constructs a stream based on the specified point set *p*. *p* must be a point set from either the `haltonset` class or `sobolset` class.

**Examples** Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
  Halton quasi-random stream in 3 dimensions
  Point set properties:
      Skip : 1000
      Leap : 100
      ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
     1
```

Use `grand` to generate two samples of size four:

```
X1 = grand(q,4)
```

# grandstream

---

```
X1 =  
    0.0928    0.3475    0.0051  
    0.6958    0.2035    0.2371  
    0.3013    0.8496    0.4307  
    0.9087    0.5629    0.6166  
nextIdx = q.State  
nextIdx =  
    5
```

```
X2 = grand(q,4)  
X2 =  
    0.2446    0.0238    0.8102  
    0.5298    0.7540    0.0438  
    0.3843    0.5112    0.2758  
    0.8335    0.2245    0.4694  
nextIdx = q.State  
nextIdx =  
    9
```

Use `reset` to reset the stream, and then generate another sample:

```
reset(q)  
nextIdx = q.State  
nextIdx =  
    1  
  
X = grand(q,4)  
X =  
    0.0928    0.3475    0.0051  
    0.6958    0.2035    0.2371  
    0.3013    0.8496    0.4307  
    0.9087    0.5629    0.6166
```

## See Also

`haltonset` | `grand` | `reset` | `sobolset`

**Purpose** Quantile-quantile plot

**Syntax**

```
qqplot(X)
qqplot(X,Y)
qqplot(X,PD)
qqplot(X,Y,pvec)
h = qqplot(X,Y,pvec)
```

**Description** `qqplot(X)` displays a quantile-quantile plot of the sample quantiles of  $X$  versus theoretical quantiles from a normal distribution. If the distribution of  $X$  is normal, the plot will be close to linear.

`qqplot(X,Y)` displays a quantile-quantile plot of two samples. If the samples do come from the same distribution, the plot will be linear.

`qqplot(X,PD)` makes an empirical quantile-quantile plot of the quantiles of the data in the vector  $X$  versus the quantiles of the distribution specified by  $PD$ , a `ProbDist` object of the `ProbDistUnivParam` class or `ProbDistUnivKernel` class.

For matrix  $X$  and  $Y$ , `qqplot` displays a separate line for each pair of columns. The plotted quantiles are the quantiles of the smaller data set.

The plot has the sample data displayed with the plot symbol '+'. Superimposed on the plot is a line joining the first and third quartiles of each distribution (this is a robust linear fit of the order statistics of the two samples). This line is extrapolated out to the ends of the sample to help evaluate the linearity of the data.

Use `qqplot(X,Y,pvec)` to specify the quantiles in the vector `pvec`.

`h = qqplot(X,Y,pvec)` returns handles to the lines in `h`.

## Examples **Quantile-Quantile Plot With Two Samples**

This example shows how to create a quantile-quantile plot using two sets of sample data.

Generate random numbers from two Poisson distributions. The vector `x` contains 50 random numbers from a Poisson distribution with `lambda`

# qqplot

---

= 10. The vector `y` contains 100 random numbers from a Poisson distribution with `lambda = 5`.

```
rng('default'); % For reproducibility
x = poissrnd(10,50,1);
y = poissrnd(5,100,1);
```

Create a quantile-quantile plot using the two sets of sample data.

```
qqplot(x,y);
```

The solid line in the plot joins the first and third quartiles. The dashed line extrapolates the solid line.

**How To**

- `normplot`

# quantile

---

## Purpose

Quantiles of a data set

## Syntax

`Y = quantile(X,p)`  
`Y = quantile(X,p,dim)`

`Y = quantile(X,N)`  
`Y = quantile(X,N,dim)`

## Description

`Y = quantile(X,p)` returns quantiles of the values in data vector or matrix `X` for the cumulative probability or probabilities `p` in the interval `[0,1]`.

- If `X` is a vector, then `Y` is a scalar or a vector having the same length as `p`.
- If `X` is a matrix, then `Y` is a row vector or a matrix where the number of rows of `Y` is equal to the length of `p`.
- For multidimensional arrays, `quantile` operates along the first nonsingleton dimension of `X`.

`Y = quantile(X,p,dim)` returns quantiles along dimension `dim`.

`Y = quantile(X,N)` returns quantiles for `N` evenly spaced cumulative probabilities  $(1/(N+1), 2/(N+1), \dots, N/(N+1))$  for integer  $N > 1$ .

- If `X` is a vector, then `Y` is a scalar or a vector with length `N`.
- If `X` is a matrix, then `Y` is a matrix where the number of rows of `Y` is equal to `N`.
- For multidimensional arrays, `quantile` operates along the first nonsingleton dimension of `X`.

`Y = quantile(X,N,dim)` returns quantiles at the `N` evenly-spaced cumulative probabilities  $(1/(N+1), 2/(N+1), \dots, N/(N+1))$  for integer  $N > 1$  along dimension `dim`.

**Input Arguments****X - Input data**

vector | array

Input data, specified as a vector or array.

**Data Types**

double | single

**p - Cumulative probabilities**

scalar | vector

Cumulative probabilities, for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1.

**Example:** 0.3**Example:** [0.25, 0.5, 0.75]**Example:** (0:0.25:1)**Data Types**

double | single

**N - Number of quantiles**

positive integer

Number of quantiles to compute, specified as a positive integer. `quantile` returns N quantiles that divide the data set into evenly distributed N+1 segments.**Data Types**

double | single

**dim - Dimension**

1 (default) | positive integer

Dimension along which the quantiles of a matrix X are required, specified as a positive integer. For example, for a matrix X, when `dim = 1`, `quantile` returns the quantile(s) of the columns of X and when `dim = 2`, `quantile` returns the quantile(s) of the rows of X. For a multidimensional array X, the length of the `dim`th dimension of Y is same as length of p.

# quantile

---

## Output Arguments

### Y - Quantiles

scalar | array

Quantiles of a data vector or matrix, returned as a scalar or array for one or multiple values of cumulative probabilities.

- If  $X$  is a vector, then  $Y$  is a scalar or a vector with the same length as the number of quantiles required ( $N$  or  $\text{length}(p)$ ).  $Y(i)$  contains the  $p(i)$  quantile.
- If  $X$  is a matrix, then  $Y$  is a vector or a matrix with the length of  $\text{dimth}$  dimension equal to the number of quantiles required ( $N$  or  $\text{length}(p)$ ). When  $\text{dim} = 1$ , for example, the  $i$ th row of  $Y$  contains the  $p(i)$  quantiles of columns of  $X$ .
- If  $X$  is an array of dimension  $d$ , then  $Y$  is an array with the length of  $\text{dimth}$  dimension equal to the number of quantiles required ( $N$  or  $\text{length}(p)$ ).

## Definitions

### Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if  $X$  is a 1-by-3-by-4 array, then  $X$  is a 3-D array.

### First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if  $X$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $X$ .

### Linear Interpolation

Linear interpolation uses linear polynomials to find  $y_i = f(x_i)$ , the values of the underlying function  $Y = f(X)$  at the points in the vector or array  $x$ . Given the data points  $(x_1, y_1)$  and  $(x_2, y_2)$ , where  $y_1 = f(x_1)$  and  $y_2 = f(x_2)$ , linear interpolation finds  $y = f(x)$  for a given  $x$  between  $x_1$  and  $x_2$  as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the  $1.5/n$  quantile is  $y_{1.5/n}$  and the  $2.5/n$  quantile is  $y_{2.5/n}$ , then linear interpolation finds the  $2.3/n$  quantile  $y_{2.3/n}$  as

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)} \left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

## Algorithms

For an  $n$ -element vector  $X$ , `quantile` computes quantiles as follows:

- 1** The sorted values in  $X$  are taken as the  $(0.5/n)$ ,  $(1.5/n)$ , ...,  $([n - 0.5]/n)$  quantiles. For example:
  - For a data vector of five elements such as  $\{6, 3, 2, 10, 1\}$ , the sorted elements  $\{1, 2, 3, 6, 10\}$  respectively correspond to the 0.1, 0.3, 0.5, 0.7, 0.9 quantiles.
  - For a data vector of six elements such as  $\{6, 3, 2, 10, 8, 1\}$ , the sorted elements  $\{1, 2, 3, 6, 8, 10\}$  respectively correspond to the  $(0.5/6)$ ,  $(1.5/6)$ ,  $(2.5/6)$ ,  $(3.5/6)$ ,  $(4.5/6)$ ,  $(5.5/6)$  quantiles.
- 2** `quantile` uses Linear interpolation to compute quantiles for probabilities between  $(0.5/n)$  and  $([n - 0.5]/n)$ .
- 3** For the quantiles corresponding to the probabilities outside that range, `quantile` assigns the minimum or maximum values in  $X$ .

`quantile` treats NaNs as missing values and removes them.

## Examples

### Quantiles for Given Probabilities

Calculate the quantiles of a data set for specified probabilities.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

# quantile

---

```
x =  
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336
```

Calculate the 0.3 quantile.

```
y = quantile(x,0.30)
```

```
y =  
   -0.0574
```

Calculate the quantiles for the cumulative probabilities 0.025, 0.25, 0.5, 0.75, and 0.975.

```
y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
```

```
y =  
   -2.2588   -0.4336    0.4401    1.8339    3.5784
```

## Quantiles of a Matrix for Given Probabilities

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.

```
rng('default'); % for reproducibility  
X = normrnd(0,1,4,6)
```

```
X =  
    0.5377    0.3188    3.5784    0.7254   -0.1241    0.6715  
    1.8339   -1.3077    2.7694   -0.0631    1.4897   -1.2075  
   -2.2588   -0.4336   -1.3499    0.7147    1.4090    0.7172  
    0.8622    0.3426    3.0349   -0.2050    1.4172    1.6302
```

Calculate the 0.3 quantile for each column of X (dim = 1).

```
y = quantile(x,0.3,1)
```

```
y =
    -0.3013    -0.6958     1.5336    -0.1056     0.9491     0.1078
```

`quantile` returns a row vector `y` when calculating one quantile for each column of a matrix. For example, `-0.3013` is the 0.3 quantile of the first column of `X` with elements `(0.5377, 1.8339, -2.2588, 0.8622)`. `y = quantile(X,0.3)` returns the same answer because the default value of `dim` is 1.

Calculate the 0.3 quantile for each row of `X` (`dim = 2`).

```
y = quantile(x,0.3,2)
```

```
y =
    0.3844
   -0.8642
   -1.0750
    0.4985
```

`quantile` returns a column vector `y` when calculating one quantile for each row of a matrix. For example `0.3844` is the 0.3 quantile of the first row of `X` with elements `(0.5377, 0.3188, 3.5784, 0.7254, -0.1241, 0.6715)`.

## Quantiles for *N* Evenly Spaced Cumulative Probabilities

Calculate the quantiles of a data set for a given number of quantiles.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x =
    0.5377     1.8339    -2.2588     0.8622     0.3188    -1.3077    -0.4330
```

Calculate four evenly spaced quantiles.

```
y = quantile(x,4)
```

# quantile

---

```
y =  
    -0.8706    0.3307    0.6999    2.3017
```

Using `y = quantile(x,[0.2,0.4,0.6,0.8])` is another way to return the four evenly spaced quantiles.

## Quantiles of a Matrix for Given Number of Quantiles

Calculate the  $N$  evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.

```
rng('default'); % for reproducibility  
X = unidrnd(10,6,7)
```

```
X =  
  
     9     3    10     8     7     8     7  
    10     6     5    10     8     1     4  
     2    10     9     7     8     3    10  
    10    10     2     1     4     1     1  
     7     2     5     9     7     1     5  
     1    10    10    10     2     9     4
```

Calculate three evenly spaced quantiles for each column of  $X$  (`dim = 1`).

```
y = quantile(X,3,1)
```

```
y =  
  
    2.0000    3.0000    5.0000    7.0000    4.0000    1.0000    4.0000  
    8.0000    8.0000    7.0000    8.5000    7.0000    2.0000    4.5000  
   10.0000   10.0000   10.0000   10.0000    8.0000    8.0000    7.0000
```

Each column of matrix  $y$  corresponds to the three evenly spaced quantiles of each column of matrix  $X$ . For example, the first column of  $y$  with elements (2, 8, 10) has the quantiles for the first column of  $X$

with elements (9, 10, 2, 10, 7, 1). `y = quantile(X,3)` returns the same answer because the default value of `dim` is 1.

Calculate three evenly spaced quantiles for each row of `X` (`dim = 2`).

```
y = quantile(X,3,2)
```

```
y =
```

```

7.0000    8.0000    8.7500
4.2500    6.0000    9.5000
4.0000    8.0000    9.7500
1.0000    2.0000    8.5000
2.7500    5.0000    7.0000
2.5000    9.0000   10.0000

```

Each row of matrix `y` corresponds to the three evenly spaced quantiles of each row of matrix `X`. For example, the first row of `y` with elements (7, 8, 8.75) has the quantiles for the first column of `X` with elements (9, 3, 10, 8, 7, 8, 7).

## Median and Quartiles for Even Number of Data Elements

Find median and quartiles of a vector, `x`, with even number of elements.

Enter the data.

```
x = [2 5 6 10 11 13]
```

```
x =
```

```

2      5      6      10     11     13

```

Calculate the median of `x`.

```
y = quantile(x,0.50)
```

```
y =
```

```
8
```

# quantile

---

Calculate the quartiles of  $x$ .

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y =  
    5    8   11
```

Using `y = quantile(x,3)` is another way to compute the quartiles of  $x$ .

These results might be different than the textbook definitions because `quantile` uses linear interpolation to find the median and quartiles.

## **Median and Quartiles for Odd Number of Data Elements**

Find median and quartiles of a vector,  $x$ , with odd number of elements.

Enter the data.

```
x = [2 4 6 8 10 12 14]
```

```
x =  
    2    4    6    8   10   12   14
```

Find the median of  $x$ .

```
y = quantile(x,0.50)
```

```
y =  
    8
```

Find the quartiles of  $x$ .

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y =  
    4.5000    8.0000   11.5000
```

Using `y = quantile(x,3)` is another way to compute the quartiles of  $x$ .

These results might be different than the textbook definitions because `quantile` uses linear interpolation to find the median and quartiles.

**Concepts**

- “Quantiles and Percentiles” on page 3-7

# grandstream.rand

---

**Purpose** Generate quasi-random points from stream

**Syntax**

```
rand
rand(q,n)
rand(q)
rand(q,m,n)
rand(q,[m,n])
rand(q,m,n,p,...)
rand(q,[m,n,p,...])
```

**Description** rand returns a matrix of quasi-random values and is intended to allow objects of the grandstream class to be used in code that contains calls to the rand method of the MATLAB pseudo-random randstream class. Due to the multidimensional nature of quasi-random numbers, only some syntaxes of rand are supported by the grandstream class.

rand(q,n) returns an n-by-n matrix only when n is equal to the number of dimensions. Any other value of n produces an error.

rand(q) returns a scalar only when the stream is in one dimension. Having more than one dimension in q produces an error.

rand(q,m,n) or rand(q,[m,n]) returns an m-by-n matrix only when n is equal to the number of dimensions in the stream. Any other value of n produces an error.

rand(q,m,n,p,...) or rand(q,[m,n,p,...]) produces an error unless p and all following dimensions sizes are equal to one.

**Examples** Generate the first 256 points from a 5-D Sobol sequence:

```
q = grandstream('sobol',5);
X = rand(q,256,5);
```

**See Also** grandstream | grand | rand

**Purpose** Gamma random numbers with unit scale

**Syntax**

```
Y = randg
Y = randg(A)
Y = randg(A,m)
Y = randg(A,m,n,p,...)
Y = randg(A,[m,n,p,...])
```

**Description**

`Y = randg` returns a scalar random value chosen from a gamma distribution with unit scale and shape.

`Y = randg(A)` returns a matrix of random values chosen from gamma distributions with unit scale. `Y` is the same size as `A`, and `randg` generates each element of `Y` using a shape parameter equal to the corresponding element of `A`.

`Y = randg(A,m)` returns an `m`-by-`m` matrix of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`m` matrix or a scalar. If `A` is a scalar, `randg` uses that single shape parameter value to generate all elements of `Y`.

`Y = randg(A,m,n,p,...)` or `Y = randg(A,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-... array of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`n`-by-`p`-by-... array or a scalar.

`randg` produces pseudo-random numbers using the MATLAB functions `rand` and `randn`. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies `rand` and `randn`. Control that shared random number generator using `rng`. See the `rng` documentation for more information.

---

**Note** To generate gamma random numbers and specify both the scale and shape parameters, you should call `gamrnd`.

---

## Examples

### Example 1

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3.

```
r = randg(3,100,1);
```

### Example 2

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2.

```
A = [ones(100,1)*3,ones(100,1)*2];  
r = randg(A,[100,2]);
```

### Example 3

To create reproducible output from `randg`, reset the random number generator used by `rand` and `randn` to its default startup settings. This way `randg` produces the same random numbers as if you restarted MATLAB.

```
rng('default')  
randg(3,1,5)
```

```
ans =
```

```
6.9223    4.3369    1.0505    3.2662   11.3269
```

### Example 4

Save the settings for the random number generator used by `rand` and `randn`, generate 5 values from `randg`, restore the settings, and repeat those values.

```
s = rng; % Obtain the current state of the random stream  
r1 = randg(10,1,5)
```

```
r1 =
```

```
9.4719    9.0433   15.0774   14.7763    6.3775
```

```
rng(s); % Reset the stream to the previous state
r2 = randg(10,1,5)
```

```
r2 =
```

```
    9.4719    9.0433   15.0774   14.7763    6.3775
```

r2 contains exactly the same values as r1.

### Example 5

Reinitialize the random number generator used by `rand` and `randn` with a seed based on the current time. `randg` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.

```
rng('shuffle');
randg(2,1,5);
```

# random

---

## Purpose

Random numbers

## Syntax

```
Y = random(name,A)
Y = random(name,A,B)
Y = random(name,A,B,C)
Y = random(name,A,m,n,...)
Y = random(name,A,[m,n,...])
Y = random(name,A,B,m,n,...)
Y = random(name,A,B,[m,n,...])
Y = random(name,A,B,C,m,n,...)
Y = random(name,A,B,C,[m,n,...])
```

## Description

`Y = random(name,A)` where `name` is the name of a distribution that takes a single parameter, returns random numbers `Y` from the one-parameter family of distributions specified by `name`. Parameter values for the distribution are given in `A`.

`Y` is the same size as `A`.

`Y = random(name,A,B)` returns random numbers `Y` from a two-parameter family of distributions. Parameter values for the distribution are given in `A` and `B`.

If `A` and `B` are arrays, they must be the same size. If either `A` or `B` are scalars, they are expanded to constant matrices of the same size.

`Y = random(name,A,B,C)` returns random numbers `Y` from a three-parameter family of distributions. Parameter values for the distribution are given in `A`, `B`, and `C`.

If `A`, `B`, and `C` are arrays, they must be the same size. If any of `A`, `B`, or `C` are scalars, they are expanded to constant matrices of the same size.

`Y = random(name,A,m,n,...)` or `Y = random(name,A,[m,n,...])` returns an `m`-by-`n`-by... matrix of random numbers.

Similarly, `Y = random(name,A,B,m,n,...)` or `Y = random(name,A,B,[m,n,...])` returns an `m`-by-`n`-by... matrix of random numbers for distributions that require two parameters. `Y = random(name,A,B,C,m,n,...)` or `Y =`

`random(name, A, B, C, [m, n, ...])` returns an m-by-n-by... matrix of random numbers for distributions that require three parameters.

If any of A, B, or C are arrays, then the specified dimensions must match the common dimensions of A, B, and C after any necessary scalar expansion.

The following table denotes the acceptable strings for name, as well as the parameters for that distribution:

## Examples

Generate a 2-by-4 array of random values from the normal distribution with mean 0 and standard deviation 1:

```
x1 = random('Normal',0,1,2,4)
x1 =
```

```
1.1650  0.0751  -0.6965  0.0591
0.6268  0.3516  1.6961  1.7971
```

The order of the parameters is the same as for `normrnd`.

Generate a single random value from Poisson distributions with rate parameters 1, 2, ..., 6, respectively:

```
x2 = random('Poisson',1:6,1,6)
x2 =
    0     0     1     2     5     7
```

# GeneralizedLinearModel.random

---

**Purpose** Simulate responses for generalized linear regression model

**Syntax**  
`ysim = random mdl, Xnew`  
`ysim = random mdl, Xnew, Name, Value`

**Description**  
`ysim = random mdl, Xnew` simulates responses from the `mdl` generalized linear model to the data in `Xnew`.  
`ysim = random mdl, Xnew, Name, Value` simulates responses with additional options specified by one or more `Name, Value` pair arguments.

## Input Arguments

### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### **'BinomialSize'**

The value of the binomial  $n$  parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or

a scalar that applies to each row. The default value 1 produces `ysim` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

**Default:** 1

## 'Offset'

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1. In other words, if `b` is the fitted coefficient vector, and `link` is the link function,

$$\text{link}(\text{ysim}) = \text{Offset} + \text{Xnew} * \text{b}.$$

**Default:** `zeros(size(Xnew,1))`

## Output Arguments

### `ysim`

Vector of simulated values at `Xnew`.

`random` generates `ysim` using random values with mean given by the fitted model, and with the distribution used in `mdl`. The values in `ysim` are independent conditional on the predictors. For binomial and Poisson fits, `random` generates `ysim` with the specified distribution with no adjustment for any estimated dispersion.

## Examples

### Generalized Linear Model Simulation

Create a generalized linear model, and simulate its response to new data.

Generate artificial data for the model, Poisson random numbers with one underlying predictors `X`.

```
rng('default') % reproducible
X = rand(20,1);
```

# GeneralizedLinearModel.random

---

```
mu = exp(1 + 2*X);  
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1','distr','poisson');
```

Create points for prediction.

```
Xnew = (0:.05:1)';
```

Simulate responses at the new points.

```
ysim = random(mdl,Xnew);
```

Plot the simulated values along with the original values.

```
plot(X,y,'rx',Xnew,ysim,'bo',...  
      Xnew,feval(mdl,Xnew),'g-')  
legend('Data','Simulated','Fitted Mean',...  
       'Location','best')
```

## Alternatives

For predictions without random noise, use `predict` or `feval`.

## See Also

# gmdistribution.random

---

**Purpose** Random numbers from Gaussian mixture distribution

**Syntax**  
`y = random(obj)`  
`Y = random(obj,n)`  
`[Y,idx] = random(obj,n)`

**Description** `y = random(obj)` generates a 1-by- $d$  vector  $y$  drawn at random from the  $d$ -dimensional Gaussian mixture distribution defined by `obj`. `obj` is an object created by `gmdistribution` or `fitgmdist`.

`Y = random(obj,n)` generates an  $n$ -by- $d$  matrix  $Y$  of  $n$   $d$ -dimensional random samples.

`[Y,idx] = random(obj,n)` also returns an  $n$ -by-1 vector `idx`, where `idx(I)` is the index of the component used to generate  $Y(I,:)$ .

## Examples **Generate Gaussian Mixture Variates**

Create a `gmdistribution` object defining a two-component mixture of bivariate Gaussian distributions.

```
MU = [1 2;-3 -5];  
SIGMA = cat(3,[2 0;0 .5],[1 0;0 1]);  
p = ones(1,2)/2;  
obj = gmdistribution(MU,SIGMA,p);  
  
ezcontour(@(x,y)pdf(obj,[x y]),[-10 10],[-10 10])  
hold on
```

Generate 1000 random values.

```
rng(1); % For reproducibility  
Y = random(obj,1000);
```

```
scatter(Y(:,1),Y(:,2),10,'.')
```

**How To** • “Linear Regression” on page 9-12

# LinearMixedModel.random

---

**Purpose** Generate random responses from fitted linear mixed-effects model

**Syntax**

```
ysim = random(lme)
ysim = random(lme,tblnew)
ysim = random(lme,Xnew,Znew)
ysim = random(lme,Xnew,Znew,Gnew)
```

**Description** `ysim = random(lme)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the original fixed- and random-effects design points, used to fit `lme`.

`random` simulates new random-effects vector and new observation errors. So, the simulated response is

$$y_{sim} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

where  $\hat{\beta}$  is the estimated fixed-effects coefficients,  $\hat{b}$  is the new random effects, and  $\varepsilon$  is the new observation error.

`random` also accounts for the effect of observation weights, if you use any when fitting the model.

`ysim = random(lme,tblnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `random` if you use a table or dataset array for fitting the model `lme`.

`ysim = random(lme,Xnew,Znew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. Use the matrix format for `random` if you use design matrices for fitting the model `lme`.

`ysim = random(lme, Xnew, Znew, Gnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

## Input Arguments

### **lme** - Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **tblnew** - New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

### Data Types

single | double | logical | char

### **Xnew** - New fixed-effects design matrix

$n$ -by- $p$  matrix

New fixed-effects design matrix, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of fixed predictor variables. Each row of `X` corresponds to one observation and each column of `X` corresponds to one variable.

### Data Types

single | double

### **Znew** - New random-effects design

$n$ -by- $q$  matrix | cell array of length  $R$

# LinearMixedModel.random

---

New random-effects design, specified as an  $n$ -by- $q$  matrix or a cell array of  $R$  design matrices  $Z\{r\}$ , where  $r = 1, 2, \dots, R$ . If  $Z_{\text{new}}$  is a cell array, then each  $Z\{r\}$  is an  $n$ -by- $q(r)$  matrix, where  $n$  is the number of observations, and  $q(r)$  is the number of random predictor variables.

## Data Types

single | double | logical | char | cell

## Gnew - New grouping variable or variables

vector | cell array of grouping variables of length  $R$

New grouping variable or variables, specified as a vector or a cell array, of length  $R$ , of grouping variables used to fit the linear mixed-effects model, `lme`.

`random` treats all levels of each grouping variable as new levels. It draws an independent random effects vector for each level of each grouping variable.

## Data Types

single | double | logical | char | cell

## Output Arguments

### ysim - Simulated response values

$n$ -by-1 vector

Simulated response values, returned as an  $n$ -by-1 vector, where  $n$  is the number of observations.

## Examples

### Generate Random Responses at the Original Design Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Generate random response values at the original design points. Display the first five values.

```
rng(123, 'twister') % For reproducibility  
ysim = random(lme);  
ysim(1:5)
```

```
ans =
```

```
114.8785  
134.2018  
154.2818  
169.7554  
84.6089
```

# LinearMixedModel.random

---

## Plot Randomly Generated vs. Observed Response Values

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed-effects for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG,Weight,Model_Year);  
lme = fitlme(tbl,'MPG ~ Weight + (1|Model_Year)');
```

Randomly generate responses using the original data.

```
rng(123,'twister') % For reproducibility  
ysim = random(lme,tbl);
```

Plot the original and the randomly generated responses to see how they differ. Group them by model year.

```
figure()  
gscatter(Weight,MPG,Model_Year)  
hold on  
gscatter(Weight,ysim,Model_Year,[],'o+x')  
legend('70-data','76-data','82-data','70-sim','76-sim','82-sim')  
hold off
```

Note that the simulated random response values for year 82 are lower than the original data for that year. This might be due to a lower simulated random effect for year 82 than the estimated random effect in the original data.

## Generate Responses Using a New Dataset Array

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

# LinearMixedModel.random

---

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();  
dsnew.Soil = nominal({'Sandy'; 'Silty'; 'Silty'});  
dsnew.Tomato = nominal({'Cherry'; 'Vine'; 'Plum'});  
dsnew.Fertilizer = nominal([2;2;4]);
```

Generate random responses at the new points.

```
rng(123, 'twister') % For reproducibility
```

```
ysim = random(lme,dsnew)
```

```
ysim =  
    99.6006  
    101.9911  
    161.4026
```

## Generate Random Responses Using New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];  
Z = [ones(406,1) Acceleration];  
Model_Year = nominal(Model_Year);  
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...  
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...  
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column

# LinearMixedModel.random

---

must contain the same Acceleration values as in Xnew. The original grouping variable in G is the model year. So, Gnew must contain values for the model year. Note that Gnew must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];  
Znew = [1,13.5; 1,17; 1,21.2];  
Gnew = nominal([73 77 82]);
```

Generate random responses for the data in the new design matrices.

```
rng(123,'twister') % For reproducibility  
ysim = random(lme,Xnew,Znew,Gnew)
```

```
ysim =
```

```
    15.7416  
    10.6085  
     6.8796
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, fit the model.

```
Z = {ones(406,1),Acceleration};  
G = {Model_Year,Model_Year};
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...  
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...  
{{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, Znew, and the grouping variable design, Gnew, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};  
MY = nominal([73 77 82]);  
Gnew = {MY,MY};
```

Generate random responses using the new design matrices.

```
rng(123,'twister') % For reproducibility  
ysim = random(lme,Xnew,Znew,Gnew)
```

```
ysim =  
  
    16.8280  
    10.4375  
     4.1027
```

## See Also

[predict](#) | [fitlme](#) | [fitlmematrix](#) | [LinearMixedModel](#)

# NonLinearModel.random

---

**Purpose** Simulate responses for nonlinear regression model

**Syntax**  
`ysim = random mdl`  
`ysim = random mdl,Xnew`  
`ysim = random mdl,Xnew,'Weights',W`

**Description**  
`ysim = random mdl` simulates responses from the fitted nonlinear model `mdl` at the original design points.  
`ysim = random mdl,Xnew` simulates responses from the fitted nonlinear model `mdl` to the data in `Xnew`, adding random noise.  
`ysim = random mdl,Xnew,'Weights',W` simulates responses using the observation weights, `W`.

## Input Arguments

### **mdl**

Nonlinear regression model, constructed by `fitnlm`.

### **Xnew**

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

### **W**

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights,  $W$ , random estimates the error variance at observation  $i$  by  $MSE * (1/W(i))$ , where MSE is the mean squared error.

**Default:** No weights

## Output Arguments

### **ysim**

Vector of predicted mean values at  $X_{new}$ , perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

## Examples

### **Simulate Responses**

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```

# NonLinearModel.random

## Alternatives

For predictions without added noise, use `predict`.

# ProbDist.random

---

**Purpose** Generate random number drawn from ProbDist object

**Syntax**  
 $Y = \text{random}(PD)$   
 $Y = \text{random}(PD, N)$   
 $Y = \text{random}(PD, N, M, \dots)$

**Description**  
 $Y = \text{random}(PD)$  generates a random number drawn from the distribution specified by  $PD$ , a ProbDist object.  
 $Y = \text{random}(PD, N)$  generates an  $N$ -by- $N$  array of random numbers drawn from the distribution specified by  $PD$ , a ProbDist object.  
 $Y = \text{random}(PD, N, M, \dots)$  generates an  $N$ -by- $M$ -by- $\dots$  array of random numbers drawn from the distribution specified by  $PD$ , a ProbDist object.

**Input Arguments**

$PD$	An object of the class ProbDistUnivParam or ProbDistUnivKernel.
$N$	A positive integer.
$M$	A positive integer.

**Output Arguments**

$Y$	A random number drawn from the distribution specified by $PD$ .

# RepeatedMeasuresModel.random

---

<b>Purpose</b>	Generate new random response values given predictor values
<b>Syntax</b>	<code>ysim = random(rm,tnew)</code>
<b>Description</b>	<code>ysim = random(rm,tnew)</code> generates random response values from the repeated measures model <code>rm</code> using the predictor variables from table <code>tnew</code> .
<b>Input Arguments</b>	<p><b>rm - Repeated measures model</b> RepeatedMeasuresModel object</p> <p>Repeated measures model, returned as a RepeatedMeasuresModel object.</p> <p>For properties and methods of this object, see RepeatedMeasuresModel.</p> <p><b>tnew - New data</b> table used to create <code>rm</code> (default)   table</p> <p>New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, <code>rm</code>, specified as a table. <code>tnew</code> must contain all of the between-subject factors used to create <code>rm</code>.</p>
<b>Output Arguments</b>	<p><b>ysim - Random response values</b> <i>n</i>-by-<i>r</i> matrix</p> <p>Random response values random generates, returned as an <i>n</i>-by-<i>r</i> matrix, where <i>n</i> is the number of rows in <code>tnew</code>, and <i>r</i> is the number of repeated measures in <code>rm</code>.</p>
<b>Examples</b>	<p><b>Randomly Generate New Response Values</b></p> <p>Load the sample data.</p> <pre>load fisheriris</pre>

# RepeatedMeasuresModel.random

---

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Randomly generate new response values.

```
ysim = random(rm);
```

`random` uses the predictor values in the original sample data you use to fit the repeated measures model `rm` in table `t`.

## Randomly Generate Response Values Using New Data

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between,'y1-y8 ~ Group*Gender + Age + IQ','WithinDesign',withi
```

Define a table with new values for the predictor variables.

```
tnew = table(16,93,{'B'},{'Male'},'VariableNames',{'Age','IQ','Group'}
```

```
tnew =
```

Age	IQ	Group	Gender
16	93	'B'	'Male'

Randomly generate new response values using the values in the new table tnew.

```
ysim = random(rm,tnew)
```

```
ysim =
```

```
159.0920 114.8927 -6.5618 46.9944 38.6707 -5.6725 70.8690
```

## Algorithms

random computes ysim by creating predicted values and adding random noise values. For each row, the noise has a multivariate normal distribution with covariance the same as rm.Covariance.

# prob.TruncatableDistribution.random

---

**Purpose** Generate random numbers from probability distribution object

**Syntax**

```
r = random(pd)
r = random(pd, sz1, ..., szN)
r = random(pd, [sz1, ..., szN])
```

**Description**

`r = random(pd)` generates a random number `r` from the probability distribution `pd`.

`r = random(pd, sz1, ..., szN)` generates a `sz1`-by-...-by-`szN` array of random numbers from the probability distribution `pd`.

`r = random(pd, [sz1, ..., szN])` generates a `sz1`-by-...-by-`szN` array of random numbers from the probability distribution `pd`.

## Input Arguments

### **pd - Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

### **sz1,...,szN - Size of each dimension**

two or more integer values | vector of integer values

Size of each dimension, specified as two or more integer values, or a vector of such values. For example, specifying `5,3,2` or `[5,3,2]` generates a 5-by-3-by-2 array of random numbers from the probability distribution `pd`.

### **Data Types**

single | double

## Output Arguments

### **r - Random number**

scalar value | array of values

Random number generated from the probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1`, ..., `szN`.

## Examples

### **Generate One Random Number**

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Generate one random number from the distribution.

```
r = random(pd)
```

```
r =
```

```
0.5377
```

### **Generate Multiple Random Numbers**

Create a Weibull probability distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

```
pd =
```

```
WeibullDistribution
```

# prob.TruncatableDistribution.random

---

```
Weibull distribution  
A = 1  
B = 1
```

Generate random numbers from distribution and visualize with a histogram.

```
r = random(pd,10000,1);  
hist(r,100)
```

## Generate a Multidimensional Array of Random Numbers

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Generate a 2-by-3-by-2 array of random numbers from the distribution.

```
r = random(pd,[2,3,2])
```

```
random_make_array(:,:,1) =
```

```
-1.0689    -2.9443     0.3252  
-0.8095     1.4384    -0.7549
```

```
random_make_array(:,:,2) =
```

```
1.3703    -0.1022     0.3192  
-1.7115    -0.2414     0.3129
```

## See Also

[makedist](#) | [fitdist](#) | [dfittool](#)

# LinearMixedModel.randomEffects

---

**Purpose** Estimates of random effects and related statistics

**Syntax**

```
B = randomEffects(lme)
[B,Bnames] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme)
[B,Bnames,stats] = randomEffects(lme,Name,Value)
```

**Description** `B = randomEffects(lme)` returns the estimates of the best linear unbiased predictors (BLUPs) of random effects in the linear mixed-effects model `lme`.

`[B,Bnames] = randomEffects(lme)` also returns the names of the coefficients in `Bnames`. Each name corresponds to a coefficient in `B`.

`[B,Bnames,stats] = randomEffects(lme)` also returns the estimated BLUPs of random effects in the linear mixed-effects model `lme` and related statistics.

`[B,Bnames,stats] = randomEffects(lme,Name,Value)` also returns the BLUPs of random effects in the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **lme - Linear mixed-effects model**

`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

For properties and methods of this object, see `LinearMixedModel`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

## 'Alpha' - Confidence level

0.05 (default) | scalar value in the range 0 to 1

Confidence level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 to 1. For a value  $\alpha$ , the confidence level is  $100*(1-\alpha)\%$ .

For example, for 99% confidence intervals, you can specify the confidence level as follows.

**Example:** 'Alpha', 0.01

## Data Types

single | double

## 'DFMethod' - Method for computing approximate degrees of freedom

'Residual' (default) | 'Satterthwaite' | 'None'

Method for computing approximate degrees of freedom for the  $t$ -statistics that test the random-effects coefficients against 0, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

'Residual'	Default. The degrees of freedom are assumed to be constant and equal to $n - p$ , where $n$ is the number of observations and $p$ is the number of fixed effects.
'Satterthwaite'	Satterthwaite approximation.
'None'	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

# LinearMixedModel.randomEffects

---

Example: 'DFMethod', 'Satterthwaite'

## Output Arguments

### **B - Estimated best linear unbiased predictors of random effects**

column vector

Estimated best linear unbiased predictors of random effects of linear mixed-effects model `lme`, returned as a column vector.

Suppose `lme` has  $R$  grouping variables  $g_1, g_2, \dots, g_R$ , with levels  $m_1, m_2, \dots, m_R$ , respectively. Also suppose  $q_1, q_2, \dots, q_R$  are the lengths of the random-effects vectors that are associated with  $g_1, g_2, \dots, g_R$ , respectively. Then, `B` is a column vector of length  $q_1 * m_1 + q_2 * m_2 + \dots + q_R * m_R$ .

`randomEffects` creates `B` by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

### **Bnames - Names of random-effects coefficients**

table

Names of random-effects coefficients in `B`, returned as a table.

### **stats - Estimates of random effects BLUPs and related statistics**

dataset array

Estimates of random effects BLUPs and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Group	Grouping variable associated with the random effect
Level	Level within the grouping variable corresponding to the random effect
Name	Name of the random-effect coefficient

Estimate	Best linear unbiased predictor (BLUP) of random effect
SEPred	Standard error of the estimate (BLUP minus random effect)
tStat	$t$ -statistic for a test that the random effect is zero
DF	Estimated degrees of freedom for the $t$ -statistic
pValue	$p$ -value for the $t$ -statistic
Lower	Lower limit of a 95% confidence interval for the random effect
Upper	Upper limit of a 95% confidence interval for the random effect

## Examples

### Display Random-Effects Estimates and Coefficient Names

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration, grouped by the model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the BLUPs of the random-effects coefficients and display the names of the corresponding random effects.

```
[B,Bnames] = randomEffects(lme)
```

'Model_Year'      '77'      'Acceleration'  
'Model_Year'      '78'      '(Intercept)'  
'Model_Year'      '78'      'Acceleration'  
'Model_Year'      '79'      '(Intercept)'  
'Model_Year'      '79'      'Acceleration'  
'Model_Year'      '80'      '(Intercept)'  
'Model_Year'      '80'      'Acceleration'  
'Model_Year'      '81'      '(Intercept)'  
'Model_Year'      '81'      'Acceleration'  
'Model_Year'      '82'      '(Intercept)'  
'Model_Year'      '82'      'Acceleration'
```

Since intercept and acceleration have potentially correlated random effects, grouped by model year of the cars, `randomEffects` creates a separate row for intercept and acceleration at each level of the grouping variable.

Compute the covariance parameters of the random effects.

```
[~,~,stats] = covarianceParameters(lme)  
stats{1}
```

```
ans =
```

```
Covariance Type: FullCholesky
```

# LinearMixedModel.randomEffects

---

Group	Name1	Name2	Type
Model_Year	'(Intercept)'	'(Intercept)'	'std'
Model_Year	'Weight'	'(Intercept)'	'corr'
Model_Year	'Weight'	'Weight'	'std'

The correlation value suggests that random effects seem negatively correlated. Plot the random effects for intercept versus acceleration to confirm this.

```
plot(B(1:2:end),B(2:2:end),'r*')
```

## Compute Random-Effects Estimates and Related Statistics

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load fertilizer
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

Compute the BLUPs and related statistics for random effects.

```
[~,~,stats] = randomEffects(lme)
```

```
stats =
```

# LinearMixedModel.randomEffects

---

Random effect coefficients: DFMethod = 'Residual', Alpha = 0.05

Group	Level	Name	Est
'Soil'	'Loamy'	'(Intercept)'	1.
'Soil'	'Sandy'	'(Intercept)'	-1.
'Soil'	'Silty'	'(Intercept)'	0.5
'Soil:Tomato'	'Loamy Cherry'	'(Intercept)'	1
'Soil:Tomato'	'Loamy Grape'	'(Intercept)'	-2.
'Soil:Tomato'	'Loamy Heirloom'	'(Intercept)'	16
'Soil:Tomato'	'Loamy Plum'	'(Intercept)'	-5.
'Soil:Tomato'	'Loamy Vine'	'(Intercept)'	-4.
'Soil:Tomato'	'Sandy Cherry'	'(Intercept)'	-17.
'Soil:Tomato'	'Sandy Grape'	'(Intercept)'	-7.
'Soil:Tomato'	'Sandy Heirloom'	'(Intercept)'	-8
'Soil:Tomato'	'Sandy Plum'	'(Intercept)'	7
'Soil:Tomato'	'Sandy Vine'	'(Intercept)'	0.2
'Soil:Tomato'	'Silty Cherry'	'(Intercept)'	4.
'Soil:Tomato'	'Silty Grape'	'(Intercept)'	10
'Soil:Tomato'	'Silty Heirloom'	'(Intercept)'	-8.
'Soil:Tomato'	'Silty Plum'	'(Intercept)'	-2.
'Soil:Tomato'	'Silty Vine'	'(Intercept)'	4

The first three rows contain the random-effects estimates and the statistics for the three levels, Loamy, Sandy, and Silty of the grouping variable Soil. The corresponding  $p$ -values 0.66918, 0.51825, and 0.82593 indicate that these random-effects are not significantly different from 0. The following 15 rows include the BLUPS of random-effects estimates for the intercept, grouped by the variable Tomato nested in Soil, i.e. interaction of Tomato and Soil.

## Compute Confidence Intervals with Specified Options

Load the sample data.

```
load carsmall
```

# LinearMixedModel.randomEffects

---

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);  
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is a significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for random effects using the residuals option to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = randomEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Group	Level	Name	Estimate	SEPr
'Operator'	'1'	'(Intercept)'	0.57753	0.90
'Operator'	'2'	'(Intercept)'	1.1757	0.90
'Operator'	'3'	'(Intercept)'	-2.1715	0.90
'Operator'	'4'	'(Intercept)'	2.3655	0.90
'Operator'	'5'	'(Intercept)'	-1.9472	0.90

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = randomEffects(lme, 'DFMethod', 'Satterthwaite', 'alpha', 0.01)
```

```
stats =
```

# LinearMixedModel.randomEffects

---

Random effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01

Group	Level	Name	Estimate	SEPred
'Operator'	'1'	'(Intercept)'	0.57753	0.90378
'Operator'	'2'	'(Intercept)'	1.1757	0.90378
'Operator'	'3'	'(Intercept)'	-2.1715	0.90378
'Operator'	'4'	'(Intercept)'	2.3655	0.90378
'Operator'	'5'	'(Intercept)'	-1.9472	0.90378

The Satterthwaite method usually produces smaller values for the degrees of freedom (DF), which results in larger  $p$ -values (pValue) and larger confidence intervals (Lower and Upper) for the random-effects estimates.

## See Also

## Purpose

Random sample

## Syntax

```
y = randsample(n,k)
y = randsample(population,k)
y = randsample(n,k,replacement)
y = randsample(population,k,replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s,...)
```

## Description

`y = randsample(n,k)` returns a  $k$ -by-1 vector  $y$  of values sampled uniformly at random, without replacement, from the integers 1 to  $n$ .

`y = randsample(population,k)` returns a vector of  $k$  values sampled uniformly at random, without replacement, from the values in the vector `population`. The orientation of  $y$  (row or column) is the same as `population`.

`y = randsample(n,k,replacement)` or `y = randsample(population,k,replacement)` returns a sample taken with replacement if `replacement` is `true`, or without replacement if `replacement` is `false`. The default is `false`.

`y = randsample(n,k,true,w)` or `y = randsample(population,k,true,w)` returns a weighted sample taken with replacement, using a vector of positive weights  $w$ , whose length is  $n$ . The probability that the integer  $i$  is selected for an entry of  $y$  is  $w(i) / \text{sum}(w)$ . Usually,  $w$  is a vector of probabilities. `randsample` does not support weighted sampling without replacement.

`y = randsample(s,...)` uses the stream `s` for random number generation. `s` is a member of the `RandStream` class. Default is the MATLAB default random number stream.

## Examples

Draw a single value from the integers 1 through 10:

```
n = 10;
x = randsample(n,1);
```

# randsample

---

Draw a single value from the population 1 through n, where  $n > 1$ :

```
y = randsample(1:n,1);
```

---

**Note** If population is a numeric vector containing only nonnegative integer values, and population can have length 1, use

```
y = population(randsample(length(population),k))
```

instead of `y = randsample(population,k)`.

---

Generate a random sequence of the characters A, C, G, and T, with replacement, according to the specified probabilities.

```
R = randsample('ACGT',48,true,[0.15 0.35 0.35 0.15])
```

- To randomly sample data, with or without replacement, use `datasample`.

## See Also

`rand` | `randperm` | `datasample` | `RandStream`

**Purpose** Interactive random number generation

**Syntax** randtool

**Description** randtool opens the Random Number Generation Tool.

The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.

# randtool

Start by selecting a distribution, then enter the desired sample size.

You can also

- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

**See Also**

`disttool` | `dfittool`

# range

---

**Purpose** Range of values

**Syntax** `range(X)`  
`y = range(X,dim)`

**Description** `range(X)` returns the difference between the maximum and the minimum of a sample. For vectors, `range(x)` is the range of the elements. For matrices, `range(X)` is a row vector containing the range of each column of `X`. For N-dimensional arrays, `range` operates along the first nonsingleton dimension of `X`.

`y = range(X,dim)` operates along the dimension `dim` of `X`.

`range` treats NaNs as missing values and ignores them.

The range is an easily-calculated estimate of the spread of a sample. Outliers have an undue influence on this statistic, which makes it an unreliable estimator.

**Examples** The range of a large sample of standard normal random numbers is approximately six. This is the motivation for the process capability indices  $C_p$  and  $C_{pk}$  in statistical quality control applications.

```
rv = normrnd(0,1,1000,5);  
near6 = range(rv)  
near6 =  
    6.1451    6.4986    6.2909    5.8894    7.0002
```

**See Also** `std` | `iqr` | `mad`

**Purpose**

Find all neighbors within specified distance

**Syntax**

```
idx = rangesearch(X,Y,r)
[idx,D]= rangesearch(X,Y,r)
[idx,D]= rangesearch(X,Y,r,Name,Value)
```

**Description**

`idx = rangesearch(X,Y,r)` finds all the *X* points that are within distance *r* of the *Y* points. Rows of *X* and *Y* correspond to observations, and columns correspond to variables.

`[idx,D]= rangesearch(X,Y,r)` returns the distances between each row of *Y* and the rows of *X* that are *r* or less distant.

`[idx,D]= rangesearch(X,Y,r,Name,Value)` finds nearby points with additional options specified by one or more *Name,Value* pair arguments.

**Tips**

- For a fixed positive integer *K*, `knnsearch` finds *K* points in *X* that are nearest each *Y* point. In contrast, for a fixed positive real value *r*, `rangesearch` finds all the *X* points that are within a distance *r* of each *Y* point.

**Input Arguments****X**

*m*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal as the number of columns in *Y*.

**Y**

*m*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal as the number of columns in *X*.

**r**

Search radius, a scalar. `rangesearch` finds all *X* points (rows) that are within distance *r* of each *Y* point. The meaning of distance depends on the `Distance` name-value pair.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'BucketSize'

Maximum number of data points in the leaf node of the *kd*-tree. This argument is only meaningful when *kd*-tree is used for finding nearest neighbors.

**Default:** 50

### 'Cov'

Positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This argument is only valid when the `Distance` name-value pair is 'mahalanobis'.

**Default:** `nancov(X)`

### 'Distance'

String or function handle specifying the distance metric.

Value	Description
'euclidean'	Euclidean distance.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between <code>X</code> and a query point is scaled, meaning divided by a scale value <code>S</code> . The default value of <code>S</code> is the standard deviation computed from <code>X</code> , <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use the <code>Scale</code> name-value pair.

Value	Description
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix $C$ . The default value of $C$ is the sample covariance matrix of $X$ , as computed by <code>nancov(X)</code> . To specify a different value for $C$ , use the 'Cov' name-value pair.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.

# rangesearch

---

Value	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form  function D2 = DISTFUN(ZI,ZJ) ...  where <ul style="list-style-type: none"><li>• ZI is a 1-by-N vector containing one row of X or Y.</li><li>• ZJ is an M2-by-N matrix containing multiple rows of X or Y.</li><li>• D2 is an M2-by-1 vector of distances, D2(k) is the distance between the observations ZI and ZJ(J,:).</li></ul>

For definitions, see “Distance Metrics” on page 16-9.

**Default:** 'euclidean'

**'NSMethod'**

Nearest neighbors search method.

Value	Meaning
'kdtree'	Creates and uses a <i>kd</i> -tree to find nearest neighbors. 'kdtree' is only valid when the distance metric is one of: <ul style="list-style-type: none"> <li>• 'chebyshev'</li> <li>• 'cityblock'</li> <li>• 'euclidean'</li> <li>• 'minkowski'</li> </ul>
'exhaustive'	Uses the exhaustive search algorithm. The distances from all X points to each Y point are computed to find nearest neighbors.

**Default:** 'kdtree' when the number of columns of X is not greater than 10, X is not sparse, and the distance metric is one of the valid 'kdtree' metrics. Otherwise, the default is 'exhaustive'.

**'P'**

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the Distance name-value pair is 'minkowski'.

**Default:** 2

**'Scale'**

Vector S containing nonnegative values, with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of S. This argument is only valid when the Distance name-value pair is 'seuclidean'.

**Default:** nanstd(X)

# rangesearch

---

## Output Arguments

### **idx**

*my*-by-1 cell array, where *my* is the number of rows in *Y*. `idx{I}` contains the indices of points (rows) in *X* whose distances to  $Y(I, :)$  are not greater than *r*. The entries in `idx{I}` are in ascending order of distance.

### **D**

*my*-by-1 cell array, where *my* is the number of rows in *Y*. `D{I}` contains the distance values between  $Y(I, :)$  and the corresponding points in `idx{I}`.

## Definitions

### **Distance Metrics**

For definitions, see “Distance Metrics” on page 16-9.

## Examples

Find the *X* points that are within a Euclidean distance 1.5 of each *Y* point. Both *X* and *Y* are samples of 5-D normally distributed variables.

```
rng('default') % for reproducibility
X = randn(100,5);
Y = randn(10,5);
[idx, dist] = rangesearch(X,Y,1.5)
```

```
idx =
    [1x7 double]
    [1x2 double]
    [1x11 double]
    [1x2 double]
    [1x12 double]
    [1x9 double]
    [      89]
    [1x0 double]
    [1x0 double]
    [1x0 double]
```

```
dist =
```

```

[1x7 double]
[1x2 double]
[1x11 double]
[1x2 double]
[1x12 double]
[1x9 double]
[    1.1739]
[1x0 double]
[1x0 double]
[1x0 double]

```

In this case, the last three  $Y$  points are more than 1.5 distant from any  $X$  point.  $X(89, :)$  is 1.1739 distant from  $Y(7, :)$ , and there is no other  $X$  point that is within distance 1.5 of  $Y(7, :)$ . There are 12 points in  $X$  within distance 1.5 of  $Y(5, :)$ .

## Algorithms

For an overview of the  $kd$ -tree algorithm, see “ $k$ -Nearest Neighbor Search Using a  $kd$ -Tree” on page 16-14.

The exhaustive search algorithm finds the distance of each point in  $X$  to each point in  $Y$ .

## Alternatives

`rangesearch` is the `ExhaustiveSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'exhaustive'`.

`rangesearch` is the `KDTreeSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'kdtree'`.

## See Also

`createns` | `ExhaustiveSearcher` | `KDTreeSearcher` | `knnsearch` | `pdist2`

## How To

- “ $k$ -Nearest Neighbor Search and Radius Search” on page 16-12

# ExhaustiveSearcher.rangesearch

---

**Purpose** Find all neighbors within specified distance using ExhaustiveSearcher object

**Syntax**  
`idx = rangesearch(NS,Y,r)`  
`[idx,D]= rangesearch(NS,Y,r)`  
`[idx,D]= rangesearch(NS,Y,r,Name,Value)`

**Description** `idx = rangesearch(NS,Y,r)` finds all points in `NS.X` that are within distance `r` of the `Y` points. Rows of `NS.X` and `Y` correspond to observations, and columns correspond to variables.

`[idx,D]= rangesearch(NS,Y,r)` returns the distances between each row of `Y` and the rows of `NS.X` that are `r` or less distant.

`[idx,D]= rangesearch(NS,Y,r,Name,Value)` finds nearby points with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For a fixed positive integer `K`, `knnsearch` finds the `K` points in `NS.X` that are nearest each `Y` point. In contrast, for a fixed positive real value `r`, `rangesearch` finds all the points in `NS.X` that are within a distance `r` of each `Y` point.

## Input Arguments

### **NS**

ExhaustiveSearcher object, constructed using ExhaustiveSearcher or createns.

### **Y**

*m*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal the number of columns in `NS.X`.

### **r**

Search radius, a scalar. `rangesearch` finds all `NS.X` points (rows) that are within distance `r` of each `Y` point. The meaning of distance depends on the `Distance` name-value pair.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

### 'Cov'

Positive definite matrix indicating the covariance matrix when computing the Mahalanobis distance. This argument is only valid when the `Distance` name-value pair is 'mahalanobis'.

**Default:** `nancov(X)`

### 'Distance'

String or function handle specifying the distance metric.

Value	Description
'euclidean'	Euclidean distance.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between <code>X</code> and a query point is scaled, meaning divided by a scale value <code>S</code> . The default value of <code>S</code> is the standard deviation computed from <code>X</code> , <code>S=nanstd(X)</code> . To specify another value for <code>S</code> , use the <code>Scale</code> name-value pair.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix <code>C</code> . The default value of <code>C</code> is the sample covariance matrix of <code>X</code> , as computed by <code>nancov(X)</code> . To specify a different value for <code>C</code> , use the 'Cov' name-value pair.
'cityblock'	City block distance.

# ExhaustiveSearcher.rangearch

---

Value	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form  function D2 = DISTFUN(ZI,ZJ) ...  where <ul style="list-style-type: none"><li>• ZI is a 1-by-N vector containing one row of X or Y.</li><li>• ZJ is an M2-by-N matrix containing multiple rows of X or Y.</li></ul>

Value	Description
	<ul style="list-style-type: none"><li>D2 is an M2-by-1 vector of distances, D2(k) is the distance between the observations ZI and ZJ(J, :).</li></ul>

For definitions, see “Distance Metrics” on page 16-9.

**Default:** 'euclidean'

**'P'**

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the Distance name-value pair is 'minkowski'.

**Default:** 2

**'Scale'**

Vector S containing nonnegative values, with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of S. This argument is only valid when the Distance name-value pair is 'seuclidean'.

**Default:** nanstd(X)

## Output Arguments

**idx**

*m<sub>y</sub>*-by-1 cell array, where *m<sub>y</sub>* is the number of rows in Y. idx{I} contains the indices of points (rows) in NS.X whose distances to Y(I, :) are not greater than r. The entries in idx{I} are in ascending order of distance.

**D**

# ExhaustiveSearcher.rangearch

---

$m_y$ -by-1 cell array, where  $m_y$  is the number of rows in  $Y$ .  
 $D\{I\}$  contains the distance values between  $Y(I,:)$  and the corresponding points in  $idx\{I\}$ .

## Definitions

### Distance Metrics

For definitions, see “Distance Metrics” on page 16-9.

## Examples

Create  $X$  and  $Y$  as samples of 5-D normally distributed variables. Create an ExhaustiveSearcher object  $NS$  from  $X$ . Find the points in  $NS.X$  that are within a Euclidean distance 1.5 of each point in  $Y$ .

```
rng('default') % for reproducibility
X = randn(100,5);
Y = randn(10,5);
NS = ExhaustiveSearcher(X);
[idx, dist] = rangearch(NS,Y,1.5)
```

```
idx =
    [1x7 double]
    [1x2 double]
    [1x11 double]
    [1x2 double]
    [1x12 double]
    [1x9 double]
    [          89]
    [1x0 double]
    [1x0 double]
    [1x0 double]
```

```
dist =
    [1x7 double]
    [1x2 double]
    [1x11 double]
    [1x2 double]
    [1x12 double]
    [1x9 double]
```

```
[      1.1739]
[1x0 double]
[1x0 double]
[1x0 double]
```

In this case, the last three points in  $Y$  are more than 1.5 distant from any point in  $NS.X$ .  $NS.X(89, :)$  is 1.1739 distant from  $Y(7, :)$ , and there is no other point in  $NS.X$  that is within distance 1.5 of  $Y(7, :)$ . There are 12 points in  $NS.X$  within distance 1.5 of  $Y(5, :)$ .

## Algorithms

The exhaustive search algorithm finds the distance of each point in  $X$  to each point in  $Y$ .

## Alternatives

`rangesearch` is the `ExhaustiveSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'exhaustive'`.

`rangesearch` is the `KDTreeSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'kdtree'`.

## See Also

`createns` | `ExhaustiveSearcher` | `knnsearch` | `pdist2` | `rangesearch`

# KDTreeSearcher.rangesearch

---

**Purpose** Find all neighbors within specified distance using KDTreeSearcher object

**Syntax**  
`idx = rangesearch(NS,Y,r)`  
`[idx,D]= rangesearch(NS,Y,r)`  
`[idx,D]= rangesearch(NS,Y,r,Name,Value)`

**Description** `idx = rangesearch(NS,Y,r)` finds all points in `NS.X` that are within distance `r` of the `Y` points. Rows of `NS.X` and `Y` correspond to observations, and columns correspond to variables.

`[idx,D]= rangesearch(NS,Y,r)` returns the distances between each row of `Y` and the rows of `NS.X` that are `r` or less distant.

`[idx,D]= rangesearch(NS,Y,r,Name,Value)` finds nearby points with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- For a fixed positive integer `K`, `knnsearch` finds the `K` points in `NS.X` that are nearest each `Y` point. In contrast, for a fixed positive real value `r`, `rangesearch` finds all the points in `NS.X` that are within a distance `r` of each `Y` point.

## Input Arguments

### **NS**

KDTreeSearcher object, constructed using KDTreeSearcher or createns.

### **Y**

*m*-by-*n* numeric matrix, where each row represents one *n*-dimensional point. The number of columns *n* must equal the number of columns in `NS.X`.

### **r**

Search radius, a scalar. `rangesearch` finds all `NS.X` points (rows) that are within distance `r` of each `Y` point. The meaning of distance depends on the `Distance` name-value pair.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

### 'Distance'

String or function handle specifying the distance metric.

Value	Description
'euclidean'	Euclidean distance.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair.
'chebychev'	Chebychev distance (maximum coordinate difference).

For definitions, see “Distance Metrics” on page 16-9.

**Default:** `NS.Distance`

### 'P'

Positive scalar indicating the exponent of Minkowski distance. This argument is only valid when the `Distance` name-value pair is `'minkowski'`.

**Default:** 2

## Output Arguments

### `idx`

$m_y$ -by-1 cell array, where  $m_y$  is the number of rows in `Y`. `idx{I}` contains the indices of points (rows) in `NS.X` whose distances

# KDTreeSearcher.rangesearch

---

to  $Y(I, :)$  are not greater than  $r$ . The entries in  $idx\{I\}$  are in ascending order of distance.

## **D**

$m_y$ -by-1 cell array, where  $m_y$  is the number of rows in  $Y$ .  
 $D\{I\}$  contains the distance values between  $Y(I, :)$  and the corresponding points in  $idx\{I\}$ .

## **Definitions**

### **Distance Metrics**

For definitions, see “Distance Metrics” on page 16-9.

## **Examples**

Create  $X$  and  $Y$  as samples of 5-D normally distributed variables. Create a KDTreeSearcher object  $NS$  from  $X$ . Find the points in  $NS.X$  that are within a Euclidean distance 1.5 of each point in  $Y$ .

```
rng('default') % for reproducibility
X = randn(100,5);
Y = randn(10,5);
NS = KDTreeSearcher(X);
[idx, dist] = rangesearch(NS,Y,1.5)
```

```
idx =
    [1x7 double]
    [1x2 double]
    [1x11 double]
    [1x2 double]
    [1x12 double]
    [1x9 double]
    [      89]
    [1x0 double]
    [1x0 double]
    [1x0 double]
```

```
dist =
    [1x7 double]
    [1x2 double]
```

```
[1x11 double]
[1x2  double]
[1x12 double]
[1x9  double]
[      1.1739]
[1x0  double]
[1x0  double]
[1x0  double]
```

In this case, the last three points in *Y* are more than 1.5 distant from any point in *NS.X*. *NS.X*(89,:) is 1.1739 distant from *Y*(7,:), and there is no other point in *NS.X* that is within distance 1.5 of *Y*(7,:). There are 12 points in *NS.X* within distance 1.5 of *Y*(5,:).

## Algorithms

For an overview of the *kd*-tree algorithm, see “*k*-Nearest Neighbor Search Using a *kd*-Tree” on page 16-14.

## Alternatives

`rangesearch` is the `KDTreeSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'kdtree'`.

`rangesearch` is the `ExhaustiveSearcher` method for distance search. It is equivalent to the `rangesearch` function with the `NSMethod` name-value pair set to `'exhaustive'`.

## See Also

`createns` | `KDTreeSearcher` | `knnsearch` | `pdist2` | `rangesearch`

# ranksum

---

**Purpose** Wilcoxon rank sum test

**Syntax**

```
p = ranksum(x,y)
[p,h] = ranksum(x,y)
[p,h,stats] = ranksum(x,y)
[ ___ ] = ranksum(x,y,Name,Value)
```

**Description** `p = ranksum(x,y)` returns the  $p$ -value of a two-sided Wilcoxon rank sum test. `ranksum` tests the null hypothesis that data in `x` and `y` are samples from continuous distributions with equal medians, against the alternative that they are not. The test assumes that the two samples are independent. `x` and `y` can have different lengths.

This test is equivalent to a Mann-Whitney U-test.

`[p,h] = ranksum(x,y)` also returns a logical value indicating the test decision. The result `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level.

`[p,h,stats] = ranksum(x,y)` also returns the structure `stats` with information about the test statistic.

`[ ___ ] = ranksum(x,y,Name,Value)` returns any of the output arguments in the previous syntaxes, for a rank sum test with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **x - Sample data**

vector

Sample data, specified as a vector.

### **Data Types**

single | double

### **y - Sample data**

vector

Sample data, specified as a vector. The length of *y* does not have to be the same as the length of *x*.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of *Name*, *Value* arguments. *Name* is the argument name and *Value* is the corresponding value. *Name* must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as *Name1*, *Value1*, ..., *NameN*, *ValueN*.

**Example:** 'alpha',0.01,'method','approximate','tail','right' specifies a right-tailed rank sum test with 1% significance level, which returns the approximate *p*-value.

### 'alpha' - Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1. The significance level of *h* is 100 \* alpha%.

**Example:** 'alpha',0.01

### Data Types

double | single

### 'method' - Computation method of the *p*-value

'exact' | 'approximate'

Computation method of the *p*-value, *p*, specified as the comma-separated pair consisting of 'method' and one of the following:

'exact'	Exact computation of the <i>p</i> -value, <i>p</i> .
'approximate'	Normal approximation while computing the <i>p</i> -value, <i>p</i> .

# ranksum

---

When 'method' is unspecified, the default is:

- 'exact' if  $\min(n_x, n_y) < 10$  and  $n_x + n_y < 20$
- 'approximate' otherwise

$n_x$  and  $n_y$  are the sizes of the samples in x and y, respectively.

**Example:** 'method', 'exact'

## Data Types

char

## 'tail' - Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

'both'	Two-sided hypothesis test, where the alternative hypothesis states that x and y have different medians. Default test type if 'tail' is not specified.
'right'	Right-tailed hypothesis test, where the alternative hypothesis states that the median of x is greater than the median of y.
'left'	Left-tailed hypothesis test, where the alternative hypothesis states that the median of x is less than the median of y.

**Example:** 'tail', 'left'

## Data Types

char

## Output Arguments

### p - p-value of the test

nonnegative scalar

$p$ -value of the test, returned as a positive scalar from 0 to 1.  $p$  is the probability of observing a test statistic as or more extreme than

the observed value under the null hypothesis. `ranksum` computes the two-sided  $p$ -value by doubling the most significant one-sided value.

### **h - Result of the hypothesis test**

1 | 0

Result of the hypothesis test, returned as a logical value.

- If  $h = 1$ , this indicates rejection of the null hypothesis at the  $100 * \alpha\%$  significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the  $100 * \alpha\%$  significance level.

### **stats - Test statistics**

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `ranksum` : Value of the rank sum test statistic
- `zval`: Value of the z-statistic (computed when 'method' is 'approximate')

## **Examples**

### **Test for Equal Median of Two Populations**

Test the hypothesis of equal medians for two independent unequal-sized samples.

Generate sample data.

```
rng('default') % for reproducibility
x = unifrnd(0,1,10,1);
y = unifrnd(0.25,1.25,15,1);
```

These samples come from populations with identical distributions except for a shift of 0.25 in the location.

Test the equality of medians of  $x$  and  $y$ .

```
p = ranksum(x,y)
```

```
p =  
0.0375
```

The  $p$ -value of 0.0375 indicates that `ranksum` rejects the null hypothesis of equal medians at the default 5% significance level.

## Statistics of the Test for Two Population Medians

Obtain the statistics of the test for the equality of two population medians.

Load the sample data.

```
load mileage
```

Test if the mileage per gallon is the same for the first and second type of cars.

```
[p,h,stats] = ranksum(mileage(:,1),mileage(:,2))
```

```
p =  
0.0043
```

```
h =  
1
```

```
stats =  
ranksum: 21.5000
```

Both the  $p$ -value, 0.043, and  $h = 1$  indicate the rejection of the null hypothesis of equal medians at the default 5% significance level. Because the sample sizes are small (six each), `ranksum` calculates the  $p$ -value using the exact method. The structure `stats` includes only the value of the rank sum test statistic.

## Increase in the Median

Test the hypothesis of an increase in the population median.

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weather
```

The weather data shows the daily high temperatures taken in the same month in two consecutive years.

Perform a left-sided test to assess the increase in the median at the 1% significance level.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...
'tail','left')
```

```
p =
```

```
    0.1271
```

```
h =
```

```
    0
```

```
stats =
```

```
    zval: -1.1403
    ranksum: 837.5000
```

Both the  $p$ -value of 0.1271 and  $h = 0$  indicate that there is not enough evidence to reject the null hypothesis and conclude that there is a positive shift in the median of observed high temperatures in the same month from year 1 to year 2 at the 1% significance level. Notice that

ranksum uses the approximate method to calculate the  $p$ -value due to the large sample sizes.

Use the exact method to calculate the  $p$ -value.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...  
'tail','left','method','exact')
```

```
p =
```

```
    0.1273
```

```
h =
```

```
    0
```

```
stats =
```

```
ranksum: 837.5000
```

The results of the approximate and exact methods are consistent with each other.

## Definitions

### Wilcoxon Rank Sum Test

The Wilcoxon rank sum test is a nonparametric test for two populations when samples are independent. If  $X$  and  $Y$  are independent samples with different sample sizes, the test statistic which ranksum returns is the rank sum of the first sample.

The Wilcoxon rank sum test is equivalent to the Mann-Whitney U-test. The Mann-Whitney U-test is a nonparametric test for equality of population medians of two independent samples  $X$  and  $Y$ .

The Mann-Whitney U-test statistic,  $U$ , is the number of times a  $y$  precedes an  $x$  in an ordered arrangement of the elements in the two

independent samples  $X$  and  $Y$ . It is related to the Wilcoxon rank sum statistic in the following way: If  $X$  is a sample of size  $n_X$ , then

$$U = W - \frac{n_X(n_X + 1)}{2}.$$

### **z-Statistic**

For large samples, ranksum uses a  $z$ -statistic to compute the approximate  $p$ -value of the test.

If  $X$  and  $Y$  are two independent samples of size  $n_X$  and  $n_Y$ , where  $n_X < n_Y$  the  $z$ -statistic is

$$z = \frac{W - E(W)}{\sqrt{V(W)}} = \frac{W - \left[ \frac{n_X n_Y + n_X(n_X + 1)}{2} \right] - 0.5 * \text{sign}(W - E(W))}{\sqrt{\frac{n_X n_Y (n_X + n_Y + 1) - \text{tiescor}}{12}}},$$

with continuity correction and tie adjustment. Here *tiescor* is given by

$$\text{tiescor} = \frac{2 * \text{tieadj}}{(n_X + n_Y)(n_X + n_Y - 1)},$$

where ranksum uses `[ranks, tieadj] = tiedrank(x, y)` to obtain tie adjustments. The standard normal distribution gives the  $p$ -value for this  $z$ -statistic.

## **Algorithms**

ranksum treats NaNs in  $x$  and  $y$  as missing values and ignores them.

For a two-sided test of medians with unequal sample sizes, the test statistic that ranksum returns is the rank sum of the first sample.

**Purpose** Repeated measures analysis of variance

**Syntax**  
`ranovatbl = ranova(rm)`  
`ranovatbl = ranova(rm, 'WithinModel', WM)`  
`[ranovatbl, A, C, D] = ranova( ___ )`

**Description** `ranovatbl = ranova(rm)` returns the results of repeated measures analysis of variance for a repeated measures model `rm` in table `ranovatbl`.

`ranovatbl = ranova(rm, 'WithinModel', WM)` returns the results of repeated measures analysis of variance using the responses specified by the within-subject model `WM`.

`[ranovatbl, A, C, D] = ranova( ___ )` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form  $A*B*C = D$ , where `D` is zero.

## Input Arguments

### **rm - Repeated measures model**

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

### **WM - Model specifying responses**

'separatemeans' (default) | *r*-by-*nc* contrast matrix | string that defines a model specification

Model specifying the responses, specified as one of the following:

- 'separatemeans' — Compute a separate mean for each group.
- *C* — *r*-by-*nc* contrast matrix specifying the *nc* contrasts among the *r* repeated measures. If *Y* represents a matrix of repeated measures, `ranova` tests the hypothesis that the means of  $Y*C$  are zero.

# RepeatedMeasuresModel.ranova

- A string that defines a model specification in the within-subject factors. You can define the model based on the rules for the terms in the `modelspec` argument of `fitrm`. Also see “Model Specification for Repeated Measures Models” on page 8-54.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

**Example:** `'WithinModel', 'w1+w2+w2*w3'`

## Data Types

single | double

## Output Arguments

### **ranovatbl - Results of repeated measures anova**

table

Results of repeated measures anova, returned as a table.

`ranovatbl` includes a term represents all differences across the within-subjects factors. This term has either the name of the within-subjects factor if specified while fitting the model, or the name `Time` if the name of the within-subjects factor is not specified while fitting the model or there are more than one within-subjects factors. `ranovatbl` also includes all interactions between the terms in the within-subject model and all between-subject model terms. It contains the following columns.

Column Name	Definition
SumSq	Sum of squares.
DF	Degrees of freedom.
MeanSq	Mean squared error.
F	<i>F</i> -statistic.
pValue	<i>p</i> -value for the corresponding <i>F</i> -statistic. A small <i>p</i> -value indicates significant term effect.

Column Name	Definition
pValueGG	$p$ -value with Greenhouse-Geisser adjustment.
pValueHF	$p$ -value with Huynh-Feldt adjustment.
pValueLB	$p$ -value with Lower bound adjustment.

The last three  $p$ -values are the adjusted  $p$ -values for use when the compound symmetry assumption is not satisfied. For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 8-56. The mauchy method tests for sphericity (hence, compound symmetry) and epsilon method returns the epsilon adjustment values.

## A - Specification based on between-subjects model

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of **B** (within time hypothesis). If `ranovatbl` contains multiple hypothesis tests, **A** might be a cell array.

### Data Types

single | double | cell

## C - Specification based on within-subjects model

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of **B** (between time hypotheses). If `ranovatbl` contains multiple hypothesis tests, **C** might be a cell array.

### Data Types

single | double | cell

## D - Hypothesis value

0

# RepeatedMeasuresModel.ranova

---

Hypothesis value, returned as 0.

## Examples Repeated Measures Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ans =
```

	SumSq	DF	MeanSq	F	
(Intercept):Measurements	1656.3	3	552.09	6873.3	
species:Measurements	282.47	6	47.078	586.1	1.
Error(Measurements)	35.423	441	0.080324		

There are four measurements, three types of species, and 150 observations. So, degrees of freedom for measurements is  $(4-1) =$

3, for species-measurements interaction it is  $(4-1)*(3-1) = 6$ , and for error it is  $(150-4)*(3-1) = 441$ . `ranova` computes the last three *p*-values using Greenhouse-Geisser, Huynh-Feldt, and Lower bound corrections, respectively. You can check the compound symmetry (sphericity) assumption using the `mauchly` method, and display the epsilon corrections using the `epsilon` method.

## Longitudinal Data

Navigate to the folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load('longitudinalData')
```

The matrix `Y` contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of `Y` corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M']
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5),...
'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

# RepeatedMeasuresModel.ranova

---

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl =
```

	SumSq	DF	MeanSq	F	pValue
(Intercept):Time	881.7	4	220.43	37.539	3.0348e-15
Gender:Time	17.65	4	4.4125	0.75146	0.56126
Error(Time)	328.83	56	5.872		

There are 5 time points, 2 genders, and 16 observations. So, the degrees of freedom for time is  $(5-1) = 4$ , for gender-time interaction it is  $(5-1)*(2-1) = 4$ , and for error it is  $(16-2)*(5-1) = 56$ . The small  $p$ -value of  $2.6198e-05$  indicates that there is a significant effect of time on blood pressure. The  $p$ -value of 0.40063 indicates that there is no significant gender-time interaction.

## Specify the Within-Subjects Model

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the

# RepeatedMeasuresModel.ranova

group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', w1)
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl =
```

	SumSq	DF	MeanSq	F	pValue
(Intercept):Time	6645.2	7	949.31	2.2689	0.0316
Age:Time	5824.3	7	832.05	1.9887	0.0599
IQ:Time	5188.3	7	741.18	1.7715	0.0967
Group:Time	15800	14	1128.6	2.6975	0.0014
Gender:Time	4455.8	7	636.55	1.5214	0.163
Group:Gender:Time	4247.3	14	303.38	0.72511	0.74
Error(Time)	64433	154	418.39		

Specify the model for the within-subject factors. Also display the matrices used in the hypothesis test.

```
[ranovatbl,A,C,D] = ranova(rm, 'WithinModel', 'w1+w2')
```

```
ranovatbl =
```

	SumSq	DF	MeanSq	F	pValue
(Intercept)	3141.7	1	3141.7	2.5034	0.1278
Age	537.48	1	537.48	0.42828	0.5196
IQ	2975.9	1	2975.9	2.3712	0.1378
Group	20836	2	10418	8.3012	0.002060
Gender	3036.3	1	3036.3	2.4194	0.1341
Group:Gender	211.8	2	105.9	0.084385	0.9193

# RepeatedMeasuresModel.ranova

---

Error	27609	22	1255		
(Intercept):w1	146.75	1	146.75	0.23326	0.63389
Age:w1	942.02	1	942.02	1.4974	0.23402

## Algorithms

`ranova` computes the regular  $p$ -value (in the `pValue` column of the `rmanova` table) using the  $F$ -statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor  $\epsilon$ ,  $\epsilon$ , to compute the corrected  $p$ -values as follows:

$$p\text{-value\_corrected} = 1 - \text{fcdf}(F, \epsilon^* v_1, \epsilon^* v_2).$$

# RepeatedMeasuresModel.ranova

---

The mauchly method tests for sphericity (hence, compound symmetry) and epsilon method returns the epsilon adjustment values.

## Concepts

- “Model Specification for Repeated Measures Models” on page 8-54
- “Compound Symmetry Assumption and Epsilon Corrections” on page 8-56
- “Mauchly’s Test of Sphericity” on page 8-58

**Purpose**

Rayleigh cumulative distribution function

**Syntax**

```
p = raylcdf(x,b)
p = raylcdf(x,b,'upper')
```

**Description**

`p = raylcdf(x,b)` returns the Rayleigh cdf at each value in `x` using the corresponding scale parameter, `b`. `x` and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x` or `b` is expanded to a constant array with the same dimensions as the other input.

`p = raylcdf(x,b,'upper')` returns the complement of the Rayleigh cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Rayleigh cdf is

$$y = F(x | b) = \int_0^x \frac{t}{b^2} e^{\left(\frac{-t^2}{2b^2}\right)} dt$$

**Examples****Compute and Plot Rayleigh Distribution cdf**

Compute the cdf of a Rayleigh distribution with parameter `B = 1`.

```
x = 0:0.1:3;
p = raylcdf(x,1);
```

Plot the cdf.

```
figure;
plot(x,p)
```

# raylcdf

---

## How To

- “Rayleigh Distribution” on page B-133

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Rayleigh probability distribution object

**Description** `prob.RayleighDistribution` is an object consisting of parameters, a model description, and sample data for a normal probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Rayleigh')` creates a Rayleigh probability distribution object using the default parameter values.

`pd = makedist('Rayleigh','b',b)` creates a Rayleigh probability distribution object using the specified parameter value.

## Input Arguments

### **b** - Defining parameter

1 (default) | positive scalar value

Defining parameter for the Rayleigh distribution, specified as a positive scalar value.

### Data Types

single | double

**Properties** **b** - Defining parameter

positive scalar value

Defining parameter for the Rayleigh distribution, stored as a positive scalar value.

### Data Types

single | double

### **DistributionName** - Probability distribution name

probability distribution name string

# prob.RayleighDistribution

---

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## InputData - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## IsTruncated - Logical flag for truncated distribution

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

### **Data Types**

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

### **Data Types**

char

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

# prob.RayleighDistribution

---

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object

paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Rayleigh Distribution

The Rayleigh distribution is a special case of the Weibull distribution. It is often used in communication theory to model scattered signals that reach a receiver by multiple paths.

The Rayleigh distribution uses the following parameter.

Parameter	Description	Support
b	Defining parameter	$b > 0$

The probability density function (pdf) is

# prob.RayleighDistribution

---

$$f(x|b) = \frac{x}{b^2} \exp\left\{\frac{-x^2}{2b^2}\right\} ; \quad x \geq 0.$$

## Examples

### Create a Rayleigh Distribution Object Using Default Parameters

Create a Rayleigh distribution object using the default parameter values.

```
pd = makedist('Rayleigh')
```

```
pd =
```

```
RayleighDistribution
```

```
Rayleigh distribution
```

```
B = 1
```

### Create a Rayleigh Distribution Object Using Specified Parameters

Create a Rayleigh distribution object by specifying the parameter values.

```
pd = makedist('Rayleigh','b',3)
```

```
pd =
```

```
RayleighDistribution
```

```
Rayleigh distribution
```

```
B = 3
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```

- Property Attributes

# raylfit

---

**Purpose** Rayleigh parameter estimates

**Syntax** `raylfit(data,alpha)`  
`[phat,pci] = raylfit(data,alpha)`

**Description** `raylfit(data,alpha)` returns the maximum likelihood estimates of the parameter of the Rayleigh distribution given the data in the vector `data`.  
`[phat,pci] = raylfit(data,alpha)` returns the maximum likelihood estimate and  $100(1 - \alpha)\%$  confidence interval given the data. The default value of the optional parameter `alpha` is 0.05, corresponding to 95% confidence intervals.

**See Also** `mle` | `raylpdf` | `raylcdf` | `raylinv` | `raylstat` | `raylrnd`

**How To** • “Rayleigh Distribution” on page B-133

---

<b>Purpose</b>	Rayleigh inverse cumulative distribution function
<b>Syntax</b>	<code>X = raylinv(P,B)</code>
<b>Description</b>	<code>X = raylinv(P,B)</code> returns the inverse of the Rayleigh cumulative distribution function using the corresponding scale parameter, <code>B</code> at the corresponding probabilities in <code>P</code> . <code>P</code> and <code>B</code> can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for <code>P</code> or <code>B</code> is expanded to a constant array with the same dimensions as the other input.
<b>Examples</b>	<pre>x = raylinv(0.9,1) x =     2.1460</pre>
<b>See Also</b>	<code>raylcdf</code>   <code>raylpdf</code>   <code>raylrnd</code>   <code>raylstat</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• <code>icdf</code></li><li>• “Rayleigh Distribution” on page B-133</li></ul>

# raylpdf

---

**Purpose** Rayleigh probability density function

**Syntax** `Y = raylpdf(X,B)`

**Description** `Y = raylpdf(X,B)` computes the Rayleigh pdf at each of the values in `X` using the corresponding scale parameter, `B`. `X` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X` or `B` is expanded to a constant array with the same dimensions as the other input.

The Rayleigh pdf is

$$y = f(x | b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

## **Examples**      **Compute and Plot Rayleigh Distribution pdf**

Compute the pdf of a Rayleigh distribution with parameter `B = 0.5`.

```
x = [0:0.01:2];  
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;  
plot(x,p)
```

**How To**

- “Rayleigh Distribution” on page B-133

# raylrnd

---

**Purpose** Rayleigh random numbers

**Syntax**  
`R = raylrnd(B)`  
`R = raylrnd(B,v)`  
`R = raylrnd(B,m,n)`

**Description** `R = raylrnd(B)` returns a matrix of random numbers chosen from the Rayleigh distribution with scale parameter, `B`. `B` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `B`.

`R = raylrnd(B,v)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where `v` is a row vector. If `v` is a 1-by-2 vector, `R` is a matrix with `v(1)` rows and `v(2)` columns. If `v` is 1-by-`n`, `R` is an `n`-dimensional array.

`R = raylrnd(B,m,n)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where scalars `m` and `n` are the row and column dimensions of `R`.

**Examples**

```
r = raylrnd(1:5)
r =
    1.7986    0.8795    3.3473    8.9159    3.5182
```

**See Also** `random` | `raylpdf` | `raylcdf` | `raylinv` | `raylstat` | `raylfit`

**How To**

- “Rayleigh Distribution” on page B-133

**Purpose** Rayleigh mean and variance

**Syntax** [M,V] = raylstat(B)

**Description** [M,V] = raylstat(B) returns the mean of and variance for the Rayleigh distribution with scale parameter B.

The mean of the Rayleigh distribution with parameter  $b$  is  $b\sqrt{\pi/2}$  and the variance is

$$\frac{4-\pi}{2}b^2$$

**Examples** [mn,v] = raylstat(1)

```
mn =  
    1.2533  
v =  
    0.4292
```

**See Also** raylpdf | raylcdf | raylinv | raylfit | raylrnd

**How To** • “Rayleigh Distribution” on page B-133

# rcoplot

**Purpose** Residual case order plot

**Syntax** `rcoplot(r,rint)`

**Description** `rcoplot(r,rint)` displays an errorbar plot of the confidence intervals on the residuals from a regression. The residuals appear in the plot in case order. Inputs `r` and `rint` are outputs from the `regress` function.

**Examples** The following plots residuals and prediction intervals from a regression of a linearly additive model to the data in `moore.mat`:

```
load moore
X = [ones(size(moore,1),1) moore(:,1:5)];
y = moore(:,6);
alpha = 0.05;
[betahat,Ibeta,res,Ires,stats] = regress(y,X,alpha);
rcoplot(res,Ires)
```

The interval around the first residual, shown in red, does not contain zero. This indicates that the residual is larger than expected in 95% of new observations, and suggests the data point is an outlier.

**See Also**

`regress`

# refcurve

---

**Purpose** Add reference curve to plot

**Syntax** `refcurve(p)`  
`refcurve`  
`hcurve = refcurve(...)`

**Description** `refcurve(p)` adds a polynomial reference curve with coefficients `p` to the current axes. If `p` is a vector with `n+1` elements, the curve is:

$$y = p(1)*x^n + p(2)*x^{(n-1)} + \dots + p(n)*x + p(n+1)$$

`refcurve` with no input arguments adds a line along the  $x$  axis.

`hcurve = refcurve(...)` returns the handle `hcurve` to the curve.

## **Examples** **Add Population and Fitted Mean Functions**

Generate data with a polynomial trend.

```
p = [1 -2 -1 0];  
t = 0:0.1:3;  
rng('default') % for reproducibility  
y = polyval(p,t) + 0.5*randn(size(t));
```

Plot data and add the population mean function using `refcurve`.

```
plot(t,y,'ro')  
h = refcurve(p);  
set(h,'Color','r')
```

Also add the fitted mean function.

```
q = polyfit(t,y,3);  
refcurve(q)  
legend('Data','Population Mean','Fitted Mean',...  
      'Location','NW')
```

# refcurve

## Plot Trajectories of a Batted Baseball Using refcurve

Introduce the relevant physical constants.

```
M = 0.145;      % Mass (kg)
R = 0.0366;    % Radius (m)
A = pi*R^2;    % Area (m^2)
rho = 1.2;     % Density of air (kg/m^3)
C = 0.5;      % Drag coefficient
D = rho*C*A/2; % Drag proportional to the square of the speed
```

```

g = 9.8;          % Acceleration due to gravity (m/s^2)

Simulate the trajectory with drag proportional to the square of the
speed, assuming constant acceleration in each time interval.

dt = 1e-2;       % Simulation time interval (s)
r0 = [0 1];      % Initial position (m)
s0 = 50;         % Initial speed (m/s)
alpha0 = 35;     % Initial angle (deg)
v0 = s0*[cosd(alpha0) sind(alpha0)]; % Initial velocity (m/s)

r = r0;
v = v0;
trajectory = r0;
while r(2) > 0
    a = [0 -g] - (D/M)*norm(v)*v;
    v = v + a*dt;
    r = r + v*dt + (1/2)*a*(dt^2);
    trajectory = [trajectory;r];
end

Plot trajectory and use refcurve to add the drag-free parabolic trajectory
(found analytically) to the plot of trajectory.

plot(trajectory(:,1),trajectory(:,2),'m','LineWidth',2)
xlim([0,250])
h = refcurve([-g/(2*v0(1)^2),...
    (g*r0(1)/v0(1)^2) + (v0(2)/v0(1)),...
    (-g*r0(1)^2/(2*v0(1)^2)) - (v0(2)*r0(1)/v0(1)) + r0(2)]);
set(h,'Color','c','LineWidth',2)
axis equal
ylim([0,50])
grid on
xlabel('Distance (m)')
ylabel('Height (m)')
title('{\bf Baseball Trajectories}')
legend('With Drag','Without Drag')

```

**See Also** `refline` | `lsline` | `gline` | `polyfit`

**Purpose** Add reference line to plot

**Syntax**

```
refline(m,b)
refline(coeffs)
refline
hline = refline(...)
```

**Description** `refline(m,b)` adds a reference line with slope `m` and intercept `b` to the current axes.

`refline(coeffs)`, where `coeffs` is a two-element coefficient vector, adds the line

$$y = \text{coeffs}(1)*x + \text{coeffs}(2)$$

to the figure.

`refline` with no input arguments is equivalent to `lsline`.

`hline = refline(...)` returns the handle `hline` to the line.

## Examples **Add a Reference Line at the Mean**

Generate sample data for independent variable `x` and a dependent variable `y`.

```
x = 1:10;
y = x + randn(1,10);
```

Create a scatter plot of `x` and `y`.

```
scatter(x,y,25,'b','*')
```

# refline

---

Superimpose a least-squares line on the scatter plot.

```
lsline
```

Add a reference line at the mean of the scatter and its least-squares line.

```
mu = mean(y);  
hline = refline([0 mu]);  
set(hline, 'Color', 'r')
```

# refline

---

The red line shows the reference line at the mean of data.

## See Also

[refcurve](#) | [lslines](#) | [gline](#)

**Purpose**

Multiple linear regression

**Syntax**

```
b = regress(y,X)
[b,bint] = regress(y,X)
[b,bint,r] = regress(y,X)
[b,bint,r,rint] = regress(y,X)
[b,bint,r,rint,stats] = regress(y,X)
[...] = regress(y,X,alpha)
```

**Description**

`b = regress(y,X)` returns a  $p$ -by-1 vector `b` of coefficient estimates for a multilinear regression of the responses in `y` on the predictors in `X`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `y` is an  $n$ -by-1 vector of observed responses.

`regress` treats NaNs in `X` or `y` as missing values, and ignores them.

If the columns of `X` are linearly dependent, `regress` obtains a basic solution by setting the maximum number of elements of `b` to zero.

`[b,bint] = regress(y,X)` returns a  $p$ -by-2 matrix `bint` of 95% confidence intervals for the coefficient estimates. The first column of `bint` contains lower confidence bounds for each of the  $p$  coefficient estimates; the second column contains upper confidence bounds.

If the columns of `X` are linearly dependent, `regress` returns zeros in elements of `bint` corresponding to the zero elements of `b`.

`[b,bint,r] = regress(y,X)` returns an  $n$ -by-1 vector `r` of residuals.

`[b,bint,r,rint] = regress(y,X)` returns an  $n$ -by-2 matrix `rint` of intervals that can be used to diagnose outliers. If the interval `rint(i,:)` for observation `i` does not contain zero, the corresponding residual is larger than expected in 95% of new observations, suggesting an outlier.

In a linear model, observed values of `y` are random variables, and so are their residuals. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, they are “Studentized,” that is, they are divided by an estimate of their standard deviation that is independent of their value. Studentized residuals have  $t$  distributions with known

# regress

---

degrees of freedom. The intervals returned in `rint` are shifts of the 95% confidence intervals of these  $t$  distributions, centered at the residuals.

`[b,bint,r,rint,stats] = regress(y,X)` returns a 1-by-4 vector `stats` that contains, in order, the  $R^2$  statistic, the  $F$  statistic and its  $p$  value, and an estimate of the error variance.

---

**Note** When computing statistics,  $X$  should include a column of 1s so that the model contains a constant term. The  $F$  statistic and its  $p$  value are computed under this assumption, and they are not correct for models without a constant.

The  $F$  statistic is the test statistic of the F-test on the regression model, for a significant linear regression relationship between the response variable and the predictor variables.

The  $R^2$  statistic can be negative for models without a constant, indicating that the model is not appropriate for the data.

---

`[...] = regress(y,X,alpha)` uses a  $100*(1-\text{alpha})\%$  confidence level to compute `bint` and `rint`.

## Examples

### Estimate Multiple Linear Regression Coefficients

This example shows how to estimate the coefficients of a multiple linear regression.

Load the sample data. Identify weight and horsepower as predictors, and mileage as the response.

```
load carsmall
x1 = Weight;
x2 = Horsepower;    % Contains NaN data
y = MPG;
```

Compute the regression coefficients for a linear model with an interaction term.

```
X = [ones(size(x1)) x1 x2 x1.*x2];  
b = regress(y,X)    % Removes NaN data
```

```
b =
```

```
    60.7104  
   -0.0102  
   -0.1882  
    0.0000
```

Plot the data and the model.

```
scatter3(x1,x2,y,'filled')  
hold on  
x1fit = min(x1):100:max(x1);  
x2fit = min(x2):10:max(x2);  
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);  
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT + b(4)*X1FIT.*X2FIT;  
mesh(X1FIT,X2FIT,YFIT)  
xlabel('Weight')  
ylabel('Horsepower')  
zlabel('MPG')  
view(50,10)
```

<b>Superclasses</b>	RegressionEnsemble
<b>Purpose</b>	Regression ensemble grown by resampling
<b>Description</b>	RegressionBaggedEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.
<b>Construction</b>	<pre>ens = fitensemble(X,Y,'bag',nlearn,learners,'type','regression')</pre> creates a bagged regression ensemble. For more information on the syntax, see the <code>fitensemble</code> function reference page.
<b>Properties</b>	<p><b>CategoricalPredictors</b></p> <p>List of categorical predictors. <code>CategoricalPredictors</code> is a numeric vector with indices from 1 to <code>p</code>, where <code>p</code> is the number of columns of <code>X</code>.</p> <p><b>CombineWeights</b></p> <p>A string describing how the ensemble combines learner predictions.</p> <p><b>FitInfo</b></p> <p>A numeric array of fit information. The <code>FitInfoDescription</code> property describes the content of this array.</p> <p><b>FitInfoDescription</b></p> <p>String describing the meaning of the <code>FitInfo</code> array.</p> <p><b>FResample</b></p> <p>A numeric scalar between 0 and 1. <code>FResample</code> is the fraction of training data <code>fitensemble</code> resampled at random for every weak learner when constructing the ensemble.</p> <p><b>LearnerNames</b></p>

# RegressionBaggedEnsemble

---

Cell array of strings with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{'Tree'}`.

## **Method**

A string with the name of the algorithm `fitensemble` used for training the ensemble.

## **ModelParameters**

Parameters used in training `ens`.

## **NumObservations**

Numeric scalar containing the number of observations in the training data.

## **NumTrained**

Number of trained learners in the ensemble, a positive scalar.

## **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

## **ReasonForTermination**

A string describing the reason `fitensemble` stopped adding weak learners to the ensemble.

## **Regularization**

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

## **Replace**

Boolean flag indicating if training data for weak learners in this ensemble were sampled with replacement. `Replace` is `true` for sampling with replacement, `false` otherwise.

## ResponseName

A string with the name of the response variable  $Y$ .

## ResponseTransform

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means  $@(x)x$ .

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

## Trained

The trained learners, a cell array of compact regression models.

## TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

## UseObsForLearner

A logical matrix of size  $N$ -by- $\text{NumTrained}$ , where  $N$  is the number of rows (observations) in the training data  $X$ , and  $\text{NumTrained}$  is the number of trained weak learners. `UseObsForLearner(I,J)` is true if observation  $I$  was used for training learner  $J$ , and is false otherwise.

## W

The scaled `weights`, a vector with length  $n$ , the number of rows in  $X$ . The sum of the elements of  $W$  is 1.

## X

The matrix of predictor values that trained the ensemble. Each column of  $X$  represents one variable, and each row represents one observation.

## Y

# RegressionBaggedEnsemble

---

The numeric column vector with the same number of rows as X that trained the ensemble. Each entry in Y is the response to the data in the corresponding row of X.

## Methods

<code>oobLoss</code>	Out-of-bag regression error
<code>oobPredict</code>	Predict out-of-bag response of ensemble

## Inherited Methods

<code>compact</code>	Create compact regression ensemble
<code>crossval</code>	Cross validate ensemble
<code>cvshrink</code>	Cross validate shrinking (pruning) ensemble
<code>regularize</code>	Find weights to minimize resubstitution error plus penalty term
<code>resubLoss</code>	Regression error by resubstitution
<code>resubPredict</code>	Predict response of ensemble by resubstitution
<code>resume</code>	Resume training ensemble
<code>shrink</code>	Prune ensemble
<code>loss</code>	Regression error
<code>predict</code>	Predict response of ensemble
<code>predictorImportance</code>	Estimates of predictor importance
<code>removeLearners</code>	Remove members of compact regression ensemble

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Create a bagged regression ensemble to predict the mileage of cars in the `carsmall` data set based on their engine displacement, horsepower, and weight:

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'bag',100,'Tree',...
    'type','regression')

ens =

classreg.learning.regr.RegressionBaggedEnsemble:
    PredictorNames: {'x1' 'x2' 'x3'}
    CategoricalPredictors: []
    ResponseName: 'Y'
    ResponseTransform: 'none'
    NumObservations: 94
    NumTrained: 100
    Method: 'Bag'
    LearnerNames: {'Tree'}
    ReasonForTermination: [1x77 char]
    FitInfo: []
    FitInfoDescription: 'None'
    Regularization: []
    FResample: 1
    Replace: 1
    UseObsForLearner: [94x100 logical]
```

Predict the mileage of a car whose characteristics are the average of those of the first 10 cars:

```
car10 = mean(X(1:10,:));
predict(ens,car10)
```

# RegressionBaggedEnsemble

---

```
ans =  
    14.6569
```

<b>Superclasses</b>	CompactRegressionEnsemble
<b>Purpose</b>	Ensemble regression
<b>Description</b>	RegressionEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.
<b>Construction</b>	<p><code>ens = fitensemble(X,Y,method,nlearn,learners)</code> returns an ensemble model that can predict responses to data. The ensemble consists of models listed in <code>learners</code>. For more information on the syntax, see the <code>fitensemble</code> function reference page.</p> <p><code>ens = fitensemble(X,Y,method,nlearn,learners,Name,Value)</code> returns an ensemble model with additional options specified by one or more <code>Name,Value</code> pair arguments. For more information on the syntax, see the <code>fitensemble</code> function reference page.</p>
<b>Properties</b>	<p><b>CategoricalPredictors</b></p> <p>List of categorical predictors. <code>CategoricalPredictors</code> is a numeric vector with indices from 1 to <code>p</code>, where <code>p</code> is the number of columns of <code>X</code>.</p> <p><b>CombineWeights</b></p> <p>A string describing how the ensemble combines learner predictions.</p> <p><b>FitInfo</b></p> <p>A numeric array of fit information. The <code>FitInfoDescription</code> property describes the content of this array.</p> <p><b>FitInfoDescription</b></p> <p>String describing the meaning of the <code>FitInfo</code> array.</p> <p><b>LearnerNames</b></p>

# RegressionEnsemble

---

Cell array of strings with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{'Tree'}`.

## **Method**

A string with the name of the algorithm `fitensemble` used for training the ensemble.

## **ModelParameters**

Parameters used in training `ens`.

## **NumObservations**

Numeric scalar containing the number of observations in the training data.

## **NumTrained**

Number of trained learners in the ensemble, a positive scalar.

## **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in `X`.

## **ReasonForTermination**

A string describing the reason `fitensemble` stopped adding weak learners to the ensemble.

## **Regularization**

A structure containing the result of the `regularize` method. Use Regularization with `shrink` to lower resubstitution error and shrink the ensemble.

## **ResponseName**

A string with the name of the response variable `Y`.

## **ResponseTransform**

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means  $@(x)x$ .

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

## Trained

The trained learners, a cell array of compact regression models.

## TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

## W

The scaled **weights**, a vector with length  $n$ , the number of rows in  $X$ . The sum of the elements of  $W$  is 1.

## X

The matrix of predictor values that trained the ensemble. Each column of  $X$  represents one variable, and each row represents one observation.

## Y

The numeric column vector with the same number of rows as  $X$  that trained the ensemble. Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

## Methods

compact	Create compact regression ensemble
crossval	Cross validate ensemble
cvshrink	Cross validate shrinking (pruning) ensemble

# RegressionEnsemble

---

regularize	Find weights to minimize resubstitution error plus penalty term
resubLoss	Regression error by resubstitution
resubPredict	Predict response of ensemble by resubstitution
resume	Resume training ensemble
shrink	Prune ensemble

## Inherited Methods

loss	Regression error
predict	Predict response of ensemble
predictorImportance	Estimates of predictor importance
removeLearners	Remove members of compact regression ensemble

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Create a boosted regression ensemble to predict the mileage of cars in the `carsmall` data set based on their weights and numbers of cylinders:

```
load carsmall
learner = templateTree('MinParent',20);
ens = fitensemble([Weight, Cylinders],MPG,...
    'LSBoost',100,learner,'PredictorNames',{'W','C'},...
    'categoricalpredictors',2)

ens =
classreg.learning.regr.RegressionEnsemble:
    PredictorNames: {'W' 'C'}
    CategoricalPredictors: 2
```

```
    ResponseName: 'Response'  
    ResponseTransform: 'none'  
    NumObservations: 94  
    NumTrained: 100  
    Method: 'LSBoost'  
    LearnerNames: {'Tree'}  
    ReasonForTermination: [1x77 char]  
    FitInfo: [100x1 double]  
    FitInfoDescription: [2x83 char]  
    Regularization: []
```

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders:

```
mileage4K = predict(ens,[4000 4; 4000 6; 4000 8])
```

```
mileage4K =  
    20.0294  
    19.4206  
    15.5000
```

# RegressionPartitionedEnsemble

---

**Superclasses** RegressionPartitionedModel

**Purpose** Cross-validated regression ensemble

**Description** RegressionPartitionedEnsemble is a set of regression ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldfun`, `kfoldLoss`, or `kfoldPredict`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on  $X$  and  $Y$  with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on  $X$  and  $Y$  with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

**Construction** `cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. For syntax details, see the `crossval` method reference page.

`cvens = fitensemble(X,Y,method,nlearn,learners,name,value)` creates a cross-validated ensemble when `name` is one of 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'. For syntax details, see the `fitensemble` function reference page.

## Input Arguments

**ens**

A regression ensemble constructed with `fitensemble`.

## Properties

### **CategoricalPredictors**

List of categorical predictors. `CategoricalPredictors` is a numeric vector with indices from 1 to  $p$ , where  $p$  is the number of columns of  $X$ .

### **CrossValidatedModel**

Name of the cross-validated model, a string.

### **Kfold**

Number of folds used in a cross-validated tree, a positive integer.

### **ModelParameters**

Object holding parameters of tree.

### **NumObservations**

Numeric scalar containing the number of observations in the training data.

### **NTrainedPerFold**

Vector of `Kfold` elements. Each entry contains the number of trained learners in this cross-validation fold.

### **Partition**

The partition of class `cvpartition` used in creating the cross-validated ensemble.

### **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in  $X$ .

### **ResponseName**

Name of the response variable  $Y$ , a string.

### **ResponseTransform**

Function handle for transforming scores, or string representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means  $@(x)x$ .

# RegressionPartitionedEnsemble

---

Add or change a ResponseTransform function using dot notation:

```
ens.ResponseTransform = @function
```

## Trainable

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

## Trained

Cell array of compact ensembles trained on cross-validation folds.

## W

The scaled weights, a vector with length  $n$ , the number of rows in  $X$ .

## X

A matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

## Y

A numeric column vector with the same number of rows as  $X$ . Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

## Methods

kfoldLoss	Cross-validation loss of partitioned regression ensemble
resume	Resume training ensemble

## Inherited Methods

kfoldfun	Cross validate function
kfoldLoss	Cross-validation loss of partitioned regression model
kfoldPredict	Predict response for observations not used for training.

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

Construct a partitioned regression ensemble, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
rens = fitensemble(XX,YY,'LSBoost',100,'Tree');
cvrens = crossval(rens);
L = kfoldLoss(cvrens,'mode','individual')
```

```
L =
    42.4468
    12.3158
    65.9432
    39.0019
    30.5908
    16.6225
    17.3071
    46.1769
     8.0561
    12.9689
```

# RegressionPartitionedModel

---

**Purpose** Cross-validated regression model

**Description** RegressionPartitionedModel is a set of regression models trained on cross-validated folds. Estimate the quality of regression by cross validation using one or more “kfold” methods: kfoldPredict, kfoldLoss, and kfoldfun. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in Trained{1} was trained on X and Y with the first 1/5 excluded, the second model stored in Trained{2} was trained on X and Y with the second 1/5 excluded, and so on. When you call kfoldPredict, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by kfoldPredict using the model trained without this observation.

**Construction** cvmodel = crossval(tree) creates a cross-validated classification model from a regression tree. For syntax details, see the crossval method reference page.

cvmodel = fitrtree(X,Y,Name,Value) creates a cross-validated model when name is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see the fitrtree function reference page.

## Input Arguments

### tree

A regression tree constructed with fitrtree.

## Properties

### CategoricalPredictors

List of categorical predictors. CategoricalPredictors is a numeric vector with indices from 1 to p, where p is the number of columns of X.

## **CrossValidatedModel**

Name of the cross-validated model, a string.

## **Kfold**

Number of folds used in a cross-validated tree, a positive integer.

## **ModelParameters**

Object holding parameters of `tree`.

## **Partition**

The partition of class `cvpartition` used in the cross-validated model.

## **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in  $X$ .

## **ResponseName**

Name of the response variable  $Y$ , a string.

## **ResponseTransform**

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
ctree.ResponseTransform = @function
```

## **Trained**

The trained learners, a cell array of compact regression models.

## **W**

The scaled `weights`, a vector with length  $n$ , the number of rows in  $X$ .

# RegressionPartitionedModel

---

## **X**

A matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

## **Y**

A numeric column vector with the same number of rows as  $X$ . Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

## **Methods**

<code>kfoldfun</code>	Cross validate function
<code>kfoldLoss</code>	Cross-validation loss of partitioned regression model
<code>kfoldPredict</code>	Predict response for observations not used for training.

## **Copy Semantics**

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## **Examples**

### **Evaluate Cross-Validation Error**

Load the sample data. Create a variable  $X$  containing the Horsepower and Weight data.

```
load carsmall
X = [Horsepower Weight];
```

Construct a regression tree using the sample data.

```
tree = fitrtree(X,MPG);
```

Evaluate the cross-validation error of the `carsmall` data using Horsepower and Weight as predictor variables for mileage (MPG).

```
L = kfoldLoss(cvtree)
```

L =

26.4414

[ClassificationPartitionedModel](#)

# RegressionTree

---

**Superclasses** CompactRegressionTree

**Purpose** Regression tree

**Description** A decision tree with binary splits for regression. An object of class `RegressionTree` can predict responses for new data with the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

**Construction** `tree = fitrtree(x,y)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) `x` and output (response) `y`. `tree` is a binary tree where each branching node is split based on the values of a column of `x`.

`tree = fitrtree(x,y,Name,Value)` fits a tree with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **x**

A matrix of predictor values. Each column of `x` represents one variable, and each row represents one observation.

`fitrtree` considers NaN values in `x` as missing values. `fitrtree` does not use observations with all missing values for `x` the fit. `fitrtree` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

### **y**

A numeric column vector with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

`fitrtree` considers NaN values in `y` to be missing values. `fitrtree` does not use observations with missing values for `y` in the fit.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## **CategoricalPredictors - Categorical predictors list**

numeric or logical vector | cell array of strings | character matrix  
| 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to  $p$ , where  $p$  is the number of columns of  $x$ .
- A logical vector of length  $p$ , where a true entry means that the corresponding column of  $x$  is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

## **Data Types**

single | double | logical | char | struct | cell

## **CrossVal - Cross-validation flag**

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `fitrtree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using

# RegressionTree

---

one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. Note that you can only use one of these four options ('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

**Example:** 'CrossVal', 'on'

## **CVPartition - Partition for cross-validation tree**

`cvpartition` object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

## **Holdout - Fraction of data for holdout validation**

0 (default) | scalar value in the range [0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

**Example:** 'Holdout',0.1

## **Data Types**

single | double

## **KFold - Number of folds**

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

**Example:** 'KFold',8

## Data Types

single | double

## Leaveout - Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

**Example:** 'Leaveout', 'on'

## MergeLeaves - Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', fitrtree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', fitrtree does not merge leaves.

**Example:** 'MergeLeaves', 'off'

## MinLeaf - Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and

# RegressionTree

---

MinLeaf, fitrtree uses the setting that gives larger leaves:  
 $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Example:** 'MinLeaf',3

## Data Types

single | double

## MinParent - Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, fitrtree uses the setting that gives larger leaves:  
 $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Example:** 'MinParent',8

## Data Types

single | double

## NVarToSample - Number of predictors for split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

**Example:** 'NVarToSample',3

## Data Types

single | double

## PredictorNames - Predictor variable names

{ 'x1', 'x2', ... } (default) | cell array of strings

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of strings containing the names for the predictor variables, in the order in which they appear in x.

## Data Types

cell

### Prune - Pruning flag

'on' (default) | 'off'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `fitrtree` computes the full tree and the optimal sequence of pruned subtrees. When 'off' `fitrtree` computes the full tree without pruning.

**Example:** 'Prune', 'off'

### PruneCriterion - Pruning criterion

'error' (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'error'.

**Example:** 'PruneCriterion', 'error'

### QEToler - Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below  $QEToler * QED$ , where QED is the quadratic error for the entire data computed before the decision tree is grown.

**Example:** 'QEToler', 1e-4

### ResponseName - Response variable name

'Y' (default) | string

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a string containing the name of the response variable in  $y$ .

**Example:** 'ResponseName', 'Response'

# RegressionTree

---

## Data Types

char

### ResponseTransform - Response transform function

'none' (default) | function handle

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a ResponseTransform function using dot notation:

```
tree.ResponseTransform = @function
```

## Data Types

function\_handle

### SplitCriterion - Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

**Example:** 'SplitCriterion', 'MSE'

### Surrogate - Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `fitrtree` finds at most the specified number of surrogate splits at each branch node.

- When set to 'all', `fitrtree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Example:** 'Surrogate', 'on'

### Data Types

single | double

### Weights - Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `x`.

### Data Types

single | double

## Properties

### CategoricalPredictors

List of categorical predictors, a numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.

### CatSplit

An  $n$ -by-2 cell array, where  $n$  is the number of categorical splits in `tree`. Each row in `CatSplit` gives left and right values for a categorical split. For each branch node with categorical split `j` based on a categorical predictor variable `z`, the left child is chosen if `z` is in `CatSplit(j,1)` and the right child is chosen if `z` is in `CatSplit(j,2)`. The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting 'categorical' cuts from top to bottom.

### Children

# RegressionTree

---

An  $n$ -by-2 array containing the numbers of the child nodes for each node in `tree`, where  $n$  is the number of nodes. Leaf nodes have child node 0.

## **CutCategories**

An  $n$ -by-2 cell array of the categories used at branches in `tree`, where  $n$  is the number of nodes. For each branch node  $i$  based on a categorical predictor variable  $x$ , the left child is chosen if  $x$  is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if  $x$  is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

## **CutPoint**

An  $n$ -element vector of the values used as cut points in `tree`, where  $n$  is the number of nodes. For each branch node  $i$  based on a continuous predictor variable  $x$ , the left child is chosen if  $x < \text{CutPoint}(i)$  and the right child is chosen if  $x \geq \text{CutPoint}(i)$ . `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

## **CutType**

An  $n$ -element cell array indicating the type of cut at each node in `tree`, where  $n$  is the number of nodes. For each node  $i$ , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form  $x < v$  for a variable  $x$  and cut point  $v$ .
- 'categorical' — If the cut is defined by whether a variable  $x$  takes a value in a set of categories.
- '' — If  $i$  is a leaf node.

CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

## **CutVar**

An  $n$ -element cell array of the names of the variables used for branching in each node in `tree`, where  $n$  is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, CutVar contains an empty string.

CutPoint contains the cut points for 'continuous' cuts, and CutCategories contains the set of categories.

## **IsBranch**

An  $n$ -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of `tree`.

## **ModelParameters**

Object holding parameters of `tree`.

## **NumObservations**

Number of observations in the training data, a numeric scalar. NumObservations can be less than the number of rows of input data  $X$  when there are missing values in  $X$  or response  $Y$ .

## **NodeErr**

An  $n$ -element vector `e` of the errors of the nodes in `tree`, where  $n$  is the number of nodes. `e(i)` is the misclassification probability for node  $i$ .

## **NodeMean**

An  $n$ -element numeric array with mean values in each node of `tree`, where  $n$  is the number of nodes in the tree. Every element in NodeMean is the average of the true  $Y$  values over all observations in the node.

## **NodeProb**

# RegressionTree

---

An  $n$ -element vector  $\mathbf{p}$  of the probabilities of the nodes in `tree`, where  $n$  is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

## **NodeRisk**

An  $n$ -element vector of the risk of the nodes in the tree, where  $n$  is the number of nodes. The risk for each node is the node error weighted by the node probability.

## **NodeSize**

An  $n$ -element vector `sizes` of the sizes of the nodes in `tree`, where  $n$  is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

## **NumNodes**

The number of nodes  $n$  in `tree`.

## **Parent**

An  $n$ -element vector  $\mathbf{p}$  containing the number of the parent node for each node in `tree`, where  $n$  is the number of nodes. The parent of the root node is 0.

## **PredictorNames**

A cell array of names for the predictor variables, in the order in which they appear in  $X$ .

## **PruneAlpha**

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to  $M$ , then `PruneAlpha` has  $M + 1$  elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

## **PruneList**

An  $n$ -element numeric vector with the pruning levels in each node of `tree`, where  $n$  is the number of nodes. The pruning levels range from 0 (no pruning) to  $M$ , where  $M$  is the distance between the deepest leaf and the root node.

## **ResponseName**

Name of the response variable  $Y$ , a string.

## **ResponseTransform**

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default string 'none' means  $@(x)x$ , or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

## **SurrCutCategories**

An  $n$ -element cell array of the categories used for surrogate splits in `tree`, where  $n$  is the number of nodes in `tree`. For each node  $k$ , `SurrCutCategories{k}` is a cell array. The length of `SurrCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrCutCategories{k}` is either an empty string for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrCutCategories` contains an empty cell.

## **SurrCutFlip**

An  $n$ -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where  $n$  is the number of nodes in `tree`. For each node  $k$ , `SurrCutFlip{k}` is a numeric vector. The length of `SurrCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either  $-1$  or  $+1$ . For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z \geq C$  and the cut assignment for this surrogate split is  $-1$ . Similarly, the right child is chosen if  $Z \geq C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z < C$  and the cut assignment for this surrogate split is  $-1$ . The order of the surrogate split variables at each node is matched to the order of variables in `SurrCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrCutFlip` contains an empty array.

## **SurrCutPoint**

An  $n$ -element cell array of the numeric values used for surrogate splits in `tree`, where  $n$  is the number of nodes in `tree`. For each node  $k$ , `SurrCutPoint{k}` is a numeric vector. The length of `SurrCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and `SurrCutFlip` for this surrogate split is  $-1$ . Similarly, the right child is chosen if  $Z \geq C$  and `SurrCutFlip` for this surrogate split is  $+1$ , or if  $Z < C$  and `SurrCutFlip` for this surrogate split is  $-1$ . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrCutPoint` contains an empty cell.

## **SurrCutType**

An  $n$ -element cell array indicating types of surrogate splits at each node in `tree`, where  $n$  is the number of nodes in `tree`. For each node  $k$ , `SurrCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrCutVar`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form  $Z < V$  for a variable  $Z$  and cut point  $V$  or 'categorical' if the cut is defined by whether  $Z$  takes a value in a set of categories.

## **SurrCutVar**

An  $n$ -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where  $n$  is the number of nodes in `tree`. Every element of `SurrCutVar` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrCutVar` contains an empty cell.

## **SurrVarAssoc**

An  $n$ -element cell array of the predictive measures of association for surrogate splits in `tree`, where  $n$  is the number of nodes in `tree`. For each node  $k$ , `SurrVarAssoc{k}` is a numeric vector. The length of `SurrVarAssoc{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrVarAssoc{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrCutVar`.

# RegressionTree

---

The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, SurrVarAssoc contains an empty cell.

## **W**

The scaled **weights**, a vector with length  $n$ , the number of rows in  $X$ .

## **X**

A matrix of predictor values. Each column of  $X$  represents one variable, and each row represents one observation.

## **Y**

A numeric column vector with the same number of rows as  $X$ . Each entry in  $Y$  is the response to the data in the corresponding row of  $X$ .

## **Methods**

compact	Compact regression tree
crossval	Cross-validated decision tree
cvloss	Regression error by cross validation
prune	Produce sequence of subtrees by pruning
resubLoss	Regression error by resubstitution
resubPredict	Predict resubstitution response of tree

## **Inherited Methods**

loss	Regression error
meanSurrVarAssoc	Mean predictive measure of association for surrogate splits in decision tree

<code>predict</code>	Predict response of regression tree
<code>predictorImportance</code>	Estimates of predictor importance
<code>view</code>	View tree

## Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects in the MATLAB documentation.

## Examples

### Construct a Regression Tree

Load the sample data.

```
load carsmall;
```

Construct a regression tree using the sample data.

```
tree = fitrtree([Weight, Cylinders],MPG,...  
               'categoricalpredictors',2,'MinParent',20,...  
               'PredictorNames',{'W','C'})
```

```
tree =
```

```
RegressionTree  
    PredictorNames: {'W' 'C'}  
    ResponseName: 'Y'  
    ResponseTransform: 'none'  
    CategoricalPredictors: 2  
    NumObservations: 94
```

Properties, Methods

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
mileage4K = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
mileage4K =
```

## Tutorials

- “Classification Trees and Regression Trees” on page 16-31

**Purpose**

Regression diagnostics

**Syntax**

```
regstats(y,X,model)
stats = regstats(...)
stats = regstats(y,X,model,whichstats)
```

**Description**

`regstats(y,X,model)` performs a multilinear regression of the responses in  $y$  on the predictors in  $X$ .  $X$  is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations.  $y$  is an  $n$ -by-1 vector of observed responses.

---

**Note** By default, `regstats` adds a first column of 1s to  $X$ , corresponding to a constant term in the model. Do not enter a column of 1s directly into  $X$ .

---

The optional input `model` controls the regression model. By default, `regstats` uses a linear additive model with a constant term. `model` can be any one of the following strings:

- 'linear' — Constant and linear terms (the default)
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

Alternatively, `model` can be a matrix of model terms accepted by the `x2fx` function. See `x2fx` for a description of this matrix and for a description of the order in which terms appear. You can use this matrix to specify other models including ones without a constant term.

With this syntax, the function displays a graphical user interface (GUI) with a list of diagnostic statistics, as shown in the following figure.

# regstats

**Regstats Export to Workspace**

<input type="checkbox"/> Q from QR Decomposition	Q
<input type="checkbox"/> R from QR Decomposition	R
<input type="checkbox"/> Coefficients	beta
<input type="checkbox"/> Coefficient Covariance	covb
<input type="checkbox"/> Fitted Values	yhat
<input type="checkbox"/> Residuals	r
<input type="checkbox"/> Mean Square Error	mse
<input type="checkbox"/> R-square Statistic	rsquare
<input type="checkbox"/> Adjusted R-square Statistic	adjrsquare
<input type="checkbox"/> Leverage	leverage
<input type="checkbox"/> Hat Matrix	hatmat
<input type="checkbox"/> Delete-1 Variance	s2_i
<input type="checkbox"/> Delete-1 Coefficients	beta_i
<input type="checkbox"/> Standardized Residuals	standres
<input type="checkbox"/> Studentized Residuals	studres
<input type="checkbox"/> Change in Beta	dfbetas
<input type="checkbox"/> Change in Fitted Value	dffit
<input type="checkbox"/> Scaled Change in Fit	dffits
<input type="checkbox"/> Change in Covariance	covratio
<input type="checkbox"/> Cook's Distance	cookd
<input type="checkbox"/> t Statistics	tstat
<input type="checkbox"/> F Statistic	fstat
<input type="checkbox"/> DW Statistic	dwstat

**OK**   **Cancel**   **Help**

When you select check boxes corresponding to the statistics you want to compute and click **OK**, `regstats` returns the selected statistics to the MATLAB workspace. The names of the workspace variables are displayed on the right-hand side of the interface. You can change the name of the workspace variable to any valid MATLAB variable name.

`stats = regstats(...)` creates the structure `stats`, whose fields contain all of the diagnostic statistics for the regression. This syntax does not open the GUI. The fields of `stats` are listed in the following table.

Field	Description
Q	$Q$ from the $QR$ decomposition of the design matrix
R	$R$ from the $QR$ decomposition of the design matrix
beta	Regression coefficients
covb	Covariance of regression coefficients
yhat	Fitted values of the response data
r	Residuals
mse	Mean squared error
rsquare	$R^2$ statistic
adjrsquare	Adjusted $R^2$ statistic
leverage	Leverage
hatmat	Hat matrix
s2_i	Delete-1 variance
beta_i	Delete-1 coefficients
standres	Standardized residuals
studres	Studentized residuals
dfbetas	Scaled change in regression coefficients
dffit	Change in fitted values

## regstats

---

Field	Description
dffits	Scaled change in fitted values
covratio	Change in covariance
cookd	Cook's distance
tstat	$t$ statistics and $p$ -values for coefficients
fstat	$F$ statistic and $p$ -value
dwstat	Durbin-Watson statistic and $p$ -value

Note that the fields names of `stats` correspond to the names of the variables returned to the MATLAB workspace when you use the GUI. For example, `stats.beta` corresponds to the variable `beta` that is returned when you select **Coefficients** in the GUI and click **OK**.

`stats = regstats(y,X,model,whichstats)` returns only the statistics that you specify in `whichstats`. `whichstats` can be a single string such as `'leverage'` or a cell array of strings such as `{'leverage' 'standres' 'studres'}`. Set `whichstats` to `'all'` to return all of the statistics.

---

**Note** The  $F$  statistic is computed under the assumption that the model contains a constant term. It is not correct for models without a constant. The  $R^2$  statistic can be negative for models without a constant, which indicates that the model is not appropriate for the data.

---

### Examples

Open the `regstats` GUI using data from `hald.mat`:

```
load hald
regstats(heat,ingredients,'linear');
```

Select **Fitted Values** and **Residuals** in the GUI:

Click **OK** to export the fitted values and residuals to the MATLAB workspace in variables named `yhat` and `r`, respectively.

You can create the same variables using the `stats` output, without opening the GUI:

```
whichstats = {'yhat', 'r'};
stats = regstats(heat, ingredients, 'linear', whichstats);
yhat = stats.yhat;
r = stats.r;
```

# RegressionEnsemble.regularize

---

**Purpose** Find weights to minimize resubstitution error plus penalty term

**Syntax**  
`ens1 = regularize(ens)`  
`ens1 = regularize(ens,Name,Value)`

**Description** `ens1 = regularize(ens)` finds optimal weights for learners in `ens` by lasso regularization. `regularize` returns a regression ensemble identical to `ens`, but with a populated `Regularization` property.

`ens1 = regularize(ens,Name,Value)` computes optimal weights with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ,NameN,ValueN`.

## Input Arguments

**ens**  
A regression ensemble, created by `fitensemble`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### 'lambda'

Vector of nonnegative regularization parameter values for lasso. For the default setting of `lambda`, `regularize` calculates the smallest value `lambda_max` for which all optimal weights for learners are 0. The default value of `lambda` is a vector including 0 and nine exponentially-spaced numbers from `lambda_max/1000` to `lambda_max`.

**Default:** `[0  
logspace(log10(lambda_max/1000),log10(lambda_max),9)]`

### 'npass'

Maximal number of passes for lasso optimization, a positive integer.

**Default:** 10

## 'reltol'

Relative tolerance on the regularized loss for lasso, a numeric positive scalar.

**Default:** 1e-3

## 'verbose'

Verbosity level, either 0 or 1. When set to 1, `regularize` displays more information as it runs.

**Default:** 0

## Output Arguments

### **ens1**

A regression ensemble. Usually you set `ens1` to the same name as `ens`.

## Definitions

### **Lasso**

The lasso algorithm finds an optimal set of learner weights  $\alpha_t$  that minimize

$$\sum_{n=1}^N w_n g \left( \left( \sum_{t=1}^T \alpha_t h_t(x_n) \right), y_n \right) + \lambda \sum_{t=1}^T |\alpha_t|.$$

Here

- $\lambda \geq 0$  is a parameter you provide, called the lasso parameter.
- $h_t$  is a weak learner in the ensemble trained on  $N$  observations with predictors  $x_n$ , responses  $y_n$ , and weights  $w_n$ .

# RegressionEnsemble.regularize

---

- $g(f,y) = (f - y)^2$  is the squared error.

## Examples

Regularize an ensemble of bagged trees:

```
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
bag = fitensemble(X,Y,'Bag',300,'Tree',...
    'type','regression');
bag = regularize(bag,'lambda',[0.001 0.1],'verbose',1);
```

regularize reports on its progress.

To see the resulting regularization structure:

```
bag.Regularization
ans =
    Method: 'Lasso'
    TrainedWeights: [300x2 double]
    Lambda: [1.0000e-003 0.1000]
    ResubstitutionMSE: [0.0616 0.0812]
    CombineWeights: @classreg.learning.combiner.WeightedSum
```

See how many learners in the regularized ensemble have positive weights (so would be included in a shrunken ensemble):

```
sum(bag.Regularization.TrainedWeights > 0)
```

```
ans =
    116    91
```

To shrink the ensemble using the weights from Lambda = 0.1:

```
cmp = shrink(bag,'weightcolumn',2)
```

```
cmp =
```

```
classreg.learning.regr.CompactRegressionEnsemble:
    PredictorNames: {1x20 cell}
```

```
CategoricalPredictors: []  
  ResponseName: 'Y'  
  ResponseTransform: 'none'  
  NumTrained: 91
```

There are 91 members in the regularized ensemble, which is less than 1/3 of the original 300.

# gmdistribution.RegV property

---

**Purpose** Value of 'Regularize' parameter

**Description** The value of the parameter 'Regularize'.

---

**Note** This property applies only to gmdistribution objects constructed with fitgmdist.

---

<b>Purpose</b>	Importance of attributes (predictors) using ReliefF algorithm
<b>Syntax</b>	<pre>[RANKED,WEIGHT] = relieff(X,Y,K) [RANKED,WEIGHT] = relieff(X,Y,K, 'PARAM1',val1, 'PARAM2',val2,...)</pre>
<b>Description</b>	<p>[RANKED,WEIGHT] = relieff(X,Y,K) computes ranks and weights of attributes (predictors) for input data matrix X and response vector Y using the ReliefF algorithm for classification or RReliefF for regression with K nearest neighbors. For classification, relieff uses K nearest neighbors per class. RANKED are indices of columns in X ordered by attribute importance, meaning RANKED(1) is the index of the most important predictor. WEIGHT are attribute weights ranging from -1 to 1 with large positive weights assigned to important attributes.</p> <p>If Y is numeric, relieff by default performs RReliefF analysis for regression. If Y is categorical, logical, a character array, or a cell array of strings, relieff by default performs ReliefF analysis for classification.</p> <p>Attribute ranks and weights computed by relieff usually depend on K. If you set K to 1, the estimates computed by relieff can be unreliable for noisy data. If you set K to a value comparable with the number of observations (rows) in X, relieff can fail to find important attributes. You can start with K = 10 and investigate the stability and reliability of relieff ranks and weights for various values of K.</p> <pre>[RANKED,WEIGHT] = relieff(X,Y,K, 'PARAM1',val1, 'PARAM2',val2,...) specifies optional parameter name/value pairs.</pre>
<b>Name-Value Pair Arguments</b>	<p>Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.</p>

**method**

Either 'regression' (default if Y is numeric) or 'classification' (default if Y is not numeric).

## **prior**

Prior probabilities for each class, specified as a string ('empirical' or 'uniform') or as a vector (one value for each distinct group name) or as a structure S with two fields:

- S.group containing the group names as a categorical variable, character array, or cell array of strings
- S.prob containing a vector of corresponding probabilities

If the input value is 'empirical' (default), class probabilities are determined from class frequencies in Y. If the input value is 'uniform', all class probabilities are set equal.

## **updates**

Number of observations to select at random for computing the weight of every attribute. By default all observations are used.

## **categoricalx**

'on' or 'off', 'off' by default. If 'on', treat all predictors in X as categorical. If 'off', treat all predictors in X as numerical. You cannot mix numerical and categorical predictors.

## **sigma**

Distance scaling factor. For observation  $i$ , influence on the attribute weight from its nearest neighbor  $j$  is multiplied by  $\exp(-\text{rank}(i,j)/\text{sigma}^2)$ , where  $\text{rank}(i,j)$  is the position of  $j$  in the list of nearest neighbors of  $i$  sorted by distance in the ascending order. Default is Inf (all nearest neighbors have the same influence) for classification and 50 for regression.

## **Examples**

### **Rank Predictors by Importance**

Load the sample data.

```
load ionosphere;
```

Rank the predictors based on importance.

```
[ranked,weights] = relieff(X,Y,10);
```

Create a bar plot of predictor importance weights.

```
bar(weights(ranked));  
xlabel('Predictor rank');  
ylabel('Predictor importance weight');
```

# relieff

---

## Determine the Important Predictors

Load the sample data.

```
load fisheriris
```

Find the important predictors.

```
[ranked,weight] = relieff(meas,species,10)
```

ranked =

4 3 1 2

weight =

0.1399 0.1226 0.3590 0.3754

The fourth predictor is the most important, and the second predictor is the least important.

# CompactClassificationEnsemble.removeLearners

---

**Purpose** Remove members of compact classification ensemble

**Syntax** `cens1 = removeLearners(cens,idx)`

**Description** `cens1 = removeLearners(cens,idx)` creates a compact classification ensemble identical to `cens` only without the ensemble members in the `idx` vector.

**Tips**

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

## Input Arguments

**cens**

Compact classification ensemble, constructed with `compact`.

**idx**

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains all members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

## Output Arguments

**cens1**

Compact classification ensemble, identical to `cens` except `cens1` does not contain those members of `cens` with indices in `idx`.

## Examples

### Remove Learners from an Ensemble

Create a compact classification ensemble. Compact it further by removing members of the ensemble.

Create a compact classification ensemble for the ionosphere data.

```
load ionosphere
ens = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

# CompactClassificationEnsemble.removeLearners

---

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;  
cens1 = removeLearners(cens,idx);
```

**See Also** CompactClassificationEnsemble

## Related Examples

# CompactRegressionEnsemble.removeLearners

---

**Purpose** Remove members of compact regression ensemble

**Syntax** `cens1 = removeLearners(cens,idx)`

**Description** `cens1 = removeLearners(cens,idx)` creates a compact regression ensemble identical to `cens` only without the ensemble members in the `idx` vector.

- Tips**
- Typically, set `cens1` equal to `cens` to retain just one ensemble.
  - Removing learners reduces the memory used by the ensemble and speeds up its predictions.

**Input Arguments**

**cens**  
Compact regression ensemble, constructed with `compact`.

**idx**  
Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains the members of `cens` except those with indices in `idx`.  
Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

**Output Arguments**

**cens1**  
Compact regression ensemble, identical to `cens` except `cens1` does not contain members of `cens` with indices in `idx`.

## Examples **Remove Learners from an Ensemble**

Create a compact regression ensemble. Compact it further by removing members of the ensemble.

Create a compact regression ensemble for the `carsmall` data.

```
load carsmall
X = [Weight Cylinders];
```

# CompactRegressionEnsemble.removeLearners

---

```
ens = fitensemble(X,MPG,'LSBoost',100,'Tree','categorical',2);  
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;  
cens1 = removeLearners(cens,idx);
```

**See Also** CompactRegressionEnsemble

# GeneralizedLinearModel.removeTerms

---

**Purpose** Remove terms from generalized linear model

**Syntax** `mdl1 = removeTerms(mdl, terms)`

**Description** `mdl1 = removeTerms(mdl, terms)` returns a linear model the same as `mdl` but with fewer terms.

## Input Arguments

### **mdl**

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

### **terms**

Terms to remove from the `mdl` regression model. Specify as either a:

- Text string representing one or more terms to remove. For details, see “Wilkinson Notation” on page 21-3356.
- Row or rows in the terms matrix (see `modelspec` in `fitglm`). For example, if there are three variables A, B, and C:

```
[0 0 0] represents a constant term or intercept
[0 1 0] represents B; equivalently, A^0 * B^1 * C^0
[1 0 1] represents A*C
[2 0 0] represents A^2
[0 1 2] represents B*(C^2)
```

## Output Arguments

### **mdl1**

Generalized linear model, the same as `mdl` but without the terms given in `terms`. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

## Definitions

### **Wilkinson Notation**

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

# GeneralizedLinearModel.removeTerms

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$
$A + B$	$A, B$
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include $B$
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For details, see Wilkinson and Rogers [1].

## Examples

### Remove a Term from a Generalized Linear Regression Model

This example makes a model using two predictors, then removes one.

Generate artificial data for the model, Poisson random numbers with two underlying predictors  $X(1)$  and  $X(2)$ .

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson')
```

# GeneralizedLinearModel.removeTerms

---

```
mdl =
```

```
Generalized Linear regression model:
```

```
log(y) ~ 1 + x1 + x2
```

```
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

```
100 observations, 97 error degrees of freedom
```

```
Dispersion: 1
```

```
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

```
Remove the second predictor from the model.
```

```
mdl1 = removeTerms(mdl, 'x2')
```

```
mdl1 =
```

```
Generalized Linear regression model:
```

```
log(y) ~ 1 + x1
```

```
Distribution = Poisson
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	2.7784	0.014043	197.85	0
x1	1.1732	0.0033653	348.6	0

```
100 observations, 98 error degrees of freedom
```

```
Dispersion: 1
```

# GeneralizedLinearModel.removeTerms

---

Chi<sup>2</sup>-statistic vs. constant model: 1.25e+05, p-value = 0

For example, if there are three variables A, B, and C:  <code>[0 0 0]</code> represents a constant term or intercept <code>[0 1 0]</code> represents B; equivalently, <math>A^0 * B^1 * C^0</math> <code>[1 0 1]</code> represents <math>A * C</math> <code>[2 0 0]</code> represents <math>A^2</math> <code>[0 1 2]</code> represents <math>B * (C^2)</math></li></ul>
<b>Output Arguments</b>	<p><b>mdl1</b></p> <p>Linear model, the same as <code>mdl</code> but with terms removed. You can set <code>mdl1</code> equal to <code>mdl</code> to overwrite <code>mdl</code>.</p>
<b>Definitions</b>	<p><b>Wilkinson Notation</b></p> <p>Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.</p>

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$
$A + B$	$A, B$
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include $B$
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For details, see Wilkinson and Rogers [1].

## Examples

### Remove Terms from Model

Construct a default linear model of the Hald data. Remove terms with high  $p$ -values.

Load the data.

```
load hald
X = ingredients; % predictor variables
y = heat; % response
```

Fit a default linear model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
```

# LinearModel.removeTerms

---

Linear regression model:  
 $y \sim 1 + x1 + x2 + x3 + x4$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 2.45  
R-squared: 0.982, Adjusted R-Squared 0.974  
F-statistic vs. constant model: 111, p-value = 4.76e-07

Remove the x3 and x4 terms because their *p*-values are so high.

```
terms = 'x3 + x4'; % terms to remove  
mdl1 = removeTerms(mdl, terms)
```

```
mdl1 =
```

Linear regression model:  
 $y \sim 1 + x1 + x2$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

Number of observations: 13, Error degrees of freedom: 10  
Root Mean Squared Error: 2.41  
R-squared: 0.979, Adjusted R-Squared 0.974

F-statistic vs. constant model: 230, p-value = 4.41e-09

The new model has the same adjusted R-Squared value (0.974) as the previous model, meaning it is about as good a fit. All the terms in the new model have extremely low  $p$ -values.

## References

- “Linear Regression” on page 9-12

# categorical.reorderlevels

---

## Purpose

Reorder levels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
B = reorderlevels(A,newlevels)
```

## Description

`B = reorderlevels(A,newlevels)` reorders the levels of the categorical array `A`. `newlevels` is a cell array of strings or a 2-D character matrix that specifies the new order. `newlevels` must be a reordering of `getlabels(A)`.

The order of the levels of an ordinal array has significance for relational operators, minimum and maximum, and for sorting.

## Examples

Reorder hockey standings:

```
standings = ordinal(1:3,{'Leafs','Canadiens','Bruins'});
getlabels(standings)
ans =
    'Leafs'    'Canadiens'    'Bruins'

standings = reorderlevels(standings,...
    {'Canadiens','Leafs','Bruins'});
getlabels(standings)
ans =
    'Canadiens'    'Leafs'    'Bruins'
```

## See Also

[addlevels](#) | [droplevels](#) | [getlabels](#) | [islevel](#) | [mergelevels](#)

**Purpose** Repartition data for cross-validation

**Syntax** `cnew = repartition(c)`

**Description** `cnew = repartition(c)` constructs an object `cnew` of the `cvpartition` class defining a random partition of the same type as `c`, where `c` is also an object of the `cvpartition` class.

Repartitioning is useful for Monte-Carlo repetitions of cross-validation analyses. `repartition` is called by `crossval` when the `'mcreps'` parameter is specified.

**Examples** Partition and repartition 100 observations for 3-fold cross-validation:

```
c = cvpartition(100,'kfold',3)
c =
K-fold cross validation partition
      N: 100
  NumTestSets: 3
   TrainSize: 67 66 67
   TestSize: 33 34 33

cnew = repartition(c)
cnew =
K-fold cross validation partition
      N: 100
  NumTestSets: 3
   TrainSize: 67 66 67
   TestSize: 33 34 33
```

Check for equality of the test data in the first fold:

```
isequal(test(c,1),test(cnew,1))
ans =
     0
```

**See Also** `cvpartition`

# RepeatedMeasuresModel

---

**Purpose** Repeated measures model class

**Description** A RepeatedMeasuresModel object represents a model fitted to data with multiple measurements per subject. The object comprises data, fitted coefficients, covariance parameters, design matrix, error degrees of freedom, and between- and within-subjects factor names for a repeated measures model. You can predict model responses using the `predict` method and generate random data at new design points using the `random` method.

**Construction** You can fit a repeated measures model using `fitrm(t,modelspec)`.

## Input Arguments

### **t - Input data**

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

### **Data Types**

table

### **modelspec - Formula for model specification**

string of the form 'y1-yk ~ terms'

Formula for model specification, specified as a string of the form 'y1-yk ~ terms'. Specify the terms using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, char arrays, or a cell array of strings.

**Example:** 'y1-y4 ~ x1 + x2 \* x3'

## Properties

### **BetweenDesign - Design for between-subject factors**

table

Design for between-subject factors and values of repeated measures, stored as a table.

## Data Types

table

### **BetweenModel - Model for between-subjects factors**

string

Model for between-subjects factors, stored as a string. This string is the text representation to the right of the tilde in the model specification you provide when fitting the repeated measures model using `fitrm`.

## Data Types

char

### **BetweenFactorNames - Names of variables used as between-subject factors**

cell array of strings

Names of variables used as between-subject factors in the repeated measures model, `rm`, stored as a cell array of strings.

## Data Types

cell

### **ResponseNames - Names of variables used as response variables**

cell array of strings

Names of variables used as response variables in the repeated measures model, `rm`, stored as a cell array of strings.

## Data Types

cell

### **WithinDesign - Values of within-subject factors**

table

Values of the within-subject factors, stored as a table.

## Data Types

table

### **WithinModel - Model for within-subjects factors**

# RepeatedMeasuresModel

---

string

Model for within-subjects factors, stored as a string.

## Data Types

char

## WithinFactorNames - Names of within-subject factors

cell array of strings

Names of the within-subject factors, stored as a cell array of strings.

## Data Types

cell

## Coefficients - Values of estimated coefficients

table

Values of the estimated coefficients for fitting the repeated measures as a function of the terms in the between-subjects model, stored as a table.

`fitrm` defines the coefficients for a categorical term using 'effects' coding, which means coefficients sum to 0. There is one coefficient for each level except the first. The implied coefficient for the first level is the sum of the other coefficients for the term.

You can display the coefficient values as a matrix rather than a table using `coef = r.Coefficients{:, :}`.

You can display marginal means for all levels using the `margmean` method.

## Data Types

table

## Covariance - Estimated response covariances

table

Estimated response covariances, that is, covariance of the repeated measures, stored as a table. `fitrm` computes the

covariances around the mean returned by the fitted repeated measures model `rm`.

You can display the covariance values as a matrix rather than a table using `coef = r.Covariance{:, :}`.

## Data Types

table

## DFE - Error degrees of freedom

scalar value

Error degrees of freedom, stored as a scalar value. DFE is the number of observations minus the number of estimated coefficients in the between-subjects model.

## Data Types

double

## Methods

<code>anova</code>	Analysis of variance for between-subject effects
<code>epsilon</code>	Epsilon adjustment for repeated measures anova
<code>grpstats</code>	Compute descriptive statistics of repeated measures data by group
<code>manova</code>	Multivariate analysis of variance
<code>margmean</code>	Estimate marginal means
<code>mauchly</code>	Mauchly's test for sphericity
<code>multcompare</code>	Multiple comparison of estimated marginal means
<code>plot</code>	Plot data with optional grouping
<code>plotprofile</code>	Plot expected marginal means with optional grouping

# Repeated Measures Model

---

predict	Compute predicted values given predictor values
random	Generate new random response values given predictor values
ranova	Repeated measures analysis of variance

## Definitions

### Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

Use these rules to specify the responses in `modelspec`.

Wilkinson Notation	Description
Y1, Y2, Y3	Specific list of variables
Y1 - Y5	All table variables from Y1 through Y5

Use these rules to specify terms in `modelspec`.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$X^k$ , where $k$ is a positive integer	$X, X^2, \dots, X^k$
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$

Wilkinson Notation	Factors in Standard Notation
$X1*X2*X3 - X1:X2:X3$	$X1, X2, X3, X1*X2, X1*X3, X2*X3$
$X1*(X2 + X3)$	$X1, X2, X3, X1*X2, X1*X3$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Examples

### Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4-species','WithinDesign',Meas)
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```
BetweenDesign: [150x5 table]
```

```
ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
```

```
BetweenFactorNames: {'species'}
```

# RepeatedMeasuresModel

---

```
BetweenModel: '1 + species'
```

```
Within Subjects:
```

```
  WithinDesign: [4x1 table]
```

```
  WithinFactorNames: {'Measurements'}
```

```
  WithinModel: 'separatemeans'
```

```
Estimates:
```

```
  Coefficients: [3x4 table]
```

```
  Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans =
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

`fitrm` uses the 'effects' contrasts, which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species\_setosa} = \begin{cases} 1, & \text{if } \textit{setosa} \\ 0, & \text{if } \textit{versicolor} \\ -1, & \text{if } \textit{virginica} \end{cases} \quad \text{and} \quad \text{species\_versicolor} = \begin{cases} 0, & \text{if } \textit{setosa} \\ 1, & \text{if } \textit{versicolor} \\ -1, & \text{if } \textit{virginica} \end{cases}$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans =
```

	meas1	meas2	meas3	meas4
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

Display the error degrees of freedom.

```
rm.DFE
```

```
ans =
```

```
147
```

The error degrees of freedom is the number of observations minus the number of estimated coefficients in the between-subjects model, e.g.  $150 - 3 = 147$ .

# dataset.replacdata

---

## Purpose

Replace dataset variables

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
B = replacdata(A,X)
B = replacdata(A,X,vars)
B = replacdata(A,fun)
B = replacdata(A,fun,vars)
```

## Description

`B = replacdata(A,X)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for those variables replaced by the data in the array `X`. `replacdata` creates each variable in `B` using one or more columns from `X`, in order. `X` must have as many columns as the total number of columns in all of the variables in `A`, and as many rows as `A` has observations.

`B = replacdata(A,X,vars)` creates a dataset array `B` with the same variables as the dataset array `A`, but with the data for the variables specified in `vars` replaced by the data in the array `X`. The remaining variables in `B` are copies of the corresponding variables in `A`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. Each variable in `B` has as many columns as the corresponding variable in `A`. `X` must have as many columns as the total number of columns in all the variables specified in `vars`.

`B = replacdata(A,fun)` or `B = replacdata(A,fun,vars)` creates a dataset array `B` by applying the function `fun` to the values in `A`'s variables. `replacdata` first horizontally concatenates `A`'s variables into a single array, then applies the function `fun`. The specified variables in `A` must have types and sizes compatible with the concatenation. `fun` is a function handle that accepts a single input array and returns an array with the same number of rows and columns as the input.

## Examples

```
data = dataset({rand(3,3)}, 'Var1', 'Var2', 'Var3')
```

```
% Use ZSCORE to normalize each variable in a dataset array
% separately, by explicitly extracting and transforming the
% data, and then replacing it.
X = double(data);
X = zscore(X);
data = replacedata(data,X)

% Equivalently, provide a handle to ZSCORE.
data = replacedata(data,@zscore)

% Use ZSCORE to normalize each observation in a dataset
% array separately by creating an anonymous function.
data = replacedata(data,@(x) zscore(x,[],2))
```

dataset

# dataset.replaceWithMissing

---

## Purpose

Insert missing data indicators into a dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
ds2 = replaceWithMissing(ds,Name,Value)
```

## Description

`ds2 = replaceWithMissing(ds,Name,Value)` replaces specified values in a dataset array with standard missing data indicators using options specified by one or more `Name,Value` pair arguments. Use `replaceWithMissing` to specify:

- Which numeric missing value indicators to replace with NaN.
- Which string missing value indicators to replace with an empty string.
- Which categorical levels to replace with `<undefined>`.

## Input Arguments

**ds**  
dataset array.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

#### 'NumericValues'

Vector of numeric values that `replaceWithMissing` replaces with NaN.

#### 'CategoricalLevels'

String or cell array of strings naming the categorical levels that `replaceWithMissing` replaces with `<undefined>`.

## 'Strings'

String or cell array of strings containing the strings that `replaceWithMissing` replaces with the empty string, ''.

## 'DataVars'

Specified set of variables in `ds` for which `replaceWithMissing` replaces values. You can specify a positive integer or vector of positive integers indicating the variable column numbers, a variable name or a cell array of variables names, or a logical vector indicating which variables to replace missing values in.

**Default:** All variables in `ds`.

## Output Arguments

### `ds2`

dataset array that has the specified missing value indicators, in the specified variables of `ds`, replaced with standard missing value indicators.

## Examples

### Replace Nonstandard Missing Value Indicators

Replace nonstandard missing value indicators with standard missing value indicators.

Replace numeric missing values coded 99 with NaN, and string missing values coded '.' with the empty string.

```
ds = replaceWithMissing(ds,'NumericValues',99,'Strings','');
```

# categorical repmat

---

## Purpose

Replicate and tile categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## Syntax

```
B = repmat(A,m,n)
B = repmat(A,[m n p ...])
```

## Description

`B = repmat(A,m,n)` creates a large array `B` consisting of an `m`-by-`n` tiling of copies of the categorical array `A`. The size of `B` is `[size(A,1)*M size(A,2)*N, size(A,3), ...]`. `repmat(A,n)` creates an `n`-by-`n` tiling.

`B = repmat(A,[m n p ...])` tiles the categorical array `A` to produce a multidimensional array `B` composed of copies of `A`. The size of `B` is `[size(A,1)*M, size(A,2)*N, size(A,3)*P, ...]`.

## See Also

`ndims` | `size`

**Purpose** Reset state

**Syntax** reset(q)

**Description** reset(q) resets the state of the quasi-random number stream q of the grandstream class back to its initial state, 1. Subsequent points drawn from the stream will be the same as those drawn from a new stream. The command is equivalent to q.State = 1.

**Examples** Use grandstream to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
    Halton quasi-random stream in 3 dimensions
    Point set properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none

nextIdx = q.State
nextIdx =
     1
```

Use grand to generate two samples of size four:

```
X1 = grand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166

nextIdx = q.State
nextIdx =
     5
```

```
X2 = grand(q,4)
```

# grandstream.reset

---

```
X2 =  
    0.2446    0.0238    0.8102  
    0.5298    0.7540    0.0438  
    0.3843    0.5112    0.2758  
    0.8335    0.2245    0.4694  
nextIdx = q.State  
nextIdx =  
    9
```

Use reset to reset the stream, then generate another sample:

```
reset(q)  
nextIdx = q.State  
nextIdx =  
    1  
  
X = grand(q,4)  
X =  
    0.0928    0.3475    0.0051  
    0.6958    0.2035    0.2371  
    0.3013    0.8496    0.4307  
    0.9087    0.5629    0.6166
```

## See Also

## Purpose

Resize categorical array

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
B = reshape(A,M,N)
B = reshape(A,m,n,p,...)
reshape(A,[m n p ...])
B = reshape(A,...,[],...)
```

## Description

`B = reshape(A,M,N)` returns an  $m$ -by- $n$  categorical matrix whose elements are taken columnwise from the categorical array `A`. An error results if `A` does not have  $m*n$  elements.

`B = reshape(A,m,n,p,...)` or `reshape(A,[m n p ...])` returns an array with the same elements as `A` but reshaped to have the size  $m$ -by- $n$ -by- $p$ -by-... .  $m*n*p*...$  must be the same as `numel(A)`.

`B = reshape(A,...,[],...)` calculates the length of the dimension represented by `[]`, such that the product of the dimensions equals `numel(A)`. `numel(A)` must be evenly divisible by the product of the known dimensions. You can use only one occurrence of `[]`.

In general, `reshape(A,siz)` returns an array with the same elements as `A` but reshaped to the size `siz`. `prod(siz)` must be the same as `numel(A)`.

# LinearMixedModel.residuals

---

**Purpose** Residuals of fitted linear mixed-effects model

**Syntax**  
R = residuals(lme)  
R = residuals(lme,Name,Value)

**Description** R = residuals(lme) returns the raw conditional residuals from a fitted linear mixed-effects model lme.

R = residuals(lme,Name,Value) returns the residuals from the linear mixed-effects model lme with additional options specified by one or more Name,Value pair arguments.

For example, you can specify Pearson or standardized residuals, or residuals with contributions from only fixed effects.

## Input Arguments

### **lme - Linear mixed-effects model**

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

For properties and methods of this object, see LinearMixedModel.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### **'Conditional' - Indicator for conditional residuals**

True (default) | False

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

True	Contribution from both fixed effects and random effects (conditional)
False	Contribution from only fixed effects (marginal)

**Example:** 'Conditional', 'False'

## 'ResidualType' - Residual type

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Z\hat{b}]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\text{Var}_{y,b}(y - X\hat{\beta} - Z\hat{b})]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\text{Var}_y(y - X\hat{\beta})]_{ii}}}$
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\text{Var}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\text{Var}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see [Definitions](#) at the end of this page.

**Example:** 'ResidualType', 'Standardized'

# LinearMixedModel.residuals

---

## Output Arguments

### R - Residuals

*n*-by-1 vector

Residuals of the fitted linear mixed-effects model `lme` returned as an *n*-by-1 vector, where *n* is the number of observations.

## Examples

### Plot Residuals vs. Fitted Values

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load weight
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl,'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();  
gscatter(F,R,Program)
```

# LinearMixedModel.residuals

The residuals seem to behave similarly across levels of the program as expected.

## Compute Conditional and Marginal Pearson Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + Cylinders + (Accel
```

Compute the conditional Pearson residuals and display the first five residuals.

```
PR = residuals(lme,'ResidualType','Pearson');  
PR(1:5)
```

```
ans =
```

```
-0.0533  
0.0652  
0.3655  
-0.0106  
-0.3340
```

Compute the marginal Pearson residuals and display the first five residuals.

```
PRM = residuals(lme,'ResidualType','Pearson','Conditional',false);  
PRM(1:5)
```

```
ans =
```

```
-0.1250  
0.0130  
0.3242  
-0.0861  
-0.3006
```

# LinearMixedModel.residuals

---

## Examine Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + Cylinders + (Accelerat
```

Draw a histogram of the raw residuals with a normal fit.

```
r = residuals(lme);  
histfit(r)
```

Normal distribution seems to be a good fit for the residuals.

Compute the conditional Pearson and standardized residuals and create box plots of all three types of residuals.

```
pr = residuals(lme, 'ResidualType', 'Pearson');  
st = residuals(lme, 'ResidualType', 'Standardized');  
X = [r pr st];  
figure();  
boxplot(X)
```

# LinearMixedModel.residuals

Red plus signs show the observations with residuals above or below  $q3 + 1.5(q3 - q1)$  and  $q1 - 1.5(q3 - q1)$ , where  $q1$  and  $q3$  are the 25th and 75th percentiles, respectively.

Find the observations with residuals that are 2.5 standard deviations above and below the mean.

```
find(r > nanmean(r) + 2.5*nanstd(r))
```

```
ans =
```

```
62  
252  
255  
330  
337  
341  
396
```

```
find(r < nanmean(r) - 2.5*nanstd(r))
```

```
ans =
```

```
119  
324  
375
```

## Definitions

### Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an  $n$ -by- $p$  fixed-effects design matrix  $X$  and an  $n$ -by- $q$  random-effects design matrix  $Z$ . Also, suppose the  $p$ -by-1 estimated fixed-effects vector is  $\hat{\beta}$ , and the  $q$ -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is  $\hat{b}$ . The fitted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

and the fitted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta}.$$

# LinearMixedModel.residuals

---

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\hat{\beta} - Z\hat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\hat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

ClassificationDiscriminant | fitcdiscr | edge | resubMargin

## How To

- “Discriminant Analysis” on page 15-3

# ClassificationEnsemble.resubEdge

---

**Purpose** Classification edge by resubstitution

**Syntax**  
edge = resubEdge(ens)  
edge = resubEdge(ens,Name,Value)

**Description**  
edge = resubEdge(ens) returns the classification edge obtained by ens on its training data.  
edge = resubEdge(ens,Name,Value) calculates edge with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**ens**  
A classification ensemble created with fitensemble.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

#### 'learners'

Indices of weak learners in the ensemble ranging from 1 to NumTrained. resubEdge uses only these learners for calculating edge.

**Default:** 1:NumTrained

#### 'mode'

String representing the meaning of the output edge:

- 'ensemble' — edge is a scalar value, the loss for the entire ensemble.

- 'individual' — edge is a vector with one element per trained learner.
- 'cumulative' — edge is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

### edge

Classification edge obtained by `ens` by resubstituting the training data into the calculation of edge. Classification edge is classification margin averaged over the entire data. edge can be a scalar or vector, depending on the setting of the `mode` name-value pair.

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

# ClassificationEnsemble.resubEdge

---

## Examples

Find the resubstitution edge for an ensemble that classifies the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
edge = resubEdge(ens)
```

```
edge =
    3.2486
```

## See Also

[resubMargin](#) | [resubLoss](#) | [resubPredict](#) | [resubEdge](#)

<b>Purpose</b>	Edge of $k$ -nearest neighbor classifier by resubstitution
<b>Syntax</b>	<code>E = resubEdge(md1)</code>
<b>Description</b>	<code>E = resubEdge(md1)</code> returns the classification edge for <code>md1</code> with the data used to train <code>md1</code> (see “Edge” on page 21-3401).
<b>Input Arguments</b>	<p><b>mdl - Classifier model</b> classifier model object</p> <p><math>k</math>-nearest neighbor classifier model, returned as a classifier model object.</p> <p>Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class <code>ClassificationPartitionedModel</code>. You cannot use a partitioned tree for prediction, so this kind of tree does not have a <code>predict</code> method.</p> <p>Otherwise, <code>mdl</code> is of class <code>ClassificationKNN</code>, and you can use the <code>predict</code> method to make predictions.</p>
<b>Output Arguments</b>	<p><b>E</b></p> <p>Classification edge, a scalar that is the mean classification margin (see “Margin” on page 21-3401).</p>
<b>Definitions</b>	<p><b>Edge</b></p> <p>The <i>edge</i> is the mean value of the classification <i>margin</i>.</p> <p><b>Margin</b></p> <p>The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes.</p> <p>Margin is a column vector with the same number of rows as in the training data.</p>

# ClassificationKNN.resubEdge

---

## Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-2997.

## Examples

### Resubstitution Edge Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the resubstitution edge of the classifier.

```
E = resubEdge(mdl)
```

```
E =
```

```
0.9253
```

ClassificationKNN | fitcknn | resubLoss | resubMargin | resubPredict

## Related Examples

- “Examine the Quality of a KNN Classifier” on page 16-27

## Concepts

- “Classification Using Nearest Neighbors” on page 16-9

<b>Purpose</b>	Classification edge by resubstitution
<b>Syntax</b>	<code>e = resubEdge(SVMModel)</code>
<b>Description</b>	<code>e = resubEdge(SVMModel)</code> returns the resubstitution classification edge ( <code>e</code> ) for the support vector machine (SVM) classifier <code>SVMModel</code> using the training data stored in <code>SVMModel.X</code> and corresponding class labels stored in <code>SVMModel.Y</code> .
<b>Input Arguments</b>	<b>SVMModel - SVM classifier</b> <code>ClassificationSVM</code> classifier  SVM classifier that was trained using <code>fitcsvm</code> , specified as a <code>ClassificationSVM</code> classifier.
<b>Output Arguments</b>	<b>e - Classification edge</b> scalar  Classification edge, returned as a scalar. <code>e</code> represents the weighted mean of the classification margins.
<b>Definitions</b>	<b>Edge</b> The <i>edge</i> is the weighted mean of the <i>classification margins</i> .  The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.  One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.  <b>Classification Margins</b> The <i>margins</i> are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification

# ClassificationSVM.resubEdge

---

confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [2].

## Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Estimate the Resubstitution Edge of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to standardize the predictors and define the class order.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

SVMModel is a trained ClassificationSVM classifier. 'b' is the negative class and 'g' is the positive class.

Estimate the resubstitution edge.

```
e = resubEdge(SVMModel)
```

```
e =
```

```
5.0998
```

The mean of the training sample margins is 5.0999.

## Select SVM Classifier Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the ionosphere data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullSVMModel)
partEdge = resubEdge(PartSVMModel)
```

```
fullEdge =
```

```
    3.3653
```

```
partEdge =
```

# ClassificationSVM.resubEdge

---

2.0471

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained using all of the predictors has a better in-sample fit.

## Algorithms

For binary classification, the software defines the margin for observation  $j$ ,  $m_j$ , as

$$m_j = 2y_j f(x_j),$$

where  $y_j \in \{-1, 1\}$ , and  $f(x_j)$  is the predicted score of observation  $j$  for the positive class. However, the literature commonly uses  $m_j = y_j f(x_j)$  to define the margin.

<b>Output Arguments</b>	<b>edge</b> Classification edge obtained by resubstituting the training data into the calculation of <code>edge</code> .

## Definitions

### Edge

The *edge* is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`.

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`.

### Score (tree)

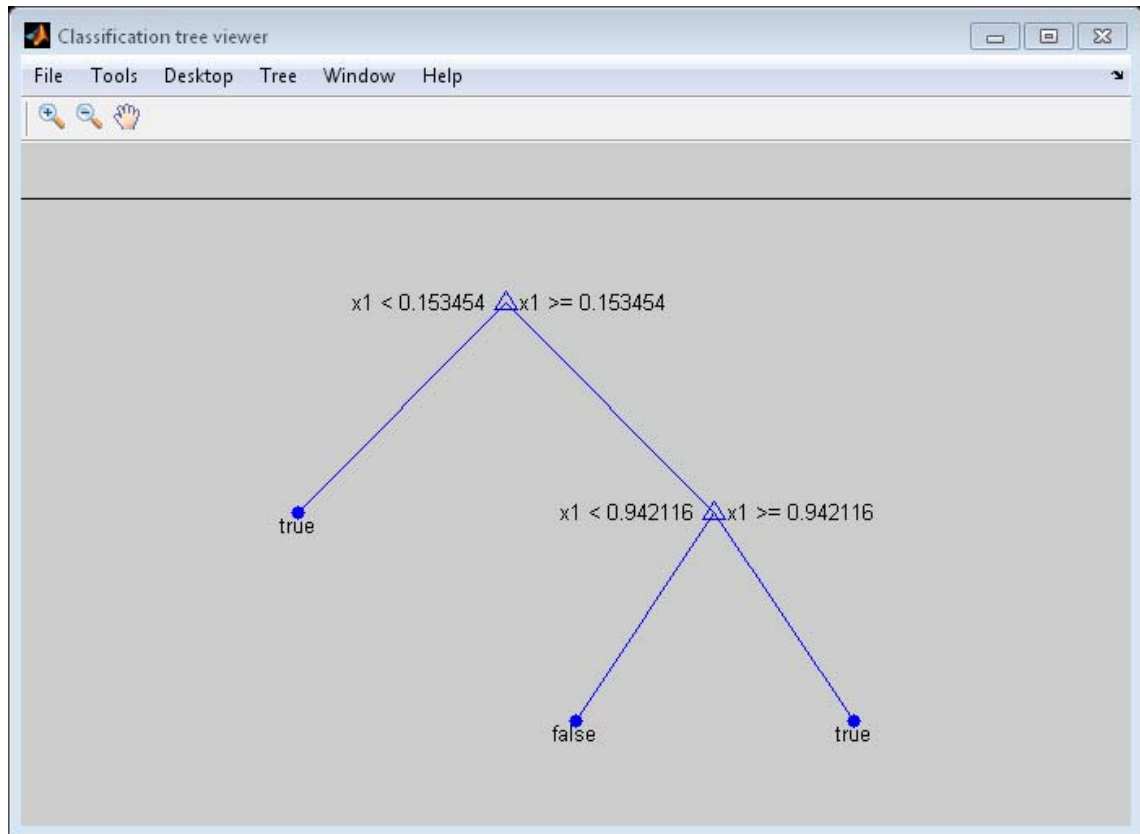

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is `false` otherwise.

Generate 100 random points and classify them:

# ClassificationTree.resubEdge

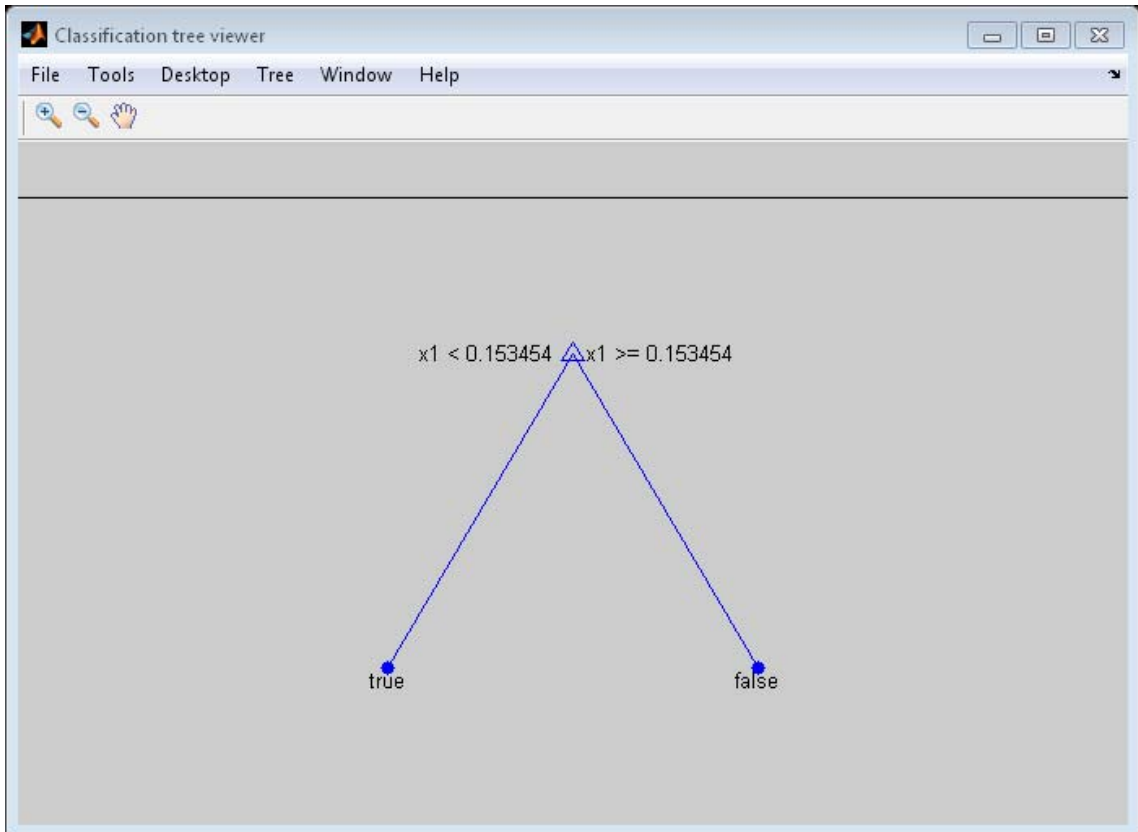

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree,'Level',1);
view(tree1,'Mode','Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for `true`, and about  $.8/.85=.94$  for `false`.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

# ClassificationTree.resubEdge

---

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Estimate the quality of a classification tree for the Fisher iris data by resubstitution.

```
load fisheriris  
tree = fitctree(meas,species);  
redge = resubEdge(tree)
```

```
redge =  
    0.9384
```

## See Also

## Purpose

Classification error by resubstitution

## Syntax

```
L = resubLoss(obj)
L = resubLoss(obj,Name,Value)
```

## Description

`L = resubLoss(obj)` returns the resubstitution loss, meaning the loss computed for the data that `fitcdiscr` used to create `obj`.

`L = resubLoss(obj,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **obj**

Discriminant analysis classifier, produced using `fitcdiscr`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'lossfun'**

Function handle or string representing a loss function. Built-in loss functions are:

- 'binodeviance' — See “Loss Functions” on page 21-3412.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-3412.
- 'exponential' — See “Loss Functions” on page 21-3412.
- 'mincost' — Smallest misclassification cost as given by the `obj.Cost` matrix.

# ClassificationDiscriminant.resubLoss

---

You can write your own loss function using the syntax described in “Loss Functions” on page 21-3412.

**Default:** 'mincost'

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-3412.

## Definitions

### Classification Error

The default classification error is the fraction of the training data  $X$  that `obj` misclassifies.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `obj` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.

- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `Cost` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `X`.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one true per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the posterior output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Posterior Probability

The posterior probability that a point  $z$  belongs to class  $j$  is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean  $\mu_j$  and covariance  $\Sigma_j$  at a point  $z$  is

# ClassificationDiscriminant.resubLoss

---

$$P(x | k) = \frac{1}{(2\pi |\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where  $|\Sigma_k|$  is the determinant of  $\Sigma_k$ , and  $\Sigma_k^{-1}$  is the inverse matrix.

Let  $P(k)$  represent the prior probability of class  $k$ . Then the posterior probability that an observation  $x$  is of class  $k$  is

$$\hat{P}(k | x) = \frac{P(x | k)P(k)}{P(x)},$$

where  $P(x)$  is a normalization constant, the sum over  $k$  of  $P(x | k)P(k)$ .

## Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class  $k$  is one over the total number of classes.
- 'empirical' — The prior probability of class  $k$  is the number of training samples of class  $k$  divided by the total number of training samples.
- Custom — The prior probability of class  $k$  is the  $k$ th element of the prior vector. See `fitcdiscr`.

After creating a classifier `obj`, you can set the prior using dot notation:

```
obj.Prior = v;
```

where `v` is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

## Cost

The matrix of expected costs per observation is defined in “Cost” on page 15-8.

## Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
L = resubLoss(obj)
```

```
L =
    0.0200
```

## How To

- “Discriminant Analysis” on page 15-3

# ClassificationEnsemble.resubLoss

---

**Purpose** Classification error by resubstitution

**Syntax**  
L = resubLoss(ens)  
L = resubLoss(ens,Name,Value)

**Description** L = resubLoss(ens) returns the resubstitution loss, meaning the loss computed for the data that fitensemble used to create ens.

L = resubLoss(ens,Name,Value) calculates loss with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

## Input Arguments

**ens**  
A classification ensemble created with fitensemble.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as Name1,Value1, ...,NameN,ValueN.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to NumTrained. resubLoss uses only these learners for calculating loss.

**Default:** 1:NumTrained

### 'lossfun'

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-3418

- 'classiferror' — Fraction of misclassified data
- 'exponential' — See “Loss Functions” on page 21-3418

You can write your own loss function in the syntax described in “Loss Functions” on page 21-3418.

**Default:** 'classiferror'

## 'mode'

String representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

**Default:** 'ensemble'

## Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

## Definitions

### Classification Error

The default classification error is the fraction of the training data X that `ens` misclassifies.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `tree` misclassifies the  $i$ th row of X, divided by the sum of the weights.

# ClassificationEnsemble.resubLoss

---

## Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'classiferror' — Fraction of misclassified data, weighted by  $w$ .
- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

To write your own loss function, create a function file of the form

```
function loss = lossfun(C,S,W,COST)
```

- N is the number of rows of `ens.X`.
- K is the number of classes in `ens`, represented in `ens.ClassNames`.
- C is an N-by-K logical matrix, with one true per row for the true class. The index for each class is its position in `tree.ClassNames`.
- S is an N-by-K numeric matrix. S is a matrix of posterior probabilities for classes with one row per observation, similar to the score output from `predict`.
- W is a numeric vector with N elements, the observation weights.
- COST is a K-by-K numeric matrix of misclassification costs. The default 'classiferror' gives a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Compute the resubstitution loss for a classification ensemble for the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
loss = resubLoss(ens)

loss =
    0.0333
```

## See Also

# ClassificationKNN.resubLoss

---

**Purpose** Loss of  $k$ -nearest neighbor classifier by resubstitution

**Syntax**  
L = resubLoss(md1)  
L = resubLoss(md1,Name,Value)

**Description**  
L = resubLoss(md1) returns the resubstitution loss, meaning the loss computed for the data that fitcknn used to create md1.  
L = resubLoss(md1,Name,Value) returns loss statistics with additional options specified by one or more Name,Value pair arguments.

**Input Arguments** **mdl - Classifier model**  
classifier model object

$k$ -nearest neighbor classifier model, returned as a classifier model object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, mdl is of class ClassificationKNN, and you can use the predict method to make predictions.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'lossfun'

Function handle or string representing a loss function. Built-in loss functions are:

- 'binodeviance' — See “Loss Functions” on page 21-3421.
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-3421.
- 'exponential' — See “Loss Functions” on page 21-3421.
- 'mincost' — Smallest misclassification cost as given by the `mdl.Cost` matrix.

You can write your own loss function using the syntax described in “Loss Functions” on page 21-3421.

**Default:** 'mincost'

## Output Arguments

**L**

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Error” on page 21-3421.

## Definitions

### Classification Error

The default classification error is the fraction of data  $X$  that `mdl` misclassifies, where  $Y$  represents the true classifications.

The weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `mdl` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

# ClassificationKNN.resubLoss

---

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- `N` is the number of rows of `X`.
- `K` is the number of classes in the classifier, represented in the `ClassNames` property.
- `C` is an `N`-by-`K` logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- `S` is an `N`-by-`K` numeric matrix. `S` is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- `W` is a numeric vector with `N` elements, the observation weights. If you pass `W`, the elements are normalized to sum to the prior probabilities in the respective classes.
- `COST` is a `K`-by-`K` numeric matrix of misclassification costs. For example, you can use `COST = ones(K) - eye(K)`, which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i≠j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns, among other outputs, a `cost` matrix of size `Nobs-by-K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X_{new}(n)) C(k | i),$$

where

- $K$  is the number of classes.

# ClassificationKNN.resubLoss

---

- $\hat{P}(i | X_{new}(n))$  is the posterior probability of class  $i$  for observation  $X_{new}(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## Examples

### Loss Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the resubstitution loss of the classifier.

```
L = resubLoss(mdl)
```

```
L =
```

```
0.0333
```

The classifier predicts incorrect classifications for 1/30 of its training data.

# ClassificationSVM.resubLoss

---

**Purpose** Classification loss by resubstitution

**Syntax**  
L = resubLoss(SVMModel)  
L = resubLoss(SVMModel,Name,Value)

**Description** L = resubLoss(SVMModel) returns the classification loss by resubstitution (L), the in-sample classification loss, for the support vector machine (SVM) classifier SVMModel using the training data stored in SVMModel.X and corresponding class labels stored in SVMModel.Y.

L = resubLoss(SVMModel,Name,Value) returns the classification loss by resubstitution with additional options specified by one or more Name,Value pair arguments.

**Input Arguments** **SVMModel - SVM classifier**  
ClassificationSVM classifier

SVM classifier that was trained using fitcsvm, specified as a ClassificationSVM classifier.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

## **'LossFun' - Loss function**

'ClassifError' (default) | function handle | string

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or string.

- The following lists available loss functions. Specify one using its corresponding string.

Loss Function	String
Binomial deviance	'BinoDeviance'
Classification error	'ClassifError'
Exponential loss	'Exponential'
Hinge loss	'Hinge'

- Specify your own function using function handle notation.

Suppose that  $n = \text{size}(X,1)$  is the sample size and  $k = \text{size}(\text{SVMModel.ClassNames},1)$  is the number of classes. Your function must have the signature  $\text{loss} = \text{lossfun}(C,S,W,\text{Cost})$ , where:

- The output argument  $\text{loss}$  is a scalar.
- You choose the function name ( $\text{lossfun}$ ).
- $C$  is an  $n$ -by- $k$  logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in  $\text{SVMModel.ClassNames}$ .  
Construct  $C$  by setting  $C(p,q) = 1$  if observation  $p$  is in class  $q$ , for each row. Set all other elements of row  $p$  to 0.
- $S$  is an  $n$ -by- $k$  numeric matrix of classification scores. The column order corresponds to the class order in  $\text{SVMModel.ClassNames}$ .  $S$  is a matrix of classification scores, similar to the output of `predict`.
- $W$  is an  $n$ -by-1 numeric vector of observation weights. If you pass  $W$ , the software normalizes them to sum to 1.
- $\text{Cost}$  is a  $k$ -by- $k$  numeric matrix of misclassification costs. For example,  $\text{Cost} = \text{ones}(K) - \text{eye}(K)$  specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using 'LossFun', @*lossfun*.

# ClassificationSVM.resubLoss

---

## Output Arguments

### L - Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme.

## Definitions

### Binomial Deviance

The binomial deviance is a binary classification error measure that has the form

$$L = \sum_{j=1}^n w_j \log\left(1 + \exp\left(-2y_j f(X_j)\right)\right),$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [1].

### Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n \sum_{k=1}^K w_j c_{jk}}{\sum_{j=1}^n w_j},$$

where:

- $w_j$  is the weight for observation  $j$ . The software renormalizes the weights to sum to 1.
- $c_{jk} = 1$  if the true class of observation  $j$  is  $k$ , and 0 otherwise.

The default classification error (`ClassifError`) is the proportion of observations that the classifier misclassifies.

## Exponential Loss

A binary classification error measure that is similar to binomial deviance, and has the form

$$L = \sum_{j=1}^n w_j \exp(-y_j f(X_j)),$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

## Hinge Loss

Hinge loss is a binary classification error measure that has the form

$$L = \sum_{j=1}^n w_j \max\{0, 1 - y_j f(X_j)\},$$

where:

- $w_j$  is weight  $j$ . The software renormalizes the weights to sum to 1.
- $y_j = \{-1, 1\}$ .
- $f(X_j)$  is the score for observation  $j$ .

# ClassificationSVM.resubLoss

---

Hinge loss linearly penalizes for misclassified observations, and is related to the SVM objective function used for optimization. For more details on hinge loss, see [1].

## Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Determine the Resubstitution Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a trained ClassificationSVM classifier. The negative class is 'b' and the positive class is 'g'.

Estimate the resubstitution loss (i.e., the in-sample classification error).

```
L = resubLoss(SVMModel)
```

```
L =
```

```
0.0570
```

The SVM classifier misclassifies 5.7% of the training sample radar returns.

## Determine the Resubstitution Hinge Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a trained ClassificationSVM classifier. The negative class is 'b' and the positive class is 'g'.

Estimate the in-sample hinge loss.

```
L = resubLoss(SVMModel,'LossFun','Hinge')
```

```
L =
```

```
    0.1603
```

The hinge loss is 0.1603. Classifiers with hinge losses close to 0 are desirable.

## References

## Purpose

Classification error by resubstitution

## Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'subtrees',subtreevector)
[L,se] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf,bestlevel] =
resubLoss(tree,'subtrees',subtreevector)
[L,...] =
resubLoss(tree,'subtrees',subtreevector,Name,Value)
```

## Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitctree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

`L = resubLoss(tree,'subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'subtrees',subtreevector)` returns the best pruning level as defined in the `treesize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more

# ClassificationTree.resubLoss

---

Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## Input Arguments

### **tree**

A classification tree constructed by `fitctree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### **'lossfun'**

Function handle or string representing a loss function. Built-in loss functions:

- 'binodeviance' — See “Loss Functions” on page 21-3436
- 'classiferror' — Fraction of misclassified observations. See “Loss Functions” on page 21-3436.
- 'exponential' — See “Loss Functions” on page 21-3436
- 'mincost' — Smallest misclassification cost as given by the `tree.Cost` matrix. See “Loss Functions” on page 21-3436.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-3436.

**Default:** 'mincost'

Name, Value arguments associated with pruning subtrees:

### **'subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`.

**Default:** 0

**'treesize'**

One of the following strings:

- 'se' — loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- 'min' — loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Output Arguments

**L**

Classification error, a vector the length of subtrees. The meaning of the error depends on the values in `weights` and `lossfun`; see “Classification Error” on page 21-3436.

**se**

Standard error of loss, a vector the length of subtrees.

**NLeaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

**bestlevel**

A scalar whose value depends on `treesize`:

- `treesize = 'se'` — loss returns the highest pruning level with loss within one standard deviation of the minimum ( $L+se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- `treesize = 'min'` — loss returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

# ClassificationTree.resubLoss

---

## Definitions

### Classification Error

The default classification error is the fraction of the training data  $X$  that `tree` misclassifies.

Weighted classification error is the sum of weight  $i$  times the Boolean value that is 1 when `tree` misclassifies the  $i$ th row of  $X$ , divided by the sum of the weights.

### Loss Functions

The built-in loss functions are:

- 'binodeviance' — For binary classification, assume the classes  $y_n$  are -1 and 1. With weight vector  $w$  normalized to have sum 1, and predictions of row  $n$  of data  $X$  as  $f(X_n)$ , the binomial deviance is

$$\sum w_n \log(1 + \exp(-2y_n f(X_n))).$$

- 'exponential' — With the same definitions as for 'binodeviance', the exponential loss is

$$\sum w_n \exp(-y_n f(X_n)).$$

- 'classiferror' — Predict the label with the largest posterior probability. The loss is then the fraction of misclassified observations.
- 'mincost' — Predict the label with the smallest expected misclassification cost, with expectation taken over the posterior probability, and cost as given by the `COST` property of the classifier (a matrix). The loss is then the true misclassification cost averaged over the observations.

To write your own loss function, create a function file in this form:

```
function loss = lossfun(C,S,W,COST)
```

- $N$  is the number of rows of  $X$ .

- $K$  is the number of classes in the classifier, represented in the `ClassNames` property.
- $C$  is an  $N$ -by- $K$  logical matrix, with one `true` per row for the true class. The index for each class is its position in the `ClassNames` property.
- $S$  is an  $N$ -by- $K$  numeric matrix.  $S$  is a matrix of posterior probabilities for classes with one row per observation, similar to the `posterior` output from `predict`.
- $W$  is a numeric vector with  $N$  elements, the observation weights. If you pass  $W$ , the elements are normalized to sum to the prior probabilities in the respective classes.
- $COST$  is a  $K$ -by- $K$  numeric matrix of misclassification costs. For example, you can use  $COST = \text{ones}(K) - \text{eye}(K)$ , which means a cost of 0 for correct classification, and 1 for misclassification.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method.  $Cost(i, j)$  is the cost of classifying an observation into class  $j$  if its true class is  $i$ . By default,  $Cost(i, j) = 1$  if  $i \neq j$ , and  $Cost(i, j) = 0$  if  $i = j$ . In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

# ClassificationTree.resubLoss

---

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | Xnew(n)) C(k | i),$$

where

- `K` is the number of classes.
- $\hat{P}(i | Xnew(n))$  is the posterior probability of class `i` for observation `Xnew(n)`.
- $C(k | i)$  is the true misclassification cost of classifying an observation as `k` when its true class is `i`.

## Examples

### Compute the Resubstituted Classification Error

Compute the resubstituted classification error for the ionosphere data.

```
load ionosphere
tree = fitctree(X,Y);
L = resubLoss(tree)
```

```
L =
    0.0114
```

## See Also

`loss` | `resubEdge` | `resubMargin` | `resubPredict` | `fitctree`

## Purpose

Regression error by resubstitution

## Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

## Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the mean squared error computed for the data that `fitensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **ens**

A regression ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

**Default:** `1:NumTrained`

### **'lossfun'**

Function handle for loss function, or the string `'mse'`, meaning mean squared error. If you pass a function handle `fun`, `resubLoss` calls it as

# RegressionEnsemble.resubLoss

---

`FUN(Y, Yfit, W)`

where `Y`, `Yfit`, and `W` are numeric vectors of the same length. `Y` is the observed response, `Yfit` is the predicted response, and `W` is the observation weights.

**Default:** `'mse'`

## **'mode'**

String representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

**Default:** `'ensemble'`

## **Output Arguments**

**L**

Loss, by default the mean squared error. `L` can be a vector, and can mean different things, depending on the name-value pair settings.

## **Examples**

Find the resubstitution predictions of mileage from the `carsmall` data based on horsepower and weight, and look at their mean square difference from the training data.

```
load carsmall
X = [Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
MSE = resubLoss(ens)
```

```
MSE =
    6.4336
```

**See Also**      [resubPredict](#) | [resubLoss](#) | [loss](#)

# RegressionTree.resubLoss

---

**Purpose** Regression error by resubstitution

**Syntax**

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'subtrees',subtreevector)
[L,se] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector)
[L,se,NLeaf,bestlevel] =
resubLoss(tree,'subtrees',subtreevector)
[L,...] =
resubLoss(tree,'subtrees',subtreevector,Name,Value)
```

**Description** `L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitrtree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ,NameN,ValueN`.

`L = resubLoss(tree,'subtrees',subtreevector)` returns a vector of mean squared errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'subtrees',subtreevector)` returns the best pruning level as defined in the `treesize` name-value pair. By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L,...] = resubLoss(tree,'subtrees',subtreevector,Name,Value)` returns loss statistics with additional options specified by one or more

Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

## Input Arguments

### **tree**

A regression tree constructed using fitrtree.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

### **'lossfun'**

Function handle, or the string 'mse' meaning mean squared error.

You can write your own loss function in the syntax described in “Loss Functions” on page 21-3444.

**Default:** 'mse'

Name, Value arguments associated with pruning subtrees:

### **'subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`.

**Default:** 0

### **'treesize'**

One of the following strings:

# RegressionTree.resubLoss

---

- 'se' — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L + se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- 'min' — `loss` returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Output Arguments

**L**

Mean squared error, a vector the length of subtrees. The meaning of the error depends on the values in `weights` and `lossfun`.

**se**

Standard error of loss, a vector the length of subtrees.

**Nleaf**

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of subtrees.

**bestlevel**

A scalar whose value depends on `treesize`:

- `treesize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ( $L + se$ , where  $L$  and  $se$  relate to the smallest value in subtrees).
- `treesize = 'min'` — `loss` returns the element of subtrees with smallest loss, usually the smallest element of subtrees.

## Definitions

### Loss Functions

The built-in loss function is 'mse', meaning mean squared error.

To write your own loss function, create a function file of the form

```
function loss = lossfun(Y,Yfit,W)
```

- $N$  is the number of rows of `tree.X`.
- $Y$  is an  $N$ -element vector representing the observed response.

- `Yfit` is an N-element vector representing the predicted responses.
- `W` is an N-element vector representing the observation weights.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `lossfun` name-value pair.

## Examples

Find the mean square error of a model of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
resubLoss(tree)
```

```
ans =
    4.8952
```

# ClassificationEnsemble.resubMargin

---

<b>Purpose</b>	Classification margins by resubstitution
<b>Syntax</b>	<code>margin = resubMargin(ens)</code> <code>margin = resubMargin(ens,Name,Value)</code>
<b>Description</b>	<code>margin = resubMargin(ens)</code> returns the classification margin obtained by <code>ens</code> on its training data. <code>margin = resubMargin(ens,Name,Value)</code> calculates margins with additional options specified by one or more <code>Name,Value</code> pair arguments.
<b>Input Arguments</b>	<b>ens</b> A classification ensemble created with <code>fitensemble</code> . <b>Name-Value Pair Arguments</b> Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as <code>Name1,Value1,...,NameN,ValueN</code> . <b>'learners'</b> Indices of weak learners in the ensemble ranging from 1 to <code>NumTrained</code> . <code>resubMargin</code> uses only these learners for calculating margin. <b>Default:</b> <code>1:NumTrained</code>
<b>Output Arguments</b>	<b>margin</b> A numeric column-vector of length <code>size(ens.X,1)</code> containing the classification margins.

## Definitions

### Margin

The classification *margin* is the difference between the classification *score* for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the resubstitution margins for an ensemble that classifies the Fisher iris data:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
margin = resubMargin(ens);
[min(margin) mean(margin) max(margin)]
```

```
ans =
    -0.5674     3.2486     4.6245
```

## See Also

`resubEdge` | `resubLoss` | `resubPredict` | `resubMargin`

# ClassificationKNN.resubMargin

---

<b>Purpose</b>	Margin of $k$ -nearest neighbor classifier by resubstitution
<b>Syntax</b>	<code>m = resubMargin mdl</code>
<b>Description</b>	<code>m = resubMargin mdl</code> returns the classification margins of the data used to train <code>mdl</code> . For the definition, see “Margin” on page 21-3450.
<b>Input Arguments</b>	<b>mdl - Classifier model</b> classifier model object  <i>k</i> -nearest neighbor classifier model, returned as a classifier model object.  Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.  Otherwise, <code>mdl</code> is of class ClassificationKNN, and you can use the predict method to make predictions.
<b>Output Arguments</b>	<b>m</b>  A numeric column vector of length <code>size mdl.X, 1</code> , where <code>mdl.X</code> is the training data for <code>mdl</code> . Each entry in <code>m</code> represents the margin for the corresponding row of <code>mdl.X</code> and (true class) <code>mdl.Y</code> .
<b>Definitions</b>	<b>Margin</b>  The classification <i>margin</i> is the difference between the classification <i>score</i> for the true class and maximal classification score for the false classes.  Margin is a column vector with the same number of rows as in the training data.

## Score

The *score* of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors that have that classification, divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 21-2997.

## Examples

### Resubstitution Margin Calculation

Construct a  $k$ -nearest neighbor classifier for the Fisher iris data, where  $k = 5$ .

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine some statistics of the resubstitution margin of the classifier.

```
m = resubMargin(mdl);
[max(m) min(m) mean(m)]
```

```
ans =
```

```
1.0000 -0.6000 0.9253
```

The mean margin is over 0.9, indicating fairly high classification accuracy for resubstitution. For more reliable assessment of model accuracy, consider cross validation, such as `kfoldLoss`.

---

## **Related Examples**

- “Examine the Quality of a KNN Classifier” on page 16-27

## **Concepts**

- “Classification Using Nearest Neighbors” on page 16-9

<b>Purpose</b>	Classification margins by resubstitution
<b>Syntax</b>	<code>m = resubMargin(SVMModel)</code>
<b>Description</b>	<code>m = resubMargin(SVMModel)</code> returns the resubstitution classification margins ( <code>m</code> ) for the support vector machine (SVM) classifier <code>SVMModel</code> using the training data stored in <code>SVMModel.X</code> and corresponding class labels stored in <code>SVMModel.Y</code> .
<b>Input Arguments</b>	<b>SVMModel - SVM classifier</b> ClassificationSVM classifier  SVM classifier that was trained using <code>fitcsvm</code> , specified as a ClassificationSVM classifier.
<b>Output Arguments</b>	<b>m - Classification margins</b> numeric vector  Classification margins, returned as a numeric vector.  <code>m</code> has the same length as <code>Y</code> . The software estimates each entry of <code>m</code> using the trained SVM classifier <code>SVMModel</code> , the corresponding row of <code>X</code> , and the true class label <code>Y</code> .
<b>Definitions</b>	<b>Margins</b>  The <i>margins</i> are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better [2].  <b>Edge</b>  The <i>edge</i> is the weighted mean of the <i>classification margins</i> .  The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in

# ClassificationSVM.resubMargin

---

the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

## Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

## Examples

### Estimate In-Sample Classification Margins of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier. The negative class is 'b' and the positive class is 'g'.

Estimate the in-sample classification margins.

```
m = resubMargin(SVMModel);  
m(10:20)
```

```
ans =
```

```
5.5622
4.2918
1.9993
4.5520
-1.4897
3.2816
4.0260
4.5419
16.4449
2.0006
23.3782
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

## Select SVM Classifier Features by Examining In-Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare in-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load the ionosphere data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

# ClassificationSVM.resubMargin

---

```
FullSVMModel = fitcsvm(fullX,Y);  
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the in-sample margins for each classifier.

```
fullMargins = resubMargin(FullSVMModel);  
partMargins = resubMargin(PartSVMModel);  
n = size(X,1);  
p = sum(fullMargins<partMargins)/n
```

p =

0.2222

Approximately 22% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained using all of the predictors is better.

## Algorithms

For binary classification, the software defines the margin for observation  $j$ ,  $m_j$ , as

$$m_j = 2y_j f(x_j),$$

where  $y_j \in \{-1,1\}$ , and  $f(x_j)$  is the predicted score of observation  $j$  for the positive class. However, the literature commonly uses  $m_j = y_j f(x_j)$  to define the margin.

<b>Purpose</b>	Classification margins by resubstitution
<b>Syntax</b>	<code>M = resubMargin(tree)</code>
<b>Description</b>	<code>M = resubMargin(tree)</code> returns resubstitution classification margins for <code>tree</code> .
<b>Input Arguments</b>	<b>tree</b> A classification tree created by <code>fitctree</code> .
<b>Output Arguments</b>	<b>M</b> A numeric column-vector of length <code>size(tree.X,1)</code> containing the classification margins.

## Definitions **Margin**

Classification *margin* is the difference between classification *score* for the true class and maximal classification score for the false classes. A high value of margin indicates a more reliable prediction than a low value.

## **Score (tree)**

For trees, the *score* of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

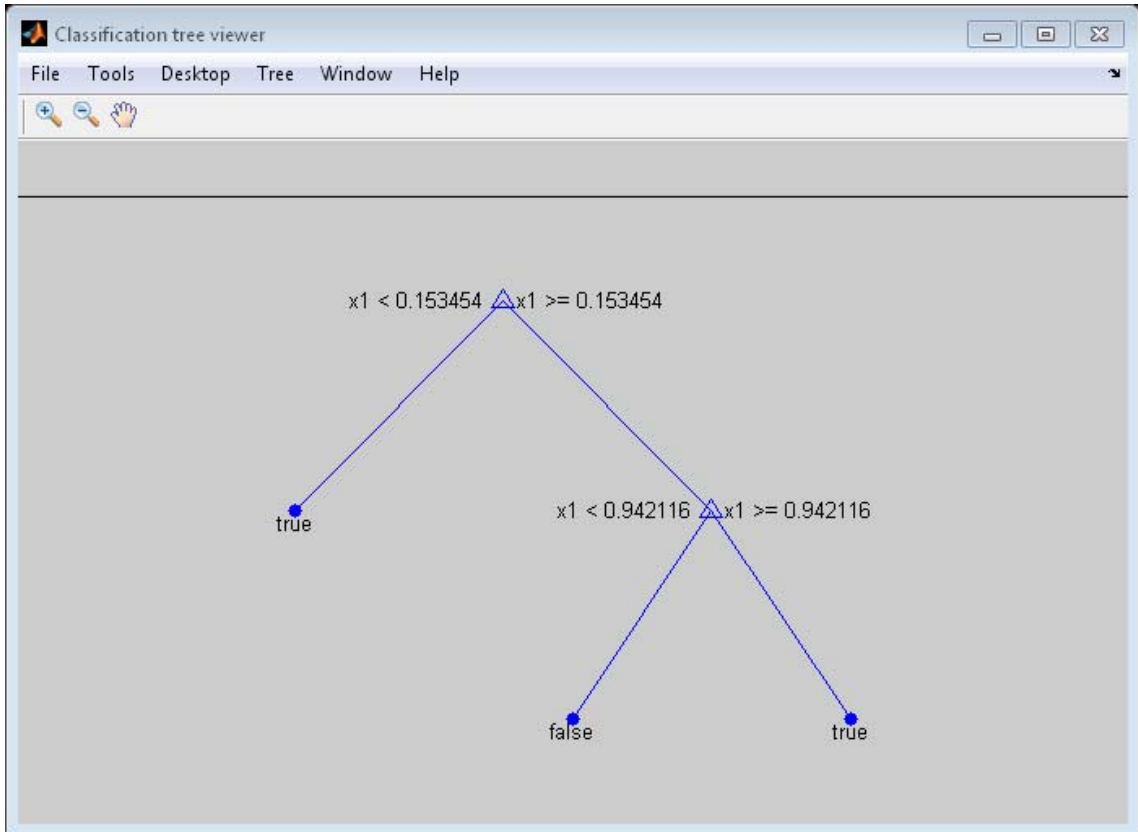

For example, consider classifying a predictor `X` as true when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
```

# ClassificationTree.resubMargin

```
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

# ClassificationTree.resubMargin

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations from .15 to .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore, the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans =  
  
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of  $X$  (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of  $X$  have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in  $X$  in the range  $(.95, 1)$  instead of the expected 5 observations.

## Examples

Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries:

```
load fisheriris  
tree = fitctree(meas,species);  
M = resubMargin(tree);  
M(1:25:end)
```

```
ans =  
    1.0000  
    1.0000  
    1.0000  
    1.0000  
    0.9565  
    0.9565
```

# ClassificationDiscriminant.resubPredict

---

## Definitions

### Posterior Probability

`posterior(i,k)` is the posterior probability of class `k` for observation `i`. For the mathematical definition, see “Posterior Probability” on page 15-7.

## Examples

Find the total number of misclassifications of the Fisher iris data for a discriminant analysis classifier:

```
load fisheriris
obj = fitcdiscr(meas,species);
Ypredict = resubPredict(obj); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?

ans =
     3
```

## See Also

[ClassificationDiscriminant](#) | [fitcdiscr](#) | [predict](#)

## How To

- “Discriminant Analysis” on page 15-3

## Purpose

Predict ensemble response by resubstitution

## Syntax

```
label = resubPredict(ens)
[label,score] = resubPredict(ens)
[label,score] = resubPredict(ens,Name,Value)
```

## Description

`label = resubPredict(ens)` returns the labels `ens` predicts for the data `ens.X`. `label` is the predictions of `ens` on the data that `fitensemble` used to create `ens`.

`[label,score] = resubPredict(ens)` also returns scores for all classes.

`[label,score] = resubPredict(ens,Name,Value)` finds resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A classification ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'learners'**

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

**Default:** `1:NumTrained`

# ClassificationEnsemble.resubPredict

---

## Output Arguments

### label

The response `ens` predicts for the training data. `label` is the same data type as the training response data `ens.Y`, and has the same number of entries as the number of rows in `ens.X`.

### score

An N-by-K matrix, where N is the number of rows in `ens.X`, and K is the number of classes in `ens`. High score value indicates that an observation likely comes from this class.

## Definitions

### Score (ensemble)

For ensembles, a classification *score* represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from  $-\infty$  to  $\infty$ .
- Bag scores range from 0 to 1.

## Examples

Find the total number of misclassifications of the Fisher iris data for a classification ensemble:

```
load fisheriris
ens = fitensemble(meas,species,'AdaBoostM2',100,'Tree');
Ypredict = resubPredict(ens); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?

ans =
    5
```

<b>Purpose</b>	Predict resubstitution response of $k$ -nearest neighbor classifier
<b>Syntax</b>	<pre>label = resubPredict mdl [label, score] = resubPredict mdl [label, score, cost] = resubPredict mdl</pre>
<b>Description</b>	<p><code>label = resubPredict mdl</code> returns the labels <code>mdl</code> predicts for the data <code>mdl.X</code>. <code>label</code> is the predictions of <code>mdl</code> on the data that <code>fitcknn</code> used to create <code>mdl</code>.</p> <p><code>[label, score] = resubPredict mdl</code> returns the posterior class probabilities for the predictions.</p> <p><code>[label, score, cost] = resubPredict mdl</code> returns the misclassification costs.</p>
<b>Input Arguments</b>	<p><b>mdl - Classifier model</b> classifier model object</p> <p><math>k</math>-nearest neighbor classifier model, returned as a classifier model object.</p> <p>Note that using the 'CrossVal', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a model of class <code>ClassificationPartitionedModel</code>. You cannot use a partitioned tree for prediction, so this kind of tree does not have a <code>predict</code> method.</p> <p>Otherwise, <code>mdl</code> is of class <code>ClassificationKNN</code>, and you can use the <code>predict</code> method to make predictions.</p>
<b>Output Arguments</b>	<p><b>label</b></p> <p>Predicted class labels for the points in the training data <code>X</code>, a vector with length equal to the number of rows in the training data <code>X</code>. The label is the class with minimal expected cost (see “Expected Cost” on page 21-3469).</p> <p><b>score</b></p>

Numeric matrix of size N-by-K, where N is the number of observations (rows) in the training data  $X$ , and K is the number of classes (in `mdl.ClassNames`). `score(i, j)` is the posterior probability that row  $i$  of  $X$  is of class  $j$ . See “Posterior Probability” on page 21-3468.

## **cost**

Matrix of expected costs of size N-by-K, where N is the number of observations (rows) in the training data  $X$ , and K is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row  $i$  of  $X$  as class  $j$ . See “Expected Cost” on page 21-3469.

## **Definitions**

### **Posterior Probability**

For a vector (single query point)  $X$  and model `mdl`, let

- $K$  be the number of nearest neighbors used in prediction, `mdl.NumNeighbors`
- `nbd(mdl, X)` be the  $K$  nearest neighbors to  $X$  in `mdl.X`
- $Y(\text{nbd})$  be the classifications of the points in `nbd(mdl, X)`, namely `mdl.Y(nbd)`
- $W(\text{nbd})$  be the weights of the points in `nbd(mdl, X)`
- `prior` be the priors of the classes in `mdl.Y`

If there is a vector of prior probabilities, then the observation weights  $W$  are normalized by class to sum to the priors. This might involve a calculation for the point  $X$ , because weights can depend on the distance from  $X$  to the points in `mdl.X`.

The posterior probability  $p(j | X)$  is

$$p(j | X) = \frac{\sum_{i \in \text{nbd}} W(i) 1_{Y(X(i)=j)}}{\sum_{i \in \text{nbd}} W(i)}.$$

Here  $1_{Y(X(i)=j)}$  means 1 when  $\text{mdl.Y}(i) = j$ , and 0 otherwise.

## Expected Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`. Suppose you have `K` classes. You place the observations into a matrix `X` with one observation per row. The command

```
[label,score,cost] = predict(mdl,X)
```

returns, among other outputs, a `cost` matrix of size `Nobs-by-K`. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,k)` is

$$\sum_{i=1}^K \hat{P}(i | X(n)) C(k | i),$$

where

- $K$  is the number of classes.
- $\hat{P}(i | X(n))$  is the posterior probability of class  $i$  for observation  $X(n)$ .
- $C(k | i)$  is the true misclassification cost of classifying an observation as  $k$  when its true class is  $i$ .

## True Misclassification Cost

There are two costs associated with KNN classification: the true misclassification cost per class, and the expected misclassification cost per observation.

# ClassificationKNN.resubPredict

---

You can set the true misclassification cost per class in the `Cost` name-value pair when you run `fitcknn`. `Cost(i,j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i,j)=1` if `i~j`, and `Cost(i,j)=0` if `i=j`. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

## Examples

### Resubstitution Prediction

Examine the quality of a classifier by its resubstitution predictions.

Load the data.

```
load fisheriris
X = meas;
Y = species;
```

Construct a classifier for 5-nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Generate the resubstitution predictions.

```
label = resubPredict(mdl);
```

Calculate the number of differences between the predictions `label` and the original data `Y`.

```
mydiff = not(strcmp(Y,label)); % mydiff(i) = 1 means they differ
sum(mydiff) % number of differences
```

```
ans =
     5
```

# ClassificationSVM.resubPredict

---

If the `ScoreTransform` property of `SVMModel` is `none`, then `Score` is a matrix of scores indicating the likelihood that an observation comes from a particular class.

- For one-class learning, `Score` has the same number of rows as `SVMModel.X`, and one column. The elements are the positive class scores for the corresponding observations.
- For two-class learning, `Score` has the same number of rows as `SVMModel.X`, and two columns. The elements of the first column of `Score` correspond to the negative class (`SVMModel.ClassNames{1}`) scores. The elements of the second column correspond to the positive class (`SVMModel.ClassNames{2}`) scores for the corresponding observations. If the `ScoreTransform` property of `SVMModel` is not `none`, then `Score` is a matrix of posterior probabilities that an observation comes from a particular class.

## Data Types

`double` | `single`

## Definitions

### Score

The SVM *score* for classifying observation  $x$  is the numerical predicted response,  $f(x)$ , computed by the trained SVM classification function

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where  $(\alpha_1, \dots, \alpha_n, b)$  are the estimated SVM parameters,  $G(x_j, x)$  is the dot product in the predictor space between  $x$  and the support vectors, and the sum includes the training set observations.

### Posterior Probability

The probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score,  $P(s)$ , that observation  $j$  is in class  $k = \{-1, 1\}$ .

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k=-1} s_k \\ \pi; & \max_{y_k=-1} s_k \leq s_j \leq \min_{y_k=+1} s_k, \\ 1; & s_j > \min_{y_k=+1} s_k \end{cases}$$

where:

- $s_j$  is the score of observation  $j$ .
- $+1$  and  $-1$  denote the positive and negative classes, respectively.
- $\pi$  is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters  $A$  and  $B$  are the slope and intercept parameters.

- For one-class learning, the posterior probability is 1 or 0. A posterior probability of 1 indicates that the observation is from the positive class, and 0 indicates that it is not from the positive class.

## Prior Probability

The *prior probability* is the believed relative frequency that observations from a class occur in the population, for each class.

# ClassificationSVM.resubPredict

---

## Examples

### Label Training Sample Observations for SVM Classifiers Using resubPredict

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier. The positive class is 'g'.

Predict the training sample labels and scores. Display the results for the first 10 observations.

```
[label,score] = resubPredict(SVMModel);  
table(Y(1:10),label(1:10),score(1:10,2),'VariableNames',...  
      {'TrueLabel','PredictedLabel','Score'})
```

ans =

TrueLabel	PredictedLabel	Score
'g'	'g'	1.4861
'b'	'b'	-1.0004
'g'	'g'	1.8685
'b'	'b'	-2.6458
'g'	'g'	1.2805
'b'	'b'	-1.4617
'g'	'g'	2.1672
'b'	'b'	-5.7085
'g'	'g'	2.4797
'b'	'b'	-2.7811

## Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. It is good practice to specify the class order and standardize the data.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier. The positive class is 'g'.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)
```

```
ScoreSVMModel =
```

```
ClassificationSVM
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
```

NumObservations: 351

```
  Alpha: [90x1 double]
  Bias: -0.1343
  KernelParameters: [1x1 struct]
    Mu: [1x34 double]
    Sigma: [1x34 double]
  BoxConstraints: [351x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [351x1 logical]
  Solver: 'SMO'
```

# ClassificationSVM.resubPredict

---

Since the classes are inseparable, the score transformation function (ScoreSVMModel.ScoreTransform) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);  
[~,postProbs] = resubPredict(ScoreSVMModel);  
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames'  
      {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

ans =

TrueLabel	PredictedLabel	Score	PosteriorProbability
'g'	'g'	1.4861	0.82215
'b'	'b'	-1.0004	0.30436
'g'	'g'	1.8685	0.86916
'b'	'b'	-2.6458	0.084183
'g'	'g'	1.2805	0.79184
'b'	'b'	-1.4617	0.22028
'g'	'g'	2.1672	0.89814
'b'	'b'	-5.7085	0.0050122
'g'	'g'	2.4797	0.92223
'b'	'b'	-2.7811	0.074805

## Algorithms

- By default, the software computes optimal posterior probabilities using Platt's method [1]:
  - 1 Performing 10-fold cross validation
  - 2 Fitting the sigmoid function parameters to the scores returned from the cross validation

- 3 Estimating the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function
- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` classifies observations into the class yielding the largest score (i.e., the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector  $P$ , misclassification cost matrix  $C$ , and observation weight vector  $w$ , the software defines a new vector of observation weights ( $W$ ) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

# ClassificationTree.resubPredict

---

**Purpose** Predict resubstitution response of tree

**Syntax**

```
label = resubPredict(tree)
[label,posterior] = resubPredict(tree)
[label,posterior,node] = resubPredict(tree)
[label,posterior,node,cnum] = resubPredict(tree)
[label,...] = resubPredict(tree,Name,Value)
```

**Description** `label = resubPredict(tree)` returns the labels tree predicts for the data `tree.X`. `label` is the predictions of tree on the data that `fitctree` used to create tree.

`[label,posterior] = resubPredict(tree)` returns the posterior class probabilities for the predictions.

`[label,posterior,node] = resubPredict(tree)` returns the node numbers of tree for the resubstituted data.

`[label,posterior,node,cnum] = resubPredict(tree)` returns the predicted class numbers for the predictions.

`[label,...] = resubPredict(tree,Name,Value)` returns resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A classification tree constructed by `fitctree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. `subtrees` must be in ascending order.

**Default:** 0

## Output Arguments

### label

The response `tree` predicts for the training data. `label` is the same data type as the training response data `tree.Y`.

If the `subtrees` name-value argument contains  $m > 1$  entries, `label` has  $m$  columns, each of which represents the predictions of the corresponding subtree. Otherwise, `label` is a vector.

### posterior

Matrix or array of posterior probabilities for classes `tree` predicts.

If the `subtrees` name-value argument is a scalar or is missing, `posterior` is an  $n$ -by- $k$  matrix, where  $n$  is the number of rows in the training data `tree.X`, and  $k$  is the number of classes.

If `subtrees` contains  $m > 1$  entries, `posterior` is an  $n$ -by- $k$ -by- $m$  array, where the matrix for each  $m$  gives posterior probabilities for the corresponding subtree.

### node

The node numbers of `tree` where each data row resolves.

If the `subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with  $n$  rows, the same number of rows as `tree.X`.

If `subtrees` contains  $m > 1$  entries, `node` is a  $n$ -by- $m$  matrix. Each column represents the node predictions of the corresponding subtree.

### cnum

The class numbers that `tree` predicts for the resubstituted data.

# ClassificationTree.resubPredict

---

If the `subtrees` name-value argument is a scalar or is missing, `cnum` is a numeric column vector with `n` rows, the same number of rows as `tree.X`.

If `subtrees` contains `m>1` entries, `cnum` is a `n`-by-`m` matrix. Each column represents the class predictions of the corresponding subtree.

## Definitions

### Posterior Probability

The posterior probability of the classification at a node is the number of training sequences that lead to that node with this classification, divided by the number of training sequences that lead to that node.

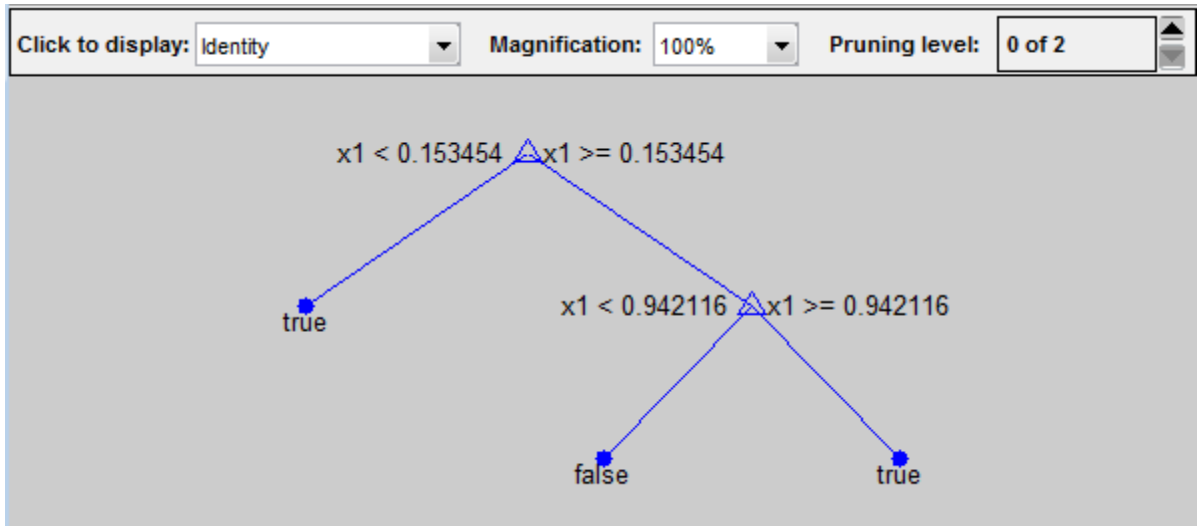

For example, consider classifying a predictor `X` as `true` when `X<0.15` or `X>0.95`, and `X` is `false` otherwise.

**1**

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'mode','graph')
```

**2**

Prune the tree:

```
tree1 = prune(tree, 'level', 1);
view(tree1, 'mode', 'graph')
```

# ClassificationTree.resubPredict

The pruned tree correctly classifies observations that are less than 0.15 as true. It also correctly classifies observations between .15 and .94 as false. However, it incorrectly classifies observations that are greater than .94 as false. Therefore the score for observations that are greater than .15 should be about  $.05/.85=.06$  for true, and about  $.8/.85=.94$  for false.

### 3

Compute the prediction scores for the first 10 rows of X:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans =
    0.9405    0.0595    0.6555
    0.9405    0.0595    0.1712
    0.9405    0.0595    0.7060
         0     1.0000    0.0318
    0.9405    0.0595    0.2769
         0     1.0000    0.0462
```

0	1.0000	0.0971
0.9405	0.0595	0.8235
0.9405	0.0595	0.6948
0.9405	0.0595	0.3171

Indeed, every value of X (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.94 and 0.06.

## Examples

Find the total number of misclassifications of the Fisher iris data for a classification tree:

```
load fisheriris
tree = fitctree(meas,species);
Ypredict = resubPredict(tree); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?

ans =
    3
```

## See Also

[resubEdge](#) | [resubMargin](#) | [resubLoss](#) | [predict](#) | [fitctree](#)

# RegressionEnsemble.resubPredict

---

**Purpose** Predict response of ensemble by resubstitution

**Syntax**  
`Yfit = resubPredict(ens)`  
`Yfit = resubPredict(ens,Name,Value)`

**Description** `Yfit = resubPredict(ens)` returns the response `ens` predicts for the data `ens.X`. `Yfit` is the predictions of `ens` on the data that `fitensemble` used to create `ens`.

`Yfit = resubPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ens**  
A regression ensemble created with `fitensemble`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### 'learners'

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

**Default:** `1:NumTrained`

## Output Arguments

**Yfit**  
A vector of predicted responses to the training data, with `ens.X` elements.

## Examples

Find the resubstitution predictions of mileage from the `carsmall` data based on horsepower and weight, and look at their mean square difference from the training data.

```
load carsmall
X = [Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,'Tree');
Yfit = resubPredict(ens);
MSE = mean((Yfit - ens.Y).^2)
```

```
MSE =
    6.4336
```

This is the same as the result of `resubLoss`:

```
resubLoss(ens)

ans =
    6.4336
```

## See Also

[resubLoss](#) | [resubPredict](#) | [predict](#)

# RegressionTree.resubPredict

---

## Purpose

Predict resubstitution response of tree

## Syntax

```
Yfit = resubPredict(tree)
[Yfit,node] = resubPredict(tree)
[Yfit,node] = resubPredict(tree,Name,Value)
```

## Description

`Yfit = resubPredict(tree)` returns the responses tree predicts for the data `tree.X`. `Yfit` is the predictions of tree on the data that `fitrtree` used to create tree.

`[Yfit,node] = resubPredict(tree)` returns the node numbers of tree for the resubstituted data.

`[Yfit,node] = resubPredict(tree,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **tree**

A regression tree constructed using `fitrtree`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'subtrees'**

A vector with integer values from 0 (full unpruned tree) to the maximal pruning level `max(tree.PruneList)`. `subtrees` must be in ascending order.

**Default:** 0

## Output Arguments

### **Yfit**

The response tree predicts for the training data.

If the `subtrees` name-value argument is a scalar or is missing, `label` is the same data type as the training response data `tree.Y`.

If `subtrees` contains  $m > 1$  entries, `label` has  $m$  columns, each of which represents the predictions of the corresponding subtree.

## **node**

The tree node numbers where `tree` sends each data row.

If the `subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with  $n$  rows, the same number of rows as `tree.X`.

If `subtrees` contains  $m > 1$  entries, `node` is a  $n$ -by- $m$  matrix. Each column represents the node predictions of the corresponding subtree.

## **Examples**

Find the mean square error of a model of the `carsmall` data:

```
load carsmall
X = [Displacement Horsepower Weight];
tree = fitrtree(X,MPG);
Yfit = resubPredict(tree);
mean((Yfit - tree.Y).^2)
```

```
ans =
    4.8952
```

You can get the same answer using `resubLoss`:

```
resubLoss(tree)

ans =
    4.8952
```

## **See Also**

# ClassificationEnsemble.resume

---

**Purpose** Resume training ensemble

**Syntax**  
`ens1 = resume(ens,nlearn)`  
`ens1 = resume(ens,nlearn,Name,Value)`

**Description** `ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

---

**Note** You cannot resume training when `ens` is a Subspace ensemble created with 'AllPredictorCombinations' number of learners.

---

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**ens**  
A classification ensemble, created with `fitensemble`.

**nlearn**  
A positive integer, the number of cycles for additional training of `ens`.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'nprint'**  
Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## Output Arguments

**ens1**

The classification ensemble `ens`, augmented with additional training.

## Examples

Train a classification ensemble for 10 cycles. Examine the resubstitution error. Then train for 10 more cycles and examine the new resubstitution error.

```
load ionosphere
ens = fitensemble(X,Y,'GentleBoost',10,'Tree');
L = resubLoss(ens)
```

```
L =
    0.0484
```

```
ens1 = resume(ens,10);
L = resubLoss(ens1)
```

```
L =
    0.0256
```

The new ensemble has much less resubstitution error than the original.

## See Also

`fitensemble`

# ClassificationPartitionedEnsemble.resume

---

**Purpose** Resume training learners on cross-validation folds

**Syntax**  
`ens1 = resume(ens,nlearn)`  
`ens1 = resume(ens,nlearn,Name,Value)`

**Description** `ens1 = resume(ens,nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **ens**

A cross-validated classification ensemble. `ens` is the result of either:

- The `fitensemble` function with a cross-validation name-value pair. The names are `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`.
- The `crossval` method applied to a classification ensemble.

### **nlearn**

A positive integer, the number of cycles for additional training of `ens`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'nprint'**

Printout frequency, a positive integer scalar or `'off'` (no printouts). Returns to the command line the number of weak

# ClassificationPartitionedEnsemble.resume

---

learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## Output Arguments

**ens1**

The cross-validated classification ensemble `ens`, augmented with additional training.

## Examples

Train a partitioned classification ensemble for 10 cycles. Examine the error. Then train for 10 more cycles and examine the new error.

```
load ionosphere
cvens = fitensemble(X,Y,'GentleBoost',10,'Tree',...
    'crossval','on');
L = kfoldLoss(cvens)
```

```
L =
    0.0883
```

```
cvens = resume(cvens,10);
L = kfoldLoss(cvens)
```

```
L =
    0.0769
```

The ensemble has less cross-validation error after training for ten more cycles.

# ClassificationSVM.resume

---

<b>Purpose</b>	Resume training support vector machine classifier
<b>Syntax</b>	<code>UpdatedSVMModel = resume(SVMModel,numIter)</code> <code>UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)</code>
<b>Description</b>	<p><code>UpdatedSVMModel = resume(SVMModel,numIter)</code> returns an updated support vector machine (SVM) classifier (<code>UpdatedSVMModel</code>) by training the support vector machine classifier <code>SVMModel</code> for <code>numIter</code> more iterations.</p> <p><code>resume</code> continues applying the training options that you set for <code>fitcsvm</code> to train <code>SVMModel</code>.</p> <p><code>UpdatedSVMModel = resume(SVMModel,numIter,Name,Value)</code> returns an updated support vector machine classifier (<code>UpdatedSVMModel</code>) with additional options specified by one or more <code>Name,Value</code> pair arguments.</p>
<b>Tips</b>	If optimization has not converged and the solver is 'SMO' or 'ISDA', then try to resume training the SVM classifier.
<b>Input Arguments</b>	<p><b>SVMModel - SVM classifier</b> ClassificationSVM classifier</p> <p>SVM classifier that was trained using <code>fitcsvm</code>, specified as a ClassificationSVM classifier.</p> <p><b>numIter - Number of iterations</b> Positive integer</p> <p>Number of iterations to continue training the SVM classifier, specified as a positive integer.</p> <p><b>Data Types</b> double</p>

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

## 'Verbose' - Verbosity level

0 | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0, 1, or 2. Verbose controls the amount of optimization information that the software displays to the Command Window and is saved as a structure to `SVMMModel.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <i>numprint</i> iterations, where <i>numprint</i> is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

By default, Verbose is the value that `fitcsvm` used to train `SVMMModel`.

# ClassificationSVM.resume

---

**Example:** 'Verbose',1

## Data Types

double

## 'NumPrint' - Number of iterations between diagnostic message printouts

nonnegative integer

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you set 'Verbose',1 and 'NumPrint',*numprint*, then the software displays all optimization diagnostic messages from SMO and ISDA every *numprint* iterations to the Command Window.

By default, NumPrint is the value that `fitcsvm` used to train `SVModel`.

**Example:** 'NumPrint',500

## Data Types

double

## Output Arguments

### UpdatedSVModel - Updated SVM classifier

ClassificationSVM classifier

Updated SVM classifier, returned as a ClassificationSVM classifier.

## Examples

### Resume Training an SVM Classifier

If you trained an SVM classifier, and the solver failed to converge onto a solution, then you can resume training the classifier without having to restart the entire learning process.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. For illustration, specify that the optimization routine uses at most 50 iterations.

```
SVMMModel = fitcsvm(X,Y,'IterationLimit',50);  
DidConverge = SVMMModel.ConvergenceInfo.Converged  
Reason = SVMMModel.ConvergenceInfo.ReasonForConvergence
```

```
DidConverge =
```

```
0
```

```
Reason =
```

```
NoConvergence
```

`DidConverge = 0` indicates that the optimization routine did not converge onto a solution. `Reason` states the reason why the routine did not converge. Therefore, `SVMMModel` is a partially trained, SVM classifier.

Resume training the SVM classifier for another 1500 iterations.

```
UpdatedSVMMModel = resume(SVMMModel,1500);  
DidConverge = UpdatedSVMMModel.ConvergenceInfo.Converged  
Reason = UpdatedSVMMModel.ConvergenceInfo.ReasonForConvergence
```

```
DidConverge =
```

```
1
```

```
Reason =
```

```
DeltaGradient
```

# ClassificationSVM.resume

---

DidConverge indicates that the optimization routine converged onto a solution. Reason indicates that the gradient difference (DeltaGradient) reached its tolerance level (DeltaGradientTolerance). Therefore, SVMModel is a fully trained SVM classifier.

## Monitor Training of an SVM Classifier

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. For illustration, specify that the optimization routine uses at most 100 iterations. Monitor the algorithm specifying that the software prints diagnostic information every 50 iterations.

```
SVMModel = fitcsvm(X,Y,'IterationLimit',100,'Verbose',1,'NumPrint',50);
```

```
=====
| Iteration | Set | Set Size | Feasibility | Delta |
|           |    |         | Gap         | Gradient |
|=====|
|           0 | active | 351 | 9.971591e-01 | 2.000000e+00 | 1
|           50 | active | 351 | 8.214794e-01 | 3.736929e+00 | 3
```

SVM optimization did not converge to the required tolerance.

The software prints an iterative display to the Command Window. The printout indicates that the optimization routine has not converged onto a solution.

Estimate the resubstitution loss of the partially trained SVM classifier.

```
partialLoss = resubLoss(SVMModel)
```

```
partialLoss =
```

```
0.1054
```

The training sample misclassification error is approximately 11%.

Resume training the classifier for another 1500 iterations. Specify that the software print diagnostic information every 250 iterations.

```
UpdatedSVMModel = resume(SVMModel,1500,'NumPrint',250)
```

```
=====
| Iteration | Set | Set Size | Feasibility | Delta |
|           |    |          | Gap          | Gradient |
|=====|
|         250 | active | 351 | 7.907170e-01 | 1.701201e+00 |
|         500 | active | 351 | 7.974990e-01 | 9.155364e-02 |
|         750 | active | 351 | 7.993931e-01 | 1.367091e-02 |
|        1000 | active | 351 | 7.995543e-01 | 1.551900e-03 |
|        1044 | active | 351 | 7.995688e-01 | 9.382457e-04 |
```

Exiting Active Set upon convergence due to DeltaGradient.

```
UpdatedSVMModel =
```

```
ClassificationSVM
  PredictorNames: {1x34 cell}
  ResponseName: 'Y'
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
  NumObservations: 351
  Alpha: [103x1 double]
  Bias: -3.8828
  KernelParameters: [1x1 struct]
  BoxConstraints: [351x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [351x1 logical]
  Solver: 'SMO'
```

# ClassificationSVM.resume

---

The software resumes at iteration 1000, and uses the same verbosity level as you set when you trained the model using `fitcsvm`. The printout indicates that the algorithm converged. Therefore, `UpdatedSVMModel` is a fully trained `ClassificationSVM` classifier.

```
updatedLoss = resubLoss(UpdatedSVMModel)
```

```
updatedLoss =
```

```
    0.0769
```

The training sample misclassification error of the fully trained classifier is approximately 8%.

**Purpose** Resume training ensemble

**Syntax**  
`ens1 = resume(ens,nlearn)`  
`ens1 = resume(ens,nlearn,Name,Value)`

**Description**  
`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles.  
`resume` uses the same training options `fitensemble` used to create `ens`.  
`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments**  
**ens**  
A regression ensemble, created with `fitensemble`.

**nlearn**  
A positive integer, the number of cycles for additional training of `ens`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**'nprint'**  
Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

# RegressionEnsemble.resume

---

## Output Arguments

**ens1**

The regression ensemble `ens`, augmented with additional training.

## Examples

Train a regression ensemble for 50 cycles. Examine the resubstitution error. Then train for 50 more cycles and examine the new resubstitution error.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',50,'Tree');
L = resubLoss(ens)
```

```
L =
    6.2681
```

```
ens = resume(ens,50);
L = resubLoss(ens)
```

```
L =
    4.3904
```

The new ensemble has much less resubstitution error than the original.

## See Also

`fitensemble`

# RegressionPartitionedEnsemble.resume

---

learners trained so far. Useful when you train ensembles with many learners on large data sets.

**Default:** 'off'

## Output Arguments

**ens1**

The cross-validated regression ensemble `ens`, augmented with additional training.

## Examples

Train a regression ensemble for 50 cycles, and cross validate it. Examine the cross-validation error. Then train for 50 more cycles and examine the new cross-validation error.

```
load carsmall
X = [Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',50,'Tree');
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L =
    25.6573
```

```
cvens = resume(cvens,50);
L = kfoldLoss(cvens)
```

```
L =
    26.7563
```

The additional training did not improve the cross-validation error.

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Rician probability distribution object

**Description** `prob.RicianDistribution` is an object consisting of parameters, a model description, and sample data for a Rician probability distribution. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Rician')` creates a Rician probability distribution object using the default parameter values.

`pd = makedist('Rician','s',s,'sigma',sigma)` creates a Rician probability distribution object using the specified parameter values.

## Input Arguments

### **s - Noncentrality parameter**

1 (default) | nonnegative scalar value

Noncentrality parameter for the Rician distribution, specified as a nonnegative scalar value.

### **Data Types**

single | double

### **sigma - scale parameter**

1 (default) | positive scalar value

Scale parameter for the Rician distribution, specified as a positive scalar value.

### **Data Types**

single | double

**Properties** **s - Noncentrality parameter**  
nonnegative scalar value

# prob.RicianDistribution

---

Noncentrality parameter of the Rician distribution, stored as a nonnegative scalar value.

## Data Types

single | double

## **sigma - scale parameter**

positive scalar value

Scale parameter for the Rician distribution, stored as a positive scalar value.

## Data Types

single | double

## **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

# prob.RicianDistribution

---

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

### **Data Types**

char

## **ParameterValues - Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

### **Data Types**

single | double

## **Truncation - Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

### **Data Types**

single | double

# prob.RicianDistribution

---

## Definitions

### Rician Distribution

The Rician distribution is used in communications theory to model scattered signals that reach a receiver using multiple paths.

The Rician distribution uses the following parameters.

Name	Description	Support
s	Noncentrality parameter	$s \geq 0$
sigma	Scale parameter	$\sigma > 0$

The probability density function (pdf) is

$$f(x | s, \sigma) = I_0 \left( \frac{xs}{\sigma^2} \right) \left( \frac{x}{\sigma^2} \right) \exp \left\{ -\frac{x^2 + s^2}{2\sigma^2} \right\} ; \quad x \geq 0,$$

where  $I_0$  is the zero-order modified Bessel function of the first kind.

## Examples

### Create a Rician Distribution Object Using Default Parameters

Create a Rician distribution object using the default parameter values.

```
pd = makedist('Rician')
```

```
pd =
```

```
RicianDistribution
```

```
Rician distribution
```

```
    s = 1
```

```

```

### Create a Rician Distribution Object Using Specified Parameters

Create a Rician distribution object by specifying the parameter values.

```
pd = makedist('Rician','s',0,'sigma',2)
```

```
pd =
```

```
RicianDistribution
```

```
Rician distribution
```

```
    s = 0
```

```
    sigma = 2
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
    2.5066
```

# ridge

---

**Purpose** Ridge regression

**Syntax**  
`b = ridge(y,X,k)`  
`b = ridge(y,X,k,scaled)`

**Description** `b = ridge(y,X,k)` returns a vector `b` of coefficient estimates for a multilinear ridge regression of the responses in `y` on the predictors in `X`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `y` is an  $n$ -by-1 vector of observed responses. `k` is a vector of ridge parameters. If `k` has  $m$  elements, `b` is  $p$ -by- $m$ . By default, `b` is computed after centering and scaling the predictors to have mean 0 and standard deviation 1. The model does not include a constant term, and `X` should not contain a column of 1s.

`b = ridge(y,X,k,scaled)` uses the {0,1}-valued flag `scaled` to determine if the coefficient estimates in `b` are restored to the scale of the original data. `ridge(y,X,k,0)` performs this additional transformation. In this case, `b` contains  $p+1$  coefficients for each value of `k`, with the first row corresponding to a constant term in the model. `ridge(y,X,k,1)` is the same as `ridge(y,X,k)`. In this case, `b` contains  $p$  coefficients, without a coefficient for a constant term.

The relationship between `b0 = ridge(y,X,k,0)` and `b1 = ridge(y,X,k,1)` is given by

```
m = mean(X);
s = std(X,0,1)';
b1_scaled = b1./s;
b0 = [mean(y)-m*b1_scaled; b1_scaled]
```

This can be seen by replacing the  $x_i$  ( $i = 1, \dots, n$ ) in the multilinear model  $y = b_0^0 + b_1^0 x_1 + \dots + b_n^0 x_n$  with the  $z$ -scores  $z_i = (x_i - \mu_i)/\sigma_i$ , and replacing  $y$  with  $y - \mu_y$ .

In general, `b1` is more useful for producing plots in which the coefficients are to be displayed on the same scale, such as a *ridge trace* (a plot of the regression coefficients as a function of the ridge parameter). `b0` is more useful for making predictions.

Coefficient estimates for multiple linear regression models rely on the independence of the model terms. When terms are correlated and the columns of the design matrix  $X$  have an approximate linear dependence, the matrix  $(X^T X)^{-1}$  becomes close to singular. As a result, the least-squares estimate

$$\hat{\beta} = (X^T X)^{-1} X^T y$$

becomes highly sensitive to random errors in the observed response  $y$ , producing a large variance. This situation of *multicollinearity* can arise, for example, when data are collected without an experimental design.

*Ridge regression* addresses the problem by estimating regression coefficients using

$$\hat{\beta} = (X^T X + kI)^{-1} X^T y$$

where  $k$  is the *ridge parameter* and  $I$  is the identity matrix. Small positive values of  $k$  improve the conditioning of the problem and reduce the variance of the estimates. While biased, the reduced variance of ridge estimates often result in a smaller mean square error when compared to least-squares estimates.

## Examples

### Ridge Regression

Load the sample data.

```
load acetylene
```

acetylene has observations for the predictor variables  $x_1$ ,  $x_2$ ,  $x_3$ , and the response variable  $y$ .

Plot the predictor variables against each other.

```
subplot(1,3,1)
plot(x1,x2,'.')
xlabel('x1'); ylabel('x2'); grid on; axis square
```

# ridge

```
subplot(1,3,2)
plot(x1,x3, '.' )
xlabel('x1'); ylabel('x3'); grid on; axis square

subplot(1,3,3)
plot(x2,x3, '.' )
xlabel('x2'); ylabel('x3'); grid on; axis square
```

Note the correlation between x1 and the other two predictor variables.

Compute coefficient estimates for a multilinear model with interaction terms, for a range of ridge parameters using `ridge` and `x2fx`.

```
X = [x1 x2 x3];
D = x2fx(X,'interaction');
D(:,1) = []; % No constant term
k = 0:1e-5:5e-3;
b = ridge(y,D,k);
```

Plot the ridge trace.

```
figure
plot(k,b,'LineWidth',2)
ylim([-100 100])
grid on
xlabel('Ridge Parameter')
ylabel('Standardized Coefficient')
title('\bf Ridge Trace')
legend('x1','x2','x3','x1x2','x1x3','x2x3')
```

The estimates stabilize to the right of the plot. Note that the coefficient of the x2x3 interaction term changes sign at a value of the ridge parameter  $\approx 5 \times 10^{-4}$ .

# classregtree.risk

---

**Purpose** Node risks

**Syntax** `r = risk(t)`  
`r = risk(t,nodes)`

**Description** `r = risk(t)` returns an  $n$ -element vector  $r$  of the risk of the nodes in the tree  $t$ , where  $n$  is the number of nodes. The risk  $r(i)$  for node  $i$  is the node error  $e(i)$  (computed by `nodeerr`) weighted by the node probability  $p(i)$  (computed by `nodeprob`).

`r = risk(t,nodes)` takes a vector `nodes` of node numbers and returns the risk values for the specified nodes.

**Examples** Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica

classregtree | nodeerr | nodeprob

**Purpose** Interactive robust regression

**Syntax** `robustdemo`  
`robustdemo(x,y)`

**Description** `robustdemo` shows the difference between ordinary least squares and robust regression for data with a single predictor. With no input arguments, `robustdemo` displays a scatter plot of a sample of roughly linear data with one outlier. The bottom of the figure displays equations of lines fitted to the data using ordinary least squares and robust methods, together with estimates of the root mean squared errors.

Use the right mouse button to click on a point and view its least-squares leverage and robust weight.

Use the left mouse button to click-and-drag a point. The displays will update.

`robustdemo(x,y)` uses `x` and `y` data vectors you supply, in place of the sample data supplied with the function.

**Examples** The following steps show you how to use `robustdemo`.

**1 Start the example.** To begin using `robustdemo` with the built-in data, simply type the function name:

```
robustdemo
```

# robustdemo

Least squares:	$Y = -0.188327 + 1.10351 * X$	RMS error = 2.21375
Robust:	$Y = -1.77278 + 1.50415 * X$	RMS error = 1.43663

The resulting figure shows a scatter plot with two fitted lines. The red line is the fit using ordinary least-squares regression. The green line is the fit using robust regression. At the bottom of the figure are the equations for the fitted lines, together with the estimated root mean squared errors for each fit.

**2 View leverages and robust weights.** Right-click on any data point to see its least-squares leverage and robust weight:

Least squares:  $Y = -0.188327 + 1.10351 \cdot X$       RMS error = 2.21375

Robust:  $Y = -1.77278 + 1.50415 \cdot X$       RMS error = 1.43663

In the built-in data, the right-most point has a relatively high leverage of 0.35. The point exerts a large influence on the least-squares fit, but its small robust weight shows that it is effectively excluded from the robust fit.

- 3 See how changes in the data affect the fits.** With the left mouse button, click and hold on any data point and drag it to a new location. When you release the mouse button, the displays update:

# robustdemo

Least squares:	$Y = -1.0661 + 1.33785 * X$	RMS error = 1.21477
Robust:	$Y = -1.18916 + 1.36459 * X$	RMS error = 1.27697

Bringing the right-most data point closer to the least-squares line makes the two fitted lines nearly identical. The adjusted right-most data point has significant weight in the robust fit.

**See Also** [robustfit](#) | [leverage](#)

**Purpose**

Robust regression

**Syntax**

```

b = robustfit(X,y)
b = robustfit(X,y,wfun,tune)
b = robustfit(X,y,wfun,tune,const)
[b,stats] = robustfit(...)

```

**Description**

`b = robustfit(X,y)` returns a  $(p + 1)$ -by-1 vector `b` of coefficient estimates for a robust multilinear regression of the responses in `y` on the predictors in `X`. `X` is an  $n$ -by- $p$  matrix of  $p$  predictors at each of  $n$  observations. `y` is an  $n$ -by-1 vector of observed responses. By default, the algorithm uses iteratively reweighted least squares with a bisquare weighting function.

---

**Note** By default, `robustfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `robustfit` using the input `const`, below.

---

`robustfit` treats NaNs in `X` or `y` as missing values, and removes them.

`b = robustfit(X,y,wfun,tune)` specifies a weighting function `wfun`. `tune` is a tuning constant that is divided into the residual vector before computing weights.

The weighting function `wfun` can be any one of the following strings:

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385

Weight Function	Equation	Default Tuning Constant
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

If `tune` is unspecified, the default value in the table is used. Default tuning constants give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

The value  $r$  in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h})$$

where `resid` is the vector of residuals from the previous iteration, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745$$

Here `MAD` is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are  $p$  columns in  $X$ , the smallest  $p$  absolute deviations are excluded when computing the median.

You can write your own weight function. The function must take a vector of scaled residuals as input and produce a vector of weights as

output. In this case, *wfun* is specified using a function handle @ (as in @myfun), and the input *tune* is required.

`b = robustfit(X,y,wfun,tune,const)` controls whether or not the model will include a constant term. *const* is 'on' to include the constant term (the default), or 'off' to omit it. When *const* is 'on', `robustfit` adds a first column of 1s to *X* and *b* becomes a  $(p + 1)$ -by-1 vector. When *const* is 'off', `robustfit` does not alter *X*, then *b* is a  $p$ -by-1 vector.

`[b,stats] = robustfit(...)` returns the structure *stats*, whose fields contain diagnostic statistics from the regression. The fields of *stats* are:

- `ols_s` — Sigma estimate (RMSE) from ordinary least squares
- `robust_s` — Robust estimate of sigma
- `mad_s` — Estimate of sigma computed using the median absolute deviation of the residuals from their median; used for scaling residuals during iterative fitting
- `s` — Final estimate of sigma, the larger of `robust_s` and a weighted average of `ols_s` and `robust_s`
- `resid` — Residual
- `rstud` — Studentized residual (see `regress` for more information)
- `se` — Standard error of coefficient estimates
- `covb` — Estimated covariance matrix for coefficient estimates
- `coeffcorr` — Estimated correlation of coefficient estimates
- `t` — Ratio of *b* to *se*
- `p` —  $p$ -values for *t*
- `w` — Vector of weights for robust fit
- `R` —  $R$  factor in  $QR$  decomposition of *X*
- `dfe` — Degrees of freedom for error

- `h` — Vector of leverage values for least-squares fit

The `robustfit` function estimates the variance-covariance matrix of the coefficient estimates using `inv(X'*X)*stats.s^2`. Standard errors and correlations are derived from this estimate.

## Examples

### Compare Robust and Least-Squares Regression

Generate data with the trend  $y = 10 - 2x$ , then change one value to simulate an outlier.

```
x = (1:10)';  
rng('default') % For reproducibility  
y = 10 - 2*x + randn(10,1);  
y(10) = 0;
```

Fit a straight line using ordinary least squares regression.

```
b1s = regress(y,[ones(10,1) x])
```

```
b1s =  
  
    7.8518  
   -1.3644
```

Now use robust regression to estimate a straight-line fit.

```
brob = robustfit(x,y)
```

```
brob =  
  
    8.4504  
   -1.5278
```

Create scatter plot of the data together with the fits.

```
scatter(x,y,'filled'); grid on; hold on  
plot(x,bls(1)+bls(2)*x,'r','LineWidth',2);  
plot(x,brob(1)+brob(2)*x,'g','LineWidth',2)  
legend('Data','Ordinary Least Squares','Robust Regression')
```

The robust fit is less influenced by the outlier than the least-squares fit.

<b>Purpose</b>	Rotate categorical matrix 90 degrees  The <code>nominal</code> and <code>ordinal</code> array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB <code>categorical</code> data type instead.
<b>Syntax</b>	<code>B = rot90(A)</code> <code>B = rot90(A,k)</code>
<b>Description</b>	<code>B = rot90(A)</code> returns the 90 degree counterclockwise rotation of the 2-D categorical matrix <code>A</code> .  <code>B = rot90(A,k)</code> returns the $k*90$ degree rotation of <code>A</code> , $k = +-1, +-2, \dots$
<b>See Also</b>	<code>flipdim</code>   <code>fliplr</code>   <code>flipud</code>

# rotatefactors

---

**Purpose** Rotate factor loadings

**Syntax**

```
B = rotatefactors(A)
B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)
B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)
B = rotatefactors(A, 'Method', 'pattern', 'Target', target)
B = rotatefactors(A, 'Method', 'promax')
[B,T] = rotatefactors(A, ...)
```

**Description** `B = rotatefactors(A)` rotates the  $d$ -by- $m$  loadings matrix  $A$  to maximize the varimax criterion, and returns the result in  $B$ . Rows of  $A$  and  $B$  correspond to variables and columns correspond to factors, for example, the  $(i, j)$ th element of  $A$  is the coefficient for the  $i$ th variable on the  $j$ th factor. The matrix  $A$  usually contains principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`.

`B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)` rotates  $A$  to maximize the orthomax criterion with the coefficient `gamma`, i.e.,  $B$  is the orthogonal rotation of  $A$  that maximizes

$$\text{sum}(D * \text{sum}(B.^4, 1) - \text{GAMMA} * \text{sum}(B.^2, 1).^2)$$

The default value of 1 for `gamma` corresponds to varimax rotation. Other possibilities include `gamma = 0`, `m/2`, and `d(m - 1)/(d + m - 2)`, corresponding to quartimax, equamax, and parsimax. You can also supply the strings `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'` for the `'method'` parameter and omit the `'Coeff'` parameter.

If `'Method'` is `'orthomax'`, `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'`, then additional parameters are

- `'Normalize'` — Flag indicating whether the loadings matrix should be row-normalized for rotation. If `'on'` (the default), rows of  $A$  are normalized prior to rotation to have unit Euclidean norm, and unnormalized after rotation. If `'off'`, the raw loadings are rotated and returned.

- 'Reltol' — Relative convergence tolerance in the iterative algorithm used to find T. The default is  $\sqrt{\text{eps}}$ .
- 'Maxit' — Iteration limit in the iterative algorithm used to find T. The default is 250.

`B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)` performs an oblique procrustes rotation of A to the *d*-by-*m* target loadings matrix target.

`B = rotatefactors(A, 'Method', 'pattern', 'Target', target)` performs an oblique rotation of the loadings matrix A to the *d*-by-*m* target pattern matrix target, and returns the result in B. target defines the "restricted" elements of B, i.e., elements of B corresponding to zero elements of target are constrained to have small magnitude, while elements of B corresponding to nonzero elements of target are allowed to take on any magnitude.

If 'Method' is 'procrustes' or 'pattern', an additional parameter is 'Type', the type of rotation. If 'Type' is 'orthogonal', the rotation is orthogonal, and the factors remain uncorrelated. If 'Type' is 'oblique' (the default), the rotation is oblique, and the rotated factors might be correlated.

When 'Method' is 'pattern', there are restrictions on target. If A has *m* columns, then for orthogonal rotation, the *j*th column of target must contain at least *m* - *j* zeros. For oblique rotation, each column of target must contain at least *m* - 1 zeros.

`B = rotatefactors(A, 'Method', 'promax')` rotates A to maximize the promax criterion, equivalent to an oblique Procrustes rotation with a target created by an orthomax rotation. Use the four orthomax parameters to control the orthomax rotation used internally by promax.

An additional parameter for 'promax' is 'Power', the exponent for creating promax target matrix. 'Power' must be 1 or greater. The default is 4.

`[B,T] = rotatefactors(A,...)` returns the rotation matrix T used to create B, that is,  $B = A * T$ . You can find the correlation matrix of the rotated factors by using  $\text{inv}(T' * T)$ . For orthogonal rotation, this is the

# rotatefactors

---

identity matrix, while for oblique rotation, it has unit diagonal elements but nonzero off-diagonal elements.

## Examples

```
rng('default') % for reproducibility
X = randn(100,10);

% Default (normalized varimax) rotation:
% first three principal components.
LPC = pca(X);
[L1,T] = rotatefactors(LPC(:,1:3));

% Equamax rotation:
% first three principal components.
[L2,T] = rotatefactors(LPC(:,1:3),...
                      'method','equamax');

% Promax rotation:
% first three factors.
LFA = factoran(X,3,'Rotate','none');
[L3,T] = rotatefactors(LFA(:,1:3),...
                      'method','promax',...
                      'power',2);

% Pattern rotation:
% first three factors.
Tgt = [1 1 1 1 1 0 1 0 1 1; ...
       0 0 0 1 1 1 0 0 0 0; ...
       1 0 0 1 0 1 1 1 1 0]';
[L4,T] = rotatefactors(LFA(:,1:3),...
                      'method','pattern',...
                      'target',Tgt);
inv(T'*T) % Correlation matrix of the rotated factors
ans =

    1.0000   -0.9593   -0.7098

biplot | factoran | pca | pcacov | procrustes

**Purpose** Row exchange

**Syntax**

```
dRE = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns)
[dRE,X] = rowexch(nfactors,nruns,model)
[dRE,X] = rowexch(...,param1,val1,param2,val2,...)
```

**Description** `dRE = rowexch(nfactors,nruns)` uses a row-exchange algorithm to generate a  $D$ -optimal design `dRE` with `nruns` runs (the rows of `dRE`) for a linear additive model with `nfactors` factors (the columns of `dRE`). The model includes a constant term.

`[dRE,X] = rowexch(nfactors,nruns)` also returns the associated design matrix  $X$ , whose columns are the model terms evaluated at each treatment (row) of `dRE`.

`[dRE,X] = rowexch(nfactors,nruns,model)` uses the linear regression model specified in `model`. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of  $X$  for a full quadratic model with  $n$  terms is:

- 1** The constant term
- 2** The linear terms in order 1, 2, ...,  $n$
- 3** The interaction terms in order (1, 2), (1, 3), ..., (1,  $n$ ), (2, 3), ..., ( $n-1$ ,  $n$ )
- 4** The squared terms in order 1, 2, ...,  $n$

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X1, X2, and X3, then a row [0 1 2] in *model* specifies the term  $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$ . A row of all zeros in *model* specifies a constant term, which can be omitted.

[dRE,X] = rowexch(...,param1,va11,param2,va12,...) specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excludefun'	Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$ , where <i>S</i> is a matrix of treatments with nfactors columns and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . <i>b</i> ( <i>i</i> ) is true if the <i>i</i> th row <i>S</i> should be excluded.
'init'	Initial design as an nruns-by-nfactors matrix. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.

Parameter	Value
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the options structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> <li>• <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li> <li>• <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.</li> <li>• <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>rowexch</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> <li>▪ You have an open Parallel pool</li> <li>▪ <code>UseParallel</code> is <code>true</code></li> <li>▪ <code>UseSubstreams</code> is <code>false</code></li> </ul>                     In that case, use a cell array the same size as the Parallel pool.                 </li> </ul>
'tries'	<p>Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.</p>

## Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix  $X$  to increase  $D = |X^T X|$  at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally,  $D$ -optimal designs. Run each algorithm multiple times

and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of  $X$  with a row from a design matrix  $C$  evaluated at a candidate set of feasible treatments. The rowexch function automatically generates a  $C$  appropriate for a specified model, operating in two steps by calling the candgen and candexch functions in sequence. Provide your own  $C$  by calling candexch directly. In either case, if  $C$  is large, its static presence in memory can affect computation.

## Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_3 + \beta_{12}x_1x_2 + \beta_{13}x_1x_3 + \beta_{23}x_2x_3 + \varepsilon$$

Use rowexch to generate a  $D$ -optimal design with seven runs:

```
nfactors = 3;
nruns = 7;
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
    -1    -1     1
     1    -1     1
     1    -1    -1
     1     1     1
    -1    -1    -1
    -1     1    -1
    -1     1     1
X =
     1    -1    -1     1     1    -1    -1
     1     1    -1     1    -1     1    -1
     1     1    -1    -1    -1    -1     1
     1     1     1     1     1     1     1
     1    -1    -1    -1     1     1     1
     1    -1     1    -1    -1     1    -1
     1    -1     1     1    -1    -1     1
```

## rowexch

---

Columns of the design matrix  $X$  are the model terms evaluated at each row of the design  $dRE$ . The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use  $X$  to fit the model, as described in “Linear Regression” on page 9-12, to response data measured at the design points in  $dRE$ .

candgen | candexch | cordexch

**Purpose** Interactive response surface demonstration

**Syntax** rsmdemo

**Description** rsmdemo opens a group of three graphical user interfaces for interactively investigating response surface methodology (RSM), nonlinear fitting, and the design of experiments.

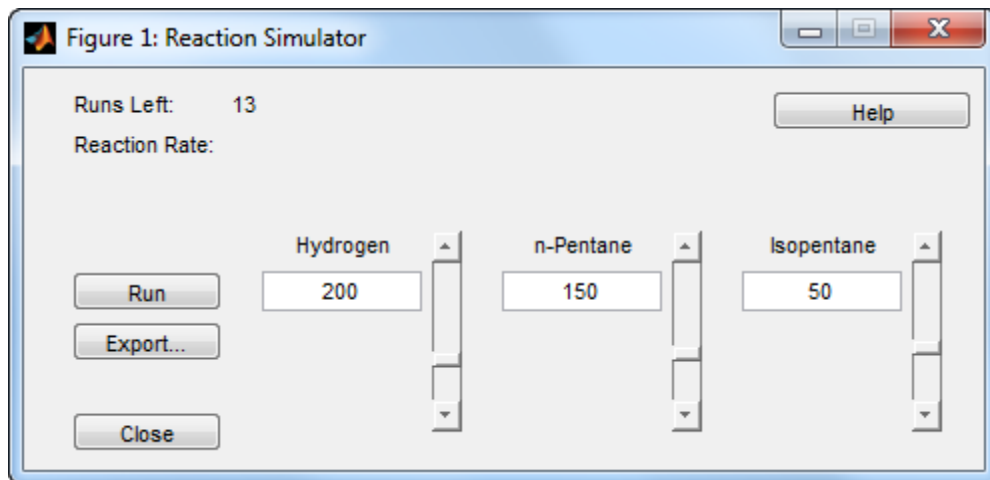

The interfaces allow you to collect and model data from a simulated chemical reaction. Experimental predictors are concentrations of three reactants (hydrogen, *n*-Pentane, and isopentane) and the response is the reaction rate. The reaction rate is simulated by a Hougen-Watson model (Bates and Watts, [2], pp. 271–272):

$$rate = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

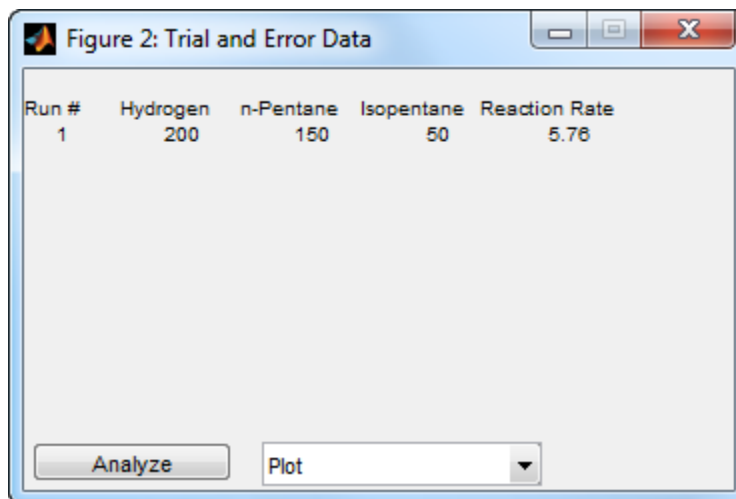

where *rate* is the reaction rate,  $x_1$ ,  $x_2$ , and  $x_3$  are the concentrations of hydrogen, *n*-pentane, and isopentane, respectively, and  $\beta_1, \beta_2, \dots, \beta_5$  are fixed parameters. Random errors are used to perturb the reaction rate for each combination of reactants.

Collect data using one of two methods:

- 1 Manually set reactant concentrations in the **Reaction Simulator** interface by editing the text boxes or by adjusting the associated sliders.

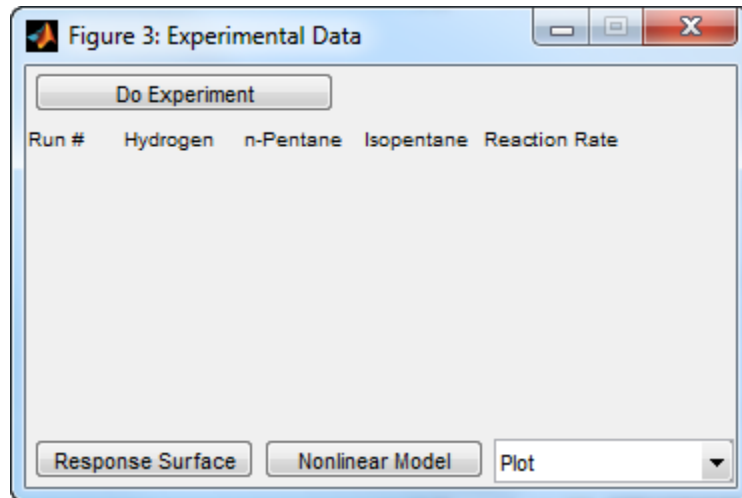

When you click **Run**, the concentrations and simulated reaction rate are recorded on the **Trial and Error Data** interface.

You are allowed up to 13 independent experimental runs for data collection.

- 2 Use a designed experiment to set reactant concentrations in the **Experimental Data** interface by clicking the **Do Experiment** button.

A 13-run  $D$ -optimal design for a full quadratic model is generated by the `cordexch` function, and the concentrations and simulated reaction rates are recorded on the same interface.

Once data is collected, scatter plots of reaction rates vs. individual predictors are generated by selecting one of the following from the **Plot** pop-up menu below the recorded data:

- **Hydrogen vs. Rate**
- **n-Pentane vs. Rate**
- **Isopentane vs. Rate**

Fit a response surface model to the data by clicking the **Analyze** button below the trial-and-error data or the **Response Surface** button below the experimental data. Both buttons load the data into the Response Surface Tool `rstool`. By default, trial-and-error data is fit with a linear additive model and experimental data is fit with a full quadratic model, but the models can be adjusted in the Response Surface Tool.

For experimental data, you have the additional option of fitting a Hougen-Watson model. Click the **Nonlinear Model** button to load the data and the model in `hougen` into the Nonlinear Fitting Tool `nlintool`.

## See Also

`hougen` | `cordexch` | `rstool` | `nlintool`

**Purpose** Interactive response surface modeling

**Syntax**

```
rstool
rstool(X,Y,model)
rstool(x,y,model,alpha)
rstool(x,y,model,alpha,xname,yname)
```

**Description** rstool opens a graphical user interface for interactively investigating one-dimensional contours of multidimensional response surface models.

By default, the interface opens with the data from `hald.mat` and a fitted response surface with constant, linear, and interaction terms.

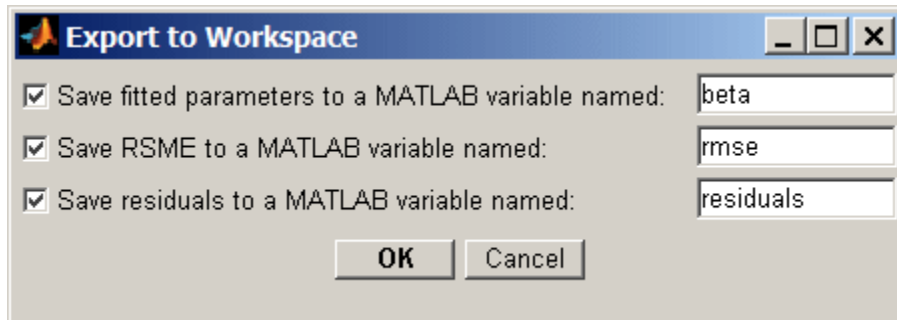

A sequence of plots is displayed, each showing a contour of the response surface against a single predictor, with all other predictors held fixed.

rstool plots a 95% simultaneous confidence band for the fitted response surface as two red curves. Predictor values are displayed in the text boxes on the horizontal axis and are marked by vertical dashed blue lines in the plots. Predictor values are changed by editing the text boxes or by dragging the dashed blue lines. When you change the value of a predictor, all plots update to show the new point in predictor space.

The pop-up menu at the lower left of the interface allows you to choose among the following models:

- Linear — Constant and linear terms (the default)
- Pure Quadratic — Constant, linear, and squared terms
- Interactions — Constant, linear, and interaction terms
- Full Quadratic — Constant, linear, interaction, and squared terms

Click **Export** to open the following dialog box:

The dialog allows you to save information about the fit to MATLAB workspace variables with valid names.

`rstool(X,Y,model)` opens the interface with the predictor data in *X*, the response data in *Y*, and the fitted model *model*. Distinct predictor variables should appear in different columns of *X*. *Y* can be a vector, corresponding to a single response, or a matrix, with columns corresponding to multiple responses. *Y* must have as many elements (or rows, if it is a matrix) as *X* has rows.

The optional input *model* can be any one of the following strings:

- 'linear' — Constant and linear terms (the default)
- 'purequadratic' — Constant, linear, and squared terms
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms

To specify a polynomial model of arbitrary order, or a model without a constant term, use a matrix for *model* as described in `x2fx`.

`rstool(x,y,model,alpha)` uses  $100(1-\alpha)\%$  global confidence intervals for new observations in the plots.

`rstool(x,y,model,alpha,xname,yname)` labels the axes using the strings in *xname* and *yname*. To label each subplot differently, *xname* and *yname* can be cell arrays of strings.

## Examples

The following uses `rstool` to visualize a quadratic response surface model of the 3-D chemical reaction data in `reaction.mat`:

```
load reaction
alpha = 0.01; % Significance level
rstool(reactants,rate,'quadratic',alpha,xn,yn)
```

The rstool interface is used by rsmdemo to visualize the results of simulated experiments with data like that in reaction.mat. As described in “Response Surface Designs” on page 18-9, rsmdemo uses a response surface model to generate simulated data at combinations of predictors specified by either the user or by a designed experiment.

x2fx | rsmdemo | nlintool

**Purpose**

Run test for randomness

**Syntax**

```
h = runstest(x)
h = runstest(x,v)
h = runstest(x,'ud')
h = runstest(...,param1,val1,param2,val2,...)
[h,p] = runstest(...)
[h,p,stats] = runstest(...)
```

**Description**

`h = runstest(x)` performs a runs test on the sequence of observations in the vector `x`. This is a test of the null hypothesis that the values in `x` come in random order, against the alternative that they do not. The test is based on the number of runs of consecutive values above or below the mean of `x`. Too few runs indicate a tendency for high and low values to cluster. Too many runs indicate a tendency for high and low values to alternate. The test returns the logical value `h = 1` if it rejects the null hypothesis at the 5% significance level, and `h = 0` if it cannot. The test treats NaN values in `x` as missing values, and ignores them.

`runstest` uses a test statistic which is approximately normally distributed when the null hypothesis is true. It is the difference between the number of runs and its mean, divided by its standard deviation.

`h = runstest(x,v)` performs the test using runs above or below the value `v`. Values exactly equal to `v` are discarded. The default value of `v` is the mean of `x`.

`h = runstest(x,'ud')` performs a test for the number of runs up or down. This also tests the hypothesis that the values in `x` come in random order. Too few runs indicate a trend. Too many runs indicate an oscillation. Values exactly equal to the preceding value are discarded.

`h = runstest(...,param1,val1,param2,val2,...)` specifies additional parameters and their values. Valid parameter/value pairs are the following:

- `'alpha'` — A scalar giving the significance level of the test
- `'method'` — Either `'exact'` to compute the  $p$  value using an exact algorithm, or `'approximate'` to use a normal approximation. The

# runstest

---

default is 'exact', except for runs up/down when the length of is 51 or more. The 'exact' method is not available for runs up/down when the length of  $x$  is over 50.

- 'tail' — Performs the test against one of the following alternative hypotheses:
  - 'both' — two-tailed test (sequence is not random)
  - 'right' — right-tailed test (like values separate for runs above/below, direction alternates for runs up/down)
  - 'left' — left-tailed test (like values cluster for runs above/below, values trend for runs up/down)

`[h,p] = runstest(...)` returns the  $p$  value of the test. The output  $p$  is computed from either the test statistic or the exact distribution of the number of runs, depending on the value of the 'method' parameter.

`[h,p,stats] = runstest(...)` returns a structure `stats` with the following fields:

- `nruns` — The number of runs
- `n1` — The number of values above  $v$
- `n0` — The number of values below  $v$
- `z` — The test statistic

## Examples

```
x = randn(40,1);  
[h,p] = runstest(x,median(x))  
h =  
    0  
p =  
    0.6286
```

`signrank` | `signtest`

# TreeBagger.SampleWithReplacement property

---

**Purpose** Flag to sample with replacement

**Description** The `SampleWithReplacement` property is a logical flag specifying if data are sampled for each decision tree with replacement. True if `TreeBagger` samples data with replacement and false otherwise. True by default.

# sampsizepwr

---

**Purpose** Sample size and power of test

**Syntax**

```
n = sampsizepwr(testtype,p0,p1)
n = sampsizepwr(testtype,p0,p1,power)
power = sampsizepwr(testtype,p0,p1,[],n)
p1 = sampsizepwr(testtype,p0,[],power,n)
[...] = sampsizepwr(...,n,param1,va11,param2,va12,...)
```

**Description** `n = sampsizepwr(testtype,p0,p1)` returns the sample size `n` required for a two-sided test of the specified type to have a power (probability of rejecting the null hypothesis when the alternative hypothesis is true) of 0.90 when the significance level (probability of rejecting the null hypothesis when the null hypothesis is true) is 0.05. `p0` specifies parameter values under the null hypothesis. `p1` specifies the single parameter value being tested under the alternative hypothesis.

The following values are available for `testtype`:

- 'z' — *z*-test for normally distributed data with known standard deviation. `p0` is a two-element vector [`mu0` `sigma0`] of the mean and standard deviation, respectively, under the null hypothesis. `p1` is the value of the mean under the alternative hypothesis.
- 't' — *t*-test for normally distributed data with unknown standard deviation. `p0` is a two-element vector [`mu0` `sigma0`] of the mean and standard deviation, respectively, under the null hypothesis. `p1` is the value of the mean under the alternative hypothesis.
- 'var' — Chi-square test of variance for normally distributed data. `p0` is the variance under the null hypothesis. `p1` is the variance under the alternative hypothesis.
- 'p' — Test of the *p* parameter (success probability) for a binomial distribution. `p0` is the value of *p* under the null hypothesis. `p1` is the value of *p* under the alternative hypothesis.

The 'p' test is a discrete test for which increasing the sample size does not always increase the power. For `n` values larger than 200, there may be values smaller than the returned `n` value that also produce the desired size and power.

`n = sampsizepwr(testtype,p0,p1,power)` returns the sample size `n` such that the power is `power` for the parameter value `p1`.

`power = sampsizepwr(testtype,p0,p1,[],n)` returns the power achieved for a sample size of `n` when the true parameter value is `p1`.

`p1 = sampsizepwr(testtype,p0,[],power,n)` returns the parameter value detectable with the specified sample size `n` and power `power`.

When computing `p1` for the 'p' test, if no alternative can be rejected for a given null hypothesis and significance level, the function displays a warning message and returns NaN.

`[...] = sampsizepwr(...,n,param1,val1,param2,val2,...)` specifies one or more of the following name/value pairs:

- 'alpha' — Significance level of the test (default 0.05)
- 'tail' — The type of test is one of the following:
  - 'both' — Two-sided test for an alternative not equal to `p0`
  - 'right' — One-sided test for an alternative larger than `p0`
  - 'left' — One-sided test for an alternative smaller than `p0`

## Examples

### Mean for Given Sample Size and Power

Compute the mean closest to 100 that can be determined to be significantly different from 100 using a *t*-test with a sample size of 60 and a power of 0.8.

```
mu1 = sampsizepwr('t',[100 10],[],0.8,60)
```

```
mu1 =
```

```
103.6770
```

## Compute Sample Size for a Binomial Test

Compute the sample size  $n$  required to distinguish  $p = 0.26$  from  $p = 0.6$  with a binomial test.

```
napprox = sampsizepwr('p',0.2,0.26,0.6)
```

Warning: Values  $N > 200$  are approximate. Plotting the power as a function of  $N$  may reveal lower  $N$  values that have the required power.

```
napprox =
```

```
244
```

The result is approximate, so make a plot to see if any smaller  $n$  values also have the required power of 0.5.

```
nn = 1:250;  
pwr = sampsizepwr('p',0.2,0.26,[],nn);  
nexact = min(nn(pwr>=0.6))
```

```
nexact =
```

```
213
```

```
plot(nn,pwr,'b-',[napprox nexact],pwr([napprox nexact]),'ro');  
grid on
```

**See Also** `vartest` | `ttest` | `ztest` | `binocdf`

# scatterhist

---

**Purpose** Scatter plot with marginal histograms

**Syntax** `scatterhist(x,y)`  
`scatterhist(x,y,Name,Value)`

`h = scatterhist( ___ )`

**Description** `scatterhist(x,y)` creates a 2-D scatter plot of the data in the vectors `x` and `y`, and puts a univariate histogram on the horizontal and vertical axes of the plot.

`scatterhist(x,y,Name,Value)` creates the plot using additional options specified by one or more name-value pair arguments. For example, you can specify a grouping variable or change the display options.

`h = scatterhist( ___ )` returns a vector of three axis handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively, using any of the input arguments in the previous syntaxes.

## Input Arguments

### **x - Sample data**

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length. If `x` or `y` contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either `x` or `y` from both data vectors when generating the scatter plot
- Removes rows with NaN values only from the corresponding `x` or `y` data vector when generating the marginal histograms

### **Data Types**

single | double

### **y - Sample data**

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

**Example:** `'Location','SouthEast','Direction','out'` specifies a plot with histograms located below and to the right of the scatter plot, with the bars directed away from the scatter plot.

### 'NBins' - Number of bins for histograms

positive integer value | vector

Number of bins for histograms, specified as the comma-separated pair consisting of `'Nbins'` and a positive integer value greater than or equal to 2, or vector of two such values. If the number of bins is specified as a positive integer value, that value is the number of bins for both the `x` and `y` histograms. If the number of bins is specified by a vector, the first value is the number of bins for the `x` data, and the second value is the number of bins for the `y` data. By default, the number of bins is computed based on the sample standard deviation using Scott's rule.

**Example:** `'NBins',[5,7]`

### Data Types

single | double

### 'Location' - Location of marginal histograms

`'SouthWest'` (default) | `'SouthEast'` | `'NorthEast'` | `'NorthWest'`

Location of the marginal histograms in the figure, specified as the comma-separated pair consisting of 'Location' and one of the following.

'SouthWest' Plot the histograms below and to the left of the scatter plot.

'SouthEast' Plot the histograms below and to the right of the scatter plot.

'NorthEast' Plot the histograms above and to the right of the scatter plot.

'NorthWest' Plot the histograms above and to the left of the scatter plot.

**Example:** 'Location', 'SouthEast'

## 'Direction' - Direction of marginal histograms

'in' (default) | 'out'

Direction of the marginal histograms, specified as the comma-separated pair consisting of 'Direction' and one of the following.

'in' Plot the histograms with the bars directed toward the scatter plot.

'out' Plot the histograms with the bars directed away from the scatter plot.

**Example:** 'Direction', 'out'

## 'Group' - Grouping variable

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as the comma-separated pair consisting of 'Group' and a categorical array, logical or numeric vector, or cell array of strings. Each unique value in a grouping variable defines a group.

For example, if Gender is a cell array of strings with values 'Male' and 'Female', you can use Gender as a grouping variable to plot your data by gender.

Multiple grouping variables can be used by specifying a cell array of grouping variable names. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender,Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

**Example:** `'Group',{Gender,Smoker}`

### Data Types

single | double | logical | cell | char

### 'Kernel' - Grouped kernel density plot indicator

`'on' | 'off' | 'overlay'`

Grouped kernel density plot indicator, specified as the comma-separated pair consisting of `'Kernel'` and one of the following.

- `'on'` Display kernel density plots for each group. This is the default if a `Group` parameter is specified.
- `'off'` Display the overall marginal distribution as histograms. This is the default if a `Group` parameter is not specified.
- `'overlay'` Display the overall marginal distribution as kernel density plots overlaid onto histograms, similar to `histfit`.

**Example:** `'Kernel','overlay'`

### 'Bandwidth' - Bandwidth of kernel smoothing window

matrix

Bandwidth of kernel smoothing window, specified as the comma-separated pair consisting of `'Bandwidth'` and a matrix of size 2-by- $K$ , where  $K$  is the number of unique groups. The first row of the matrix gives the bandwidth of each group in  $x$ , and the second row gives the bandwidth of each group in  $y$ . By default, `scatterhist` finds the optimal bandwidth for estimating normal densities. Specifying a different bandwidth value changes the smoothing characteristics of the

resulting kernel density plot. The value specified is a scaling factor for the normal distribution used to generate the kernel density plot.

**Example:** 'Bandwidth', [.5, .2, .1; .15, .25, .35]

## **Data Types**

single | double

## **'Legend' - Legend visibility indicator**

'on' | 'off'

Legend visibility indicator, specified as the comma-separated pair consisting of 'Legend' and one of the following.

'on' Set legend visible. This is the default if a **Group** parameter is specified.

'off' Set legend invisible. This is the default if a **Group** parameter is not specified.

**Example:** 'Legend', 'on'

## **'LineStyle' - Style of kernel density plot line**

valid line style string | cell array of strings

Style of kernel density plot line, specified as the comma-separated pair consisting of 'LineStyle' and a valid line style string or a cell array of valid line style strings. See `plot` for valid line style strings. The default is a solid line. Use a cell array to specify different line styles for each group. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

**Example:** 'LineStyle', {'-', ':', '-.'}

## **'LineWidth' - Width of kernel density plot line**

0.5 (default) | nonnegative scalar value | vector

Width of kernel density plot line, specified as the comma-separated pair consisting of 'LineWidth' and a nonnegative scalar value or vector of nonnegative scalar values. The specified value is the size of the kernel

density plot line measured in points. The default size is 0.5 points. Use a vector to specify different line widths for each group. When the total number of groups is greater than the number of specified values, scatterhist cycles through the specified values.

**Example:** 'LineWidth',[0.5,1,2]

#### **Data Types**

single | double

#### **'Color' - Marker color for each scatter plot group**

valid color designation char | string of chars | matrix of RGB values

Marker color for each scatter plot group, specified as the comma-separated pair consisting of 'Color' and a valid color designation character, a string of valid color designation characters, or a 3-column matrix of RGB values in the range [0,1]. See ColorSpec for predefined colors and their RGB equivalents. If colors are specified using a matrix, each row of the matrix represents a group, and the three columns represent the R value, G value, and B value, respectively. When the total number of groups exceeds the number of specified colors, scatterhist cycles through the specified colors.

**Example:** 'Color','kcm'

**Example:** 'Color',[.5,0,1;0,.5,.5]

#### **Data Types**

single | double | char

#### **'Marker' - Marker symbol for each scatterplot group**

'o' (default) | valid marker symbol | string of valid marker symbols

Marker symbol for each scatter plot group, specified as the comma-separated pair consisting of 'Marker' and a valid marker symbol or string of valid marker symbols. See plot for valid symbols. The default is 'o', a circle. When the total number of groups exceeds the number of specified symbols, scatterhist cycles through the specified symbols.

**Example:** 'Marker','+do'

# scatterhist

---

## 'MarkerSize' - Marker size for each scatter plot group

6 (default) | nonnegative scalar value | vector

Marker size for each scatter plot group, specified as the comma-separated pair consisting of 'MarkerSize' and a nonnegative scalar value or a vector of nonnegative scalar values, measured in points. When the total number of groups exceeds the number of specified values, scatterhist cycles through the specified values.

**Example:** 'MarkerSize',10

## Data Types

single | double

## Output Arguments

### h - Axes handles

vector

Axes handles for the three plots, returned as a vector. The vector contains the handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively.

## Examples

### Create a Scatterhist Plot

Load the sample data. Create data vector  $x$  from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector  $y$  from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;  
x = meas(:,1);  
y = meas(:,2);
```

Create a scatter plot and two marginal histograms to visualize the relationship between sepal length and sepal width.

```
scatterhist(x,y)
```

### Plot Grouped Data

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

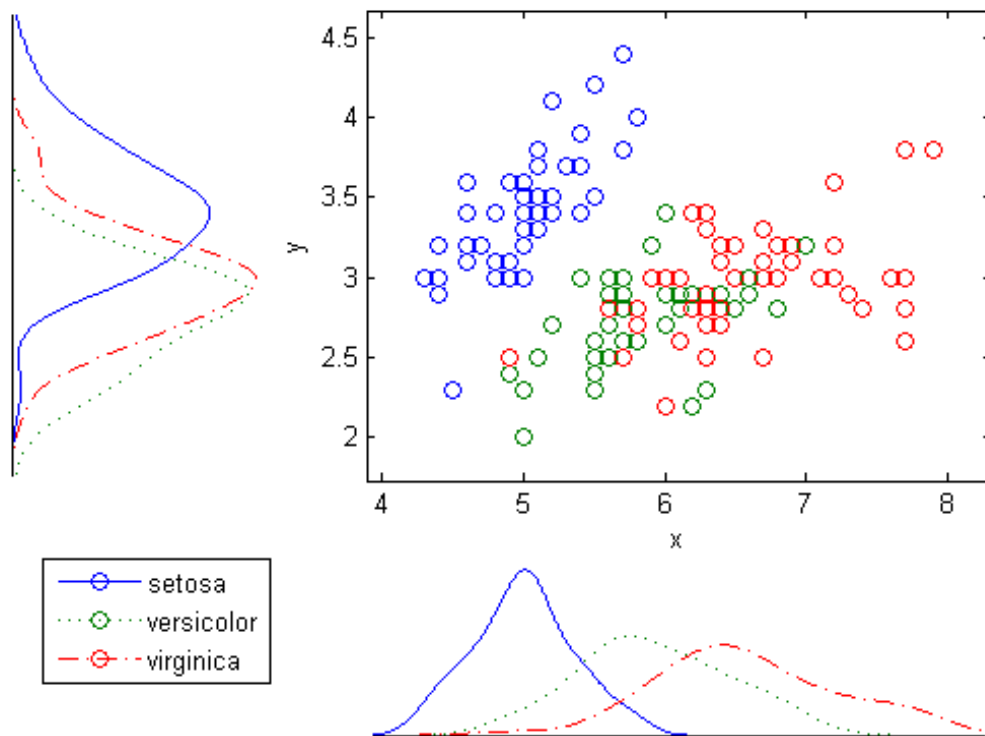

```
load fisheriris.mat;  
x = meas(:,1);
```

# scatterhist

```
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width, grouped by species.

```
scatterhist(x,y,'Group',species)
```

The plot shows that the relationship between sepal length and width varies depending on the flower species.

## Customize the Plot Display

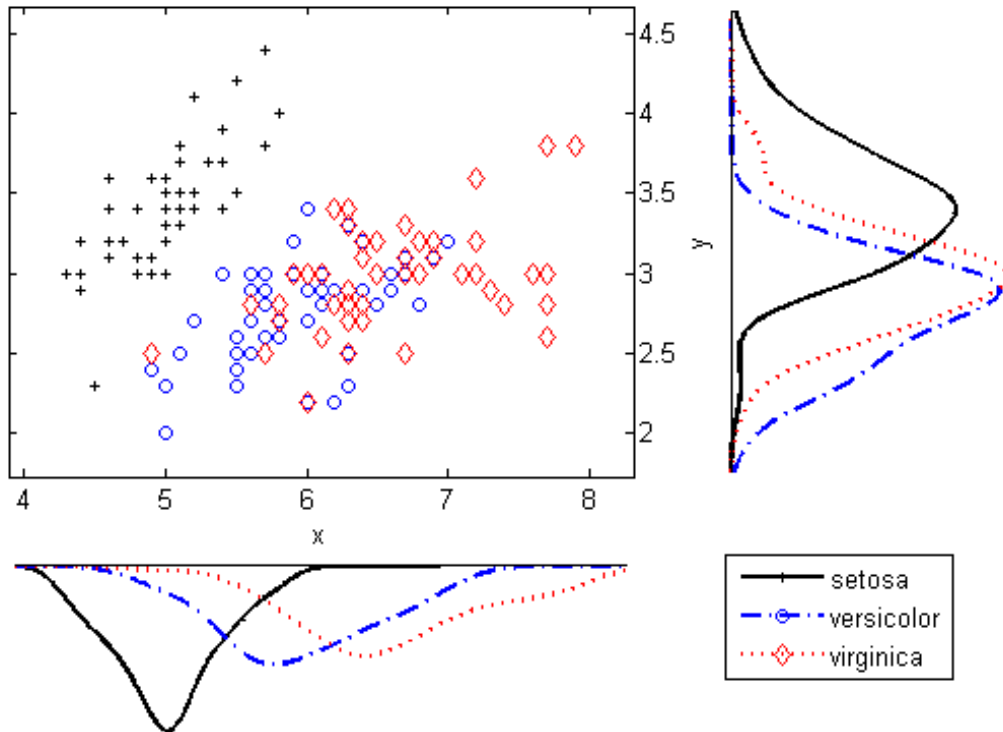

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three different species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;  
x = meas(:,1);  
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width as measured on three species of iris flowers, grouped by species. Customize the appearance of the plots.

```
scatterhist(x,y,'Group',species,'Location','SouthEast',...  
            'Direction','out','Color','kbr','LineStyle',{'-','-.'},...  
            'LineWidth',[2,2,2],'Marker','+od','MarkerSize',[4,5,6]);
```

# scatterhist

## Customize Plots Using Axes Handles

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

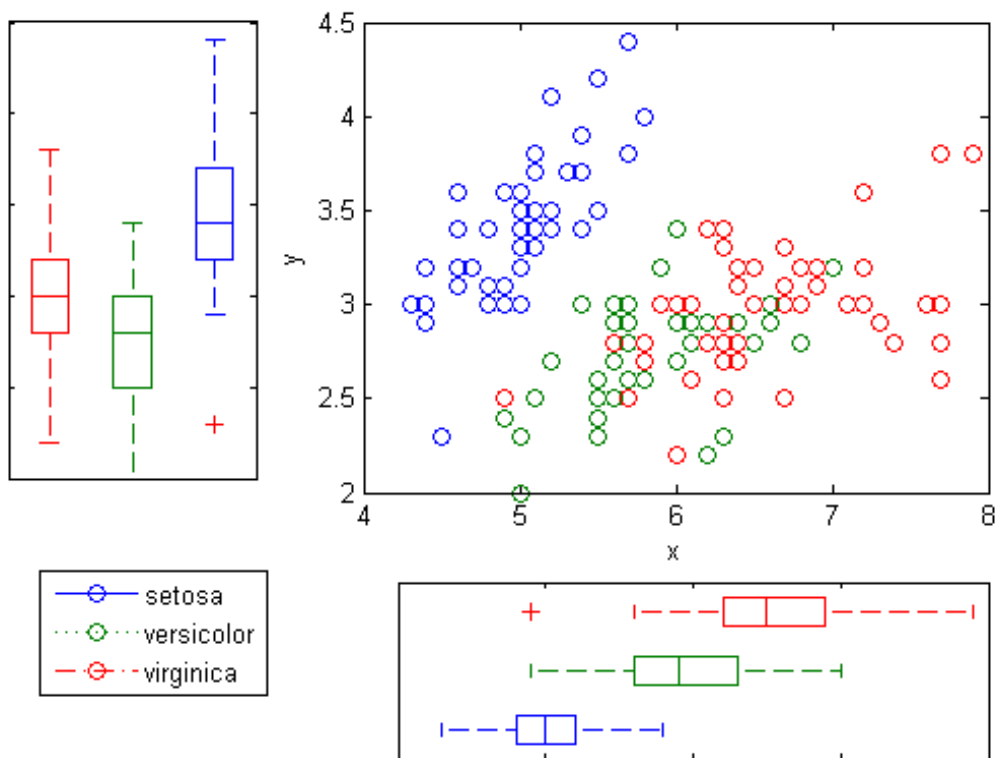

```
load fisheriris.mat;  
x = meas(:,1);
```

```
y = meas(:,2);
```

Use axis handles to replace the marginal histograms with box plots.

```
h = scatterhist(x,y,'Group',species);
hold on;
clr = get(h(1),'colororder');
boxplot(h(2),x,species,'orientation','horizontal',...
        'label',{' ',' ',' '},'color',clr);
boxplot(h(3),y,species,'orientation','horizontal',...
        'label', {' ',' ',' '},'color',clr);
set(h(2:3),'XTickLabel','');
view(h(3),[270,90]); % Rotate the Y plot
axis(h(1),'auto'); % Sync axes
hold off;
```

# scatterhist

## Concepts

- “Grouping Variables” on page 2-52

**Purpose** Scramble quasi-random point set

**Syntax**

```
ps = scramble(p, type)
ps = scramble(p, 'clear')
ps = scramble(p)
```

**Description** `ps = scramble(p, type)` returns a scrambled copy `ps` of the point set `p` of the `grandset` class, created using the scramble type specified in the string `type`. Point sets from different subclasses of `grandset` support different scramble types, as indicated in the following table.

Subclass	Scramble Types
haltonset	'RR2' — A permutation of the radical inverse coefficients derived by applying a reverse-radix operation to all of the possible coefficient values. The scramble is described in [1].
sobolset	'MatousekAffineOwen' — A random linear scramble combined with a random digital shift. The scramble is described in [2].

`ps = scramble(p, 'clear')` removes all scramble settings from `p` and returns the result in `ps`.

`ps = scramble(p)` removes all scramble settings from `p` and then adds them back in the order they were originally applied. This typically results in a different point set because of the randomness of the scrambling algorithms.

**Examples** Use `haltonset` to generate a 3-D Halton point set, skip the first 1000 values, and then retain every 101st point:

```
p = haltonset(3, 'Skip', 1e3, 'Leap', 1e2)
p =
  Halton point set in 3 dimensions (8.918019e+013 points)
  Properties:
    Skip : 1000
```

# grandset.scramble

---

```
Leap : 100
ScrambleMethod : none
```

Use scramble to apply reverse-radix scrambling:

```
p = scramble(p, 'RR2')
p =
Halton point set in 3 dimensions (8.918019e+013 points)
Properties:
    Skip : 1000
    Leap : 100
    ScrambleMethod : RR2
```

Use net to generate the first four points:

```
X0 = net(p, 4)
X0 =
    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11, :)
X =
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

# grandset.ScrambleMethod property

---

**Purpose** Settings that control scrambling

**Description** The ScrambleMethod property contains a structure that defines which scrambles to apply to the sequence. The structure consists of two fields:

- **Type:** A string containing the name of the scramble.
- **Options:** A cell array of parameter values for the scramble.

Different point sets support different scramble types as outlined in the help for each point set class. An error occurs if you set an invalid scramble type for a given point set.

The ScrambleMethod property also accepts an empty matrix as a value. This will clear all scrambling and set the property to contain a (0x0) structure.

The `scramble` method provides an alternative, easier way to set scrambles.

**Examples** Apply a random linear scramble combined with a random digital shift to a `sobolset` point set class:

```
P = sobolset(5);  
P = scramble(P, 'MatousekAffineOwen');  
P.ScrambleMethod
```

**See Also** `sobolset` | `scramble`

**Purpose** Segments containing values

**Syntax** `S = segment(obj,X,P)`

**Description** `S = segment(obj,X,P)` returns an array `S` of integers indicating which segment of the piecewise distribution object `obj` contains each value of `X` or, alternatively, `P`. One of `X` and `P` must be empty (`[]`). If `X` is nonempty, `S` is determined by comparing `X` with the quantile boundary values defined for `obj`. If `P` is nonempty, `S` is determined by comparing `P` with the probability boundary values.

**Examples** Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);
obj = paretotails(t,0.1,0.9);

pvals = 0:0.2:1;
s = segment(obj,[],pvals)
s =
     1     2     2     2     2     3
```

**See Also** `paretotails` | `boundary` | `nsegments`

# sequentialfs

---

## Purpose

Sequential feature selection

## Syntax

```
inmodel = sequentialfs(fun,X,y)
inmodel = sequentialfs(fun,X,Y,Z,...)
[inmodel,history] = sequentialfs(fun,X,...)
[] = sequentialfs(...,param1,va11,param2,va12,...)
```

## Description

`inmodel = sequentialfs(fun,X,y)` selects a subset of features from the data matrix `X` that best predict the data in `y` by sequentially selecting features until there is no improvement in prediction. Rows of `X` correspond to observations; columns correspond to variables or features. `y` is a column vector of response values or class labels for each observation in `X`. `X` and `y` must have the same number of rows. `fun` is a function handle to a function that defines the criterion used to select features and to determine when to stop. The output `inmodel` is a logical vector indicating which features are finally chosen.

Starting from an empty feature set, `sequentialfs` creates candidate feature subsets by sequentially adding each of the features not yet selected. For each candidate feature subset, `sequentialfs` performs 10-fold cross-validation by repeatedly calling `fun` with different training subsets of `X` and `y`, `XTRAIN` and `ytrain`, and test subsets of `X` and `y`, `XTEST` and `ytest`, as follows:

```
criterion = fun(XTRAIN,ytrain,XTEST,ytest)
```

`XTRAIN` and `ytrain` contain the same subset of rows of `X` and `Y`, while `XTEST` and `ytest` contain the complementary subset of rows. `XTRAIN` and `XTEST` contain the data taken from the columns of `X` that correspond to the current candidate feature set.

Each time it is called, `fun` must return a scalar value `criterion`. Typically, `fun` uses `XTRAIN` and `ytrain` to train or fit a model, then predicts values for `XTEST` using that model, and finally returns some measure of distance, or *loss*, of those predicted values from `ytest`. In the cross-validation calculation for a given candidate feature set, `sequentialfs` sums the values returned by `fun` and divides that sum

by the total number of test observations. It then uses that mean value to evaluate each candidate feature subset.

Typical loss measures include sum of squared errors for regression models (`sequentialfs` computes the mean-squared error in this case), and the number of misclassified observations for classification models (`sequentialfs` computes the misclassification rate in this case).

---

**Note** `sequentialfs` divides the sum of the values returned by `fun` across all test sets by the total number of test observations. Accordingly, `fun` should not divide its output value by the number of test observations.

---

After computing the mean criterion values for each candidate feature subset, `sequentialfs` chooses the candidate feature subset that minimizes the mean criterion value. This process continues until adding more features does not decrease the criterion.

`inmodel = sequentialfs(fun,X,Y,Z,...)` allows any number of input variables `X`, `Y`, `Z`, ... . `sequentialfs` chooses features (columns) only from `X`, but otherwise imposes no interpretation on `X`, `Y`, `Z`, ... . All data inputs, whether column vectors or matrices, must have the same number of rows. `sequentialfs` calls `fun` with training and test subsets of `X`, `Y`, `Z`, ... as follows:

```
criterion = fun(XTRAIN,YTRAIN,ZTRAIN,...,  
               XTEST,YTEST,ZTEST,...)
```

`sequentialfs` creates `XTRAIN`, `YTRAIN`, `ZTRAIN`, ... , `XTEST`, `YTEST`, `ZTEST`, ... by selecting subsets of the rows of `X`, `Y`, `Z`, ... . `fun` must return a scalar value `criterion`, but may compute that value in any way. Elements of the logical vector `inmodel` correspond to columns of `X` and indicate which features are finally chosen.

`[inmodel,history] = sequentialfs(fun,X,...)` returns information on which feature is chosen at each step. `history` is a scalar structure with the following fields:

# sequentialfs

---

- **Crit** — A vector containing the criterion values computed at each step.
- **In** — A logical matrix in which row *i* indicates the features selected at step *i*.

[ ] = sequentialfs(...,param1,val1,param2,val2,...) specifies optional parameter name/value pairs from the following table.

Parameter	Value
'cv'	<p>The validation method used to compute the criterion for each candidate feature subset.</p> <ul style="list-style-type: none"><li>• When the value is a positive integer <i>k</i>, sequentialfs uses <i>k</i>-fold cross-validation without stratification.</li><li>• When the value is an object of the <code>cvpartition</code> class, other forms of cross-validation can be specified.</li><li>• When the value is 'resubstitution', the original data are passed to <code>fun</code> as both the training and test data to compute the criterion.</li><li>• When the value is 'none', sequentialfs calls <code>fun</code> as <code>criterion = fun(X,Y,Z,...)</code>, without separating test and training sets.</li></ul> <p>The default value is 10, that is, 10-fold cross-validation without stratification.</p> <p>So-called <i>wrapper methods</i> use a function <code>fun</code> that implements a learning algorithm. These methods usually apply cross-validation to select features. So-called <i>filter methods</i> use a function</p>

Parameter	Value
	fun that measures characteristics of the data (such as correlation) to select features.
'mcreps'	A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution' or 'none'.
'direction'	The direction of the sequential search. The default is 'forward'. A value of 'backward' specifies an initial candidate set including all features and an algorithm that removes features sequentially until the criterion increases.
'keepin'	A logical vector or a vector of column numbers specifying features that must be included. The default is empty.
'keepout'	A logical vector or a vector of column numbers specifying features that must be excluded. The default is empty.
'nfeatures'	The number of features at which <code>sequentialfs</code> should stop. <code>inmodel</code> includes exactly this many features. The default value is empty, indicating that <code>sequentialfs</code> should stop when a local minimum of the criterion is found. A nonempty value overrides values of 'MaxIter' and 'TolFun' in 'options'.
'nullmodel'	A logical value, indicating whether or not the null model (containing no features from X) should be included in feature selection and in the history output. The default is false.

# sequentialfs

Parameter	Value
'options'	<p>Options structure for the iterative sequential search algorithm, as created by <code>statset</code>. <code>sequentialfs</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"><li>• <code>Display</code> — Amount of information displayed by the algorithm. The default is 'off'.</li><li>• <code>MaxIter</code> — Maximum number of iterations allowed. The default is <code>Inf</code>.</li><li>• <code>TolFun</code> — Termination tolerance for the objective function value. The default is <code>1e-6</code> if 'direction' is 'forward'; <code>0</code> if 'direction' is 'backward'.</li><li>• <code>TolTypeFun</code> — Use absolute or relative objective function tolerances. The default is 'rel'.</li><li>• <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>.</li><li>• <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.</li><li>• <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>sequentialfs</code> uses the default stream.</li></ul>

## Examples

Perform sequential feature selection for classification of noisy features:

```
load fisheriris;  
X = randn(150,10);
```

```
X(:,[1 3 5 7 ])= meas;
y = species;

c = cvpartition(y,'k',10);
opts = statset('display','iter');
fun = @(XT,yT,Xt,yt)...
      (sum(~strcmp(yt,classify(Xt,XT,yT,'quadratic'))));

[fs,history] = sequentialfs(fun,X,y,'cv',c,'options',opts)
```

```
Start forward sequential feature selection:
Initial columns included: none
Columns that can not be included: none
Step 1, added column 7, criterion value 0.04
Step 2, added column 5, criterion value 0.0266667
Final columns included: 5 7
```

```
fs =
    0  0  0  0  1  0  1  0  0  0
history =
    In: [2x10 logical]
    Crit: [0.0400 0.0267]
```

```
history.In
ans =
    0  0  0  0  0  0  1  0  0  0
    0  0  0  0  1  0  1  0  0  0
```

## How To

- “Sequential Feature Selection” on page 13-71

# dataset.set

---

## Purpose

Set and display properties

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
set(A)
set(A,PropertyName)
A = set(A,PropertyName,PropertyValue,...)
B = set(A,PropertyName,value)
```

## Description

`set(A)` displays all properties of the dataset array `A` and their possible values.

`set(A,PropertyName)` displays possible values for the property specified by the string `PropertyName`.

`A = set(A,PropertyName,PropertyValue,...)` sets property name/value pairs.

`B = set(A,PropertyName,value)` returns a dataset array `B` that is a copy of `A`, but with the property `'PropertyName'` set to the value `value`.

---

**Note** Using `set(A,'PropertyName',value)` without assigning to a variable does not modify `A`'s properties. Use `A = set(A,'PropertyName',value)` to modify `A`.

---

## Examples

Create a dataset array from Fisher's iris data and add a description:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);
iris = set(iris,'Description','Fisher''s Iris Data');
get(iris)
```

```
Description: 'Fisher's Iris Data'  
Units: {}  
DimNames: {'Observations' 'Variables'}  
UserData: []  
ObsNames: {150x1 cell}  
VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

**See Also**

`get` | `summary`

# CompactTreeBagger.setDefaultYfit

---

**Purpose** Set default value for predict

**Syntax** B = setDefaultYfit(B,Yfit)

**Description** B = setDefaultYfit(B,Yfit) sets the default prediction for ensemble B to Yfit. The default prediction must be a character variable for classification or a numeric scalar for regression. This setting controls what predicted value CompactTreeBagger returns when no prediction is possible, for example when the predict method needs to predict for an observation which has only false values in the matrix supplied through 'useifort' argument.

**See Also** predict | TreeBagger.DefaultYfit

## Purpose

Set difference for categorical arrays

## Compatibility

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
C = setdiff(A,B)
[C,IA] = setdiff(A,B)
[...] = setdiff(A,B,'rows')
[...] = setdiff(...,'legacy')
[...] = setdiff(A,B,setOrder)
[...] = setdiff(A,B,'rows',setOrder)
```

## Description

`C = setdiff(A,B)` for categorical vectors `A` and `B`, returns a categorical vector `C` containing the values in `A` that are not in `B` with no repetitions. The result `C` is sorted. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs.

`[C,IA] = setdiff(A,B)` also returns an index vector `IA` such that `C = A(IA)`. If there are repeated values in `A` that are not in `B`, then the index of the last occurrence of each repeated value is returned.

`[...] = setdiff(A,B,'rows')` for categorical matrices `A` and `B` with the same number of columns, returns the rows from `A` that are not in `B`. The rows of the matrix `C` are sorted. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs. The optional output `IA` is an index vector such that `C = C(IA,:)`.

`[...] = setdiff(...,'legacy')` preserves the pre-2012a behavior of `setdiff`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or `'rows'`.

`[...] = setdiff(A,B,setOrder)` and `[...] = setdiff(A,B,'rows',setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values or rows of `C` in sorted order. `setOrder='stable'` returns the values or rows of `C` in the same order as `A`. If `A` is a row vector, then `C` is also a row vector. Otherwise, `C` is a column vector. `IA` is a column vector. If there

# categorical.setdiff

---

are repeated values in A that are not in B, then the index of the first occurrence of each repeated value is returned.

## **See Also**

`intersect` | `ismember` | `setxor` | `union` | `unique`

**Purpose**

Set difference for dataset array observations

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
C = setdiff(A,B)
C = setdiff(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA] = setxor( ___ )
```

**Description**

`C = setdiff(A,B)` for dataset arrays `A` and `B` returns the set of observations that are in `A` but not `B`, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setdiff(A,B,vars)` returns the set of observations that are in `A` but not `B`, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA] = setxor( ___ )` also returns the index vector `iA` such that `C = A(iA,:)`. If there are repeated observations in `A`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

**Input Arguments****A,B**

Input dataset arrays.

**vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables that `setdiff` considers.

# dataset.setdiff

---

Specify vars as [] to use its default value of all variables.

## setOrder

Flag indicating the sorting order for the observations in C. The possible values of setOrder are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A.

## Output Arguments

### C

Dataset array with the observations that are in A but not B, with repetitions removed. C is in sorted order (by default), or the order specified by setOrder.

### iA

Index vector, indicating the observations from A that are in C. The vector iA contains the index to the first occurrence of any repeated observations in A.

## Examples

### Set Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';  
S(1,1).Gender = 'M';  
S(1,1).SystolicBP = 124;  
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';  
S(2,1).Gender = 'F';  
S(2,1).SystolicBP = 122;  
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';  
S(3,1).Gender = 'M';  
S(3,1).SystolicBP = 130;  
S(3,1).DiastolicBP = 92;  
  
A = struct2dataset(S(1:2));  
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the set difference of A and B.

```
[C,iA] = setdiff(A,B)
```

C =

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93

iA =

1

The first observation in A is not present in B.

## Concepts

- “Dataset Arrays” on page 2-137

# categorical.setlabels

---

## Purpose

Label levels

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
A = setlabels(A,labels)
A = setlabels(A,labels,levels)
```

## Description

`A = setlabels(A,labels)` labels the levels in the categorical array `A` using the cell array of strings or 2-D character matrix `labels`. Labels are assigned in the order given in `labels`.

`A = setlabels(A,labels,levels)` labels only the levels specified in the cell array of strings or 2-D character matrix `levels`.

## Examples

### Example 1

Relabel the species in Fisher's iris data using new categories:

```
load fisheriris
species = nominal(species);
species = mergelevels(...
    species,{'setosa','virginica'},'parent');
species = setlabels(species,'hybrid','versicolor');
getlabels(species)
ans =
    'hybrid'    'parent'
```

### Example 2

**1** Load patient data from the CSV file `hospital.dat` and store the information in a dataset array with observation names given by the first column in the data (patient identification):

```
patients = dataset('file','hospital.dat',...
    'delimiter',';',...
    'ReadObsNames',true);
```

- 2 Make the {0,1}-valued variable `smoke` nominal, and change the labels to 'No' and 'Yes':

```
patients.smoke = nominal(patients.smoke, {'No', 'Yes'});
```

- 3 Add new levels to `smoke` as placeholders for more detailed histories of smokers:

```
patients.smoke = addlevels(patients.smoke, ...
                           {'0-5 Years', '5-10 Years', 'LongTerm'});
```

- 4 Assuming the nonsmokers have never smoked, relabel the 'No' level:

```
patients.smoke = setlabels(patients.smoke, 'Never', 'No');
```

- 5 Drop the undifferentiated 'Yes' level from `smoke`:

```
patients.smoke = droplevels(patients.smoke, 'Yes');
```

Warning: OLDLEVELS contains categorical levels that were present in A, caused some array elements to have undefined levels.

Note that smokers now have an undefined level.

- 6 Set each smoker to one of the new levels, by observation name:

```
patients.smoke('YPL-320') = '5-10 Years';
```

## See Also

`getlabels`

# categorical.setxor

---

**Purpose** Set exclusive-or for categorical arrays

**Compatibility** The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
C = setxor(A,B)
[C,IA,IB] = setxor(A,B)
[...] = setxor(A,B,'rows')
[...] = setxor(...,'legacy')
[...] = setxor(A,B,setOrder)
[...] = setxor(A,B,'rows',setOrder)
```

**Description** `C = setxor(A,B)` for categorical vectors `A` and `B`, returns a categorical vector `C` containing the values not in the intersection of `A` and `B` with no repetitions. The result `C` is sorted. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs.

`[C,IA,IB] = setxor(A,B)` also returns index vectors `IA` and `IB` such that `C` is a sorted combination of the values `A(IA)` and `B(IB)`. If there are repeated values that are not in the intersection in `A` or `B` then the index of the last occurrence of each repeated value is returned.

`[...] = setxor(A,B,'rows')` for categorical matrices `A` and `B` with the same number of columns, returns the rows that are not in the intersection of `A` and `B`. The rows of the matrix `C` are sorted. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs. The optional outputs `IA` and `IB` are index vectors such that `C` is the sorted combination of rows `A(IA,:)` and `B(IB,:)`.

`[...] = setxor(...,'legacy')` preserves the pre-2012a behavior of `setxor`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `B`, or `'rows'`.

`[...] = setxor(A,B,setOrder)` and `[...] = setxor(A,B,'rows',setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values or rows of `C` in sorted order. `setOrder='stable'` returns the values or rows of `C` in the

same order as **A**. If **A** and **B** are row vectors, then **C** is also a row vector. Otherwise, **C** is a column vector. **IA** and **IB** are column vectors. If there are repeated values that are not in the intersection of **A** and **B**, then the index of the first occurrence of each repeated value is returned.

# dataset.setxor

---

## Purpose

Set exclusive or for dataset array observations

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = setxor(A,B)
C = setxor(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA,iB] = setxor( __ )
```

## Description

`C = setxor(A,B)` for dataset arrays `A` and `B` returns the set of observations that are not in the intersection of the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setxor(A,B,vars)` returns the set of observations that are not in the intersection of the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = setxor( __ )` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are repeated observations in `A` or `B`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

## Input Arguments

### **A,B**

Input dataset arrays.

### **vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables in A and B that `setxor` considers.

Specify `vars` as `[]` to use its default value of all variables.

### **setOrder**

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A, then B.

## **Output Arguments**

### **C**

Dataset array with the observations not in the intersection of A and B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

### **iA**

Index vector, indicating the observations from A that are in C. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

### **iB**

Index vector, indicating the observations from B that are in C. The vector `iB` contains the index to the first occurrence of any repeated observations in B.

## **Examples**

### **Symmetric Difference of Two Dataset Arrays**

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
```

# dataset.setxor

---

```
S(1,1).Gender = 'M';  
S(1,1).SystolicBP = 124;  
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';  
S(2,1).Gender = 'F';  
S(2,1).SystolicBP = 122;  
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';  
S(3,1).Gender = 'M';  
S(3,1).SystolicBP = 130;  
S(3,1).DiastolicBP = 92;
```

```
A = struct2dataset(S(1:2));  
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the symmetric difference of A and B.

```
[C,iA,iB] = setxor(A,B);  
C
```

```
C =
```

Name	Gender	SystolicBP	DiastolicBP
'CLARK'	'M'	124	93
'MARTIN'	'M'	130	92

```
[iA iB]
```

```
ans =
```

```
1 2
```

The symmetric difference contains the first observation from A, and the second observation from B.

## Concepts

- “Dataset Arrays” on page 2-137

# gmdistribution.SharedCov property

---

**Purpose** true if all covariance matrices are restricted to be the same

**Description** Logical true if all the covariance matrices are restricted to be the same (pooled estimate); logical false otherwise.

**Purpose**

Shift dimensions of categorical array

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
B = shiftdim(A,n)
[B,nshifts] = shiftdim(A)
```

**Description**

`B = shiftdim(A,n)` shifts the dimensions of the categorical array `A` by `N`. When `n` is positive, `shiftdim` shifts the dimensions to the left and wraps the `n` leading dimensions to the end. When `n` is negative, `shiftdim` shifts the dimensions to the right and pads with singletons.

`[B,nshifts] = shiftdim(A)` returns the array `B` with the same number of elements as `A` but with any leading singleton dimensions removed. `nshifts` returns the number of dimensions that are removed. If `A` is a scalar, `shiftdim` has no effect.

**See Also**

`circshift` | `reshape` | `squeeze`

# RegressionEnsemble.shrink

---

**Purpose** Prune ensemble

**Syntax**  
`cmp = shrink(ens)`  
`cmp = shrink(ens,Name,Value)`

**Description** `cmp = shrink(ens)` returns a compact shrunken version of `ens`, a regularized ensemble. `cmp` retains only learners with weights above a threshold.

`cmp = shrink(ens,Name,Value)` returns an ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

## Input Arguments

### **ens**

A regression ensemble created with `fitensemble`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

### **'lambda'**

Vector of nonnegative regularization parameter values for lasso. If `ens.Regularization` is nonempty (populate it with `regularize`), `shrink` regularizes `ens` using `lambda`. If `ens` contains a `Regularization` structure, you cannot pass `lambda`.

**Default:** []

### **'threshold'**

Lower cutoff on weights for weak learners, a numeric nonnegative scalar. `shrink` creates `cmp` from those learners with weights above threshold.

**Default:** 0

## 'weightcolumn'

Column index of `ens.Regularization.TrainedWeights`, a positive integer. `shrink` creates `cmp` with learner weights from this column.

**Default:** 1

## Output Arguments

### `cmp`

A regression ensemble of class `CompactRegressionEnsemble`. Use `cmp` for making predictions exactly as you use `ens`, with the `predict` method.

`shrink` orders the members of `cmp` from largest to smallest.

## Examples

Shrink a 300-member bagged regression ensemble using 0.1 for the parameter `lambda`, and view the number of members of the resulting ensemble:

```
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
bag = fitensemble(X,Y,'Bag',300,'Tree','type','regression');
cmp = shrink(bag,'lambda',0.1);
cmp.NumTrained
```

```
ans =
    83
```

# gmdistribution.Sigma property

---

**Purpose** Input array of covariances

**Description** Input array of covariances SIGMA.

# signrank

---

## Purpose

Wilcoxon signed rank test

## Syntax

```
p = signrank(x)
p = signrank(x,y)
p = signrank(x,y,Name,Value)
[p,h] = signrank( __ )
[p,h,stats] = signrank( __ )
```

```
[ __ ] = signrank(x,m)
[ __ ] = signrank(x,m,Name,Value)
```

## Description

`p = signrank(x)` returns the  $p$ -value of a two-sided Wilcoxon signed rank test.

`signrank` tests the null hypothesis that data in the vector `x` come from a distribution whose median is zero at the 5% significance level. The test assumes that the data in `x` come from a continuous distribution symmetric about its median.

`p = signrank(x,y)` returns the  $p$ -value of a paired, two-sided test for the null hypothesis that  $x - y$  comes from a distribution with zero median.

`p = signrank(x,y,Name,Value)` returns the  $p$ -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signrank( __ )` also returns a logical value indicating the test decision.  $h = 1$  indicates a rejection of the null hypothesis, and  $h = 0$  indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signrank( __ )` also returns the structure `stats` with information about the test statistic.

[ \_\_\_ ] = signrank(x,m) returns any of the output arguments in the previous syntaxes for the null hypothesis that the data in x are observations from a distribution with median m.

[ \_\_\_ ] = signrank(x,m,Name,Value) returns any of the output arguments in the previous syntaxes for the signed rank test with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### **x - Sample data**

vector

Sample data, specified as a vector.

#### **Data Types**

single | double

### **y - Sample data**

vector

Sample data, specified as a vector. y must be the same length as x.

#### **Data Types**

single | double

### **m - Hypothesized value of the median**

scalar

Hypothesized value of the median, specified as a scalar.

**Example:** signrank(x,10)

#### **Data Types**

single | double

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'alpha',0.01,'method','approximate','tail','right'  
specifies a right-tailed signed rank test with 1% significance level,  
which returns the approximate p-value.

## 'alpha' - Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1. Significance level of h is  $100 * \text{alpha}\%$ .

**Example:** 'alpha', 0.01

## Data Types

double | single

## 'method' - Computation method of p

'exact' | 'approximate'

Computation method of p, specified as the comma-separated pair consisting of 'method' and one of the following.

'exact'	Exact computation of the $p$ -value, $p$ . Default value for 15 or fewer observations in $x$ , $x - m$ , or $x - y$ when <code>method</code> is unspecified.
'approximate'	Normal approximation while computing the $p$ -value, $p$ . Default value for more than 15 observations in $x$ , $x - m$ , or $x - y$ when 'method' is unspecified because the exact method can be slow on large samples.

**Example:** 'method','exact'

## Data Types

char

## 'tail' - Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

'both'	Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> <li>• For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median different than 0 or <math>m</math>.</li> <li>• For a two-sample test, the alternate hypothesis states that the data in <math>x - y</math> come from a distribution with median different than 0.</li> </ul>
'right'	Right-tailed hypothesis test. <ul style="list-style-type: none"> <li>• For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median greater than 0 or <math>m</math>.</li> <li>• For a two-sample test, the alternate hypothesis states the data in <math>x - y</math> come from a distribution with median greater than 0.</li> </ul>
'left'	Left-tailed hypothesis test. <ul style="list-style-type: none"> <li>• For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median less than 0 or <math>m</math>.</li> <li>• For a two-sample test, the alternate hypothesis states the data in <math>x - y</math> come from a distribution with median less than 0.</li> </ul>

Example: 'tail','left'

## Output Arguments

### **p** - *p*-value of the test

nonnegative scalar

*p*-value of the test, returned as a nonnegative scalar from 0 to 1. *p* is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signrank` computes the two-sided *p*-value by doubling the most significant one-sided value.

## **h - Result of the hypothesis test**

1 | 0

Result of the hypothesis test, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the  $100 * \alpha\%$  significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the  $100 * \alpha\%$  significance level.

## **stats - Test statistics**

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `signrank`: Value of the sign rank test statistic.
- `zval`: Value of the  $z$ - statistic (computed when 'method' is 'approximate').

## **Examples**

### **Test for Zero Median of a Single Population**

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility  
x = randn(1,25) + 1.30;
```

Test the hypothesis that the data in `x` has zero median.

```
[p,h] = signrank(x)
```

```
p =
```

```
3.2229e-05
```

```
h =
```

---

1

At the default 5% significance level, the value  $h = 1$  indicates that the test rejects the null hypothesis of zero median.

### Test the Median of Differences of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2, .25, 10, 1);
y = x + trnd(2, 10, 1);
```

Test the hypothesis that  $x - y$  has zero median.

```
[p,h] = signrank(x,y)
```

```
p =
    0.3223
```

```
h =
    0
```

The results indicate that the test fails to reject the null hypothesis of zero median in the difference at the default 5% significance level.

### Signed Rank Test for Large Samples

Conduct a -sided test on a large sample using approximation.

Navigate to a folder containing sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')
```

Load the sample data.

# signrank

---

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences of students before and after participating in a tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signrank(gradespaired(:,1),...  
                      gradespaired(:,2),'tail','left')
```

```
p =
```

```
    0.0047
```

```
h =
```

```
    1
```

```
stats =
```

```
      zval: -2.5982  
 signedrank: 2.0175e+03
```

Because the sample size is greater than 15, `signrank` uses an approximate method to calculate the  $p$ -value and also returns the value of the  $z$ -statistic. The value  $h = 1$  indicates that the test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level. There is enough statistical evidence to conclude that the median grade before the tutoring program is less than the median grade after the tutoring program.

Repeat the test using the exact method.

```
[p,h,stats] = signrank(gradespaired(:,1),gradespaired(:,2),...  
                      'tail','left','method','exact')
```

```
p =
```

```
0.0045
```

```
h =
```

```
1
```

```
stats =
```

```
signedrank: 2.0175e+03
```

The results obtained using the approximate method are consistent with the exact method.

### **Two-Sided Test for the Median of a Single Population**

Load the sample data.

```
load mileage
```

The data contains the mileages per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second column differs from 33.

```
[p,h,stats] = signrank(mileage(:,2),33)
```

```
p =
```

```
0.0313
```

```
h =
```

```
1
```

```
stats =
```

```
signedrank: 21
```

At the 5% significance level, the results indicate that the median mileage for the second type of cars differs from 33. Note that `signrank` uses an exact method to calculate the  $p$ -value for small samples and does not return the  $z$ -statistic.

## Right-Sided Test for the Median of a Single Population

Use the name-value pair arguments in `signrank`.

Load the sample data.

```
load mileage
```

The data contains the mileage per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second row are larger than 33.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right')
```

```
p =  
    0.0156
```

```
h =  
    1
```

```
stats =  
    signedrank: 21
```

Repeat the same test at the 1% significance level using the approximate method.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right',...  
    'alpha',0.01,'method','approximate')
```

```
p =  
    0.0180
```

```

h =
    0

stats =
    zval: 2.0966
    signedrank: 21

```

This result,  $h = 0$ , indicates that the null hypothesis cannot be rejected at the 1% significance level.

## Definitions

### Wilcoxon Signed Rank Test

The Wilcoxon signed rank test is a nonparametric test for two populations when the observations are paired. In this case, the test statistic,  $W$ , is the sum of the ranks of positive differences between the observations in the two samples (that is,  $x - y$ ). When you use the test for one sample, then  $W$  is the sum of the ranks of positive differences between the observations and the hypothesized median value  $M_0$  (which is 0 when you use `signrank(x)` and  $m$  when you use `signrank(x, m)`).

### z-Statistic

For large samples, or when `method` is `approximate`, the `signrank` function calculates the  $p$ -value using the  $z$ -statistic, given by

$$z = \frac{(W - n(n+1)/4)}{\sqrt{\frac{n(n+1)(2n+1) - \text{tieadj}}{24}}},$$

where  $n$  is the sample size of the difference  $x - y$  or  $x - m$ . For the two-sample case, `signrank` uses `[tie_rank, tieadj] = tiedrank(abs(diffxy), 0, 0, epsdiff)` to obtain the tie adjustment value `tieadj`.

# signrank

---

## Algorithms

signrank treats NaNs in  $x$  and  $y$  as missing values and ignores them.

For the two-sample case, signrank uses a tolerance based on the values  $\text{epsdiff} = \text{eps}(x) + \text{eps}(y)$ . The signrank function treats any pair of values with difference  $d(i) = x(i) - y(i)$  that differ by no more than the sum of their two eps values ( $\text{abs}(d(i)) < \text{epsdiff}(i)$ ) as ties.

ranksum | signtest | ttest | ztest

**Purpose**

Sign test

**Syntax**

```
p = signtest(x)
p = signtest(x,y)
p = signtest(x,y,Name,Value)
[p,h] = signtest( __ )
[p,h,stats] = signtest( __ )

[ __ ] = signtest(x,m)
[ __ ] = signtest(x,m,Name,Value)
```

**Description**

`p = signtest(x)` returns the  $p$ -value for a two-sided sign test.

`signtest` tests the hypothesis that data in  $x$  has a continuous distribution with zero median against the alternative that the distribution does not have zero median at the 5% significance level.

`p = signtest(x,y)` returns the  $p$ -value of a two-sided sign test. Here, `signtest` tests for the hypothesis that the data in  $x - y$  has a distribution with zero median against the alternative that the distribution does not have zero median. Note that a hypothesis of zero median for  $x - y$  is not equivalent to a hypothesis of equal median for  $x$  and  $y$ .

`p = signtest(x,y,Name,Value)` returns the  $p$ -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signtest( __ )` also returns a logical value indicating the test decision. The value `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signtest( ___ )` also returns the structure `stats` containing information about the test statistic.

`[ ___ ] = signtest(x,m)` returns any of the output arguments in the previous syntaxes for the test whether the data in `x` are observations from a distribution with median `m` against the alternative that the median is different from `m`.

`[ ___ ] = signtest(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the sign test with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **x - Sample data**

vector

Sample data, specified as a vector.

#### **Data Types**

single | double

### **y - Sample data**

vector

Sample data, specified as a vector. `y` must be the same length as `x`.

#### **Data Types**

single | double

### **m - Hypothesized value of the median**

scalar

Hypothesized value of the median, specified as a scalar.

**Example:** `signtest(x,35)`

#### **Data Types**

single | double

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'alpha', 0.01, 'method', 'approximate', 'tail', 'right'` specifies a right-tailed sign test with 1% significance level, which returns the approximate  $p$ -value.

### 'alpha' - Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. The default value of `alpha` is 0.05. Significance level of  $h$  is  $100 * \alpha\%$ .

**Example:** `'alpha', 0.01`

### Data Types

double | single

### 'method' - $p$ -value computation method

`'exact'` | `'approximate'`

$p$ -value computation method, specified as the comma-separated pair consisting of `'method'` and one of the following:

<code>'exact'</code>	Exact computation of the $p$ -value, $p$ .
<code>'approximate'</code>	Normal approximation for computing the $p$ -value, $p$ .

The default computation method is `'exact'`, if there are fewer than 100 observations and `'approximate'` if there are 100 observations or more.

**Example:** `'method', 'exact'`

### Data Types

char

# signtest

---

## 'tail' - Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

'both'	Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"><li>• For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median different than zero (or <math>m</math>).</li><li>• For a two-sample test, the alternate hypothesis states that the data in <math>x - y</math> come from a distribution with median different than zero.</li></ul>
'right'	Right-tailed hypothesis test. <ul style="list-style-type: none"><li>• For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median greater than zero (or <math>m</math>).</li><li>• For a two-sample test, the alternate hypothesis states the data in <math>x - y</math> come from a distribution with median greater than zero.</li></ul>
'left'	Left-tailed hypothesis test. <ul style="list-style-type: none"><li>• For a one-sample test, the alternate hypothesis states that the data in <math>x</math> come from a continuous distribution with median less than zero (or <math>m</math>).</li><li>• For a two-sample test, the alternative hypothesis states the data in <math>x - y</math> come from a distribution with median less than zero.</li></ul>

Example: 'tail', 'left'

## Output Arguments

### **p** - *p*-value of the test

nonnegative scalar

*p*-value of the test, returned as a nonnegative scalar from 0 to 1. *p* is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signtest` computes the two-sided *p*-value by doubling the most significant one-sided value.

### **h** - Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If *h* = 1, this indicates rejection of the null hypothesis at the 100 \* *alpha*% significance level.
- If *h* = 0, this indicates a failure to reject the null hypothesis at the 100 \* *alpha*% significance level.

### **stats** - Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `sign`: Value of the sign test statistic.
- `zval`: Value of the z-statistic (computed only for large samples).

## Examples

### **Test for Zero Median of a Single Population**

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25);
```

The sampling distribution of *x* is symmetric with zero median.

Test the null hypothesis that *x* comes from a distribution with a median different from zero median.

```
[p,h,stats] = signtest(x,0)
```

```
p =  
    0.1078
```

```
h =  
    0
```

```
stats =  
    zval: NaN  
    sign: 17
```

At the default 5% significance level, the result  $h = 0$  indicates that `signtest` fails to reject to the null hypothesis of zero median. `signtest` calculates the  $p$ -value using the exact method, hence it does not calculate `zval` and returns it as a NaN.

## Test for Zero Median for the Difference of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility  
before = lognrnd(2, .25, 10, 1);  
after = before + (lognrnd(0, .5, 10, 1) - 1);
```

The sampling distribution of the difference between `before` and `after` is symmetric with zero median.

Test the null hypothesis that the difference of `before` and `after` has zero median.

```
[p,h] = signtest(before,after)
```

```
p =  
    0.7539
```

```
h =
```

```
0
```

At the default 5% significance level, the value  $h = 0$  indicates that `signtest` fails to reject to the null hypothesis of zero median in the difference.

### Medians of Paired Samples

Test the hypothesis of zero median for the difference between two paired samples using the exact and approximate methods.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2,.25,15,1);
y = x + trnd(2,15,1);
display([x y])
```

```
ans =
```

```
8.4521    7.8047
11.6869   11.4094
4.2009    5.1133
9.1664   12.1655
8.0020   10.0300
5.3285    6.0153
6.6300    5.1235
8.0499    8.6737
18.0763   19.2164
14.7665   15.3380
5.2726    8.4187
15.7798   16.2093
8.8583    8.5575
7.2735    7.4783
```

# signtest

---

```
8.8347 7.8894
```

Test the hypothesis that  $x - y$  has zero median.

```
[p,h,stats] = signtest(x,y)
```

```
p =
```

```
0.3018
```

```
h =
```

```
0
```

```
stats =
```

```
zval: NaN
```

```
sign: 5
```

At the default 5% significance level, the value  $h = 0$  indicates that the test fails to reject the null hypothesis of zero median in the difference.

Repeat the test using the approximate method.

```
[p,h,stats] = signtest(x,y,'method','approximate')
```

```
p =
```

```
0.3017
```

```
h =
```

```
0
```

```
stats =  
  
    zval: -1.0328  
    sign: 5
```

The approximate  $p$ -value, which `signtest` obtains using the  $z$ -statistic, is really close to the exact  $p$ -value.

### Test for Large Samples

Perform a left-sided sign test for large samples.

Navigate to a folder containing sample data.

```
cd(matlabroot)  
cd('help/toolbox/stats/examples')
```

Load the sample data.

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences before and after the tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signtest(gradespaired(:,1),gradespaired(:,2),...  
'tail','left')
```

```
p =  
  
    0.0013
```

```
h =  
  
    1
```

```
stats =
```

# signtest

---

```
zval: -3.0110  
sign: 37
```

Because the sample size is large (greater than 100), `signtest` uses an approximate method to calculate the  $p$ -value and also returns the value of the  $z$ -statistic. The test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level.

## Test for Median of a Single Population

Test the hypothesis that the population median is different from a specified value.

Load the sample data.

```
load lawdata
```

The data set has 15 observations for variables `gpa` and `lsat`.

Test the hypothesis that the median `lsat` score is higher than 570.

```
[p,h,stats] = signtest(lsat,570,'tail','right')
```

```
p =
```

```
0.0176
```

```
h =
```

```
1
```

```
stats =
```

```
zval: NaN  
sign: 12
```

Both the  $p$ -value, 0.0176, and  $h = 1$  indicate that at the 5% significance level the test concludes in favor of the alternate hypothesis.

## Definitions

### Sign Test

The sign test is a nonparametric test for the median of a population or median of the difference of two populations.

For example, for tests on a single population median:

- If the test is two-sided, then the test statistic,  $S$ , is the minimum of the number of observations that are smaller or larger than the hypothesized median value,  $M_0$ .
- If the test is right-sided, then  $S$  is the number of observations that are larger than the hypothesized median value  $M_0$ .
- If the test is left-sided, then  $S$  is the number of observations that are smaller than the hypothesized median value  $M_0$ .

### z-Statistic

For a large sample, `signtest` uses the  $z$ -statistic to approximate the  $p$ -value.

The `signtest` test statistic is the number of elements that are greater than 0 (for `signtest(x)` or `signtest(x-y)`), or  $m$  (for `signtest(x,m)`). Hence, the  $z$ -statistic of the sign test, with the continuity correction, is:

$$z = \frac{(S - E(S))}{\sqrt{V(S)}} = \frac{(S - (0.5)n - 0.5\text{sign}(npos - nneg))}{\sqrt{(0.5)(0.5)n}},$$

where  $npos$  and  $nneg$  are the number of positive and negative differences from the hypothesized median value, respectively.

## Algorithms

For a one-sample test, `signtest` omits values in  $x$  that are zero or NaN.

For a two-sample test, `signtest` omits values in  $x - y$  that are zero or NaN.

**Purpose**

Silhouette plot

**Syntax**

```
silhouette(X,clust)
s = silhouette(X,clust)
[s,h] = silhouette(X,clust)
[...] = silhouette(X,clust,metric)
[...] = silhouette(X,clust,distfun,p1,p2,...)
```

**Description**

`silhouette(X,clust)` plots cluster silhouettes for the  $n$ -by- $p$  data matrix  $X$ , with clusters defined by `clust`. Rows of  $X$  correspond to points, columns correspond to coordinates. `clust` can be a categorical variable, numeric vector, character matrix, or cell array of strings containing a cluster name for each point. `silhouette` treats NaNs or empty strings in `clust` as missing values, and ignores the corresponding rows of  $X$ . By default, `silhouette` uses the squared Euclidean distance between points in  $X$ .

`s = silhouette(X,clust)` returns the silhouette values in the  $n$ -by-1 vector `s`, but does not plot the cluster silhouettes.

`[s,h] = silhouette(X,clust)` plots the silhouettes, and returns the silhouette values in the  $n$ -by-1 vector `s`, and the figure handle in `h`.

`[...] = silhouette(X,clust,metric)` plots the silhouettes using the inter-point distance function specified in `metric`. Choices for `metric` are given in the following table.

<b>Metric</b>	<b>Description</b>
'Euclidean'	Euclidean distance
'sqEuclidean'	Squared Euclidean distance (default)
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)

Metric	Description
'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ
Vector	A numeric distance matrix in upper triangular vector form, such as is created by <code>pdist</code> . <code>X</code> is not used in this case, and can safely be set to <code>[]</code> .

For more information on each metric, see “Distance Metrics” on page 16-9.

`[...] = silhouette(X, clust, distfun, p1, p2, ...)` accepts a function handle `distfun` to a metric of the form

```
d = distfun(X0, X, p1, p2, ...)
```

where `X0` is a 1-by-`p` point, `X` is an `n`-by-`p` matrix of points, and `p1, p2, ...` are optional additional arguments. The function `distfun` returns an `n`-by-1 vector `d` of distances between `X0` and each point (row) in `X`. The arguments `p1, p2, ...` are passed directly to the function `distfun`.

## Definitions

### Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value for the  $i$ th point,  $S_i$ , is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where  $a_i$  is the average distance from the  $i$ th point to the other points in the same cluster as  $i$ , and  $b_i$  is the minimum average distance from the  $i$ th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to +1. A high silhouette value indicates that  $i$  is well-matched to its own cluster, and poorly-matched to neighboring clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution may have

either too many or too few clusters. The silhouette clustering evaluation criterion can be used with any distance metric.

## Examples

### Create Silhouette Plot

Create a silhouette plot from clustered data.

Generate random sample data.

```
rng('default'); % For reproducibility  
X = [randn(10,2)+ones(10,2);randn(10,2)-ones(10,2)];
```

Cluster the data in  $X$  using `kmeans`.

```
cidx = kmeans(X,2);
```

Create a silhouette plot from the clustered data.

```
silhouette(X,cidx)
```

# silhouette

## Compute Silhouette Values

Compute the silhouette values from clustered data.

Generate random sample data.

```
rng('default'); % For reproducibility  
X = [randn(10,2)+ones(10,2);randn(10,2)-ones(10,2)];
```

Use `kmeans` to cluster the data in `X` based on the sum of absolute differences in distance.

```
cidx = kmeans(X,2,'distance','cityblock');
```

Compute the silhouette values from the clustered data. Specify metric as 'cityblock' to indicate that the kmeans clustering is based on the sum of absolute differences.

```
s = silhouette(X,cidx,'cityblock')
```

```
s =
```

## **How To**

- “Grouping Variables” on page 2-52

**Superclasses** ClusterCriterion

**Purpose** Silhouette criterion clustering evaluation object

**Description** clustering.evaluation.SilhouetteEvaluation is an object consisting of sample data, clustering data, and silhouette criterion values used to evaluate the optimal number of data clusters. Create a silhouette criterion clustering evaluation object using evalclusters.

**Construction** `eva = evalclusters(x,clust,'Silhouette')` creates a silhouette criterion clustering evaluation object.

`eva = evalclusters(x,clust,'Silhouette',Name,Value)` creates a silhouette criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

## Input Arguments

### **x - Input data**

matrix

Input data, specified as an  $N$ -by- $P$  matrix.  $N$  is the number of observations, and  $P$  is the number of variables.

### **Data Types**

single | double

### **clust - Clustering algorithm**

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

# clustering.evaluation.SilhouetteEvaluation

---

'kmeans'	Cluster the data in $x$ using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in $x$ using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in $x$ using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using the function\_handle (@) operator. The function must be of the form  $C = \text{clustfun}(\text{DATA}, K)$ , where DATA is the data to be clustered, and  $K$  is the number of clusters. The output of clustfun must be one of the following:

- A vector of integers representing the cluster index for each observation in DATA. There must be  $K$  unique values in this vector.
- A numeric  $n$ -by- $K$  matrix of score for  $n$  observations and  $K$  classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If Criterion is 'CalinskHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify clust as a  $n$ -by- $K$  matrix containing the proposed clustering solutions.  $n$  is the number of observations in the sample data, and  $K$  is the number of proposed clustering solutions. Column  $j$  contains the cluster indices for each of the  $N$  points in the  $j$ th clustering solution.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the sum of absolute differences distance measure.

## **ClusterPriors - Prior probabilities for each cluster**

`'empirical'` (default) | `'equal'`

Prior probabilities for each cluster, specified as the comma-separated pair consisting of `'ClusterPriors'` and one of the following.

`'empirical'` Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.

`'equal'` Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

**Example:** `'ClusterPriors','empirical'`

## **Distance - Distance metric**

`'sqEuclidean'` (default) | `'Euclidean'` | `'cityblock'` | vector | function | ...

# clustering.evaluation.SilhouetteEvaluation

---

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ
'Jaccard'	Percentage of nonzero coordinates that differ

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using the `function_handle` (`@`) operator. The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by- $n$  vector corresponding to a single row of the input matrix `X`, and `XJ` is an  $m_2$ -by- $n$  matrix corresponding to multiple rows of `X`. `distfun` must return an  $m_2$ -by-1 vector of distances `d2`, whose  $k$ th element is the distance between `XI` and `XJ(k,:)`.

If `Criterion` is 'silhouette', you can also specify `Distance` as the output vector output created by the function `pdist`.

When `Clust` a string representing a built-in clustering algorithm, `evalclusters` uses the distance metric specified for `Distance` to cluster the data, except for the following:

- If `Clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses Euclidean distance and Ward linkage.

- If `Clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.

In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

**Example:** 'Distance', 'Euclidean'

## **KList - List of number of clusters to evaluate**

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name string or a function handle. When `criterion` is 'gap', `clust` must be a string or a function handle, and you must specify `KList`.

**Example:** 'KList', [1:6]

## **Properties**

### **ClusteringFunction**

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name string or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

### **ClusterPriors**

Prior probabilities for each cluster, stored as valid prior probability name string.

### **ClusterSilhouettes**

Silhouette values corresponding to each proposed number of clusters in `InspectedK`, stored as a cell array of vectors.

### **CriterionName**

# clustering.evaluation.SilhouetteEvaluation

---

Name of the criterion used for clustering evaluation, stored as a valid criterion name string.

## **CriterionValues**

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

## **Distance**

Distance measure used for clustering data, stored as a valid distance measure name string.

## **InspectedK**

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

## **Missing**

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

## **NumObservations**

Number of observations in the data matrix `X`, minus the number of missing (NaN) values in `X`, stored as a positive integer value.

## **OptimalK**

Optimal number of clusters, stored as a positive integer value.

## **OptimalY**

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

## **X**

Data used for clustering, stored as a matrix of numerical values.

## Methods

### Inherited Methods

addK	Evaluate additional numbers of clusters
compact	Compact clustering evaluation object
plot	Plot clustering evaluation object criterion values

## Definitions

### Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value for the  $i$ th point,  $S_i$ , is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where  $a_i$  is the average distance from the  $i$ th point to the other points in the same cluster as  $i$ , and  $b_i$  is the minimum average distance from the  $i$ th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to +1. A high silhouette value indicates that  $i$  is well-matched to its own cluster, and poorly-matched to neighboring clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution may have either too many or too few clusters. The silhouette clustering evaluation criterion can be used with any distance metric.

## Examples

### Evaluate the Clustering Solution Using Silhouette Criterion

Evaluate the optimal number of clusters using the silhouette clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default'); % For reproducibility
```

# clustering.evaluation.SilhouetteEvaluation

---

```
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
     mvnrnd(mu2,sigma2,N);...
     mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the silhouette criterion.  
Cluster the data using kmeans.

```
E = evalclusters(X,'kmeans','silhouette','klist',[1:6])
```

```
E =
```

```
SilhouetteEvaluation with properties:
```

```
NumObservations: 600
   InspectedK: [1 2 3 4 5 6]
 CriterionValues: [NaN 0.8055 0.8551 0.7170 0.7376 0.6239]
   OptimalK: 3
```

The OptimalK value indicates that, based on the silhouette criterion,  
the optimal number of clusters is three.

Plot the silhouette criterion values for each number of clusters tested.

```
figure;
plot(E)
```

The plot shows that the highest silhouette value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;  
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```

# clustering.evaluation.SilhouetteEvaluation

---

The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is near the center of the plot, and cluster 3 is in the upper-right corner.

## Concepts

- Class Attributes
- Property Attributes

# categorical.single

---

<b>Purpose</b>	Convert categorical array to single array The <code>nominal</code> and <code>ordinal</code> array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB <code>categorical</code> data type instead.
<b>Syntax</b>	<code>B = single(A)</code>
<b>Description</b>	<code>B = single(A)</code> converts the categorical array <code>A</code> to a single array. Each element of <code>B</code> contains the internal categorical level code for the corresponding element of <code>A</code> .
<b>See Also</b>	<code>double</code>

## Purpose

Convert dataset variables to single array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
B = single(A)
B = single(A,vars)
```

## Description

`B = single(A)` returns the contents of the dataset `A`, converted to one single array. The classes of the variables in the dataset must support the conversion.

`B = single(A,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector.

## See Also

`dataset` | `double` | `replacedata`

# categorical.size

---

## Purpose

Size of categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## Syntax

```
d = size(A)
[m,n] = size(A)
[m1,m2,m3,...,mn] = size(A)
m = size(A,dim)
```

## Description

`d = size(A)` returns the two-element row vector `d = [m,n]` containing the number of rows and columns in the matrix for an `m`-by-`n` categorical matrix `A`. For `n`-D categorical arrays, `size(A)` returns a 1-by-`n` vector of dimension lengths. Trailing singleton dimensions are ignored.

`[m,n] = size(A)` for a categorical matrix `A`, returns the number of rows and columns in `A` as separate output variables.

`[m1,m2,m3,...,mn] = size(A)`, for `n>1`, returns the sizes of the first `n` dimensions of the categorical array `A`. If the number of output arguments `n` does not equal `ndims(A)`, then for:

`n > ndims(A)`                    `size` returns ones in the "extra" variables, i.e., outputs `ndims(A)+1` through `n`.

`n < ndims(A)`                    `mn` contains the product of the sizes of dimensions `n` through `ndims(A)`.

`m = size(A,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(A,1)` returns the number of rows. If `dim > ndims(A)`, `m` will be 1.

## See Also

`length` | `ndims` | `numel`

## Purpose

Size of dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the `MATLAB table` data type instead. See `MATLAB table` documentation for more information.

## Syntax

```
D = SIZE(A)
[NOBS,NVARS] = SIZE(A)
[M1,M2,M3,...,MN] = SIZE(A)
M = size(A,dim)
```

## Description

`D = SIZE(A)` returns the two-element row vector `D = [NOBS,NVARS]` containing the number of observations and number of variables in the dataset `A`. A dataset array always has two dimensions.

`[NOBS,NVARS] = SIZE(A)` returns the numbers of observations and variables in the dataset `A` as separate output variables.

`[M1,M2,M3,...,MN] = SIZE(A)`, for `N > 2`, returns `M1 = NOBS`, `M2 = NVARS`, and `M3,...,MN = 1`.

`M = size(A,dim)` returns the length of the dimension specified by the scalar `dim`:

- `M = size(A,1)` returns `NOBS`
- `M = size(A,2)` returns `NVARS`
- `M = size(A,k)` returns `1` for `k > 2`

# grandset.size

---

**Purpose** Number of dimensions in matrix

**Syntax**  
`d = size(p)`  
`[m,n] = size(p)`  
`m = size(p,dim)`

**Description** `d = size(p)` returns the two-element row vector `d = [m,n]` containing the number of points in the point set and the number of dimensions the points are in, for the point set `p`. These correspond to the number of rows and columns in the matrix that would be produced by the expression `p(:, :)`.

`[m,n] = size(p)` returns the number of points and dimensions for `p` as separate output variables.

`m = size(p,dim)` returns the length of the dimension specified by the scalar `dim`. For example, `size(p,1)` returns the number of rows (points in the point set). If `dim` is greater than 2, `m` will be 1.

**Examples** The commands

```
P = sobolset(12);  
d = size(P)
```

return

```
d = [9.0072e+015 12]
```

The command

```
[m,n] = size(P)
```

returns

```
m = 9.0072e+015  
n = 12
```

The command

```
m2 = size(P, 2)
```

returns

```
m2 = 12
```

## See Also

[length](#) | [ndims](#) | [grandset](#)

# slicesample

---

**Purpose** Slice sampler

**Syntax**

```
rnd = slicesample(initial,nsamples,'pdf',pdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...,Name,Value)
```

**Description**

`rnd = slicesample(initial,nsamples,'pdf',pdf)` generates `nsamples` random samples using the slice sampling method (see “Algorithms” on page 21-3651). `pdf` gives the target probability density function (pdf). `initial` is a row vector or scalar containing the initial value of the random sample sequences.

`rnd = slicesample(initial,nsamples,'logpdf',logpdf)` generates samples using the logarithm of the pdf.

`[rnd,neval] = slicesample(initial,...)` returns the average number of function evaluations that occurred in the slice sampling.

`[rnd,neval] = slicesample(initial,...,Name,Value)` generates random samples with additional options specified by one or more `Name,Value` pair arguments.

**Tips**

- There are no definitive suggestions for choosing appropriate values for `burnin`, `thin`, or `width`. Choose starting values of `burnin` and `thin`, and increase them, if necessary, to give the requisite independence and marginal distributions. See Neal [1] for details of the effect of adjusting `width`.

**Input Arguments**

**initial**  
Initial point, a scalar or row vector. Set `initial` so `pdf(initial)` is a strictly positive scalar. `length(initial)` is the number of dimensions of each sample.

**nsamples**  
Positive integer, the number of samples that `slicesample` generates.

**pdf**

Handle to a function that generates the probability density function, specified with @. pdf can be unnormalized, meaning it need not integrate to 1.

**logpdf**

Handle to a function that generates the logarithm of the probability density function, specified with @. logpdf can be the logarithm of an unnormalized pdf.

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**'burnin'**

Nonnegative integer, the number of samples to generate and discard before generating the samples to return. The slice sampling algorithm is a Markov chain whose stationary distribution is proportional to that of the pdf argument. Set `burnin` to a high enough value that you believe the Markov chain approximately reaches stationarity after `burnin` samples.

**Default:** 0

**'thin'**

Positive integer, where `slicesample` discards every `thin - 1` samples and returns the next. The slice sampling algorithm is a Markov chain, so the samples are serially correlated. To reduce the serial correlation, choose a larger value of `thin`.

**Default:** 1

# slicesample

---

## 'width'

Width of the interval around the current sample, a scalar or vector of positive values. `slicesample` begins with this interval and searches for an appropriate region containing the points of pdf that evaluate to a large enough value.

- If `width` is a scalar and the samples have multiple dimensions, `slicesample` uses `width` for each dimension.
- If `width` is a vector, it should have the same length as `initial`.

**Default:** 10

## Output Arguments

### `rnd`

`nsamples-by-length(initial)` matrix, where each row is one sample.

### `neval`

Scalar, the mean number of function evaluations per sample. `neval` includes the `burnin` and `thin` evaluations, not just the evaluations of samples returned in `rnd`. Therefore the total number of function evaluations is

```
neval*(nsamples*thin + burnin).
```

## Examples

### Generate Random Samples From a Multimodal Density

This example shows how to generate random samples from a multimodal density using `slicesample`.

Define a function proportional to a multimodal density.

```
rng('default'); % For reproducibility
f = @(x) exp(-x.^2/2).*(1 + (sin(3*x)).^2).*...
    (1 + (cos(5*x)).^2));
area = integral(f,-5,5);
```

Generate 2000 samples from the density, using a burn-in period of 1000, and keeping one in five samples.

```
N = 2000;  
x = slicesample(1,N,'pdf',f,'thin',5,'burnin',1000);
```

Plot a histogram of the sample.

```
[binheight,bincenter] = hist(x,50);  
h = bar(bincenter,binheight,'hist');  
set(h,'facecolor',[0.8 .8 1]);
```

# slicesample

---

Scale the density to have the same area as the histogram, and superimpose it on the histogram.

```
hold on
xd = get(gca,'XLim');
xgrid = linspace(xd(1),xd(2),1000);
binwidth = (bincenter(2)-bincenter(1));
y = (N*binwidth/area) * f(xgrid);
plot(xgrid,y,'r','LineWidth',2)
hold off
```

The samples seem to fit the theoretical distribution well, so the burnin value seems adequate.

## Algorithms

At each point in the sequence of random samples, `slicesample` selects the next point by “slicing” the density to form a neighborhood around the previous point where the density is above some value. Consequently, the sample points are not independent. Nearby points in the sequence tend to be closer together than they would be from a

# slicesample

---

sample of independent values. For many purposes, the entire set of points can be used as a sample from the target distribution. However, when this type of serial correlation is a problem, the `burnin` and `thin` parameters can help reduce that correlation.

`slicesample` uses the slice sampling algorithm of Neal [1]. For numerical stability, it converts a `pdf` function into a `logpdf` function. The algorithm to resize the support region for each level, called “stepping-out” and “stepping-in,” was suggested by Neal.

**Purpose**

Skewness

**Syntax**

```
y = skewness(X)
y = skewness(X, flag)
y = skewness(X, flag, dim)
```

**Description**

`y = skewness(X)` returns the sample skewness of `X`. For vectors, `skewness(x)` is the skewness of the elements of `x`. For matrices, `skewness(X)` is a row vector containing the sample skewness of each column. For N-dimensional arrays, `skewness` operates along the first nonsingleton dimension of `X`.

`y = skewness(X, flag)` specifies whether to correct for bias (`flag = 0`) or not (`flag = 1`, the default). When `X` represents a sample from a population, the skewness of `X` is biased; that is, it will tend to differ from the population skewness by a systematic amount that depends on the size of the sample. You can set `flag = 0` to correct for this systematic bias.

`y = skewness(X, flag, dim)` takes the skewness along dimension `dim` of `X`.

`skewness` treats NaNs as missing values and removes them.

**Algorithms**

Skewness is a measure of the asymmetry of the data around the sample mean. If skewness is negative, the data are spread out more to the left of the mean than to the right. If skewness is positive, the data are spread out more to the right. The skewness of the normal distribution (or any perfectly symmetric distribution) is zero.

The skewness of a distribution is defined as

$$s = \frac{E(x - \mu)^3}{\sigma^3}$$

where  $\mu$  is the mean of  $x$ ,  $\sigma$  is the standard deviation of  $x$ , and  $E(t)$  represents the expected value of the quantity  $t$ . `skewness` computes a sample version of this population value.

# skewness

---

When you set `flag` to 1, the following equation applies:

$$s_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^3}{\left( \sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \right)^3}$$

When you set `flag` to 0, the following equation applies:

$$s_0 = \frac{\sqrt{n(n-1)}}{n-2} s_1$$

This bias-corrected formula requires that X contain at least three elements.

## Examples

```
X = randn([5 4])
X =
    1.1650    1.6961   -1.4462   -0.3600
    0.6268    0.0591   -0.7012   -0.1356
    0.0751    1.7971    1.2460   -1.3493
    0.3516    0.2641   -0.6390   -1.2704
   -0.6965    0.8717    0.5774    0.9846

y = skewness(X)
y =
   -0.2933    0.0482    0.2735    0.4641
```

**Purpose**

Number of initial points to omit from sequence

**Description**

The Skip property of a point set contains a positive integer which specifies the number of initial points in the sequence to omit from the point set. The default Skip value is 0.

Initial points of a sequence sometimes exhibit undesirable properties, for example the first point is often  $(0,0,0,\dots)$  and this may "unbalance" the sequence since its counterpart,  $(1,1,1,\dots)$ , never appears. Another common reason is that initial points often exhibit correlations among different dimensions which disappear later in the sequence.

**Examples**

Examine the difference between skipping and not skipping points:

```
% No skipping produces the standard Sobol sequence.  
P = sobolset(5);  
P(1:3,:)
```

```
% Skip the first point of the sequence. The point set now  
% starts at the second point of the basic Sobol sequence.  
P.Skip = 1;  
P(1:3,:)
```

# sobolset

---

**Superclasses**      grandset

**Purpose**              Sobol quasi-random point sets

**Description**        sobolset is a quasi-random point set class that produces points from the Sobol sequence. The Sobol sequence is a base-2 digital sequence that fills space in a highly uniform manner.

**Construction**      sobolset                              Construct Sobol quasi-random point set

## Methods

### Inherited Methods

Methods in the following table are inherited from grandset.

disp	Display grandset object
end	Last index in indexing expression for point set
length	Length of point set
ndims	Number of dimensions in matrix
net	Generate quasi-random point set
scramble	Scramble quasi-random point set
size	Number of dimensions in matrix
suboref	Subscripted reference for grandset

**Properties**              PointOrder                              Point generation method

### Inherited Properties

Properties in the following table are inherited from grandset.

Dimensions	Number of dimensions
Leap	Interval between points
ScrambleMethod	Settings that control scrambling
Skip	Number of initial points to omit from sequence
Type	Name of sequence on which point set P is based

## Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## How To

- "Quasi-Random Point Sets" on page 6-16

# sobolset

---

**Purpose** Construct Sobol quasi-random point set

**Syntax**  
`p = sobolset(d)`  
`p = sobolset(d,prop1,va11,prop2,va12,...)`

**Description**  
`p = sobolset(d)` constructs a  $d$ -dimensional point set `p` of the `sobolset` class, with default property settings.  
`p = sobolset(d,prop1,va11,prop2,va12,...)` specifies property name/value pairs used to construct `p`.

The object `p` returned by `sobolset` encapsulates properties of a specified quasi-random sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of point set indices (maximum value of  $2^{53}$ ). Values of the point set are not generated and stored in memory until you access `p` using `net` or parenthesis indexing.

**Examples**  
Generate a 3-D Sobol point set, skip the first 1000 values, and then retain every 101st point:

```
p = sobolset(3,'Skip',1e3,'Leap',1e2)
p =
    Sobol point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
        Leap : 100
    ScrambleMethod : none
        PointOrder : standard
```

Use `scramble` to apply a random linear scramble combined with a random digital shift:

```
p = scramble(p,'MatousekAffineOwen')
p =
    Sobol point set in 3 dimensions (8.918019e+013 points)
    Properties:
        Skip : 1000
```

```
Leap : 100
ScrambleMethod : MatousekAffineOwen
PointOrder : standard
```

Use net to generate the first four points:

```
X0 = net(p,4)
X0 =
    0.7601    0.5919    0.9529
    0.1795    0.0856    0.0491
    0.5488    0.0785    0.8483
    0.3882    0.8771    0.8755
```

Use parenthesis indexing to generate every third point, up to the 11th point:

```
X = p(1:3:11,:)
X =
    0.7601    0.5919    0.9529
    0.3882    0.8771    0.8755
    0.6905    0.4951    0.8464
    0.1955    0.5679    0.3192
```

haltonset | net | scramble

**Purpose**

Sort elements of ordinal array

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

**Syntax**

```
B = sort(A)
B = sort(A,dim)
B = sort(A,dim,mode)
[B,I] = sort(A,...)
```

**Description**

`B = sort(A)`, when `A` is an ordinal vector, sorts the elements of `A` in ascending order. For ordinal matrices, `sort(A)` sorts each column of `A` in ascending order. For  $N$ -D ordinal arrays, `sort(A)` sorts the along the first nonsingleton dimension of `A`. `B` is an ordinal array with the same levels as `A`.

`B = sort(A,dim)` sorts `A` along dimension `dim`.

`B = sort(A,dim,mode)` sorts `A` in the order specified by `mode`. `mode` is 'ascend' for ascending order, or 'descend' for descending order.

`[B,I] = sort(A,...)` also returns an index matrix `I`. If `A` is a vector, then `B = A(I)`. If `A` is an  $m$ -by- $n$  matrix and `dim` is 1, then `B(:,j) = A(I(:,j),j)` for `j = 1:n`.

Elements with undefined levels are sorted to the end.

**Examples**

Sort the columns of an ordinal array in ascending order:

```
A = ordinal([6 2 5; 2 4 1; 3 2 4],...
            {'lo','med','hi'},[],[0 2 4 6])
```

```
A =
      hi      med      hi
      med     hi      lo
      med     med     hi
```

```
B = sort(A)
B =
```

# ordinal.sort

---

```
med    med    lo
med    med    hi
hi     hi     hi
```

## See Also

sortrows

**Purpose** Sort rows of dataset array

**Compatibility** The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
B = sortrows(A)
B = sortrows(A,vars)
B = sortrows(A,'obsnames')
B = sortrows(A,vars,mode)
[B,idx] = sortrows(A)
```

**Description** `B = sortrows(A)` returns a copy of the dataset array `A`, with the observations sorted in ascending order by all of the variables in `A`. The observations in `B` are sorted first by the first variable, next by the second variable, and so on. Each variable in `A` must be a valid input to `sort`, or, if a variable has multiple columns, to the MATLAB `sortrows` function or to its own `sortrows` method.

`B = sortrows(A,vars)` sorts the observations in `A` by the variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, variable names, a cell array containing one or more variable names, or a logical vector.

`B = sortrows(A,'obsnames')` sorts the observations in `A` by observation name.

`B = sortrows(A,vars,mode)` sorts in the direction specified by `mode`. When `mode` is the single string `'ascend'` (the default) or `'descend'`, `sortrows` sorts `A` by the variables specified by `vars` in ascending or descending order, respectively. `mode` can also be a cell array containing the strings `'ascend'` or `'descend'`, to specify a different sorting direction for each variable in `vars`. Specify `[]` for `vars` to sort using all variables.

`[B,idx] = sortrows(A)` also returns an index vector `idx` such that `B = A(idx,:)`.

# dataset.sortrows

---

## Examples

Sort the data in `hospital.mat` by age and then by last name:

```
load hospital
hospital(1:5,1:3)
ans =
```

	LastName	Sex	Age
YPL-320	'SMITH'	Male	38
GLI-532	'JOHNSON'	Male	43
PNI-258	'WILLIAMS'	Female	38
MIJ-579	'JONES'	Female	40
XLK-030	'BROWN'	Female	49

```
hospital = sortrows(hospital,{'Age','LastName'});
hospital(1:5,1:3)
ans =
```

	LastName	Sex	Age
REV-997	'ALEXANDER'	Male	25
FZR-250	'HALL'	Male	25
LIM-480	'HILL'	Female	25
XUE-826	'JACKSON'	Male	25
SCQ-914	'JAMES'	Male	25

Sort the data in `hospital` by gender in ascending order, and age in descending order.

```
hospital = sortrows(hospital,{'Sex','Age'},{'ascend','descend'});
hospital(1:5,1:3)
ans =
```

	LastName	Sex	Age
XLK-030	'BROWN'	Female	49
GGU-691	'HUGHES'	Female	49
KKL-155	'ADAMS'	Female	48
HQO-561	'BRYANT'	Female	48
BKD-785	'CLARK'	Female	48

```
hospital(end-4:end,1:3)
ans =
```

	LastName	Sex	Age
VNL-702	'MOORE'	Male	28
REV-997	'ALEXANDER'	Male	25
FZR-250	'HALL'	Male	25
XUE-826	'JACKSON'	Male	25
SCQ-914	'JAMES'	Male	25

## Concepts

- “Dataset Arrays” on page 2-137

# ordinal.sortrows

---

## Purpose

Sort rows

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
B = sortrows(A)
B = sortrows(A,col)
[B,I] = sortrows(A)
[B,I] = sortrows(A,col)
```

## Description

`B = sortrows(A)` sorts the rows of the 2-D ordinal matrix `A` in ascending order, as a group. `B` is an ordinal array with the same levels as `A`.

`B = sortrows(A,col)` sorts `A` based on the columns specified in the vector `col`. If an element of `col` is positive, the corresponding column in `A` is sorted in ascending order; if an element of `col` is negative, the corresponding column in `A` is sorted in descending order.

`[B,I] = sortrows(A)` and `[B,I] = sortrows(A,col)` also returns an index matrix `I` such that `B = A(I,:)`.

Elements with undefined levels are sorted to the end.

## Examples

Sort the rows of an ordinal array in ascending order for the first column, and then in descending order for the second column:

```
A = ordinal([6 2 5; 2 4 1; 3 2 4],...
            {'lo','med','hi'},[],[0 2 4 6])
```

```
A =
    hi      med      hi
    med     hi      lo
    med     med     hi
```

```
B = sortrows(A,[1 -2])
B =
    med     hi      lo
```

```
med med hi  
hi med hi
```

## See Also

[sort](#) | [sortrows](#)

# squareform

---

**Purpose** Format distance matrix

**Syntax**

```
Z = squareform(y)
y = squareform(Z)
Z = squareform(y, 'tovector')
Y = squareform(Z, 'tomatrix')
```

**Description** `Z = squareform(y)`, where `y` is a vector as created by the `pdist` function, converts `y` into a square, symmetric format `Z`, in which `Z(i, j)` denotes the distance between the `i`th and `j`th objects in the original data.

`y = squareform(Z)`, where `Z` is a square, symmetric matrix with zeros along the diagonal, creates a vector `y` containing the `Z` elements below the diagonal. `y` has the same format as the output from the `pdist` function.

`Z = squareform(y, 'tovector')` forces `squareform` to treat `y` as a vector.

`Y = squareform(Z, 'tomatrix')` forces `squareform` to treat `Z` as a matrix.

The last two formats are useful if the input has a single element, so that it is ambiguous whether the input is a vector or square matrix.

## Examples

```
y = 1:6
y =
    1    2    3    4    5    6

X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0]
X =
    0    1    2    3
    1    0    4    5
    2    4    0    6
    3    5    6    0
```

Then `squareform(y) = X` and `squareform(X) = y`.

**See Also**     `pdist`

# categorical.squeeze

---

## **Purpose**

Squeeze singleton dimensions from categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`B = squeeze(A)`

## **Description**

`B = squeeze(A)` returns an array `B` with the same elements as the categorical array `A` but with all the singleton dimensions removed. A singleton is a dimension such that `size(A,dim)=1`. 2-D arrays are unaffected by `squeeze` so that row vectors remain rows.

## **See Also**

`shiftdim`

**Purpose**

Stack data from multiple variables into single variable

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
tall = stack(wide,datavars)
[tall,iwide] = stack(wide,datavars)
tall = stack(wide,datavars,Parameter,value)
```

**Description**

`tall = stack(wide,datavars)` converts a wide-format dataset array into a tall-format array, by stacking multiple variables in `wide` into a single variable in `tall`. In general, `tall` contains fewer variables but more observations than `wide`.

`datavars` specifies a group of `m` data variables in `wide`. `stack` creates a single data variable in `tall` by interleaving their values, and if `wide` has `n` observations, then `tall` has `m`-by-`n` observations. In other words, `stack` takes the `m` data values from each observation in `wide` and stacks them up to create `m` observations in `tall`. `datavars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. `stack` also creates a grouping variable in `tall` to indicate which of the `m` data variables in `wide` each observation in `tall` corresponds to.

`stack` assigns values for the "per-variable properties (e.g., `Units` and `VarDescription`) for the new data variable in `tall` from the corresponding property values for the first variable listed in `datavars`.

`stack` copies the remaining variables from `wide` to `tall` without stacking, by replicating each of their values `m` times. These variables are typically grouping variables. Because their values are constant across each group of `m` observations in `tall`, they identify which observation in `wide` an observation in `tall` came from.

`[tall,iwide] = stack(wide,datavars)` returns an index vector `iwide` indicating the correspondence between observations in `tall` and those in `wide`. `stack` creates `tall(j,:)` using `wide(iwide(j),datavars)`.

For more information on grouping variables, see “Grouping Variables” on page 2-52.

## Input Arguments

`tall = stack(wide, datavars, Parameter, value)` uses the following parameter name/value pairs to control how `stack` converts variables in `wide` to variables in `tall`:

'ConstVars '	Variables in <code>wide</code> to copy to <code>tall</code> without stacking. <code>ConstVars</code> is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. The default is all variables in <code>wide</code> not specified in <code>datavars</code> .
'NewDataVarName '	A name for the data variable to be created in <code>tall</code> . The default is a concatenation of the names of the <code>m</code> variables that are stacked up.
'IndVarName '	A name for the grouping variable to create in <code>tall</code> to indicate the source of each value in the new data variable. The default is based on the 'NewDataVarName' parameter.

You can also specify multiple groups of data variables in `wide`, each of which becomes a variable in `tall`. All groups must contain the same number of variables. Use a cell array to contain multiple parameter values for `datavars`, and a cell array of strings to contain multiple 'NewDataVarName'.

## Examples

Convert a wide format data set to tall format, and then back to a different wide format:

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated
% influenza rates (in 9 different regions, estimated from
% Google searches, plus a nationwide estimate from the
% CDC). Combine those 10 variables into a "tall" array that
% has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate
% is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')

% The second observation in FLU is for 10/16/2005. Find the
% observations in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)

% Use the 'Date' variable from that tall array to split
% 'FluRate' into 52 separate variables, each containing the
% estimated influenza rates for each unique date. The new
% "wide" array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2
% indicates the first occurrence in FLU2 of each region.
flu2(iflu2,:)
```

**How To**

- “Grouping Variables” on page 2-52

# grandstream.State property

---

**Purpose** Current state of the stream

**Description** The State property of a quasi-random stream contains the index into the associated point set of the next point to draw in the stream. Getting and resetting the State property allows you to return a stream to a previous state. The initial value of State is 1.

**Examples**

```
Q = grandstream('sobol', 5);
s = Q.State;
u1 = grand(Q, 10)
Q.State = s;
u2 = grand(Q, 10) % contains exactly the same values as u1
```

**See Also** grand

**Purpose**

Access values in statistics options structure

**Syntax**

```
val = statget(options,param)
val = statget(options,param,default)
```

**Description**

`val = statget(options,param)` returns the value of the parameter specified by the string `param` in the statistics options structure `options`. If the parameter is undefined in `options`, `statget` returns `[]`. You need to type only enough leading characters to define the parameter name uniquely. `statget` ignores case for parameter names. For available options, see Inputs.

`val = statget(options,param,default)` returns `default` if the specified parameter is undefined in the optimization options structure `options`.

**Input Arguments****DerivStep**

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.

**Display**

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.
- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

**FunValCheck**

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

## **GradObj**

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

## **Jacobian**

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

## **MaxFunEvals**

Maximum number of objective function evaluations allowed. Positive integer.

## **MaxIter**

Maximum number of iterations allowed. Positive integer.

## **OutputFcn**

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

## **Robust**

Invoke robust fitting option.

- 'off'
- 'on'

### **RobustWgtFun**

A weight function for robust fitting. Valid only when Robust is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

### **Streams**

A single instance of the RandStream class, or a cell array of RandStream instances. The Streams option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If 'UseSubstreams' is true, the Streams value must be a scalar, or must be empty. If 'UseParallel' is true and 'UseSubstreams' is false, then the Streams argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

### **TolBnd**

Parameter bound tolerance. Positive scalar.

### **TolFun**

Termination tolerance for the objective function value. Positive scalar.

### **TolTypeFun**

Use `TolFun` for absolute or relative objective function tolerances.

- 'abs'
- 'rel'

## **TolTypeX**

Use `TolX` for absolute or relative parameter tolerances.

- 'abs'
- 'rel'

## **TolX**

Termination tolerance for the parameters. Positive scalar.

## **Tune**

The tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar.

## **UseParallel**

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT parpool is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

## **UseSubstreams**

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

### WgtFun

A weight function for robust fitting. Valid only when Robust is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

### Examples

This statement returns the value of the Display statistics options parameter from the structure called my\_options.

```
val = statget(my_options, 'Display')
```

---

Return the value of the Display statistics options parameter from the structure called my\_options (as in the previous example). If the Display parameter is undefined, statget returns the value 'final'.

```
optnew = statget(my_options, 'Display', 'final');
```

### See Also

statset

# statset

---

**Purpose** Create statistics options structure

**Syntax**

```
statset
statset(statfun)
options = statset(...)
options = statset(fieldname1,val1,fieldname2,val2,...)
options =
statset(olddopts,fieldname1,val1,fieldname2,val2,...)
options = statset(olddopts,newopts)
```

**Description** `statset` with no input arguments and no output arguments displays all fields of a statistics options structure and their possible values.

`statset(statfun)` displays fields and default values used by the Statistics Toolbox function `statfun`. Specify `statfun` using a string name or a function handle.

`options = statset(...)` creates a statistics options structure `options`. With no input arguments, all fields of the options structure are an empty array (`[]`). With a specified `statfun`, function-specific fields are default values and the remaining fields are `[]`. Function-specific fields set to `[]` indicate that the function is to use its default value for that parameter. For available options, see [Inputs](#).

`options = statset(fieldname1,val1,fieldname2,val2,...)` creates an options structure in which the named fields have the specified values. Any unspecified values are `[]`. Use strings for field names. For fields that are string-valued, you must input the complete string for the value. If you provide an invalid string for a value, `statset` uses the default.

`options = statset(olddopts,fieldname1,val1,fieldname2,val2,...)` creates a copy of `olddopts` with the named parameters changed to the specified values.

`options = statset(olddopts,newopts)` combines an existing options structure, `olddopts`, with a new options structure, `newopts`. Any

parameters in `newopts` with nonempty values overwrite corresponding parameters in `oldopts`.

## Input Arguments

### DerivStep

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics Toolbox function using the options structure.

### Display

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.
- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

### FunValCheck

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

### GradObj

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

### Jacobian

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

## **MaxFunEvals**

Maximum number of objective function evaluations allowed. Positive integer.

## **MaxIter**

Maximum number of iterations allowed. Positive integer.

## **OutputFcn**

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

## **Robust**

Invoke robust fitting option.

- 'off'
- 'on'

Robust will be removed in a future software release. Use RobustWgtFun for robust fitting.

## **RobustWgtFun**

Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 21-3685.

## **Streams**

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The `Streams` option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If `'UseSubstreams'` is `true`, the `Streams` value must be a scalar, or must be empty. If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the `Streams` argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

**TolBnd**

Parameter bound tolerance. Positive scalar.

**TolFun**

Termination tolerance for the objective function value. Positive scalar.

**TolTypeFun**

Use `TolFun` for absolute or relative objective function tolerances.

- `'abs'`
- `'rel'`

**TolTypeX**

Use `TolX` for absolute or relative parameter tolerances.

- `'abs'`
- `'rel'`

**TolX**

Termination tolerance for the parameters. Positive scalar.

**Tune**

Tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the

weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar. See “Robust Options” on page 21-3685.

## **UseParallel**

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT parpool is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

## **UseSubstreams**

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

## **WgtFun**

Weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. See “Robust Options” on page 21-3685.

`WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

**Definitions****Robust Options**

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985
[]	No robust fitting	—

**Examples**

Suppose you want to change the default parameter values for the function `evfit`, which fits an extreme value distribution to data. The default parameter values are:

```
statset('evfit')
ans =
    Display: 'off'
    MaxFunEvals: []
    MaxIter: []
    TolBnd: []
    TolFun: []
    TolTypeFun: []
    TolX: 1.0000e-06
    TolTypeX: []
    GradObj: []
    Jacobian: []
```

## statset

---

```
    DerivStep: []
    FunValCheck: []
        Robust: []
    RobustWgtFun: []
        WgtFun: []
        Tune: []
    UseParallel: []
    UseSubstreams: []
        Streams: []
    OutputFcn: []
```

---

The only parameters that `evfit` uses are `Display` and `TolX`. To create an options structure with the value of `TolX` set to `1e-8`, enter:

```
options = statset('TolX',1e-8)
% Pass options to evfit:
mu = 1;
sigma = 1;
data = evrnd(mu,sigma,1,100);

paramhat = evfit(data,[],[],[],options)
```

**Purpose** Standard deviation of probability distribution object

**Syntax** `s = std(pd)`

**Description** `s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

**Input Arguments** **pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

**Output Arguments** **s - Standard deviation**  
nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

**Examples** **Standard Deviation of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
mu = 75.0083 [73.4321, 76.5846]
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
```

```
s =
```

```
8.7202
```

For a normal distribution, the standard deviation is equal to the parameter `sigma`.

# GeneralizedLinearModel.step

---

**Purpose** Improve generalized linear regression model by adding or removing terms

**Syntax**  
`mdl1 = step(mdl)`  
`mdl1 = step(mdl, Name, Value)`

**Description** `mdl1 = step(mdl)` returns an improved generalized linear model based on `mdl`, with one predictor added or removed.  
`mdl1 = step(mdl, Name, Value)` improves a generalized linear model with additional options specified by one or more `Name, Value` pair arguments.

**Tips**

- Use `addTerms` or `removeTerms` to control exactly which terms enter or leave the model.

**Input Arguments** **mdl - Generalized linear model**  
`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'Criterion' - Criterion to add or remove terms

'Deviance' | 'sse' | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- 'Deviance' — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- 'sse' — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- 'aic' — Change in the value of Akaike information criterion (AIC).
- 'bic' — Change in the value of Bayesian information criterion (BIC).
- 'rsquared' — Increase in the value of  $R^2$ .
- 'adjrsquared' — Increase in the value of adjusted  $R^2$ .

**Example:** 'Criterion','bic'

## 'Lower' - Model specification describing terms that cannot be removed from model

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

**Example:** 'Lower','linear'

## 'NSteps' - Number of steps to take

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

# GeneralizedLinearModel.step

---

## Data Types

single | double

## 'PEnter' - Improvement measure for adding term

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

Criterion	Default value	Decision
'Deviance'	0.05	If the $p$ -value of $F$ or chi-squared statistic is smaller than PEnter, add the term to the model.
'SSE'	0.05	If the SSE of the model is smaller than PEnter, add the term to the model.
'AIC'	0	If the change in the AIC of the model is smaller than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is smaller than PEnter, add the term to the model.

Criterion	Default value	Decision
'Rsquared'	0.1	If the increase in the R-squared of the model is larger than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared of the model is larger than PEnter, add the term to the model.

For more information on the criteria, see Criterion name-value pair argument.

**Example:** 'PEnter',0.075

**'PRemove' - Improvement measure for removing term**  
scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

Criterion	Default value	Decision
'Deviance'	0.10	If the $p$ -value of $F$ or chi-squared statistic is larger than PRemove, remove the term from the model.
'SSE'	0.10	If the $p$ -value of the $F$ statistic is larger than PRemove,

## GeneralizedLinearModel.step

---

Criterion	Default value	Decision
		remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is larger than <code>PRemove</code> , remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is larger than <code>PRemove</code> , remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is smaller than <code>PRemove</code> , remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is smaller than <code>PRemove</code> , remove the term from the model.

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PRemove',0.05`

**'Upper' - Model specification describing largest set of terms in fit**  
`'interaction' (default) | string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

**Example:** `'Upper','quadratic'`

**'Verbose' - Control for display of information**

`1 (default) | 0 | 2`

Control for display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

**Example:** `'Verbose',2`

## Output Arguments

### **mdl1**

Linear model, the same as `mdl` but with additional terms given in terms. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

## Examples

### **Add Predictors One at a Time**

Fit a Poisson regression model using random data and a single predictor, then step in other predictors.

Generate artificial data with 20 predictors, using three of the predictors for the responses.

# GeneralizedLinearModel.step

---

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Construct a generalized linear model using  $X(:, 1)$  as the only predictor.

```
mdl = fitglm(X,y,...
    'y ~ x1','Distribution','poisson')
```

```
mdl =
```

Generalized Linear regression model:

```
log(y) ~ 1 + x1
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.1278	0.057487	19.618	1.0904e-85
x1	0.061287	0.04848	1.2642	0.20617

100 observations, 98 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 1.59, p-value = 0.208

Add a variable to the model using `step`.

```
mdl1 = step(mdl)
```

```
1. Adding x5, Deviance = 134.2976, Chi2Stat = 50.80176, PValue = 1.021821e-12
```

```
mdl1 =

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi<sup>2</sup>-statistic vs. constant model: 80.7, p-value = 2.18e-17

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

# GeneralizedLinearModel.step

---

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1** Fit the initial model.
- 2** If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps

will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

Use `stepwiseglm` to select a model from a starting model, continuing until no single step is beneficial.

Use `addTerms` or `removeTerms` to add or remove particular terms.

# LinearModel.step

---

**Purpose** Improve linear regression model by adding or removing terms

**Syntax**

```
mdl1 = step(mdl)
mdl1 = step(mdl,Name,Value)
```

**Description** `mdl1 = step(mdl)` returns an improved linear model based on `mdl`, with one predictor added or removed.

---

**Note** You can use `step` only if `mdl.Robust = []`. This holds when you create `mdl` with `fitlm` having the `RobustOpts` name-value pair set to the default `'off'`.

---

`mdl1 = step(mdl,Name,Value)` improves a linear model with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### **mdl**

Linear model, as constructed by `fitlm` or `stepwiselm`.

### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'Criterion' - Criterion for selecting terms to add or remove**

`'SSE'` (default)

Criterion for selecting terms to add or remove, specified as the comma-separated pair consisting of `'Criterion'` and one of the following.

Criterion	PEnter	PRemove	Compared Against
'SSE'	0.05	< 0.1	$p$ -value for $F$ test
'AIC'	0	< 0.01	Change in AIC
'BIC'	0	< 0.01	Change in BIC
'Rsquared'	0.1	> 0.05	Increase in R-squared
'AdjRsquared'	0	> -0.05	Increase in adjusted R-squared

**Example:** 'Criterion', 'BIC'

**'Lower' - Model specification describing terms that cannot be removed from model**

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

**Example:** 'Lower', 'linear'

**'NSteps' - Number of steps to take**

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

**Data Types**

single | double

**'PEnter' - Improvement measure for adding term**

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

## LinearModel.step

---

Criterion	Default value	Decision
'Deviance'	0.05	If the $p$ -value of $F$ or chi-squared statistic is smaller than $P_{Enter}$ , add the term to the model.
'SSE'	0.05	If the SSE of the model is smaller than $P_{Enter}$ , add the term to the model.
'AIC'	0	If the change in the AIC of the model is smaller than $P_{Enter}$ , add the term to the model.
'BIC'	0	If the change in the BIC of the model is smaller than $P_{Enter}$ , add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared of the model is larger than $P_{Enter}$ , add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared of the model is larger than $P_{Enter}$ , add

Criterion	Default value	Decision
		the term to the model.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** 'PEnter',0.075

### 'PRemove' - Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

Criterion	Default value	Decision
'Deviance'	0.10	If the $p$ -value of $F$ or chi-squared statistic is larger than PRemove, remove the term from the model.
'SSE'	0.10	If the $p$ -value of the $F$ statistic is larger than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is larger than PRemove, remove the term from the model.

# LinearModel.step

---

Criterion	Default value	Decision
'BIC'	0.01	If the change in the BIC of the model is larger than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is smaller than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is smaller than PRemove, remove the term from the model.

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PRemove',0.05`

**'Upper' - Model specification describing largest set of terms in fit**  
'interaction' (default) | string

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the string options for `modelspec` naming the model.

**Example:** 'Upper', 'quadratic'

## 'Verbose' - Control for display of information

1 (default) | 0 | 2

Control for display of information, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

**Example:** 'Verbose', 2

## Output Arguments

### **mdl1**

Linear model. Typically you set `mdl1` equal to `mdl`.

## Examples

### **Modify a Linear Model**

Fit a linear model to car data. Use `step` to see if a quadratic model would help the fit quality.

Load `carsmall` data, and make a dataset from weight and model year predictors with MPG response.

```
load carsmall
ds = dataset(MPG,Weight);
ds.Year = ordinal(Model_Year);
```

Make a linear model of MPG as a function of Year and Weight.

```
mdl = fitlm(ds,'MPG ~ Year + Weight')
```

# LinearModel.step

---

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	40.11	1.5418	26.016	1.2024e-43
Weight	-0.0066475	0.00042802	-15.531	3.3639e-27
Year_76	1.9291	0.74761	2.5804	0.011488
Year_82	7.9093	0.84975	9.3078	7.8681e-15

```
Number of observations: 94, Error degrees of freedom: 90
```

```
Root Mean Squared Error: 2.92
```

```
R-squared: 0.873, Adjusted R-Squared 0.868
```

```
F-statistic vs. constant model: 206, p-value = 3.83e-40
```

Use step to adjust the model to potentially include full quadratic terms.

```
mdl1 = step(mdl, 'upper', 'quadratic')
```

```
1. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
```

```
mdl1 =
```

```
Linear regression model:
```

```
MPG ~ 1 + Weight + Year + Weight^2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
```

Root Mean Squared Error: 2.78  
R-squared: 0.885, Adjusted R-Squared 0.88  
F-statistic vs. constant model: 172, p-value = 5.52e-41

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the `'Criterion'` argument. The default value of `'Criterion'` is `'sse'`, and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when `'Criterion'` is `'sse'`:

- 1** Fit the initial model.
- 2** If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is `'Deviance'` and it follows a similar procedure for adding or removing terms.

# LinearModel.step

---

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

Use `stepwiselm` to select a model from a starting model, continuing until no single step is beneficial.

Use `addTerms` or `removeTerms` to add or remove particular terms.

## Tutorials

- “Linear Regression Workflow” on page 9-45
- “Change Models” on page 9-38

## How To

- “Linear Regression” on page 9-12

**Purpose** Interactive stepwise regression

**Syntax** `stepwise`  
`stepwise(X,y)`  
`stepwise(X,y,inmodel,penter,premove)`

**Description** `stepwise` uses the sample data in `hald.mat` to display a graphical user interface for performing stepwise regression of the response values in `heat` on the predictive terms in `ingredients`.

# stepwise

The upper left of the interface displays estimates of the coefficients for all potential terms, with horizontal bars indicating 90% (colored) and 95% (grey) confidence intervals. The red color indicates that, initially, the terms are not in the model. Values displayed in the table are those that would result if the terms were added to the model.

The middle portion of the interface displays summary statistics for the entire model. These statistics are updated with each step.

The lower portion of the interface, **Model History**, displays the RMSE for the model. The plot tracks the RMSE from step to step, so you can compare the optimality of different models. Hover over the blue dots in the history to see which terms were in the model at a particular step. Click on a blue dot in the history to open a copy of the interface initialized with the terms in the model at that step.

Initial models, as well as entrance/exit tolerances for the  $p$ -values of  $F$ -statistics, are specified using additional input arguments to **stepwise**. Defaults are an initial model with no terms, an entrance tolerance of 0.05, and an exit tolerance of 0.10.

To center and scale the input data (compute  $z$ -scores) to improve conditioning of the underlying least-squares problem, select **Scale Inputs** from the **Stepwise** menu.

You proceed through a stepwise regression in one of two ways:

- 1** Click **Next Step** to select the recommended next step. The recommended next step either adds the most significant term or removes the least significant term. When the regression reaches a local minimum of RMSE, the recommended next step is “Move no terms.” You can perform all of the recommended steps at once by clicking **All Steps**.
- 2** Click a line in the plot or in the table to toggle the state of the corresponding term. Clicking a red line, corresponding to a term not currently in the model, adds the term to the model and changes the line to blue. Clicking a blue line, corresponding to a term currently in the model, removes the term from the model and changes the line to red.

To call `addedvarplot` and produce an added variable plot from the **stepwise** interface, select **Added Variable Plot** from the **Stepwise** menu. A list of terms is displayed. Select the term you want to add, and then click **OK**.

Click **Export** to display a dialog box that allows you to select information from the interface to save to the MATLAB workspace.

Check the information you want to export and, optionally, change the names of the workspace variables to be created. Click **OK** to export the information.

`stepwise(X,y)` displays the interface using the  $p$  predictive terms in the  $n$ -by- $p$  matrix  $X$  and the response values in the  $n$ -by-1 vector  $y$ . Distinct predictive terms should appear in different columns of  $X$ .

---

**Note** `stepwise` automatically includes a constant term in all models. Do not enter a column of 1s directly into  $X$ .

---

`stepwise` treats NaN values in either  $X$  or  $y$  as missing values, and ignores them.

`stepwise(X,y,inmodel,penter,premove)` additionally specifies the initial model (`inmodel`) and the entrance (`penter`) and exit (`premove`) tolerances for the  $p$ -values of  $F$ -statistics. `inmodel` is either a logical vector with length equal to the number of columns of  $X$ , or a vector of indices, with values ranging from 1 to the number of columns in  $X$ . The value of `penter` must be less than or equal to the value of `premove`.

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the  $p$  value of an  $F$ -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.

- 2** If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$  value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have  $p$ -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$  value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

# GeneralizedLinearModel.stepwise

---

**Purpose** Create generalized linear regression model by stepwise regression

**Compatibility** GeneralizedLinearModel.stepwise will be removed in a future release. Use stepwiseglm instead.

**Syntax**

```
mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)
mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)
mdl =
GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)
```

**Description** `mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)` creates a generalized linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)` creates a generalized linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors.

`mdl =`  
`GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)`  
creates a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

- Tips**
- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
  - For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

## Input Arguments

### **tbl - Input data**

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## modelspec - Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Starting model for `stepwiseglm`, specified as one of the following:

# GeneralizedLinearModel.stepwise

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p+1)$  matrix, namely terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-3737.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'BinomialSize' - Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is 'binomial'.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

## Data Types

single | double

## 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of 'CategoricalVars' and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.

# GeneralizedLinearModel.stepwise

---

- If data is in matrix  $X$ , then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

## Data Types

`single` | `double` | `logical`

## 'Criterion' - Criterion to add or remove terms

`'Deviance'` | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of the following:

- `'Deviance'` — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- `'sse'` — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of  $R^2$ .
- `'adjrsquared'` — Increase in the value of adjusted  $R^2$ .

**Example:** `'Criterion','bic'`

## 'DispersionFlag' - Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

**Example:** 'DispersionFlag',true

## 'Distribution' - Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

**Example:** 'Distribution','gamma'

## 'Exclude' - Observations to exclude

logical or numeric index vector

# GeneralizedLinearModel.stepwise

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

## 'Link' - Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$

Link Function Name	Link Function	Mean (Inverse) Function
'comploglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul>	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship  $f(\mu) = X*b$  between the mean response  $\mu$  and the linear combination of predictors  $X*b$ .

For more information on the canonical link functions, see [Definitions](#).

**Example:** 'Link', 'probit'

### 'Lower' - Model specification describing terms that cannot be removed from model

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

# GeneralizedLinearModel.stepwise

---

**Example:** 'Lower', 'linear'

## **'Offset' - Offset variable**

[] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

fitglm and stepwiseglm use Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying  $\log(A)$  as an offset, you can force the model to satisfy this theoretical constraint.

## **Data Types**

single | double | char

## **'PEnter' - Improvement measure for adding term**

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

# GeneralizedLinearModel.stepwise

Criterion	Default value	Decision
'Deviance'	0.05	If the $p$ -value of $F$ or chi-squared statistic is smaller than $P_{Enter}$ , add the term to the model.
'SSE'	0.05	If the SSE of the model is smaller than $P_{Enter}$ , add the term to the model.
'AIC'	0	If the change in the AIC of the model is smaller than $P_{Enter}$ , add the term to the model.
'BIC'	0	If the change in the BIC of the model is smaller than $P_{Enter}$ , add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared of the model is larger than $P_{Enter}$ , add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared of the model is larger than $P_{Enter}$ , add

# GeneralizedLinearModel.stepwise

Criterion	Default value	Decision
		the term to the model.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PEnter',0.075`

## 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

**Example:** `'PredictorVars',logical([0 1 1 0 0 0])`

## Data Types

single | double | logical | cell

## 'PRemove' - Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value.

# GeneralizedLinearModel.stepwise

Criterion	Default value	Decision
'Deviance'	0.10	If the $p$ -value of $F$ or chi-squared statistic is larger than <code>PRemove</code> , remove the term from the model.
'SSE'	0.10	If the $p$ -value of the $F$ statistic is larger than <code>PRemove</code> , remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is larger than <code>PRemove</code> , remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is larger than <code>PRemove</code> , remove the term from the model.

# GeneralizedLinearModel.stepwise

Criterion	Default value	Decision
'Rsquared'	0.05	If the increase in the R-squared value of the model is smaller than <code>PRemove</code> , remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is smaller than <code>PRemove</code> , remove the term from the model.

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PRemove', 0.05`

## 'ResponseVar' - Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

## Data Types

`single` | `double` | `logical` | `char`

## 'Upper' - Model specification describing largest set of terms in fit

`'interaction'` (default) | `string`

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

**Example:** `'Upper','quadratic'`

## 'VarNames' - Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | `cell array of strings`

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

## Example:

`'VarNames',{ 'Horsepower','Acceleration','Model_Year','MPG' }`

## Data Types

`cell`

## 'Weights' - Observation weights

# GeneralizedLinearModel.stepwise

---

ones(n,1) (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

## Data Types

single | double

## Output Arguments

### mdl - Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

# GeneralizedLinearModel.stepwise

---

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    0    1    0    0
    0    0    1    0
    0    0    0    1
```

# GeneralizedLinearModel.stepwise

---

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

```
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337

# GeneralizedLinearModel.stepwise

x2	-0.012781	0.0060312	-2.1192	0.0368
x1:x2	-0.00010892	0.00017925	-0.6076	0.5
x2^2	9.7518e-07	7.5389e-07	1.2935	0.199

Number of observations: 94, Error degrees of freedom: 89  
Root Mean Squared Error: 4.1  
R-squared: 0.751, Adjusted R-Squared 0.739  
F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];  
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

y ~ 1 + x2

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92  
Root Mean Squared Error: 4.13  
R-squared: 0.738, Adjusted R-Squared 0.735  
F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of fitlm in the previous step.

# GeneralizedLinearModel.stepwise

---

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ ' where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable
  - $-$  means do not include the next variable
  - $:$  defines an interaction, a product of terms
  - $*$  defines an interaction **and all lower-order terms**
  - $^$  raises the predictor to a power, exactly as in  $*$  repeated, so  $^$  includes lower order terms as well
  - $()$  groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include  $-1$  in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B =$

$A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among A, B, and C, except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where k is a positive integer	A, $A^2$ , ..., $A^k$
$A + B$	A, B
$A*B$	A, B, $A*B$
$A:B$	$A*B$ only
-B	Do not include B
$A*B + C$	A, B, C, $A*B$
$A + B + C + A:B$	A, B, C, $A*B$
$A*B*C - A:B:C$	A, B, C, $A*B$ , $A*C$ , $B*C$
$A*(B + C)$	A, B, C, $A*B$ , $A*C$

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Canonical Link Function

The default link function for a generalized linear model is the *canonical link function*.

# GeneralizedLinearModel.stepwise

## Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

## Examples

### Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15]) * [.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant', 'upper', 'linear', 'Distribution', 'poisson')
```

```
1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094
```

```
mdl =
```

Generalized Linear regression model:

$\log(y) \sim 1 + x5 + x10 + x15$

Distribution = Poisson

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

# GeneralizedLinearModel.stepwise

---

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

You can also create a stepwise generalized linear model using `stepwiseglm`.

Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

# LinearModel.stepwise

---

**Purpose** Create linear regression model by stepwise regression

**Compatibility** `LinearModel.stepwise` will be removed in a future release. Use `stepwiselm` instead.

**Syntax**

```
mdl = LinearModel.stepwise(tbl,modelspec)
mdl = LinearModel.stepwise(X,y,modelspec)
mdl = LinearModel.stepwise(___,modelspec,Name,Value)
```

**Description** `mdl = LinearModel.stepwise(tbl,modelspec)` returns a linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(X,y,modelspec)` creates a linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(___,modelspec,Name,Value)` creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion `LinearModel.stepwise` uses to add or remove terms.

- Tips**
- You cannot use robust regression with stepwise regression. Check your data for outliers before using `LinearModel.stepwise`.
  - For other methods or properties of the `LinearModel` object, see `LinearModel`.

## Input Arguments

### **tbl - Input data**

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### **Data Types**

single | double | logical

### **X - Predictor variables**

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

### **Data Types**

single | double | logical

### **y - Response variable**

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

# LinearModel.stepwise

---

## Data Types

single | double

## modelspec - Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Starting model for the stepwise regression, specified as one of the following:

- String specifying the type of starting model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

If you want to specify the smallest or largest set of terms in the model, use the `Lower` and `Upper` name-value pair arguments.

- $t$ -by- $(p+1)$  matrix, namely a terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-3758.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (`' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

## 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars', [2,3]`

# LinearModel.stepwise

---

**Example:** 'CategoricalVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Criterion' - Criterion to add or remove terms

'Deviance' | 'sse' | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- 'Deviance' — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- 'sse' — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- 'aic' — Change in the value of Akaike information criterion (AIC).
- 'bic' — Change in the value of Bayesian information criterion (BIC).
- 'rsquared' — Increase in the value of  $R^2$ .
- 'adjrsquared' — Increase in the value of adjusted  $R^2$ .

**Example:** 'Criterion','bic'

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

### 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

### 'Lower' - Model specification describing terms that cannot be removed from model

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

**Example:** 'Lower','linear'

### 'NSteps' - Number of steps to take

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

## Data Types

single | double

### 'PEnter' - Improvement measure for adding term

# LinearModel.stepwise

---

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

Criterion	Default value	Decision
'Deviance'	0.05	If the $p$ -value of $F$ or chi-squared statistic is smaller than PEnter, add the term to the model.
'SSE'	0.05	If the SSE of the model is smaller than PEnter, add the term to the model.
'AIC'	0	If the change in the AIC of the model is smaller than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is smaller than PEnter, add the term to the model.

Criterion	Default value	Decision
'Rsquared'	0.1	If the increase in the R-squared of the model is larger than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared of the model is larger than PEnter, add the term to the model.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PEnter',0.075`

### 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

# LinearModel.stepwise

---

Example: 'PredictorVars',logical([0 1 1 0 0 0])

## Data Types

single | double | logical | cell

## 'PRemove' - Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

Criterion	Default value	Decision
'Deviance'	0.10	If the $p$ -value of $F$ or chi-squared statistic is larger than PRemove, remove the term from the model.
'SSE'	0.10	If the $p$ -value of the $F$ statistic is larger than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is larger than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is larger than PRemove, remove the term from the model.

Criterion	Default value	Decision
'Rsquared'	0.05	If the increase in the R-squared value of the model is smaller than <code>PRemove</code> , remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is smaller than <code>PRemove</code> , remove the term from the model.

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PRemove', 0.05`

## 'ResponseVar' - Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

# LinearModel.stepwise

---

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

## Data Types

`single` | `double` | `logical` | `char`

## 'Upper' - Model specification describing largest set of terms in fit

`'interaction'` (default) | string

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

**Example:** `'Upper','quadratic'`

## 'VarNames' - Names of variables in fit

`{'x1','x2',...,'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

## Example:

`'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

## Data Types

`cell`

## 'Verbose' - Control for display of information

1 (default) | 0 | 2

Control for display of information, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

**Example:** 'Verbose',2

### 'Weights' - Observation weights

ones(n,1) (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

### Data Types

single | double

## Output Arguments

### mdl - Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

For the properties and methods of the linear model object, mdl, see the LinearModel class page.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

# LinearModel.stepwise

---

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    0    1    0    0
    0    0    1    0
    0    0    0    1
```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```
    0    0    0
    1    0    0
    0    1    0
    1    1    0
    0    2    0
```

# LinearModel.stepwise

---

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

$$y \sim 1 + x1*x2 + x2^2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - \* defines an interaction **and all lower-order terms**
  - ^ raises the predictor to a power, exactly as in \* repeated, so ^ includes lower order terms as well
  - () groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

---

# LinearModel.stepwise

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$
$A + B$	$A, B$
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include $B$
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$

Wilkinson Notation	Factors in Standard Notation
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Examples

### Linear Model from Stepwise Regression

Fit a linear model of the Hald data using stepwise regression.

Load the data.

```
load hald
```

Fit a linear model to the data.

```
mdl = LinearModel.stepwise(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =
```

Linear regression model:

$$y \sim 1 + x1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

# LinearModel.stepwise

---

Number of observations: 13, Error degrees of freedom: 10  
Root Mean Squared Error: 2.41  
R-squared: 0.979, Adjusted R-Squared 0.974  
F-statistic vs. constant model: 230, p-value = 4.41e-09

## Simultaneously Specify the Variables and Use Formula

Simultaneously identify response and predictor variables and specify the initial model using formula in stepwise regression.

Load sample data.

```
load hospital
```

Fit a linear model to the data.

```
mdl = LinearModel.stepwise(hospital, 'Weight~1+Smoker', ...  
  'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...  
  'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605

```
mdl =
```

Linear regression model:

```
Weight ~ 1 + Sex
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	130.47	1.1995	108.77	5.2762e-104
Sex_Male	50.06	1.7496	28.612	2.2464e-49

Number of observations: 100, Error degrees of freedom: 98  
Root Mean Squared Error: 8.73  
R-squared: 0.893, Adjusted R-Squared 0.892  
F-statistic vs. constant model: 819, p-value = 2.25e-49

The weight of the patients do not seem to differ significantly according to age or the status of smoking, or interaction of these factors with gender. `LinearModel.stepwise` only includes Sex in the final linear model.

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the `'Criterion'` argument. The default value of `'Criterion'` is `'sse'`, and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when `'Criterion'` is `'sse'`:

- 1** Fit the initial model.
- 2** If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is `'Deviance'` and it follows a similar procedure for adding or removing terms.

# LinearModel.stepwise

---

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## References

[1] Draper, N. R., and H. Smith. *Applied Regression Analysis*. Hoboken, NJ: Wiley-Interscience, pp. 307–312, 1998.

## Alternatives

You can also construct a stepwise linear model using `stepwiselm`.

You can construct a model using `fitlm`, then manually adjust the model using `step`, `addTerms`, or `removeTerms`. Use `fitlm` for robust regression. You cannot use robust regression and stepwise regression together.

## Tutorials

- “Compare large and small stepwise models” on page 9-127

## How To

- “Linear Regression” on page 9-12
- “Stepwise Regression” on page 9-127

**Purpose** Create generalized linear regression model by stepwise regression

**Syntax**

```
mdl = stepwiseglm(tbl,modelspec)
mdl = stepwiseglm(X,y,modelspec)
mdl = stepwiseglm(...,modelspec,Name,Value)
```

**Description** `mdl = stepwiseglm(tbl,modelspec)` creates a generalized linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = stepwiseglm(X,y,modelspec)` creates a generalized linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors.

`mdl = stepwiseglm(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

**tbl - Input data**  
table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

# stepwiseglm

---

## Data Types

single | double | logical

## X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

## Data Types

single | double | logical

## y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

## Data Types

single | double

## modelspec - Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Starting model for `stepwiseglm`, specified as one of the following:

- String specifying the type of model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

- $t$ -by- $(p+1)$  matrix, namely terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-3782.

### Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. Name must appear inside single quotes ( ' '). You can

specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:**

`'Criterion', 'aic', 'Distribution', 'poisson', 'Upper', 'interactions'` specifies Akaike Information Criterion as the criterion to add or remove variables to the model, Poisson distribution as the distribution of the response variable, and a model with all possible interactions as the largest model to consider as the fit.

**'BinomialSize' - Number of trials for binomial distribution**

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter  $n$  for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

**Data Types**

single | double

**'CategoricalVars' - Categorical variables**

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars',[2,3]`

**Example:** `'CategoricalVars',logical([0 1 1 0 0 0])`

### Data Types

single | double | logical

### 'Criterion' - Criterion to add or remove terms

'Deviance' | 'sse' | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- 'Deviance' — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- 'sse' — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- 'aic' — Change in the value of Akaike information criterion (AIC).
- 'bic' — Change in the value of Bayesian information criterion (BIC).
- 'rsquared' — Increase in the value of  $R^2$ .
- 'adjrsquared' — Increase in the value of adjusted  $R^2$ .

**Example:** `'Criterion','bic'`

### 'DispersionFlag' - Indicator to compute dispersion parameter

# stepwiseglm

---

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

**Example:** 'DispersionFlag',true

## 'Distribution' - Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

**Example:** 'Distribution','gamma'

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

### Data Types

single | double | logical

### 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

### 'Link' - Link function

The canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comploglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$

# stepwiseglm

Link Function Name	Link Function	Mean (Inverse) Function
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> <li>• S.Link — The link function</li> <li>• S.Inverse — The inverse link function</li> <li>• S.Derivative — The derivative of the link function</li> </ul>	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship  $f(\mu) = X^*b$  between the mean response  $\mu$  and the linear combination of predictors  $X^*b$ .

For more information on the canonical link functions, see [Definitions](#).

**Example:** 'Link', 'probit'

## 'Lower' - Model specification describing terms that cannot be removed from model

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

**Example:** 'Lower', 'linear'

## 'Offset' - Offset variable

[ ] (default) | vector | string

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

fitglm and stepwiseglm use Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying  $\log(A)$  as an offset, you can force the model to satisfy this theoretical constraint.

### Data Types

single | double | char

### 'PEnter' - Improvement measure for adding term

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

Criterion	Default value	Decision
'Deviance'	0.05	If the $p$ -value of $F$ or chi-squared statistic is smaller than PEnter, add the term to the model.
'SSE'	0.05	If the SSE of the model is smaller than PEnter, add the term to the model.

# stepwiseglm

Criterion	Default value	Decision
'AIC'	0	If the change in the AIC of the model is smaller than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is smaller than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared of the model is larger than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared of the model is larger than PEnter, add the term to the model.

For more information on the criteria, see **Criterion** name-value pair argument.

**Example:** 'PEnter',0.075

## 'PredictorVars' - Predictor variables

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** `'PredictorVars',[2,3]`

**Example:** `'PredictorVars',logical([0 1 1 0 0 0])`

### Data Types

single | double | logical | cell

### 'PRemove' - Improvement measure for removing term

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value.

Criterion	Default value	Decision
'Deviance'	0.10	If the $p$ -value of $F$ or chi-squared statistic is larger than <code>PRemove</code> , remove the term from the model.
'SSE'	0.10	If the $p$ -value of the $F$ statistic is larger than <code>PRemove</code> , remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is larger than <code>PRemove</code> , remove the term from the model.

# stepwiseglm

---

Criterion	Default value	Decision
'BIC'	0.01	If the change in the BIC of the model is larger than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is smaller than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is smaller than PRemove, remove the term from the model.

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see **Criterion** name-value pair argument.

**Example:** 'PRemove',0.05

## 'ResponseVar' - Response variable

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index

vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array tbl.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### Data Types

single | double | logical | char

### 'Upper' - Model specification describing largest set of terms in fit

'interaction' (default) | string

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the string options for `modelspec` naming the model.

**Example:** `'Upper','quadratic'`

### 'VarNames' - Names of variables in fit

{'x1','x2',..., 'xn','y'} (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of 'VarNames' and a cell array of strings including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

`'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

### Data Types

cell

## 'Weights' - Observation weights

`ones(n,1)` (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

## Data Types

single | double

## Output Arguments

### mdl - Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

## Examples

### Generalized Linear Model Using Stepwise Algorithm

Create response data using just three of 20 predictors, and create a generalized linear model using stepwise algorithm to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07

3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

mdl =

Generalized Linear regression model:

$\log(y) \sim 1 + x5 + x10 + x15$

Distribution = Poisson

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

100 observations, 96 error degrees of freedom

Dispersion: 1

Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20

The starting model is the constant model. `stepwiseglm` by default uses deviance of the model as the criterion. It first adds `x5` into the model, as the  $p$ -value for the test statistic, deviance (the differences in the deviances of the two models), is less than the default threshold value 0.05. Then, it adds `x15` because given `x5` is in the model, when `x15` is added, the  $p$ -value for chi-squared test is smaller than 0.05. It then adds `x10` because given `x5` and `x15` are in the model, when `x10` is added, the  $p$ -value for the chi-square test statistic is again less than 0.05.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables A, B, and C:

# stepwiseglm

---

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1

```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0     0     0
1     0     0
0     1     0
1     1     0
0     2     0

```

# stepwiseglm

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

$$y \sim 1 + x1*x2 + x2^2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];
```

```
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

```
mdl =
```

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

## Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - + means include the next variable
  - - means do not include the next variable
  - : defines an interaction, a product of terms
  - \* defines an interaction **and all lower-order terms**
  - ^ raises the predictor to a power, exactly as in \* repeated, so ^ includes lower order terms as well
  - () groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include -1 in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

' $Y \sim A + B + C + B^2$ ' is a three-variable model with intercept and a  $B^2$  term.

' $Y \sim A + B^2 + C$ ' is the same as the previous example because  $B^2$  includes a  $B$  term.

' $Y \sim A + B + C + A:B$ ' includes an  $A*B$  term.

' $Y \sim A*B + C$ ' is the same as the previous example because  $A*B = A + B + A:B$ .

' $Y \sim A*B*C - A:B:C$ ' has all interactions among  $A$ ,  $B$ , and  $C$ , except the three-way interaction.

' $Y \sim A*(B + C + D)$ ' has all linear terms, plus products of  $A$  with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
$A^k$ , where $k$ is a positive integer	$A, A^2, \dots, A^k$
$A + B$	$A, B$
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include $B$
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$

Wilkinson Notation	Factors in Standard Notation
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

### Canonical Function

The default link function for a generalized linear model is the *canonical link function*.

### Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

### Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

### Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1** Fit the initial model.
- 2** If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps

will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Alternatives

Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

# stepwiselm

---

**Purpose** Create linear regression model using stepwise regression

**Syntax**

```
mdl = stepwiselm(tbl,modelspec)
mdl = stepwiselm(X,y,modelspec)
mdl = stepwiselm(___,Name,Value)
```

**Description** `mdl = stepwiselm(tbl,modelspec)` returns a linear model for the variables in the table or dataset array `tbl` using stepwise regression to add or remove predictors. `stepwiselm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. `modelspec` is the starting model for the stepwise procedure.

`mdl = stepwiselm(X,y,modelspec)` creates a linear model of the responses `y` to the predictor variables in the data matrix `X`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = stepwiselm(___,Name,Value)` creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion `stepwiselm` uses to add or remove terms.

## Input Arguments

**tbl - Input data**  
table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, it specifies the variables to be used as the predictors and response. Otherwise, if you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables can be numeric, or any grouping variable type, such as logical or categorical (see “Grouping Variables” on page 2-52). The response must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

### Data Types

single | double | logical

### X - Predictor variables

matrix

Predictor variables, specified as an  $n$ -by- $p$  matrix, where  $n$  is the number of observations and  $p$  is the number of predictor variables. Each column of  $X$  represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in  $X$ .

### Data Types

single | double | logical

### y - Response variable

vector

Response variable, specified as an  $n$ -by-1 vector, where  $n$  is the number of observations. Each entry in  $y$  is the response for the corresponding row of  $X$ .

### Data Types

single | double

### modelspec - Starting model

string specifying the model |  $t$ -by- $(p+1)$  terms matrix | string of the form 'Y ~ terms'

Starting model for the stepwise regression, specified as one of the following:

- String specifying the type of starting model.

String	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear terms for each predictor.
'interactions'	Model contains an intercept, linear terms, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept, linear terms, and squared terms.
'quadratic'	Model contains an intercept, linear terms, interactions, and squared terms.
'polyijk'	Model is a polynomial with all terms up to degree $i$ in the first predictor, degree $j$ in the second predictor, etc. Use numerals 0 through 9. For example, 'poly2111' has a constant plus all linear and product terms, and also contains terms with predictor 1 squared.

If you want to specify the smallest or largest set of terms in the model, use the **Lower** and **Upper** name-value pair arguments.

- $t$ -by- $(p+1)$  matrix, namely a terms matrix, specifying terms to include in model, where  $t$  is the number of terms and  $p$  is the number of predictor variables, and plus one is for the response variable.
- String representing a formula in the form

`'Y ~ terms'`,

where the terms are in “Wilkinson Notation” on page 21-3804.

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

**Example:** `'Criterion', 'aic', 'Upper', interactions, 'Verbose', 1` instructs `stepwiselm` to use the Akaike information criterion, display the action it takes at each step, and include at most the interaction terms in the model.

### 'CategoricalVars' - Categorical variables

cell array of strings | logical or numeric index vector

Categorical variables in the fit, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a cell array of strings of the names of the categorical variables in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then the default is to treat all categorical or logical variables, character arrays, or cell arrays of strings as categorical variables.
- If data is in matrix `X`, then the default value of this name-value pair argument is an empty matrix `[]`. That is, no variable is categorical unless you specify it.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

**Example:** `'CategoricalVars', [2,3]`

**Example:** `'CategoricalVars', logical([0 1 1 0 0 0])`

### Data Types

single | double | logical

### 'Criterion' - Criterion to add or remove terms

'Deviance' | 'sse' | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- 'Deviance' — Default for `stepwiseglm`.  $p$ -value for  $F$  or chi-squared test of the change in the deviance by adding or removing the term.  $F$ -test is for testing a single model. Chi-squared test is for comparing two different models. This option is not valid for `stepwiselm`.
- 'sse' — Default for `stepwiselm`.  $p$ -value for an  $F$ -test of the change in the sum of squared error by adding or removing the term.
- 'aic' — Change in the value of Akaike information criterion (AIC).
- 'bic' — Change in the value of Bayesian information criterion (BIC).
- 'rsquared' — Increase in the value of  $R^2$ .
- 'adjrsquared' — Increase in the value of adjusted  $R^2$ .

**Example:** 'Criterion','bic'

## 'Exclude' - Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

**Example:** 'Exclude',[2,3]

**Example:** 'Exclude',logical([0 1 1 0 0 0])

## Data Types

single | double | logical

## 'Intercept' - Indicator for constant term

true (default) | false

Indicator the for constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a string, not a formula or matrix.

**Example:** 'Intercept',false

### **'Lower' - Model specification describing terms that cannot be removed from model**

'constant' (default)

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the string options for `modelspec` naming the model.

**Example:** 'Lower', 'linear'

### **'NSteps' - Number of steps to take**

1 (default) | positive integer

Number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

### **Data Types**

single | double

### **'PEnter' - Improvement measure for adding term**

scalar value

Improvement measure for adding a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value. The default values are below.

# stepwiselm

---

Criterion	Default value	Decision
'Deviance'	0.05	If the $p$ -value of $F$ or chi-squared statistic is smaller than <code>PEnter</code> , add the term to the model.
'SSE'	0.05	If the SSE of the model is smaller than <code>PEnter</code> , add the term to the model.
'AIC'	0	If the change in the AIC of the model is smaller than <code>PEnter</code> , add the term to the model.
'BIC'	0	If the change in the BIC of the model is smaller than <code>PEnter</code> , add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared of the model is larger than <code>PEnter</code> , add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared of the model is larger than <code>PEnter</code> , add the term to the model.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** 'PEnter',0.075

### **'PredictorVars' - Predictor variables**

cell array of strings | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a cell array of strings of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The strings should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

**Example:** 'PredictorVars',[2,3]

**Example:** 'PredictorVars',logical([0 1 1 0 0 0])

### **Data Types**

single | double | logical | cell

### **'PRemove' - Improvement measure for removing term**

scalar value

Improvement measure for removing a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value.

# stepwiselm

---

Criterion	Default value	Decision
'Deviance'	0.10	If the $p$ -value of $F$ or chi-squared statistic is larger than <b>PRemove</b> , remove the term from the model.
'SSE'	0.10	If the $p$ -value of the $F$ statistic is larger than <b>PRemove</b> , remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is larger than <b>PRemove</b> , remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is larger than <b>PRemove</b> , remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is smaller than <b>PRemove</b> , remove the term from the model.

At each step, stepwise algorithm also checks whether any term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, it is removed, regardless of the criterion value.

For more information on the criteria, see `Criterion` name-value pair argument.

**Example:** `'PRemove',0.05`

### **'ResponseVar' - Response variable**

last column in `tbl` (default) | string for variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a string of the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

**Example:** `'ResponseVar','yield'`

**Example:** `'ResponseVar',[4]`

**Example:** `'ResponseVar',logical([0 0 0 1 0 0])`

### **Data Types**

single | double | logical | char

### **'Upper' - Model specification describing largest set of terms in fit**

`'interaction'` (default) | string

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the string options for `modelspec` naming the model.

**Example:** `'Upper','quadratic'`

### **'VarNames' - Names of variables in fit**

`{'x1','x2',..., 'xn','y'}` (default) | cell array of strings

Names of variables in fit, specified as the comma-separated pair consisting of `'VarNames'` and a cell array of strings including the names for the columns of  $X$  first, and the name for the response variable  $y$  last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

**Example:**

`'VarNames',{ 'Horsepower','Acceleration','Model_Year','MPG'}`

**Data Types**

cell

**'Verbose' - Control for display of information**

1 (default) | 0 | 2

Control for display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of the following:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Also display the actions evaluated at each step.

**Example:** `'Verbose',2`

**'Weights' - Observation weights**

`ones(n,1)` (default) |  $n$ -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an  $n$ -by-1 vector of nonnegative scalar values, where  $n$  is the number of observations.

**Data Types**

single | double

**Output Arguments****mdl - Linear model**

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

For the properties and methods of the linear model object, mdl, see the LinearModel class page.

**Examples****Linear Model Using Stepwise Regression**

Load the sample data.

```
load hald
```

hald contains hardening data for 13 different concrete compositions. heat is the heat of hardening after 180 days. ingredients is the percentage of each different ingredient in the cement sample.

Fit a linear model to the data. Set the criterion value to enter the model as 0.06.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =
```

```
Linear regression model:
```

```
y ~ 1 + x1 + x2
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07

# stepwiselm

---

```
x2                0.66225      0.045855      14.442      5.029e-08
```

```
Number of observations: 13, Error degrees of freedom: 10
Root Mean Squared Error: 2.41
R-squared: 0.979, Adjusted R-Squared 0.974
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

By default, the starting model is the constant model. `stepwiselm` performs forward selection and `x4`, `x1`, and `x2`, respectively, as the corresponding  $p$ -values are less than the `PEnter` value of 0.06. `stepwiselm` later uses backward elimination and eliminates `x4` from the model. Because, given that `x2` is in the model, the  $p$ -value of `x4` is higher than the default value of `PRemove`, 0.1.

## Specify Model Using Formula and Specify Variables

Perform stepwise regression with variables in a dataset array. Specify the starting model using formula, and identify the response and predictor variables with optional arguments.

Load the sample data.

```
load hospital
```

The `hospital` dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and `Smoker` as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital, 'Weight~1+Smoker', ...
'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding `Sex`, `FStat` = 770.0158, `pValue` = 6.262758e-48
2. Removing `Smoker`, `FStat` = 0.21224, `pValue` = 0.64605

```
mdl =
```

```
Linear regression model:
```

```
Weight ~ 1 + Sex
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	130.47	1.1995	108.77	5.2762e-104
Sex_Male	50.06	1.7496	28.612	2.2464e-49

```
Number of observations: 100, Error degrees of freedom: 98
```

```
Root Mean Squared Error: 8.73
```

```
R-squared: 0.893, Adjusted R-Squared 0.892
```

```
F-statistic vs. constant model: 819, p-value = 2.25e-49
```

At each step, `stepwiselm` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a  $p$ -value of  $6.26e-48$ . Then, removes `Smoker` from the model, since given `Sex` in the model, the variable `Smoker` becomes redundant. `stepwiselm` only includes `Sex` in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

## Definitions

### Terms Matrix

A terms matrix is a  $t$ -by- $(p + 1)$  matrix specifying terms in a model, where  $t$  is the number of terms,  $p$  is the number of predictor variables, and plus one is for the response variable.

The value of  $T(i, j)$  is the exponent of variable  $j$  in term  $i$ . Suppose there are three predictor variables  $A$ ,  $B$ , and  $C$ :

```
[0 0 0 0] % Constant term or intercept
[0 1 0 0] % B; equivalently, A^0 * B^1 * C^0
[1 0 1 0] % A*C
[2 0 0 0] % A^2
[0 1 2 0] % B*(C^2)
```

The 0 at the end of each term represents the response variable. In general,

- If you have the variables in a table or dataset array, then 0 must represent the response variable depending on the position of the response variable. The following example illustrates this.

Load the sample data and define the dataset array.

```
load hospital
ds = dataset(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,...
hospital.Smoker,'VarNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model 'BloodPressure ~ 1 + Sex + Age + Smoker' in a terms matrix. The response variable is in the second column of the dataset array, so there must be a column of 0s for the response variable in the second column of the terms matrix.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```
    0    0    0    0
    1    0    0    0
    0    0    1    0
    0    0    0    1
```

Redefine the dataset array.

```
ds = dataset(hospital.BloodPressure(:,1),hospital.Sex,hospital.Age,...
hospital.Smoker,'VarNames',{'BloodPressure','Sex','Age','Smoker'});
```

Now, the response variable is the first term in the dataset array. Specify the same linear model, 'BloodPressure ~ 1 + Sex + Age + Smoker', using a terms matrix.

```
T = [0 0 0 0;0 1 0 0;0 0 1 0;0 0 0 1]
```

```
T =
```

```

0     0     0     0
0     1     0     0
0     0     1     0
0     0     0     1

```

- If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable at the end of each term. The following example illustrates this.

Load the sample data and define the matrix of predictors.

```

load carsmall
X = [Acceleration,Weight];

```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a term matrix and fit the model to the data. This model includes the main effect and two-way interaction terms for the variables, Acceleration and Weight, and a second-order term for the variable, Weight.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T =
```

```

0     0     0
1     0     0
0     1     0
1     1     0
0     2     0

```

Fit a linear model.

```
mdl = fitlm(X,MPG,T)
```

```
mdl =
```

Linear regression model:

# stepwiselm

$$y \sim 1 + x1*x2 + x2^2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which correspond to the Weight variable, are significant at the 5% significance level.

Now, perform a stepwise regression with a constant model as the starting model and a linear model with interactions as the upper model.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0];  
mdl = stepwiselm(X,MPG,[0 0 0],'upper',T)
```

1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28

mdl =

Linear regression model:

$$y \sim 1 + x2$$

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
x2	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

Root Mean Squared Error: 4.13  
R-squared: 0.738, Adjusted R-Squared 0.735  
F-statistic vs. constant model: 259, p-value = 1.64e-28

The results of the stepwise regression are consistent with the results of `fitlm` in the previous step.

### Formula

A formula for model specification is a string of the form ' $Y \sim terms$ '

where

- $Y$  is the response name.
- $terms$  contains
  - Variable names
  - $+$  means include the next variable
  - $-$  means do not include the next variable
  - $:$  defines an interaction, a product of terms
  - $*$  defines an interaction **and all lower-order terms**
  - $^$  raises the predictor to a power, exactly as in  $*$  repeated, so  $^$  includes lower order terms as well
  - $()$  groups terms

---

**Note** Formulas include a constant (intercept) term by default. To exclude a constant term from the model, include  $-1$  in the formula.

---

For example,

' $Y \sim A + B + C$ ' means a three-variable linear model with intercept.

' $Y \sim A + B + C - 1$ ' is a three-variable linear model without intercept.

'Y ~ A + B + C + B^2' is a three-variable model with intercept and a B^2 term.

'Y ~ A + B^2 + C' is the same as the previous example because B^2 includes a B term.

'Y ~ A + B + C + A:B' includes an A\*B term.

'Y ~ A\*B + C' is the same as the previous example because  $A*B = A + B + A:B$ .

'Y ~ A\*B\*C - A:B:C' has all interactions among A, B, and C, except the three-way interaction.

'Y ~ A\*(B + C + D)' has all linear terms, plus products of A with each of the other variables.

## Wilkinson Notation

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
A^k, where k is a positive integer	A, A <sup>2</sup> , ..., A <sup>k</sup>
A + B	A, B
A*B	A, B, A*B
A:B	A*B only
-B	Do not include B
A*B + C	A, B, C, A*B
A + B + C + A:B	A, B, C, A*B
A*B*C - A:B:C	A, B, C, A*B, A*C, B*C
A*(B + C)	A, B, C, A*B, A*C

Statistics Toolbox notation always includes a constant term unless you explicitly remove the term using -1.

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

MATLAB uses forward and backward stepwise regression to determine a final model. At each step, the method searches for terms to add to or remove from the model based on the value of the 'Criterion' argument. The default value of 'Criterion' is 'sse', and in this case, `stepwiselm` uses the  $p$ -value of an  $F$ -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model.

Here is how stepwise proceeds when 'Criterion' is 'sse':

- 1** Fit the initial model.
- 2** If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$ -value and repeat this step; otherwise, go to step 3.
- 3** If any terms in the model have  $p$ -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$ -value and go to step 2; otherwise, end.

The default for `stepwiseglm` is 'Deviance' and it follows a similar procedure for adding or removing terms.

There are several other criteria available, which you can specify using the 'Criterion' argument. You can use the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, adjusted R-squared as a criterion to add or remove terms.

# stepwiselm

---

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method might build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

## Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `stepwiselm`.
- For other methods such as `anova`, or properties of the `LinearModel` object, see `LinearModel`.

## Alternative Functionality

You can construct a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, or `removeTerms`.

`LinearModel` | `step` | `fitlm`

## Related Examples

- “Compare large and small stepwise models” on page 9-127
- “Linear Regression” on page 9-12

## Concepts

- “Stepwise Regression” on page 9-127

**Purpose**

Stepwise regression

**Syntax**

```
b = stepwisefit(X,y)
[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...)
[...] = stepwisefit(X,y,param1,va11,param2,va12,...)
```

**Description**

`b = stepwisefit(X,y)` uses a stepwise method to perform a multilinear regression of the response values in the  $n$ -by-1 vector  $y$  on the  $p$  predictive terms in the  $n$ -by- $p$  matrix  $X$ . Distinct predictive terms should appear in different columns of  $X$ .

$b$  is a  $p$ -by-1 vector of estimated coefficients for all of the terms in  $X$ . The `stepwisefit` function calculates the coefficient estimate values in  $b$  as follows:

- If a term is not in the final model, then the corresponding coefficient estimate in  $b$  results from adding only that term to the predictors in the final model.
- If a term is in the final model, then the coefficient estimate in  $b$  for that term is a result of the final model, that is `stepwise` does not consider the terms it excluded from the model while computing these values.

---

**Note** `stepwisefit` automatically includes a constant term in all models. Do not enter a column of 1s directly into  $X$ .

---

`stepwisefit` treats NaN values in either  $X$  or  $y$  as missing values, and ignores them.

`[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...)` returns the following additional information:

- `se` — A vector of standard errors for  $b$
- `pval` — A vector of  $p$ -values for testing whether elements of  $b$  are 0

## stepwisefit

---

- `inmodel` — A logical vector, with length equal to the number of columns in `X`, specifying which terms are in the final model
- `stats` — A structure of additional statistics with the following fields. All statistics pertain to the final model except where noted.
  - `source` — The string 'stepwisefit'
  - `dfe` — Degrees of freedom for error
  - `df0` — Degrees of freedom for the regression
  - `SStotal` — Total sum of squares of the response
  - `SSresid` — Sum of squares of the residuals
  - `fstat` —  $F$ -statistic for testing the final model vs. no model (mean only)
  - `pval` —  $p$  value of the  $F$ -statistic
  - `rmse` — Root mean square error
  - `xr` — Residuals for predictors not in the final model, after removing the part of them explained by predictors in the model
  - `yr` — Residuals for the response using predictors in the final model
  - `B` — Coefficients for terms in final model, with values for a term not in the model set to the value that would be obtained by adding that term to the model
  - `SE` — Standard errors for coefficient estimates
  - `TSTAT` —  $t$  statistics for coefficient estimates
  - `PVAL` —  $p$ -values for coefficient estimates
  - `intercept` — Estimated intercept
  - `wasnan` — Indicates which rows in the data contained NaN values
- `nextstep` — The recommended next step—either the index of the next term to move in or out of the model, or 0 if no further steps are recommended

- **history** — Structure containing information on steps taken, with the following fields:
  - **B** — Matrix of regression coefficients, where each column is one step, and each row is one coefficient.
  - **rmse** — Root mean square errors for the model at each step.
  - **df0** — Degrees of freedom for the regression at each step.
  - **in** — Logical array indicating which predictors are in the model at each step, where each row is one step, and each column is one predictor.

[...] = `stepwisefit(X,y,param1,val1,param2,val2,...)`

specifies one or more of the name/value pairs described in the following table.

Parameter	Value
'inmodel'	A logical vector specifying terms to include in the initial fit. The default is to specify no terms.
'penter'	The maximum $p$ value for a term to be added. The default is 0.05.
'premove'	The minimum $p$ value for a term to be removed. The default is the maximum of the value of 'penter' and 0.10.
'display'	'on' displays information about each step in the command window. This is the default. 'off' omits the display.
'maxiter'	The maximum number of steps in the regression. The default is Inf.

Parameter	Value
'keep'	A logical vector specifying terms to keep in their initial state. The default is to specify no terms.
'scale'	'on' centers and scales each column of X (computes z-scores) before fitting.  'off' does not scale the terms. This is the default.

## Algorithms

*Stepwise regression* is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the  $p$  value of an  $F$ -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.
- 2 If any terms not in the model have  $p$ -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest  $p$  value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have  $p$ -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest  $p$  value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different

models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

## Examples

Load the data in `hald.mat`, which contains observations of the heat of reaction of various cement mixtures:

```
load hald
whos
```

Name	Size	Bytes	Class	Attributes
Description	22x58	2552	char	
hald	13x5	520	double	
heat	13x1	104	double	
ingredients	13x4	416	double	

The response (`heat`) depends on the quantities of the four predictors (the columns of `ingredients`).

Use `stepwisefit` to carry out the stepwise regression algorithm, beginning with no terms in the model and using entrance/exit tolerances of 0.05/0.10 on the  $p$ -values:

```
stepwisefit(ingredients,heat,...
            'penter',0.05,'premove',0.10);
Initial columns included: none
Step 1, added column 4, p=0.000576232
Step 2, added column 1, p=1.10528e-006
Final columns included: 1 4
```

'Coeff'	'Std.Err.'	'Status'	'P'
[ 1.4400]	[ 0.1384]	'In'	[1.1053e-006]
[ 0.4161]	[ 0.1856]	'Out'	[ 0.0517]
[-0.4100]	[ 0.1992]	'Out'	[ 0.0697]
[-0.6140]	[ 0.0486]	'In'	[1.8149e-007]

# stepwisefit

---

stepwisefit automatically includes an intercept term in the model, so you do not add it explicitly to ingredients as you would for regress. For terms not in the model, coefficient estimates and their standard errors are those that result by adding the corresponding term to the final model.

The inmodel parameter is used to specify terms in an initial model:

```
initialModel = ...
    [false true false false]; % Force in 2nd term
stepwisefit(ingredients,heat,...
    'inmodel',initialModel,...
    'penter',.05,'premove',0.10);
Initial columns included: 2
Step 1, added column 1, p=2.69221e-007
Final columns included: 1 2
    'Coeff'      'Std.Err.'    'Status'    'P'
    [ 1.4683]    [ 0.1213]    'In'        [2.6922e-007]
    [ 0.6623]    [ 0.0459]    'In'        [5.0290e-008]
    [ 0.2500]    [ 0.1847]    'Out'       [ 0.2089]
    [-0.2365]    [ 0.1733]    'Out'       [ 0.2054]
```

The preceding two models, built from different initial models, use different subsets of the predictive terms. Terms 2 and 4, swapped in the two models, are highly correlated:

```
term2 = ingredients(:,2);
term4 = ingredients(:,4);
R = corrcoef(term2,term4)
R =
    1.0000    -0.9730
   -0.9730    1.0000
```

To compare the models, use the stats output of stepwisefit:

```
[betahat1,se1,pval1,inmodel1,stats1] = ...
    stepwisefit(ingredients,heat,...
    'penter',.05,'premove',0.10,...
```

```
        'display','off');
[betahat2,se2,pval2,inmodel2,stats2] = ...
    stepwisefit(ingredients,heat,...
                'inmodel',initialModel,...
                'penter',.05,'premove',0.10,...
                'display','off');
```

RMSE1 = stats1.rmse  
RMSE1 =  
 2.7343  
RMSE2 = stats2.rmse  
RMSE2 =  
 2.4063

The second model has a lower Root Mean Square Error (RMSE).

# categorical.subsasgn

---

## Purpose

Subscripted assignment for categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## Syntax

`A = subsasgn(A,S,B)`

## Description

`A = subsasgn(A,S,B)` is called for the syntax `A(I) = B`, or `A.I = B` when `A` is an object. `S` is a structure array with the following fields.

<code>type</code>	String containing <code>'()'</code> , <code>'{}'</code> , or <code>','</code> specifying the subscript type.
<code>subs</code>	Cell array or string containing the actual subscripts.

## See Also

`categorical` | `subsref`

**Purpose** Subscripted reference for classregtree object

**Syntax**

**Description** Subscript assignment is not allowed for a classregtree object.

**See Also** classregtree

## Purpose

Subscripted assignment to dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Description

`A = subsasgn(A,S,B)` is called for the syntax `A(i,j)=B`, `A{i,j}=B`, or `A.var=B` when `A` is a dataset array. `S` is a structure array with the fields:

<code>type</code>	String containing <code>'()' </code> , <code>'{}' </code> , or <code>',' </code> specifying the subscript type.
<code>subs</code>	Cell array or string containing the actual subscripts.

`A(i,j) = B` assigns the contents of the dataset array `B` to a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

The assignment does not use observation names, variable names, or any other properties of `B` to modify properties of `A`; however properties of `A` are extended with default values if the assignment expands the number of observations or variables in `A`. Elements of `B` are assigned into `A` by position, not by matching names.

`A{i,j} = B` assigns the value `B` into an element of the dataset array `A`. `i` and `J` are positive integers, or logical vectors. Cell indexing cannot assign into multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `B` is cast to the type of the target variable if necessary. If the dataset element

already exists, `A{i, j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, assignments such as `A{1, 'CellVar'} = B` assign into the contents of the target dataset element in the same way that `{}`-indexing of an ordinary cell array does.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or array, an assignment such as `A{1, 'ArrayVar'} = B` assigns into the second and following dimensions of the target dataset element, i.e., the assignment adds a leading singleton dimension to `B` to account for the observation dimension of the dataset variable.

`A.var = B` or `A.(varname) = B` assigns `B` to a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. If the dataset variable already exists, the assignment completely replaces that variable. To assign into an element of the variable, `A.var` or `A.(varname)` may be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` = `B` and `A.var{obsnames, ...}` = `B` (when supported by `var`) provide assignment into a dataset variable using observation names.

`A.properties.propertyname = P` assigns to a dataset property. `propertyname` is one of the following:

- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

To assign into an element of the property, `A.properties.propertyname` may also be followed by further subscripting as supported by the property.

## dataset.subsasgn

---

You cannot assign multiple values into dataset variables or properties using assignments such as `[A.CellVar{1:2}] = B`, `[A.StructVar(1:2).field] = B`, or `[A.Properties.ObsNames{1:2}] = B`. Use multiple assignments of the form `A.CellVar{1} = B` instead.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then the contents of that variable for a single observation consists of multiple cells, and you cannot assign to all of them using the syntax `A{1, 'CellVar'} = B`. Use multiple assignments of the form `[A.CellVar{1,1}] = B` instead.

# classregtree.subsref

---

**Purpose** Subscripted reference for classregtree object

**Syntax** B = subsref(T,S)

**Description** B = subsref(T,S) is called for the syntax T(X) when T is a classregtree object. S is a structure array with the fields:

type	String containing '()', '{}', or '.' specifying the subscript type.
subs	Cell array or string containing the actual subscripts.

[...] = T(...) invokes the eval method for the tree T.

**See Also** classregtree | eval

**Purpose**

Subscripted reference for categorical array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`B = subsref(A,S)`

**Description**

`B = subsref(A,S)` is called for the syntax `A(I)`, `A{I}`, or `A.I` when `A` is an object. `S` is a structure array with the following fields.

<code>type</code>	String containing <code>'()'</code> , <code>'{'</code> , or <code>','</code> specifying the subscript type.
<code>subs</code>	Cell array or string containing the actual subscripts.

**See Also**

`categorical` | `subsasgn`

# dataset.subsref

---

## Purpose

Subscripted reference for dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

`B = subsref(A,S)`

## Description

`B = subsref(A,S)` is called for the syntax `A(i,j)`, `A{i,j}`, or `A.var` when `A` is a dataset array. `S` is a structure array with the fields:

<code>type</code>	String containing <code>'()'</code> , <code>'{}'</code> , or <code>.'</code> specifying the subscript type.
<code>subs</code>	Cell array or string containing the actual subscripts.

`B = A(i,j)` returns a dataset array that contains a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

`B` contains the same property values as `A`, subsetted for observations or variables where appropriate.

`B = A{i,j}` returns an element of a dataset variable. `i` and `j` are positive integers, or logical vectors. Cell indexing cannot return multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `A{i,j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, expressions such as `A{1, 'CellVar'}` return the contents of the referenced dataset element in the same way that `{}`-indexing on an ordinary cell array does. If the dataset variable is a single column of cells, the contents of a single cell is returned. If the dataset variable has multiple columns or is n-D, multiple outputs containing the contents of multiple cells are returned.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or an array, expressions such as `A{1, 'ArrayVar'}` return `A.ArrayVar(1, :, ...)` with the leading singleton dimension squeezed out.

`B = A.var` or `A.(varname)` returns a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. `A.var` or `A.(varname)` may also be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` and `A.var{obsnames, ...}` (when supported by `var`) provide subscripting into a dataset variable using observation names.

`P = A.Properties.propertyname` returns a dataset property. `propertyname` is one of the following:

- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

`A.properties.propertyname` may also be followed by further subscripting as supported by the property.

## Limitations

Subscripting expressions such as `A.CellVar{1:2}`, `A.StructVar(1:2).field`, or `A.Properties.ObsNames{1:2}` are valid, but result in `subsref` returning multiple outputs in the form of a comma-separated list. If you explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1,cellval2] = A.CellVar{1:2}`, those variables will receive the corresponding values. However, if there are no output arguments, only the first output in the comma-separated list is returned.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then subscripting expressions such as `A{1, 'CellVar'}` result in `subsref` returning the contents of multiple cells. You should explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1,cellval2] = A{1, 'CellVar'}`.

## See Also

`dataset` | `set` | `subsasgn`

**Purpose** Subscripted reference for Gaussian mixture distribution object

**Syntax** `B = subsref(T,S)`

**Description** `B = subsref(T,S)` is called for the syntax `T(X)` when `T` is a `gmdistribution` object. `S` is a structure array with the following fields:

<code>type</code>	String containing '()', '{}', or '.' specifying the subscript type.
<code>subs</code>	Cell array or string containing the actual subscripts.

**See Also** `gmdistribution`

# NaiveBayes.subsref

---

**Purpose** Subscripted reference for NaiveBayes object

**Syntax** `b = subsref(nb,s)`

**Description** `b = subsref(nb,s)` is called for the syntax `nb(s)` when `nb` is a NaiveBayes object. `S` is a structure array with the fields:

<code>type</code>	string containing '()', '{}', or '' specifying the subscript type.
<code>subs</code>	Cell array or string containing the actual subscripts.

**Purpose** Subscripted reference for grandset

**Syntax**  
`x = p(i,j)`  
`x = subsref(p,s)`

**Description** `x = p(i,j)` returns a matrix that contains a subset of the points from the point set `p`. The indices in `i` select points from the set and the indices in `j` select columns from those points. `i` and `j` are vector of positive integers or logical vectors. A colon used as a subscript, as in `p(i,:)`, indicates the entire row (or column).

`x = subsref(p,s)` is called for the syntax `p(i)`, `p{i}`, or `p.i`. `s` is a structure array with the fields:

`type` string containing `'()'`, `'{}'`, or `'.'` specifying the subscript type.

`subs` Cell array or string containing the actual subscripts.

## Examples

Command	Returns
<code>p = sobolset(5);</code>	The fifth point
<code>x = p(1:10,:)</code>	All columns of the first 10 points
<code>x = p(end,1)</code>	The first column of the last point
<code>x = p([1,4,5], :)</code>	Points 1, 4, and 5

**See Also** grandset

# nominal.summary

---

## Purpose

Summary statistics for nominal array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## Syntax

```
summary(A)  
C = summary(A)  
[C,labels] = summary(A)
```

## Description

`summary(A)` displays the number of elements in the nominal array `A` equal to each of the possible levels in `A`. If `A` contains any undefined elements, the output also includes the number of undefined elements.

`C = summary(A)` returns counts of the number of elements in the nominal array `A` equal to each of the possible levels in `A`. If `A` is a matrix or  $N$ -dimensional array, `C` is a matrix or array with rows corresponding to the levels of `A`. If `A` contains any undefined elements, `C` contains one more row than the number of levels of `A`, with the number of undefined elements in `c(end)` or `c(end, :)`.

`[C,labels] = summary(A)` also returns the list of categorical level labels corresponding to the counts in `C`.

## Examples

### Create and Summarize Nominal Array

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a nominal array containing the flower species data.

```
species = nominal(species);
```

Display a summary of the flower species data.

```
summary(species)
```

```
    setosa      50  
versicolor  50  
 virginica  50
```

The nominal array contains 50 elements in each level, which corresponds to measurements for 50 flowers each of the setosa, versicolor, and virginica species.

## See Also

```
islevel | ismember | levelcounts
```

# ordinal.summary

---

## Purpose

Summary statistics for ordinal array

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.

## Syntax

```
summary(A)  
C = summary(A)  
[C,labels] = summary(A)
```

## Description

`summary(A)` displays the number of elements in the ordinal array `A` equal to each of the possible levels in `A`. If `A` contains any undefined elements, the output also includes the number of undefined elements.

`C = summary(A)` returns counts of the number of elements in the ordinal array `A` equal to each of the possible levels in `A`. If `A` is a matrix or  $N$ -dimensional array, `C` is a matrix or array with rows corresponding to the levels of `A`. If `A` contains any undefined elements, `C` contains one more row than the number of levels of `A`, with the number of undefined elements in `c(end)` or `c(end,:)`.

`[C,labels] = summary(A)` also returns the list of categorical level labels corresponding to the counts in `C`.

## Examples

### Create and Summarize Ordinal Array

Load the sample data.

```
load hospital;
```

The file contains data obtained from hospital patients, including their age, gender, weight, blood pressure, and smoking status.

Create an ordinal array of the age groups represented in the data.

```
edges = 0:10:100;  
labels = strcat(num2str((0:10:90)', '%d'), {'s'});  
AgeGroup = ordinal(hospital.Age, labels, [], edges);
```

Display the number of patients in each age group.

```
summary(AgeGroup)
```

```
0s      0
10s     0
20s    15
30s    41
40s    42
50s     2
60s     0
70s     0
80s     0
90s     0
```

The results show, for example, that the data contains 15 patients of ages 20 through 29, inclusive. These patients are members of the '20s' level in the ordinal array `AgeGroup`.

## See Also

`islevel` | `ismember` | `levelcounts`

# dataset.summary

---

## Purpose

Print summary of dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
summary(A)  
s = summary(A)
```

## Description

`summary(A)` prints a summary of a dataset array and the variables that it contains.

`s = summary(A)` returns a scalar structure `s` that contains a summary of the dataset `A` and the variables that `A` contains. For more information on the fields in `s`, see [Outputs](#).

Summary information depends on the type of the variables in the data set:

- For numerical variables, `summary` computes a five-number summary of the data, giving the minimum, the first quartile, the median, the third quartile, and the maximum.
- For logical variables, `summary` counts the number of `true`s and `false`s in the data.
- For categorical variables, `summary` counts the number of data at each level.

## Output Arguments

The following list describes the fields in the structure `s`:

- `Description` — A character array containing the dataset description.
- `Variables` — A structure array with one element for each dataset variable in `A`. Each element has the following fields:
  - `Name` — A character string containing the name of the variable.
  - `Description` — A character string containing the variable's description.

- **Units** — A character string containing the variable's units.
- **Size** — A numeric vector containing the size of the variable.
- **Class** — A character string containing the class of the variable.
- **Data** — A scalar structure containing the following fields.

For numeric variables:

- **Probabilities** — A numeric vector containing the probabilities [0.0 .25 .50 .75 1.0] and NaN (if any are present in the corresponding dataset variable).
- **Quantiles** — A numeric vector containing the values that correspond to 'Probabilities' for the corresponding dataset variable, and a count of NaNs (if any are present).

For logical variables:

- **Values** — The logical vector [true false].
- **Counts** — A numeric vector of counts for each logical value.

For categorical variables:

- **Levels** — A cell array containing the labels for each level of the corresponding dataset variable.
- **Counts** — A numeric vector of counts for each level.

'Data' is empty if variable is not numeric, categorical, or logical. If a dataset variable has more than one column, then the corresponding 'Quantiles' or 'Counts' field is a matrix or an array.

## Examples

Summarize Fisher's iris data:

```
load fisheriris
species = nominal(species);
data = dataset(species,meas);
summary(data)
```

# dataset.summary

---

```
species: [150x1 nominal]
  setosa  versicolor  virginica
      50      50      50
meas: [150x4 double]
  min      4.3000      2      1      0.1000
  1st Q    5.1000    2.8000    1.6000    0.3000
  median   5.8000      3    4.3500    1.3000
  3rd Q    6.4000    3.3000    5.1000    1.8000
  max      7.9000    4.4000    6.9000    2.5000
```

---

Summarize the data in hospital.mat:

```
load hospital
summary(hospital)
```

Dataset array created from the data file hospital.dat.

The first column of the file ("id") is used for observation names. Other columns ("sex" and "smoke") have been converted from their original coded values into categorical and logical variables. Two sets of columns ("sys" and "dia", "trial1" through "trial4") have been combined into single variables with multivariate observations. Column headers have been replaced with more descriptive variable names. Units have been added where appropriate.

```
LastName: [100x1 cell string]
```

```
Sex: [100x1 nominal]
  Female  Male
      53   47
```

```
Age: [100x1 double, Units = Yrs]
```

```
  min      1st Q      median      3rd Q      max
   25        32        39        44       50
```

```
Weight: [100x1 double, Units = Lbs]
  min      1st Q      median      3rd Q      max
  111      130.5000   142.5000   180.5000   202
```

```
Smoker: [100x1 logical]
  true      false
  34        66
```

```
BloodPressure: [100x2 double, Units = mm Hg]
Systolic/Diastolic
  min          109          68
  1st Q        117.5000     77.5000
  median        122          81.5000
  3rd Q        127.5000     89
  max          138          99
```

```
Trials: [100x1 cell, Units = Counts]
From zero to four measurement trials performed
```

# ProbDist.Support property

---

**Purpose** Read-only structure containing information about support of ProbDist object

**Description** Support is a read-only property of the ProbDist class. Support is a structure containing information about the support of a ProbDist object. It includes the following fields:

- range
- closedbound
- iscontinuous

**Values** The values for the three fields in the structure are:

- range — A two-element vector [L, U], such that all of the probability is contained from L to U.
- closedbound — A two-element logical vector indicating whether the corresponding range endpoint is included. Possible values for each endpoint are 1 (true) or 0 (false).
- iscontinuous — A logical value indicates if the distribution takes values on the entire interval from L to U (true), or if it takes only integer values within this range (false). Possible values are 1 (true) or 0 (false).

Use this information to view and compare information about the support of distributions.

## Purpose

Convert structure array to dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
ds = struct2dataset(S)  
ds = struct2dataset(S,Name,Value)
```

## Description

`ds = struct2dataset(S)` converts a structure array to a dataset array.

`ds = struct2dataset(S,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

## Input Arguments

### S - Input structure array

structure array

Input structure array to convert to a dataset array, specified as a scalar structure array with  $N$  fields, each with  $M$  rows, or a nonscalar  $M$ -by-1 structure array with  $N$  fields.

### Data Types

struct

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'ReadObsNames','myField'` specifies that the structure field, `myField`, contains observation names.

### 'ReadObsNames' - Name of structure field containing observation names for dataset array

false (default) | string

# struct2dataset

---

Name of structure field containing observation names for the output dataset array, specified as the comma-separated pair consisting of 'ReadObsNames' and a string containing a field name from the input structure array, **S**. When you specify a field name, `struct2dataset` uses that field to create observation names, and sets `ds.Properties.DimNames` equal to `{ReadObsNames, 'Variables'}`.

For example, to specify that observation names are in the structure field, `Names`, use

**Example:** `'ReadObsNames', 'Names'`

By default, or if `ReadObsNames` is equal to `false`, `struct2dataset` does not create observation names unless you specify names using the name-value pair argument `ObsNames`.

## 'ObsNames' - Observation names for dataset array

cell array of strings

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a cell array of strings containing observation names. The names do not need to be valid MATLAB identifiers, but they must be unique.

## 'AsScalar' - Indicator for how to treat scalar structure

false | true

Indicator for how to treat a scalar input structure array, specified as the comma-separated pair consisting of 'AsScalar' and either `true` or `false`. The default value is `true` if **S** is a scalar structure array, and `false` otherwise.

By default, `struct2dataset` converts a scalar structure array with  $N$  fields, each with  $M$  rows, into an  $M$ -by- $N$  dataset array.

If instead you set `AsScalar` equal to `false` for a scalar input structure array, then `struct2dataset` converts **S** to a dataset array with  $N$  observations.

## Output Arguments

### **ds** - Output dataset array

dataset array

Output dataset array, returned by default with  $M$  observations and  $N$  variables.

- If **S** is a scalar structure array with  $N$  fields, each with  $M$  rows, then **ds** is an  $M$ -by- $N$  dataset array.
- If **S** is a nonscalar  $M$ -by-1 structure array with  $N$  fields, then **ds** is an  $M$ -by- $N$  dataset array.
- If **S** is a scalar structure array with  $N$  fields, each with  $M$  rows, and **AsScalar** is set equal to **false**, then **ds** is a dataset array with  $N$  observations.

## Examples

### **Convert Scalar Structure Array to Dataset Array**

Convert a scalar structure array to a dataset array using the default options.

Create a structure array to convert.

```
S.Name = {'CLARK'; 'BROWN'; 'MARTIN'};
S.Gender = {'M'; 'F'; 'M'};
S.SystolicBP = [124; 122; 130];
S.DiastolicBP = [93; 80; 92];
S
```

```
S =
```

```
      Name: {3x1 cell}
      Gender: {3x1 cell}
  SystolicBP: [3x1 double]
  DiastolicBP: [3x1 double]
```

The scalar structure array has four fields, each with three rows.

Convert the structure array to a dataset array.

```
ds = struct2dataset(S)
```

# struct2dataset

---

```
ds =  
  
      Name          Gender    SystolicBP    DiastolicBP  
      'CLARK'       'M'          124          93  
      'BROWN'       'F'          122          80  
      'MARTIN'      'M'          130          92
```

The structure field names in **S** become the variable names in the output dataset array. The size of **ds** is 3-by-4.

## Convert Nonscalar Structure Array to Dataset Array

Convert a nonscalar structure array to a dataset array, using one of the structure fields for observation names.

Create a nonscalar structure array to convert.

```
S(1,1).Name = 'CLARK';  
S(1,1).Gender = 'M';  
S(1,1).SystolicBP = 124;  
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';  
S(2,1).Gender = 'F';  
S(2,1).SystolicBP = 122;  
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';  
S(3,1).Gender = 'M';  
S(3,1).SystolicBP = 130;  
S(3,1).DiastolicBP = 92;
```

```
S
```

```
S =
```

```
3x1 struct array with fields:  
      Name
```

```
Gender
SystolicBP
DiastolicBP
```

This is a 3-by-1 structure array with 4 fields.

Convert the structure array to a dataset array, using the Name field for observation names.

```
ds = struct2dataset(S, 'ReadObsNames', 'Name')
```

```
ds =
```

	Gender	SystolicBP	DiastolicBP
CLARK	'M'	124	93
BROWN	'F'	122	80
MARTIN	'M'	130	92

The size of `ds` is 3-by-3 because the structure field `Name` is used for observation names, and not as a dataset array variable.

```
ds.Properties.DimNames
```

```
ans =
```

```
    'Name'    'Variables'
```

```
ds.Properties.ObsNames
```

```
ans =
```

```
    'CLARK'
    'BROWN'
    'MARTIN'
```

## **Related Examples**

- “Create a Dataset Array from Workspace Variables” on page 2-66
- “Create a Dataset Array from a File” on page 2-73

## **Concepts**

- “Dataset Arrays” on page 2-137

**Purpose**

Interactive contour plot

**Syntax**

```
surfht(Z)  
surfht(x,y,Z)
```

**Description**

`surfht(Z)` is an interactive contour plot of the matrix  $Z$  treating the values in  $Z$  as height above the plane. The  $x$ -values are the column indices of  $Z$  while the  $y$ -values are the row indices of  $Z$ .

`surfht(x,y,Z)` where  $x$  and  $y$  are vectors specify the  $x$  and  $y$ -axes on the contour plot. The length of  $x$  must match the number of columns in  $Z$ , and the length of  $y$  must match the number of rows in  $Z$ .

There are vertical and horizontal reference lines on the plot whose intersection defines the current  $x$  value and  $y$  value. You can drag these dotted white reference lines and watch the interpolated  $z$  value (at the top of the plot) update simultaneously. Alternatively, you can get a specific interpolated  $z$  value by typing the  $x$  value and  $y$  value into editable text fields on the  $x$ -axis and  $y$ -axis respectively.

# classregtree.surrcutcategories

---

**Purpose** Categories used for surrogate splits in decision tree

**Syntax** `C = surrcutcategories(T)`  
`C = surrcutcategories(T,J)`

**Description** `C = surrcutcategories(T)` returns an  $n$ -element cell array `C` of the categories used for surrogate splits in the decision tree `T`, where  $n$  is the number of nodes in the tree. For each node `K`, `C{K}` is a cell array. The length of `C{K}` is equal to the number of surrogate predictors found at this node. Every element of `C{K}` is either an empty string for a continuous surrogate predictor or a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables returned by `surrcutvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, `C` contains an empty cell.

`C = surrcutcategories(T,J)` takes an array `J` of node numbers and returns the categories for the specified nodes.

**See Also** `classregtree` | `surrcutvar` | `cutcategories` | `surrcuttype` | `surrcutpoint`

**Purpose** Numeric cutpoint assignments used for surrogate splits in decision tree

**Syntax**  
`V = surrcutflip(T)`  
`V = surrcutflip(T,J)`

**Description** `V = surrcutflip(T)` returns an  $n$ -element cell array  $V$  of the numeric cut assignments used for surrogate splits in the decision tree  $T$ , where  $n$  is the number of nodes in the tree. For each node  $K$ ,  $V\{K\}$  is a numeric vector. The length of  $V\{K\}$  is equal to the number of surrogate predictors found at this node. Every element of  $V\{K\}$  is either zero for a categorical surrogate predictor or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either  $-1$  or  $+1$ . For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z \geq C$  and the cut assignment for this surrogate split is  $-1$ . Similarly, the right child is chosen if  $Z \geq C$  and the cut assignment for this surrogate split is  $+1$ , or if  $Z < C$  and the cut assignment for this surrogate split is  $-1$ . The order of the surrogate split variables at each node is matched to the order of variables returned by `surrcutvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes,  $V$  contains an empty array.

`V = surrcutflip(T,J)` takes an array  $J$  of node numbers and returns the cutpoint assignments for the specified nodes.

**See Also** `classregtree` | `surrcutvar` | `surrcutcategories` | `surrcuttype` | `surrcutpoint` | `cutpoint`

# classregtree.surrcutpoint

---

**Purpose** Cutpoints used for surrogate splits in decision tree

**Syntax**  
`V = surrcutpoint(T)`  
`V = surrcutpoint(T,J)`

**Description** `V = surrcutpoint(T)` returns an  $n$ -element cell array  $V$  of the numeric values used for surrogate splits in the decision tree  $T$ , where  $n$  is the number of nodes in the tree. For each node  $K$ ,  $V\{K\}$  is a numeric vector. The length of  $V\{K\}$  is equal to the number of surrogate predictors found at this node. Every element of  $V\{K\}$  is either either `NaN` for a categorical surrogate predictor or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut  $C$  based on a continuous predictor variable  $Z$ , the left child is chosen if  $Z < C$  and `surrcutflip` for this surrogate split is `-1`. Similarly, the right child is chosen if  $Z \geq C$  and `surrcutflip` for this surrogate split is `+1`, or if  $Z < C$  and `surrcutflip` for this surrogate split is `-1`. The order of the surrogate split variables at each node is matched to the order of variables returned by `surrcutvar`. The optimal-split variable at this node is not included. For non-branch (leaf) nodes,  $V$  contains an empty cell.

`V = surrcutpoint(T,J)` takes an array  $J$  of node numbers and returns the cutpoint assignments for the specified nodes.

<b>Purpose</b>	Types of surrogate splits used at branches in decision tree
<b>Syntax</b>	<code>C = surrcuttype(T)</code> <code>C = surrcuttype(T,J)</code>
<b>Description</b>	<p><code>C = surrcuttype(T)</code> returns an <math>n</math>-element cell array <code>C</code> indicating types of surrogate splits at each node in the tree <code>T</code>, where <math>n</math> is the number of nodes in the tree. For each node <code>K</code>, <code>C{K}</code> is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables returned by <code>surrcutvar</code>. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, <code>C</code> contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form <math>Z &lt; V</math> for a variable <code>Z</code> and cutpoint <code>V</code> or 'categorical' if the cut is defined by whether <code>Z</code> takes a value in a set of categories.</p> <p><code>C = surrcuttype(T,J)</code> takes an array <code>J</code> of node numbers and returns the cut types for the specified nodes.</p>
<b>See Also</b>	<code>classregtree</code>   <code>numnodes</code>   <code>cuttype</code>   <code>surrcutvar</code>

# classregtree.surrcutvar

---

**Purpose** Variables used for surrogate splits in decision tree

**Syntax**  
`V = surrcutvar(T)`  
`V = surrcutvar(T,J)`  
`[V,NUM] = surrcutvar(...)`

**Description** `V = surrcutvar(T)` returns an  $n$ -element cell array `V` of the names of the variables used for surrogate splits in each node of the tree `T`, where  $n$  is the number of nodes in the tree. Every element of `V` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, `V` contains an empty cell.

`V = surrcutvar(T,J)` takes an array `J` of node numbers and returns the cut types for the specified nodes.

`[V,NUM] = surrcutvar(...)` also returns a cell array `NUM` with indices for each variable.

**See Also** `classregtree` | `numnodes` | `children` | `cutvar`

<b>Purpose</b>	Predictive measure of association for surrogate splits in decision tree
<b>Syntax</b>	<code>A = surrvarassoc(T)</code> <code>A = surrvarassoc(T,J)</code>
<b>Description</b>	<p><code>A = surrvarassoc(T)</code> returns an <math>n</math>-element cell array <math>A</math> of the predictive measures of association for surrogate splits in the decision tree <math>T</math>, where <math>n</math> is the number of nodes in the tree. For each node <math>K</math>, <math>A\{K\}</math> is a numeric vector. The length of <math>A\{K\}</math> is equal to the number of surrogate predictors found at this node. Every element of <math>A\{K\}</math> gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables returned by <code>surrvar</code>. The optimal-split variable at this node is not included. For non-branch (leaf) nodes, <math>V</math> contains an empty cell.</p> <p><code>A = surrvarassoc(T,J)</code> takes an array <math>J</math> of node numbers and returns the predictive measure of association for the specified nodes.</p>

# svmclassify

---

<b>Purpose</b>	Classify using support vector machine (SVM)
<b>Syntax</b>	<pre>Group = svmclassify(SVMStruct,Sample) Group = svmclassify(SVMStruct,Sample,'Showplot',true)</pre>
<b>Description</b>	<p>Group = svmclassify(SVMStruct,Sample) classifies each row of the data in Sample, a matrix of data, using the information in a support vector machine classifier structure SVMStruct, created using the svmtrain function. Like the training data used to create SVMStruct, Sample is a matrix where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. Therefore, Sample must have the same number of columns as the training data. This is because the number of columns defines the number of features. Group indicates the group to which each row of Sample has been assigned.</p> <p>Group = svmclassify(SVMStruct,Sample,'Showplot',true) plots the Sample data in the figure created using the Showplot property with the svmtrain function. This plot appears only when the data is two-dimensional.</p>
<b>Input Arguments</b>	<p><b>SVMStruct</b></p> <p>Support vector machine classifier structure created using the svmtrain function.</p> <p><b>Sample</b></p> <p>A matrix where each row corresponds to an observation or replicate, and each column corresponds to a feature or variable. Therefore, Sample must have the same number of columns as the training data. This is because the number of columns defines the dimensionality of the data space.</p> <p><b>Showplot</b></p>

Describes whether to display a plot of the classification. Displays only for 2-D problems. Follow with a Boolean argument: `true` to display the plot, `false` to give no display.

## Output Arguments

### Group

Column vector with the same number of rows as `Sample`. Each entry (row) in `Group` represents the class of the corresponding row of `Sample`.

## Examples

### Classify an Observation Using a Trained SVM Classifier.

Find a line separating the Fisher iris data on `versicolor` and `virginica` species, according to the petal length and petal width measurements. These two species are in rows 51 and higher of the data set, and the petal length and width are the third and fourth columns.

```
load fisheriris
xdata = meas(51:end,3:4);
group = species(51:end);
svmStruct = svmtrain(xdata,group,'ShowPlot',true);
```

# svmclassify

Classify a new flower with petal length 5 and petal width 2, and circle the new point:

```
species = svmclassify(svmStruct,[5 2],'ShowPlot',true)
hold on;
plot(5,2,'ro','MarkerSize',12);
hold off
```

```
species =
```

**Algorithms**

The svmclassify function uses results from svmtrain to classify vectors  $x$  according to the following equation:

$$c = \sum_i \alpha_i k(s_i, x) + b,$$

where  $s_i$  are the support vectors,  $a_i$  are the weights,  $b$  is the bias, and  $k$  is a kernel function. In the case of a linear kernel,  $k$  is the dot product. If  $c \geq 0$ , then  $x$  is classified as a member of the first group, otherwise it is classified as a member of the second group.

Each element of <code>Group</code> specifies the group of the corresponding row of <code>Training</code>. <code>Group</code> should divide <code>Training</code> into two groups. <code>Group</code> has the same number of elements as there are rows in <code>Training</code>. <code>svmtrain</code> treats each NaN, empty string, or 'undefined' in <code>Group</code> as a missing value, and ignores the corresponding row of <code>Training</code>.</p> <p><b>Name-Value Pair Arguments</b></p> <p>Specify optional comma-separated pairs of <code>Name,Value</code> arguments. <code>Name</code> is the argument name and <code>Value</code> is the corresponding value. <code>Name</code> must appear inside single quotes ( ' '). You can</p>

specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

## **'autoscale'**

Boolean specifying whether svmtrain automatically centers the data points at their mean, and scales them to have unit standard deviation, before training.

**Default:** true

## **'boxconstraint'**

Value of the box constraint  $C$  for the soft margin.  $C$  can be a scalar, or a vector of the same length as the training data.

If  $C$  is a scalar, it is automatically rescaled by  $N / (2 * N1)$  for the data points of group one and by  $N / (2 * N2)$  for the data points of group two, where  $N1$  is the number of elements in group one,  $N2$  is the number of elements in group two, and  $N = N1 + N2$ . This rescaling is done to take into account unbalanced groups, that is cases where  $N1$  and  $N2$  have very different values.

If  $C$  is an array, then each array element is taken as a box constraint for the data point with the same index.

**Default:** 1

## **'kernelcachelimit'**

Value that specifies the size of the kernel matrix cache for the SMO training method. The algorithm keeps a matrix with up to  $\text{kernelcachelimit} \times \text{kernelcachelimit}$  double-precision, floating-point numbers in memory.

**Default:** 5000

## **'kernel\_function'**

Kernel function `svmtrain` uses to map the training data into kernel space. The default kernel function is the dot product. The kernel function can be one of the following strings or a function handle:

- `'linear'` — Linear kernel, meaning dot product.
- `'quadratic'` — Quadratic kernel.
- `'polynomial'` — Polynomial kernel (default order 3). Specify another order with the `polyorder` name-value pair.
- `'rbf'` — Gaussian Radial Basis Function kernel with a default scaling factor, `sigma`, of 1. Specify another value for `sigma` with the `rbf_sigma` name-value pair.
- `'mlp'` — Multilayer Perceptron kernel with default scale `[1 1]`. Specify another scale with the `mlp_params` name-value pair.
- `@kfun` — Function handle to a kernel function. A kernel function must be of the form

```
function K = kfun(U, V)
```

The returned value, `K`, is a matrix of size `M-by-N`, where `U` and `V` have `M` and `N` rows respectively.

If `kfun` has extra parameters, include the extra parameters via an anonymous function. For example, suppose that your kernel function is:

```
function k = kfun(u,v,p1,p2)
k = tanh(p1*(u*v')+p2);
```

Set values for `p1` and `p2`, and then use an anonymous function:

```
@(u,v) kfun(u,v,p1,p2)
```

**Default:** `'linear'`

**'kktviolationlevel'**

Value that specifies the fraction of variables allowed to violate the Karush-Kuhn-Tucker (KKT) conditions for the SMO training method. Set any value in  $[0, 1)$ . For example, if you set `kktviolationlevel` to 0.05, then 5% of the variables are allowed to violate the KKT conditions.

---

**Tip** Set this option to a positive value to help the algorithm converge if it is fluctuating near a good solution.

---

For more information on KKT conditions, see Cristianini and Shawe-Taylor [4].

**Default:** 0

### 'method'

Method used to find the separating hyperplane. Options are:

- 'QP' — Quadratic programming (requires an Optimization Toolbox license). The classifier is a 2-norm soft-margin support vector machine. Give quadratic programming options with the `options` name-value pair, and create options with `optimset`.
- 'SMO' — Sequential Minimal Optimization. Give SMO options with the `options` name-value pair, and create options with `statset`.
- 'LS' — Least squares.

**Default:** SMO

### 'mlp\_params'

Parameters of the Multilayer Perceptron (mlp) kernel. The `mlp` kernel requires two parameters,  $[P1 \ P2]$ . The kernel  $K = \tanh(P1*U*V' + P2)$ , where  $P1 > 0$  and  $P2 < 0$ .

**Default:** [1 -1]

**'options'**

Options structure for training.

- When you set 'method' to 'SMO' (default), create the options structure using `statset`. Options are:

Display	String that specifies the level of information about the optimization iterations that is displayed as the algorithm runs. Choices are: <ul style="list-style-type: none"><li>▪ <code>off</code> (default) — Reports nothing.</li><li>▪ <code>iter</code> — Reports every 500 iterations.</li><li>▪ <code>final</code> — Reports only when the algorithm finishes.</li></ul>
MaxIter	Integer that specifies the maximum number of iterations of the main loop. If this limit is exceeded before the algorithm converges, then the algorithm stops and returns an error. Default is 15000.

The other name-value pairs that relate specifically to the 'SMO' method are `kernelcachelimit`, `kktviolationlevel`, and `tolkkt`.

- When you set `method` to 'QP', create the options structure using `optimset`. For details of applicable option choices, see `quadprog` options. SVM uses a convex quadratic program, so you can choose the 'interior-point-convex' `quadprog` algorithm. In limited testing, the 'interior-point-convex' algorithm was the best `quadprog` option for `svmtrain`, in both speed and memory utilization.

**'polyorder'**

Order of the polynomial kernel.

Default: 3

**'rbf\_sigma'**

Scaling factor (sigma) in the radial basis function kernel.

**Default:** 1

### **'showplot'**

Boolean indicating whether to plot the grouped data and separating line. Creates a plot only when the data has two columns (features).

**Default:** false

### **'tolkkt'**

Value that specifies the tolerance with which the Karush-Kuhn-Tucker (KKT) conditions are checked for the SMO training method. For a definition of KKT conditions, see “Karush-Kuhn-Tucker (KKT) Conditions” on page 21-3863.

**Default:** 1e-3

## **Output Arguments**

### **SVMStruct**

Structure containing information about the trained SVM classifier in the following fields:

- **SupportVectors** — Matrix of data points with each row corresponding to a support vector in the normalized data space. This matrix is a subset of the *Training* input data matrix, after normalization has been applied according to the 'AutoScale' argument.
- **Alpha** — Vector of weights for the support vectors. The sign of the weight is positive for support vectors belonging to the first group, and negative for the second group.
- **Bias** — Intercept of the hyperplane that separates the two groups in the normalized data space (according to the 'AutoScale' argument).
- **KernelFunction** — Handle to the function that maps the training data into kernel space.

- **KernelFunctionArgs** — Cell array of any additional arguments required by the kernel function.
- **GroupNames** — Categorical, numeric, or logical vector, a cell vector of strings, or a character matrix with each row representing a class label. Specifies the group identifiers for the support vectors. It has the same number of elements as there are rows in **SupportVectors**. Each element specifies the group to which the corresponding row in **SupportVectors** belongs.
- **SupportVectorIndices** — Vector of indices that specify the rows in **Training**, the training data, that were selected as support vectors after the data was normalized, according to the **AutoScale** argument.
- **ScaleData** — Field containing normalization factors. When 'AutoScale' is set to **false**, it is empty. When **AutoScale** is set to **true**, it is a structure containing two fields:
  - **shift** — Row vector of values. Each value is the negative of the mean across an observation in *Training*, the training data.
  - **scaleFactor** — Row vector of values. Each value is 1 divided by the standard deviation of an observation in *Training*, the training data.

Both **svmtrain** and **svmclassify** apply the scaling in **ScaleData**.
- **FigureHandles** — Vector of figure handles created by **svmtrain** when using the 'Showplot' argument.

## Definitions

### Karush-Kuhn-Tucker (KKT) Conditions

The Karush-Kuhn-Tucker (KKT) conditions are analogous to the condition that the gradient must be zero at a minimum, modified to take constraints into account. The difference is that the KKT conditions hold for constrained problems. The KKT conditions use the auxiliary Lagrangian function:

$$L(x, \lambda) = f(x) + \sum \lambda_{g,i} g_i(x) + \sum \lambda_{h,i} h_i(x).$$

Here  $f(x)$  is the objective function,  $g(x)$  is a vector of constraint functions  $g(x) \leq 0$ , and  $h(x)$  is a vector of constraint functions  $h(x) = 0$ . The vector  $\lambda$ , which is the concatenation of  $\lambda_g$  and  $\lambda_h$ , is the Lagrange multiplier vector. Its length is the total number of constraints.

The KKT conditions are:

$$\begin{aligned}\nabla_x L(x, \lambda) &= 0 \\ \lambda_{g,i} g_i(x) &= 0 \quad \forall i \\ g(x) &\leq 0 \\ h(x) &= 0 \\ \lambda_{g,i} &\geq 0.\end{aligned}$$

For more information, see Karush-Kuhn-Tucker conditions.

## Examples

### Train an SVM Classifier

Find a line separating the Fisher iris data on versicolor and virginica species, according to the petal length and petal width measurements. These two species are in rows 51 and higher of the data set, and the petal length and width are the third and fourth columns.

```
load fisheriris
xdata = meas(51:end,3:4);
group = species(51:end);
svmStruct = svmtrain(xdata,group,'ShowPlot',true);
```

## Algorithms

The `svmtrain` function uses an optimization method to identify support vectors  $s_i$ , weights  $a_i$ , and bias  $b$  that are used to classify vectors  $x$  according to the following equation:

$$c = \sum_i \alpha_i k(s_i, x) + b,$$

where  $k$  is a kernel function. In the case of a linear kernel,  $k$  is the dot product. If  $c \geq 0$ , then  $x$  is classified as a member of the first group, otherwise it is classified as a member of the second group.

## Memory Usage and Out of Memory Error

When you set 'Method' to 'QP', the svmtrain function operates on a data set containing  $N$  elements, and it creates an  $(N+1)$ -by- $(N+1)$  matrix to find the separating hyperplane. This matrix needs at least  $8 * (n+1)^2$  bytes of contiguous memory. If this size of contiguous memory is not available, the software displays an “out of memory” error message.

When you set 'Method' to 'SMO' (default), memory consumption is controlled by the kernelcachelimit option. The SMO algorithm stores only a submatrix of the kernel matrix, limited by the size specified by the kernelcachelimit option. However, if the number of data points exceeds the size specified by the kernelcachelimit option, the SMO algorithm slows down because it has to recalculate the kernel matrix elements.

When using svmtrain on large data sets, and you run out of memory or the optimization step is very time consuming, try either of the following:

- Use a smaller number of samples and use cross-validation to test the performance of the classifier.
- Set 'Method' to 'SMO', and set the kernelcachelimit option as large as your system permits.

# table2dataset

---

**Purpose** Convert table to dataset array

The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax** `ds = table2dataset(t)`

**Description** `ds = table2dataset(t)` converts a table to a dataset array.

**Input Arguments** **t - Input table**  
`table`

Input table to convert to a dataset array, specified as a table. Each variable in `t` becomes a variable in the output dataset array `ds`.

**Example:**

**Data Types**  
`table`

**Output Arguments** **ds - Output dataset array**  
`dataset array`

Output dataset array, returned as a dataset array containing the variables from the input table `t`.

**Examples** **Convert a Table to a Dataset Array**

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a table containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);  
Protein = Protein(1:5);  
Fat = Fat(1:5);
```

```
Name = Name(1:5);
```

```
cereal = table(Calories,Protein,Fat,'RowNames',Name)
```

```
cereal =
```

	Calories	Protein	Fat
	-----	-----	---
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Convert the table to a dataset array.

```
ds = table2dataset(cereal)
```

```
ds =
```

	Calories	Protein	Fat
100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

# tabulate

---

**Purpose** Frequency table

**Syntax** TABLE = tabulate(x)  
tabulate(x)

**Description** TABLE = tabulate(x) creates a frequency table of data in vector x. Information in TABLE is arranged as follows:

- 1st column — The unique values of x
- 2nd column — The number of instances of each value
- 3rd column — The percentage of each value

If x is a numeric array, TABLE is a numeric matrix. If the elements of x are nonnegative integers, TABLE includes 0 counts for integers between 1 and max(x) that do not appear in x.

If x is a categorical variable, character array, or cell array of strings, TABLE is a cell array.

tabulate(x) with no output arguments displays the table in the command window.

**Examples**

```
tabulate([1 2 4 4 3 4])
Value Count Percent
1         1    16.67%
2         1    16.67%
3         1    16.67%
4         3    50.00%
```

Quantitative

## See Also

[tblwrite](#) | [tdfread](#) | [caseread](#)

**Purpose** Write tabular data to file

**Syntax**

```
tblwrite(data,varnames,casenames)
tblwrite(data,varnames,casenames,filename)
tblwrite(data,varnames,casenames,filename,delimiter)
```

**Description** `tblwrite(data,varnames,casenames)` displays the **File Open** dialog box for interactive specification of the tabular data output file. The file format has variable names in the first row, case names in the first column and data starting in the (2,2) position.

`varnames` is a string matrix containing the variable names. `casenames` is a string matrix containing the names of each case in the first column. `data` is a numeric matrix with a value for each variable-case pair.

`tblwrite(data,varnames,casenames,filename)` specifies a file in the current folder, or the complete path name of any file in the string `filename`.

`tblwrite(data,varnames,casenames,filename,delimiter)` writes to the file using `delimiter` as the delimiting character. The following table lists the accepted character values for `delimiter` and their equivalent string values.

Character	String
' '	'space'
'\t'	'tab'
','	'comma'
';'	'semi'
' '	'bar'

The default value of `delimiter` is 'space'.

**Examples** Continuing the example from `tblread`:

```
tblwrite(data,varnames,casenames,'sattest.dat')
```

# tblwrite

---

```
type sattetst.dat
      Male Female
Verbal    470  530
Quantitative 520  480
```

## See Also

`casewrite` | `tblread`

**Purpose** Student's  $t$  cumulative distribution function

**Syntax**  
`p = tcdf(x,v)`  
`p = tcdf(x,v,'upper')`

**Description** `p = tcdf(x,v)` returns Student's  $t$  cdf at each value in  $x$  using the corresponding degrees of freedom in  $v$ .  $x$  and  $v$  can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

`p = tcdf(x,v,'upper')` returns the complement of the Student's  $t$  cdf at each value in  $x$ , using an algorithm that more accurately computes the extreme upper tail probabilities.

The  $t$  cdf is

$$p = F(x|v) = \int_{-\infty}^x \frac{\Gamma\left(\frac{v+1}{2}\right)}{\Gamma\left(\frac{v}{2}\right)} \frac{1}{\sqrt{v\pi}} \frac{1}{\left(1 + \frac{t^2}{v}\right)^{\frac{v+1}{2}}} dt$$

The result,  $p$ , is the probability that a single observation from the  $t$  distribution with  $v$  degrees of freedom will fall in the interval  $[-\infty, x)$ .

## Examples **Compute Student's $t$ cdf**

```
mu = 1;      % Population mean
sigma = 2;   % Population standard deviation
n = 100;     % Sample size
x = normrnd(mu,sigma,n,1); % Random sample from population
xbar = mean(x); % Sample mean
s = std(x);  % Sample standard deviation

t =
    0.2489
```

```
p = 1-tcdf(t,n-1) % Probability of larger t-statistic
```

```
p =  
    0.4020
```

This probability is the same as the  $p$  value returned by a  $t$ -test of the null hypothesis that the sample comes from a normal population with mean  $\mu$ .

```
[h,ptest] = ttest(x,mu,0.05,'right')
```

```
h =  
    0  
ptest =  
    0.4020
```

## See Also

## How To

- “Student’s  $t$  Distribution” on page B-137

**Purpose** Read tab-delimited file

**Syntax**

```
tdfread
tdfread(filename)
tdfread(filename,delimiter)
s = tdfread(filename,...)
```

**Description** tdfread displays the **File Open** dialog box for interactive selection of a data file, then reads data from the file. The file should have variable names separated by tabs in the first row, and data values separated by tabs in the remaining rows. tdfread creates variables in the workspace, one for each column of the file. The variable names are taken from the first row of the file. If a column of the file contains only numeric data in the second and following rows, tdfread creates a double variable. Otherwise, tdfread creates a char variable. After all values are imported, tdfread displays information about the imported values using the format of the tdfread command.

tdfread(*filename*) allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the string *filename*.

tdfread(*filename,delimiter*) indicates that the character specified by *delimiter* separates columns in the file. Accepted values for *delimiter* are:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default delimiter is 'tab'.

s = tdfread(*filename,...*) returns a scalar structure s whose fields each contain a variable.

# tdfread

---

## Examples

The following displays the contents of the file `sat2.dat`:

```
type sat2.dat

Test,Gender,Score
Verbal,Male,470
Verbal,Female,530
Quantitative,Male,520
Quantitative,Female,480
```

The following creates the variables `Gender`, `Score`, and `Test` from the file `sat2.dat` and displays the contents of the MATLAB workspace:

```
tdfread('sat2.dat',' ',' ')

Name      Size      Bytes      Class      Attributes
Gender    4x6        48         char
Score     4x1        32         double
Test      4x12       96         char
```

# ClassificationDiscriminant.template

---

**Purpose** Discriminant analysis classifier template for ensemble (to be removed)

**Compatibility** ClassificationDiscriminant.template will be removed in a future release. Use templateDiscriminant instead.

**Syntax**

```
t = ClassificationDiscriminant.template()  
t = ClassificationDiscriminant.template(Name,Value)
```

**Description**

t = ClassificationDiscriminant.template() returns a learner template suitable to use in the fitensemble function.

t = ClassificationDiscriminant.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'Delta' - Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of obj has magnitude smaller than Delta, obj sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set Delta to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

### Data Types

single | double

### 'DiscrimType' - Discriminant type

# ClassificationDiscriminant.template

---

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic'  
| 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

**Example:** 'DiscrimType', 'quadratic'

## 'FillCoeffs' - Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and either 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

**Example:** 'FillCoeffs', 'off'

## 'Gamma' - Regularization parameter

scalar value in the range [0,1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0,1].

- Linear discriminant — Scalar value in the range [0,1].

- If you pass a value strictly between 0 and 1, `fitcdiscr` sets the discriminant type to `'Linear'`.
- If you pass 0 for `Gamma` and `'Linear'` for `DiscrimType`, and if the correlation matrix is singular, `fitcdiscr` sets `Gamma` to the minimal value required for inverting the covariance matrix.
- If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to `'DiagLinear'`.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for `Gamma` and `'Quadratic'` for `DiscrimType`, and if one of the classes has a singular covariance matrix, `fitcdiscr` errors.
  - If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to `'DiagQuadratic'`.
  - If you set `Gamma` to a value between 0 and 1 for a quadratic discriminant, `fitcdiscr` errors.

**Example:** `'Gamma', 1`

## Data Types

`single` | `double`

## 'SaveMemory' - Flag to save covariance matrix

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

# ClassificationDiscriminant.template

---

Example: 'SaveMemory', 'on'

## Output Arguments

### **t** - Discriminant analysis classification template

classification template object

Discriminant analysis classification template suitable to use in the `fitensemble` function, returned as a classification template object. In an ensemble, `t` specifies how to create the discriminant analysis classifier.

## Examples

### **Discriminant Analysis Template for Nondefault Options**

Create a nondefault discriminant analysis template for use in `fitensemble`.

Create a template for pseudolinear discriminant analysis.

```
t = ClassificationDiscriminant.template('discrimType','pseudoLinear')
```

```
t =
```

```
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'  
Gamma: []  
Delta: []  
FillCoeffs: []  
SaveMemory: []  
Method: 'Discriminant'  
Type: 'classification'
```

You can use `t` for ensemble learning.

## See Also

`ClassificationDiscriminant` | `fitensemble` | `templateDiscriminant`

**Purpose** *k*-nearest neighbor classifier template for ensemble (to be removed)

**Compatibility** ClassificationKNN.template will be removed in a future release. Use templateKNN instead.

**Syntax**

```
t = ClassificationKNN.template()  
t = ClassificationKNN.template(Name,Value)
```

**Description**

t = ClassificationKNN.template() returns a learner template suitable to use in the fitensemble function.

t = ClassificationKNN.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

### 'BreakTies' - Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the predict method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of 'BreakTies' and one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

# ClassificationKNN.template

---

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

**Example:** 'BreakTies', 'nearest'

## **'BucketSize' - Maximum data points in node**

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when NSMethod is 'kdtree'.

**Example:** 'BucketSize', 40

## **Data Types**

single | double

## **'Cov' - Covariance matrix**

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

## **Data Types**

single | double

## **'Distance' - Distance metric**

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric string or function handle. The allowable strings depend on the NSMethod parameter, which you set in fitcknn, and which exists as a field in ModelParameters. If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

For definitions, see “Distance Metrics” on page 16-9.

This table includes valid distance metrics of ExhaustiveSearcher.

Value	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix <b>C</b> . The default value of <b>C</b> is the sample covariance matrix of <b>x</b> , as computed by <code>nancov(x)</code> . To specify a different value for <b>C</b> , use the 'Cov' name-value pair argument.

# ClassificationKNN.template

---

Value	Description
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between $x$ and a query point is scaled, meaning divided by a scale value $S$ . The default value of $S$ is the standard deviation computed from $x$ , $S = \text{nanstd}(X)$ . To specify another value for $S$ , use the <code>Scale</code> name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Distance function handle. <i>distfun</i> has the form</p> <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"><li>• <math>ZI</math> is a 1-by-<math>N</math> vector containing one row of <math>x</math> or <math>y</math>.</li><li>• <math>ZJ</math> is an <math>M2</math>-by-<math>N</math> matrix containing multiple rows of <math>x</math> or <math>y</math>.</li><li>• <math>D2</math> is an <math>M2</math>-by-1 vector of distances, and <math>D2(k)</math> is the distance between observations <math>ZI</math> and <math>ZJ(J, :)</math>.</li></ul>

Example: 'Distance', 'minkowski'

## Data Types

function\_handle

### 'DistanceWeight' - Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance <sup>2</sup>
@fcn	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to $@(d)d.^{-2}$ .

**Example:** 'DistanceWeight', 'inverse'

## Data Types

function\_handle

### 'Exponent' - Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

**Example:** 'Exponent', 3

## Data Types

single | double

# ClassificationKNN.template

---

## 'IncludeTies' - Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is true, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

**Example:** 'IncludeTies',true

## Data Types

logical

## 'NSMethod' - Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and either 'kdtree' or 'exhaustive'.

- 'kdtree' — Create and use a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
  - 'euclidean'
  - 'cityblock'
  - 'minkowski'
  - 'chebyshev'
- 'exhaustive' — Use the exhaustive search algorithm. The distance values from all points in *x* to each point in *y* are computed to find nearest neighbors.

The default is 'kdtree' when *x* has 10 or fewer columns, *x* is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

**Example:** 'NSMethod','exhaustive'

## 'NumNeighbors' - Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in  $x$  to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

**Example:** 'NumNeighbors',3

## Data Types

single | double

## 'Scale' - Distance scale

nanstd( $x$ ) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in  $x$ . Each coordinate difference between  $x$  and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

## Data Types

single | double

## Output Arguments

### **t** - Classification template

classification template object

$K$ -nearest neighbor classification template suitable to use in the fitensemble function. In an ensemble,  $t$  specifies how to create the KNN classifier.

## Examples

### **KNN template for nondefault options**

Create a nondefault  $k$ -nearest neighbor template for use in fitensemble.

Create a template for 5-nearest neighbor search.

```
t = ClassificationKNN.template('NumNeighbors',5)
```

# ClassificationKNN.template

---

```
t =  
  
Fit template for classification KNN.  
  
    NumNeighbors: 5  
      NSMethod: ''  
      Distance: ''  
    BucketSize: []  
    IncludeTies: ''  
DistanceWeight: []  
    BreakTies: []  
    Exponent: []  
      Cov: []  
    Scale: []  
    Method: 'KNN'  
    Type: 'classification'
```

You can use `t` for ensemble learning.

You can specify several name and value pair arguments in any order as Name1,Value1, . . . ,NameN,ValueN.</p> <p><b>'AlgorithmForCategorical'</b></p> <p>Algorithm to find the best split on a categorical predictor for data with <math>K = 3</math> or more classes. The available algorithms are:</p>

# ClassificationTree.template

---

'Exact'	For a categorical predictor with $C$ categories, consider all $2^{C-1} - 1$ combinations.
'PullLeft'	Start with all $C$ categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the $K$ classes among the remaining categories. Out of this sequence, choose the split that has the lowest impurity.
'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVAbyClass'	Start with all $C$ categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. Out of this sequence, choose the

split that has the minimum impurity.

**Default:** `ClassificationTree` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, `ClassificationTree` always performs the exact search.

## 'MaxCat'

`ClassificationTree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree` finds the best categorical split using one of the inexact algorithms.

Specify `MaxCat` as a numeric nonnegative scalar value. Passing a small value can lead to long computation time and memory overload.

**Default:** 10

## 'MergeLeaves'

String that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', `ClassificationTree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `ClassificationTree` does not merge leaves.

**Default:** 'off'

## 'MinLeaf'

Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

# ClassificationTree.template

---

**Default:** Half the number of training observations for boosting, 1 for bagging

## **'MinParent'**

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Number of training observations for boosting, 2 for bagging

## **'NVarToSample'**

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

**Default:** 'all' for boosting, square root of number of predictors for bagging

## **'Prune'**

When 'on', `ClassificationTree` grows the classification tree and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree` grows the tree without pruning.

**Default:** 'off'

## **'PruneCriterion'**

String with the pruning criterion, either 'error' or 'impurity'.

**Default:** 'error'

## **'SplitCriterion'**

Criterion for choosing a split. One of 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

**Default:** 'gdi'

## 'Surrogate'

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `ClassificationTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Default:** 'off'

## Output Arguments

**t**

Classification tree template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to grow the classification trees.

## Examples

### Construct a Classification Template with Surrogate Splits

Create a classification template with surrogate splits, and train an ensemble for the Fisher iris model with the template.

# ClassificationTree.template

---

```
t = ClassificationTree.template('surrogate','on');  
load fisheriris  
ens = fitensemble(meas,species,'AdaBoostM2',100,t);
```

Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `RegressionTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Half the number of training observations for boosting, 5 for bagging

## 'MinParent'

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `RegressionTree` uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

**Default:** Number of training observations for boosting, 10 for bagging

## 'NVarToSample'

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

**Default:** 'all' for boosting, one third of the number of predictors for bagging

## 'Prune'

When 'on', `RegressionTree` grows the regression tree and computes the optimal sequence of pruned subtrees. When 'off' `RegressionTree` grows the tree without pruning.

**Default:** 'off'

## 'Surrogate'

String describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', RegressionTree finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, RegressionTree finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', RegressionTree finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

**Default:** 'off'

## Output Arguments

**t**

Regression tree template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to grow the regression trees.

## Examples

Create a regression template with surrogate splits, and train an ensemble for the `carsmall` data with the template:

```
t = RegressionTree.template('surrogate','on');
load carsmall
X = [Acceleration Displacement Horsepower Weight];
ens = fitensemble(X,MPG,'LSBoost',100,t);
```

# templateDiscriminant

---

**Purpose** Discriminant analysis classifier template for ensemble

**Syntax**  
`t = templateDiscriminant()`  
`t = templateDiscriminant(Name,Value)`

**Description** `t = templateDiscriminant()` returns a learner template suitable to use in the `fitensemble` function.

`t = templateDiscriminant(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments. For example, you can specify the discriminant type or the regularization parameter.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'DiscrimType','pseudoLinear','SaveMemory','on'` specifies a template for pseudolinear discriminant analysis that does not store the full covariance matrix.

### 'Delta' - Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `obj` has magnitude smaller than `Delta`, `obj` sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be 0 for quadratic discriminant models.

### Data Types

single | double

## 'DiscrimType' - Discriminant type

'linear' (default) | 'quadratic' | 'diagLinear' | 'diagQuadratic'  
| 'pseudoLinear' | 'pseudoQuadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and one of the following:

- 'linear'
- 'quadratic'
- 'diagLinear'
- 'diagQuadratic'
- 'pseudoLinear'
- 'pseudoQuadratic'

**Example:** 'DiscrimType', 'quadratic'

## 'FillCoeffs' - Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and either 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross validating. The default is 'on', unless you specify a cross validation name-value pair, in which case the flag is set to 'off' by default.

**Example:** 'FillCoeffs', 'off'

## 'Gamma' - Regularization parameter

scalar value in the range [0,1]

Parameter for regularizing the correlation matrix of predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the range [0,1].

- Linear discriminant — Scalar value in the range [0,1].

# templateDiscriminant

---

- If you pass a value strictly between 0 and 1, `fitcdiscr` sets the discriminant type to `'Linear'`.
- If you pass 0 for `Gamma` and `'Linear'` for `DiscrimType`, and if the correlation matrix is singular, `fitcdiscr` sets `Gamma` to the minimal value required for inverting the covariance matrix.
- If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to `'DiagLinear'`.
- Quadratic discriminant — Either 0 or 1.
  - If you pass 0 for `Gamma` and `'Quadratic'` for `DiscrimType`, and if one of the classes has a singular covariance matrix, `fitcdiscr` errors.
  - If you set `Gamma` to 1, `fitcdiscr` sets the discriminant type to `'DiagQuadratic'`.
  - If you set `Gamma` to a value between 0 and 1 for a quadratic discriminant, `fitcdiscr` errors.

**Example:** `'Gamma', 1`

## Data Types

`single` | `double`

## 'SaveMemory' - Flag to save covariance matrix

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `obj`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

**Example:** `'SaveMemory', 'on'`

## Output Arguments

### **t** - Discriminant analysis classification template

classification template object

Discriminant analysis classification template suitable to use in the `fitensemble` function, returned as a classification template object. In an ensemble, `t` specifies how to create the discriminant analysis classifier.

## Examples

### **Discriminant Analysis Template for Nondefault Options**

Create a nondefault discriminant analysis template for use in `fitensemble`.

Create a template for pseudolinear discriminant analysis.

```
t = templateDiscriminant('DiscrimType','pseudoLinear')
```

```
t =
```

```
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'  
Gamma: []  
Delta: []  
FillCoeffs: []  
SaveMemory: []  
Method: 'Discriminant'  
Type: 'classification'
```

You can use `t` for ensemble learning.

`ClassificationDiscriminant` | `fitensemble` | `predict`

# templateKNN

---

**Purpose** *k*-nearest neighbor classifier template for ensemble

**Syntax**  
t = templateKNN()  
t = templateKNN(Name,Value)

**Description** t = templateKNN() returns a learner template suitable to use in the fitensemble function.

t = templateKNN(Name,Value) creates a template with additional options specified by one or more name-value pair arguments. For example, you can specify the nearest neighbor search method, the number of nearest neighbors to find, or the distance metric.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'NumNeighbors',4,'Distance','minkowski' specifies a 4-nearest neighbor classifier template using the Minkowski distance measure.

### 'BreakTies' - Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the predict method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of 'BreakTies' and one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

**Example:** 'BreakTies', 'nearest'

### **'BucketSize' - Maximum data points in node**

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when NSMethod is 'kdtree'.

**Example:** 'BucketSize', 40

### **Data Types**

single | double

### **'Cov' - Covariance matrix**

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

### **Data Types**

single | double

### **'Distance' - Distance metric**

valid distance metric string | function handle

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric string or function handle. The allowable strings depend on the NSMethod parameter, which you set in fitcknn, and which exists as a field in ModelParameters. If you specify CategoricalPredictors as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

For definitions, see “Distance Metrics” on page 16-9.

This table includes valid distance metrics of ExhaustiveSearcher.

Value	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of $x$ , as computed by <code>nancov(x)</code> . To specify a different value for C, use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.

Value	Description
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between $x$ and a query point is scaled, meaning divided by a scale value $S$ . The default value of $S$ is the standard deviation computed from $x$ , $S = \text{nanstd}(X)$ . To specify another value for $S$ , use the <code>Scale</code> name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form  <pre>function D2 = DISTFUN(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> <li>• <math>ZI</math> is a 1-by-<math>N</math> vector containing one row of <math>x</math> or <math>y</math>.</li> <li>• <math>ZJ</math> is an <math>M2</math>-by-<math>N</math> matrix containing multiple rows of <math>x</math> or <math>y</math>.</li> <li>• <math>D2</math> is an <math>M2</math>-by-1 vector of distances, and <math>D2(k)</math> is the distance between observations <math>ZI</math> and <math>ZJ(J,:)</math>.</li> </ul>

**Example:** 'Distance', 'minkowski'

## Data Types

function\_handle

## 'DistanceWeight' - Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

# templateKNN

---

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the following strings specifying the distance weighting function.

DistanceWeight	Meaning
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance <sup>2</sup>
@fcn	fcn is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

**Example:** 'DistanceWeight','inverse'

## Data Types

function\_handle

## 'Exponent' - Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

**Example:** 'Exponent',3

## Data Types

single | double

## 'IncludeTies' - Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest

distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly `K` neighbors.

**Example:** `'IncludeTies', true`

## Data Types

logical

## 'NSMethod' - Nearest neighbor search method

`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and either `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Create and use a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
  - `'euclidean'`
  - `'cityblock'`
  - `'minkowski'`
  - `'chebyshev'`
- `'exhaustive'` — Use the exhaustive search algorithm. The distance values from all points in `x` to each point in `y` are computed to find nearest neighbors.

The default is `'kdtree'` when `x` has 10 or fewer columns, `x` is not sparse, and the distance metric is a `'kdtree'` type; otherwise, `'exhaustive'`.

**Example:** `'NSMethod', 'exhaustive'`

## 'NumNeighbors' - Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in `x` to find for classifying each point when predicting, specified as the comma-separated pair consisting of `'NumNeighbors'` and a positive integer value.

**Example:** `'NumNeighbors', 3`

# templateKNN

---

## Data Types

single | double

## 'Scale' - Distance scale

nanstd(x) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in  $x$ . Each coordinate difference between  $x$  and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

## Data Types

single | double

## Output Arguments

### t - Classification template

classification template object

Classification template for  $k$ -nearest neighbor classification suitable to use in the `fitensemble` function, returned as a classification template object. In an ensemble, `t` specifies how to create the KNN classifier.

## Examples

### KNN Template for Nondefault Options

Create a nondefault  $k$ -nearest neighbor template for use in `fitensemble`.

Create a template for 5-nearest neighbor search.

```
t = templateKNN('NumNeighbors',5)
```

```
t =
```

```
Fit template for classification KNN.
```

```
NumNeighbors: 5  
NSMethod: ''  
Distance: ''  
BucketSize: []
```

```
IncludeTies: ''
DistanceWeight: []
BreakTies: []
Exponent: []
Cov: []
Scale: []
Method: 'KNN'
Type: 'classification'
```

You can use `t` for ensemble learning.

# templateTree

---

**Purpose** Create classification template

**Syntax**  
t = templateTree  
t = templateTree(Name,Value)

**Description** t = templateTree returns a learner template suitable to use in the fitensemble function.

t = templateTree(Name,Value) creates a template with additional options specified by one or more name-value pair arguments. For example, you can specify the algorithm used to find the best split on a categorical predictor, the split criterion, or the number of predictors selected for each split.

## Input Arguments

### Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

**Example:** 'Surrogate', 'on', 'NVarToSample', 'all' specifies a template with surrogate splits, and uses all available predictors at each split.

### For Classification Trees and Regression Trees

#### 'MergeLeaves' - Leaf merge flag

'off' (default) | 'on'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'.

When 'on', the decision tree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', the decision tree does not merge leaves.

**Example:** 'MergeLeaves', 'on'

### **'MinLeaf' - Minimum observations per leaf**

positive integer value

Minimum observations per leaf, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, the decision tree uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

For boosting, the default is 1. For bagging, the default is 1 for classification, or 5 for regression.

**Example:** 'MinLeaf', 2

### **'MinParent' - Minimum observations per branch node**

positive integer value

Minimum observations per branch node, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, the decision tree uses the setting that gives larger leaves:  $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$ .

For boosting, the default is the number of training observations. For bagging, the default is 2 for classification, or 10 for regression.

**Example:** 'MinParent', 4

### **'NVarToSample' - Number of predictors selected for each split**

positive integer value | 'all'

Number of predictors selected at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. Alternatively, you can specify 'all' to use all available predictors. The default for boosting is 'all'. The default for bagging is the square root of the number of predictors for classification, or one third of predictors for regression.

**Example:** 'NVarToSample',3

## **'Prune' - Pruning flag**

'off' (default) | 'on'

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', fitensemble grows unpruned trees and computes the optimal sequence of pruned subtrees for each tree. When 'off', fitensemble grows the tree without pruning.

**Example:** 'Prune','on'

## **'PruneCriterion' - Pruning criterion**

'error' | 'impurity' | 'mse'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and a pruning criterion string valid for the tree type.

- For classification trees, you can specify either 'error' (default) or 'impurity'.
- For regression, you can only specify 'mse' (default).

**Example:** 'PruneCriterion','impurity'

## **'SplitCriterion' - Split criterion**

'gdi' | 'twoing' | 'deviance' | 'mse'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and a split criterion string valid for the tree type.

- For classification trees:
  - 'gdi' for Gini's diversity index (default)
  - 'twoing' for the twoing rule
  - 'deviance' for maximum deviance reduction (also known as cross entropy)
- For regression trees:

- 'mse' for mean squared error (default)

**Example:** 'SplitCriterion', 'deviance'

## 'Surrogate' - Surrogate decision splits

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and one of 'off', 'on', 'all', or a positive integer value.

- When 'off', the decision tree does not find surrogate splits at the branch nodes.
- When 'on', the decision tree finds at most 10 surrogate splits at each branch node.
- When set to 'all', the decision tree finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, the decision tree finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors.

**Example:** 'Surrogate', 'on'

## For Classification Trees Only

### 'AlgorithmForCategorical' - Algorithm for best categorical predictor split

'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor for data with  $C$  categories for data and  $K \geq 3$  classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following.

# templateTree

---

'Exact'	Consider all $2^{C-1} - 1$ combinations.
'PullLeft'	Start with all $C$ categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the $K$ classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVByClass'	Start with all $C$ categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`ClassificationTree` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, `ClassificationTree` always performs the

exact search. Use the 'AlgorithmForCategorical' name-value pair argument to specify a particular algorithm.

**Example:** 'AlgorithmForCategorical','PCA'

### 'MaxCat' - Maximum category levels in split node

10 (default) | nonnegative scalar value

Maximum category levels in the split node, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. ClassificationTree splits a categorical predictor using the exact search algorithm if the predictor has at most MaxCat levels in the split node. Otherwise, ClassificationTree finds the best categorical split using one of the inexact algorithms. Note that passing a small value can increase computation time and memory overload.

**Example:** 'MaxCat',8

### For Regression Trees Only

### 'QEToler' - Quadratic error tolerance

1e-6 (default) | nonnegative scalar value

Quadratic error tolerance per node, specified as the comma —separated pair consisting of 'QEToler' and a nonnegative scalar value. RegressionTree stops splitting nodes when the quadratic error per node drops below QEToler \* QED, where QED is the quadratic error for the entire data computed before the decision tree is grown.  $QED = \text{NORM}(Y - \bar{Y})$ , where  $\bar{Y}$  is estimated as the average of the input array Y.

**Example:** 'QEToler',1e-4

## Output Arguments

### t - Decision tree learner template

decision tree template object

Decision tree learner template, returned as a decision tree template object suitable to use in the fitensemble function. In an ensemble, t specifies how to grow the decision trees.

# templateTree

---

## Examples

### Create a Classification Template with Surrogate Splits

Create a decision tree template with surrogate splits, and use the template to train an ensemble using sample data.

Create a decision tree template with surrogate splits.

```
t = templateTree('Surrogate','on')
```

```
t =
```

```
Fit template for Tree.  
    surrogate: 'on'
```

Load the sample data. Use the template to train an ensemble using the sample data.

```
load fisheriris;  
ens = fitensemble(meas,species,'AdaBoostM2',100,t)
```

```
ens =
```

```
classreg.learning.classif.ClassificationEnsemble  
    PredictorNames: {'x1' 'x2' 'x3' 'x4'}  
    ResponseName: 'Y'  
    ClassNames: {1x3 cell}  
    ScoreTransform: 'none'  
    NumObservations: 150  
    NumTrained: 100  
    Method: 'AdaBoostM2'  
    LearnerNames: {'Tree'}  
    ReasonForTermination: 'Terminated normally after co...'  
    FitInfo: [100x1 double]  
    FitInfoDescription: {2x1 cell}
```

[ClassificationTree](#) | [RegressionTree](#) | [fitctree](#) | [fitensemble](#)

# classregtree.test

---

**Purpose** Error rate

**Syntax**

```
cost = test(t, 'resubstitution')
cost = test(t, 'test', X, y)
cost = test(t, 'crossvalidate', X, y)
[cost, secost, ntnodes, bestlevel] = test(...)
[...] = test(..., param1, val1, param2, val2, ...)
```

**Description** `cost = test(t, 'resubstitution')` computes the cost of the tree `t` using a resubstitution method. `t` is a decision tree as created by `classregtree`. The cost of the tree is the sum over all terminal nodes of the estimated probability of a node times the cost of a node. If `t` is a classification tree, the cost of a node is the sum of the misclassification costs of the observations in that node. If `t` is a regression tree, the cost of a node is the average squared error over the observations in that node. `cost` is a vector of cost values for each subtree in the optimal pruning sequence for `t`. The resubstitution cost is based on the same sample that was used to create the original tree, so it under estimates the likely cost of applying the tree to new data.

`cost = test(t, 'test', X, y)` uses the matrix of predictors `X` and the response vector `y` as a test sample, applies the decision tree `t` to that sample, and returns a vector `cost` of cost values computed for the test sample. `X` and `y` should not be the same as the learning sample, that is, the sample that was used to fit the tree `t`.

`cost = test(t, 'crossvalidate', X, y)` uses 10-fold cross-validation to compute the cost vector. `X` and `y` should be the learning sample, that is, the sample that was used to fit the tree `t`. The function partitions the sample into 10 subsamples, chosen randomly but with roughly equal size. For classification trees, the subsamples also have roughly the same class proportions. For each subsample, `test` fits a tree to the remaining data and uses it to predict the subsample. It pools the information from all subsamples to compute the cost for the whole sample.

`[cost, secost, ntnodes, bestlevel] = test(...)` also returns the vector `secost` containing the standard error of each cost value, the vector `ntnodes` containing the number of terminal nodes for each

subtree, and the scalar `bestlevel` containing the estimated best level of pruning. A `bestlevel` of 0 means no pruning. The best level is the one that produces the smallest tree that is within one standard error of the minimum-cost subtree.

[...] = `test(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs for methods other than 'resubstitution', chosen from the following:

- 'weights' — Observation weights.
- 'nsamples' — The number of cross-validation samples (default is 10).
- 'treesize' — Either 'se' (default) to choose the smallest tree whose cost is within one standard error of the minimum cost, or 'min' to choose the minimal cost tree.

## Examples

Find the best tree for Fisher's iris data using cross-validation. Start with a large tree:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'},...
                'splitmin',5)

t =
Decision tree for classification
 1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
 2  class = setosa
 3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
 4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
 5  class = virginica
 6  if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
 7  if PW<1.55 then node 10 elseif PW>=1.55 then node 11 else virginica
 8  class = versicolor
 9  class = virginica
10  class = virginica
```

# classregtree.test

```
11 class = versicolor
```

```
view(t)
```

Click to display:  Magnification:  Pruning level:

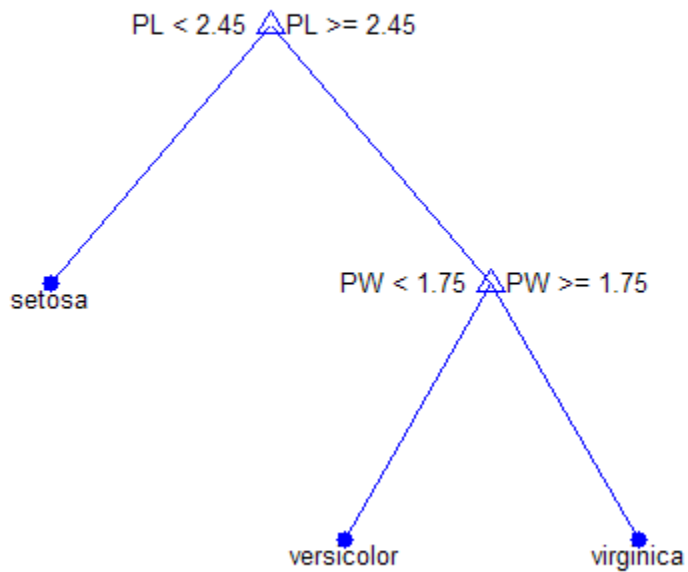

Find the minimum-cost tree:

```
[c,s,n,best] = test(t,'cross',meas,species);  
tmin = prune(t,'level',best)  
tmin =  
Decision tree for classification
```

```
1 if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2 class = setosa
3 if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4 class = versicolor
5 class = virginica
```

```
view(tmin)
```

Click to display:  Magnification:  Pruning level:

Plot the smallest tree within one standard error of the minimum cost tree:

# classregtree.test

```
[mincost,minloc] = min(c);  
plot(n,c,'b-o',...  
      n(best+1),c(best+1),'bs',...  
      n,(mincost+s(minloc))*ones(size(n)), 'k--')  
xlabel('Tree size (number of terminal nodes)')  
ylabel('Cost')
```

The solid line shows the estimated cost for each tree size, the dashed line marks one standard error above the minimum, and the square marks the smallest tree under the dashed line.

# cvpartition.test

---

**Purpose** Test indices for cross-validation

**Syntax** `idx = test(c)`  
`idx = test(c,i)`

**Description** `idx = test(c)` returns the logical vector `idx` of test indices for an object `c` of the `cvpartition` class of type `'holdout'` or `'resubstitution'`.

If `c.Type` is `'holdout'`, `idx` specifies the observations in the test set.

If `c.Type` is `'resubstitution'`, `idx` specifies all observations.

`idx = test(c,i)` returns the logical vector `idx` of test indices for repetition `i` of an object `c` of the `cvpartition` class of type `'kfold'` or `'leaveout'`.

If `c.Type` is `'kfold'`, `idx` specifies the observations in the test set in fold `i`.

If `c.Type` is `'leaveout'`, `idx` specifies the observation left out at repetition `i`.

**Examples** Identify the test indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
```

```
      N: 10
```

```

# categorical.times

---

## **Purpose**

Product of categorical arrays

The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`C = times(A,B)`

## **Description**

`C = times(A,B)` returns a categorical array each of whose elements has the level formed from the concatenation of the levels of the corresponding elements of `A` and `B`. The set of levels of `C` is the cartesian product of the sets of levels of `A` and of `B`. The syntax `A .* B` calls `C = times(A,B)`.

## **See Also**

`categorical`

**Purpose** Student's *t* inverse cumulative distribution function

**Syntax** `X = tinv(P,V)`

**Description** `X = tinv(P,V)` computes the inverse of Student's *t* cdf using the degrees of freedom in *V* for the corresponding probabilities in *P*. *P* and *V* can be vectors, matrices, or multidimensional arrays that are the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The values in *P* must lie on the interval [0 1].

The *t* inverse function in terms of the *t* cdf is

$$x = F^{-1}(p | \nu) = \{x : F(x | \nu) = p\}$$

where

$$p = F(x | \nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

The result, *x*, is the solution of the cdf integral with parameter *ν*, where you supply the desired probability *p*.

**Examples** What is the 99th percentile of the *t* distribution for one to six degrees of freedom?

```
percentile = tinv(0.99,1:6)
percentile =
    31.8205    6.9646    4.5407    3.7469    3.3649    3.1427
```

# prob.tLocationScaleDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** *t* Location-Scale probability distribution object

**Description** prob.tLocationScaleDistribution is an object consisting of parameters, a model description, and sample data for a *t* location-scale probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('tLocationScale')` creates a *t* location-scale probability distribution object using the default parameter values.

`pd = makedist('tLocationScale','mu',mu,'sigma',sigma,'nu',nu)` creates a *t* location-scale probability distribution object using the specified parameter values.

## Input Arguments

### **mu - Location parameter**

0 (default) | scalar value

Location parameter for the *t* location-scale distribution, specified as a scalar value.

### **Data Types**

single | double

### **sigma - Scale parameter**

1 (default) | positive scalar value

Scale parameter for the *t* location-scale distribution, specified as a positive scalar value.

### **Data Types**

single | double

### **nu - Degrees of freedom**

5 (default) | positive scalar value

Degrees of freedom for the  $t$  location-scale distribution, specified as a positive scalar value.

### Data Types

single | double

## Properties

### **mu - Location parameter**

scalar value

Location parameter of the  $t$  location-scale distribution, stored as a scalar value.

### Data Types

single | double

### **sigma - Scale parameter**

positive scalar value

Scale parameter of the  $t$  location-scale distribution, stored as a positive scalar value.

### Data Types

single | double

### **nu - Degrees of freedom**

positive scalar value

Degrees of freedom of the  $t$  location-scale distribution, stored as a positive scalar value.

### Data Types

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

### Data Types

char

# prob.tLocationScaleDistribution

---

## **InputData - Data used for distribution fitting**

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## **Data Types**

struct

## **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## **Data Types**

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## **Data Types**

single | double

## **ParameterCovariance - Covariance matrix of the parameter estimates**

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution.

The (i,j) element is the covariance between the estimates of the *i*th parameter and the *j*th parameter. The (i,i) element is the estimated variance of the *i*th parameter. If parameter *i* is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterIsFixed - Logical flag for fixed parameters

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

## Data Types

logical

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

# prob.tLocationScaleDistribution

---

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object

random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

mean	Mean of probability distribution object
negloglik	Negative loglikelihood of probability distribution object
paramci	Confidence intervals for probability distribution parameters
proflik	Profile likelihood function for probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### ***t* Location-Scale Distribution**

The *t* location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as  $\nu$  approaches infinity, and smaller values of  $\nu$  yield heavier tails.

The *t* location-scale distribution uses the following parameters.

Parameter	Description	Support
mu	Location parameter	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma > 0$
nu	Shape parameter	$\nu > 0$

The probability density function (pdf) is

# prob.tLocationScaleDistribution

---

$$f(x | \mu, \sigma, \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sigma\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left[ \frac{\nu + \left(\frac{x-\mu}{\sigma}\right)^2}{\nu} \right]^{-\left(\frac{\nu+1}{2}\right)} ; \quad -\infty < x < \infty,$$

where  $\Gamma(\cdot)$  is the Gamma function.

## Examples

### Create a *t* Location-Scale Distribution Object Using Default Parameters

Create a *t* location scale distribution object using the default parameter values.

```
pd = makedist('tLocationScale')
```

```
pd =
```

```
tLocationScaleDistribution  
  
t Location-Scale distribution  
    mu = 0  
    sigma = 1  
    nu = 5
```

### Create a *t* Location-Scale Distribution Object Using Specified Parameters

Create a *t* location-scale distribution object by specifying the parameter values.

```
pd = makedist('tLocationScale','mu',-2,'sigma',1,'nu',20)
```

```
pd =
```

```
tLocationScaleDistribution  
  
t Location-Scale distribution
```

```
mu = -2  
sigma = 1  
nu = 20
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)
```

```
r =
```

```
1.3739
```

# prob.ToolboxFittableParametricDistribution

---

**Superclasses** TruncatableDistribution

**Purpose** Toolbox-integrated fittable parametric probability distribution object

**Description** Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Methods**

<code>mean</code>	Mean of probability distribution object
<code>negloglik</code>	Negative loglikelihood of probability distribution object
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>proflik</code>	Profile likelihood function for probability distribution object
<code>std</code>	Standard deviation of probability distribution object
<code>var</code>	Variance of probability distribution object

## Inherited Methods

<code>cdf</code>	Cumulative distribution function of probability distribution object
<code>icdf</code>	Inverse cumulative distribution function of probability distribution object
<code>iqr</code>	Interquartile range of probability distribution object

# prob.ToolboxFittableParametricDistribution

---

median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

## See Also

## Concepts

- Class Attributes
- Property Attributes

**Purpose** Student's  $t$  probability density function

**Syntax** `Y = tpdf(X,V)`

**Description** `Y = tpdf(X,V)` computes Student's  $t$  pdf at each of the values in  $X$  using the corresponding degrees of freedom in  $V$ .  $X$  and  $V$  can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

Student's  $t$  pdf is

$$y = f(x | \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

## Examples

The mode of the  $t$  distribution is at  $x = 0$ . This example shows that the value of the function at the mode is an increasing function of the degrees of freedom.

```
tpdf(0,1:6)
ans =
    0.3183    0.3536    0.3676    0.3750    0.3796    0.3827
```

The  $t$  distribution converges to the standard normal distribution as the degrees of freedom approaches infinity. How good is the approximation for  $\nu = 30$ ?

```
difference = tpdf(-2.5:2.5,30) - normpdf(-2.5:2.5)
difference =
    0.0035   -0.0006   -0.0042   -0.0042   -0.0006    0.0035
```

**How To**

- “Student’s t Distribution” on page B-137

# cvpartition.training

---

**Purpose** Training indices for cross-validation

**Syntax** `idx = training(c)`  
`idx = training(c,i)`

**Description** `idx = training(c)` returns the logical vector `idx` of training indices for an object `c` of the `cvpartition` class of type `'holdout'` or `'resubstitution'`.

If `c.Type` is `'holdout'`, `idx` specifies the observations in the training set.

If `c.Type` is `'resubstitution'`, `idx` specifies all observations.

`idx = training(c,i)` returns the logical vector `idx` of training indices for repetition `i` of an object `c` of the `cvpartition` class of type `'kfold'` or `'leaveout'`.

If `c.Type` is `'kfold'`, `idx` specifies the observations in the training set in fold `i`.

If `c.Type` is `'leaveout'`, `idx` specifies the observations left in at repetition `i`.

**Examples** Identify the training indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
      N: 10
  NumTestSets: 3
   TrainSize: 7 6 7
   TestSize: 3 4 3

training(c,1)
ans =
     0
     0
```

1  
1  
1  
1  
1  
0  
1

**See Also**      cvpartition | test

# cvpartition.TrainSize property

---

**Purpose** Size of each training set

**Description** Value is a vector in partitions of type 'kfold' and 'leaveout'.  
Value is a scalar in partitions of type 'holdout' and 'resubstitution'.

**See Also** type

**Purpose**

Transpose categorical matrix

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

`B = transpose(A)`

**Description**

`B = transpose(A)` returns the transpose of the 2-D categorical matrix `A`. `ctranspose` is identical to `transpose` for categorical arrays. The syntax `A.'` calls `transpose`.

**See Also**

`ctranspose` | `permute`

# TreeBagger.TreeArgs property

---

**Purpose** Cell array of arguments for `classregtree`

**Description** The `TreeArgs` property is a cell array of arguments for the `classregtree` constructor. `TreeBagger` uses these arguments in growing new trees for the ensemble.

## Purpose

Bootstrap aggregation for ensemble of decision trees

## Description

TreeBagger bags an ensemble of decision trees for either classification or regression. Bagging stands for bootstrap aggregation. Every tree in the ensemble is grown on an independently drawn bootstrap replica of input data. Observations not included in this replica are "out of bag" for this tree. To compute prediction of an ensemble of trees for unseen data, TreeBagger takes an average of predictions from individual trees. To estimate the prediction error of the bagged ensemble, you can compute predictions for each tree on its out-of-bag observations, average these predictions over the entire ensemble for each observation and then compare the predicted out-of-bag response with the true value at this observation.

TreeBagger relies on the `ClassificationTree` and `RegressionTree` functionality for growing individual trees. In particular, `ClassificationTree` and `RegressionTree` accepts the number of features selected at random for each decision split as an optional input argument.

The `compact` method returns an object of another class, `CompactTreeBagger`, with sufficient information to make predictions using new data. This information includes the tree ensemble, variable names, and class names (for classification). `CompactTreeBagger` requires less memory than `TreeBagger`, but only `TreeBagger` has methods for growing more trees for the ensemble. Once you grow an ensemble of trees using `TreeBagger` and no longer need access to the training data, you can opt to work with the compact version of the trained ensemble from then on.

## Construction

`TreeBagger`

Create ensemble of bagged decision trees

# TreeBagger

---

## Methods

append	Append new trees to ensemble
compact	Compact ensemble of decision trees
error	Error (misclassification probability or MSE)
fillProximities	Proximity matrix for training data
growTrees	Train additional trees and add to ensemble
margin	Classification margin
mdsProx	Multidimensional scaling of proximity matrix
meanMargin	Mean classification margin
oobError	Out-of-bag error
oobMargin	Out-of-bag margins
oobMeanMargin	Out-of-bag mean margins
oobPredict	Ensemble predictions for out-of-bag observations
predict	Predict response

## Properties

### ClassNames

A cell array containing the class names for the response variable  $Y$ . This property is empty for regression trees.

### ComputeOOBPrediction

A logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is `false`.

If this flag is true, the following properties are available:

- `OOBIndices`
- `OOBInstanceWeight`

If this flag is true, the following methods can be called:

- `oobError`
- `oobMargin`
- `oobMeanMargin`

See also `oobError`, `OOBIndices`, `OOBInstanceWeight`, `oobMargin`, `oobMeanMargin`.

### **ComputeOOBVarImp**

A logical flag specifying whether out-of-bag estimates of variable importance should be computed. The default is `false`. If this flag is true, then `ComputeOOBPrediction` is true as well.

If this flag is true, the following properties are available:

- `OOBPermutedVarDeltaError`
- `OOBPermutedVarDeltaMeanMargin`
- `OOBPermutedVarCountRaiseMargin`

### **Cost**

A matrix with misclassification costs. This property is empty for ensembles of regression trees.

### **DefaultYfit**

Default value returned by `predict` and `oobPredict`. The `DefaultYfit` property controls what predicted value is returned when no prediction is possible. For example, when `oobPredict` needs to predict for an observation that is in-bag for all trees in the ensemble.

- For classification, you can set this property to either '' or 'MostPopular'. If you choose 'MostPopular' (the default), the property value becomes the name of the most probably class in the training data. If you choose '', the in-bag observations are excluded from computation of the out-of-bag error and margin.
- For regression, you can set this property to any numeric scalar. The default value is the mean of the response for the training data. If you set this property to NaN, the in-bag observations are excluded from computation of the out-of-bag error and margin.

### **DeltaCritDecisionSplit**

A numeric array of size 1-by-*Nvars* of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

See also `ClassificationTree.predictorImportance` and `RegressionTree.predictorImportance`.

### **FBoot**

Fraction of observations that are randomly selected with replacement for each bootstrap replica. The size of each replica is  $Nobs \times FBoot$ , where *Nobs* is the number of observations in the training set. The default value is 1.

### **MergeLeaves**

A logical flag specifying whether decision tree leaves with the same parent are merged for splits that do not decrease the total risk. The default value is `false`.

### **Method**

Method used by trees. The possible values are 'classification' for classification ensembles, and 'regression' for regression ensembles.

### **MinLeaf**

Minimum number of observations per tree leaf. By default, `MinLeaf` is 1 for classification and 5 for regression. For decision tree training, the `MinParent` value is set equal to  $2 * \text{MinLeaf}$ .

## **NTrees**

Scalar value equal to the number of decision trees in the ensemble.

## **NVarSplit**

A numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

## **NVarToSample**

Number of predictor or feature variables to select at random for each decision split. By default, `NVarToSample` is equal to the square root of the total number of variables for classification, and one third of the total number of variables for regression.

## **OOBIndices**

Logical array of size *Nobs*-by-*NTrees*, where *Nobs* is the number of observations in the training data and *NTrees* is the number of trees in the ensemble. A true value for the  $(i,j)$  element indicates that observation *i* is out-of-bag for tree *j*. In other words, observation *i* was not selected for the training data used to grow tree *j*.

## **OOBInstanceWeight**

Numeric array of size *Nobs*-by-1 containing the number of trees used for computing the out-of-bag response for each observation. *Nobs* is the number of observations in the training data used to create the ensemble.

## **OOBPermutedVarCountRaiseMargin**

A numeric array of size 1-by-*Nvars* containing a measure of variable importance for each predictor variable (feature). For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations.

This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

## **OOBPermutedVarDeltaError**

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

## **OOBPermutedVarDeltaMeanMargin**

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

## **OutlierMeasure**

A numeric array of size *Nobs*-by-1, where *Nobs* is the number of observations in the training data, containing outlier measures for each observation.

See also `CompactTreeBagger.OutlierMeasure`.

## **Prior**

A vector with prior probabilities for classes. This property is empty for ensembles of regression trees.

## **Proximity**

A numeric matrix of size *Nobs*-by-*Nobs*, where *Nobs* is the number of observations in the training data, containing measures of

the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

See also `CompactTreeBagger.proximity`.

## **Prune**

The `Prune` property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

See also `ClassificationTree.prune` and `RegressionTree.prune`.

## **SampleWithReplacement**

A logical flag specifying if data are sampled for each decision tree with replacement. True if `TreeBagger` samples data with replacement and false otherwise. True by default.

## **TreeArgs**

Cell array of arguments for `fitctree` or `fitrtree`. These arguments are used by `TreeBagger` when growing new trees for the ensemble.

## **Trees**

A cell array of size  $NTrees$ -by-1 containing the trees in the ensemble.

See also `NTrees`.

## **VarAssoc**

A matrix of size  $Nvars$ -by- $Nvars$  with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting `'surrogate'` to `'on'`, this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew

the ensemble setting 'surrogate' to 'off' (default), `VarAssoc` is diagonal.

## **VarNames**

A cell array containing the names of the predictor variables (features). `TreeBagger` takes these names from the optional 'names' parameter. The default names are 'x1', 'x2', etc.

## **W**

Numeric vector of weights of length *Nobs*, where *Nobs* is the number of observations (rows) in the training data. `TreeBagger` uses these weights for growing every decision tree in the ensemble. The default *W* is `ones(Nobs, 1)`.

## **X**

A numeric matrix of size *Nobs*-by-*Nvars*, where *Nobs* is the number of observations (rows) and *Nvars* is the number of variables (columns) in the training data. This matrix contains the predictor (or feature) values.

## **Y**

An array of true class labels for classification, or response values for regression. *Y* can be a numeric column vector, a character matrix, or a cell array of strings.

## **Copy Semantics**

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes in the MATLAB Object-Oriented Programming documentation](#).

## **How To**

- “Ensemble Methods” on page 16-64
- “Classification Trees and Regression Trees” on page 16-31
- “Grouping Variables” on page 2-52

## Purpose

Create ensemble of bagged decision trees

## Syntax

```
B = TreeBagger(NTrees,X,Y)
B = TreeBagger(NTrees,X,Y,'param1',val1,'param2',val2,...)
```

## Description

`B = TreeBagger(NTrees,X,Y)` creates an ensemble `B` of `NTrees` decision trees for predicting response `Y` as a function of predictors `X`. By default `TreeBagger` builds an ensemble of classification trees. The function can build an ensemble of regression trees by setting the optional input argument `'method'` to `'regression'`.

`X` is a numeric matrix of training data. Each row represents an observation and each column represents a predictor or feature. `Y` is an array of true class labels for classification or numeric function values for regression. True class labels can be a numeric vector, character matrix, vector cell array of strings or categorical vector. `TreeBagger` converts labels to a cell array of strings for classification.

For more information on grouping variables, see “Grouping Variables” on page 2-52.

`B = TreeBagger(NTrees,X,Y,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

- |                      |  |
|----------------------|--|
| <code>'FBoot'</code> | Fraction of input data to sample with replacement from the input data for growing each new tree. Default value is 1.   |
| <code>'Cost'</code>  | Square matrix <code>C</code> , where <code>C(i,j)</code> is the cost of classifying a point into class <code>j</code> if its true class is <code>i</code> . Alternatively, <code>cost</code> can be a structure <code>S</code> having two fields: <ul style="list-style-type: none"><li>• <code>S.ClassNames</code> containing the group names as a categorical variable, character array, or cell array of strings</li><li>• <code>S.ClassificationCosts</code> containing the cost matrix <code>C</code></li></ul> |

The default value is  $C(i, j) = 1$  if  $i \neq j$ , and  $C(i, j) = 0$  if  $i = j$ .

If `Cost` is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

- 'SampleWithReplacement' `on` to sample with replacement or 'off' to sample without replacement. If you sample without replacement, you need to set 'FBoot' to a value less than one. Default is 'on'.
- 'OOBPred' 'on' to store info on what observations are out of bag for each tree. This info can be used by `oobPredict` to compute the predicted class probabilities for each tree in the ensemble. Default is 'off'.
- 'OOBVarImp' 'on' to store out-of-bag estimates of feature importance in the ensemble. Default is 'off'. Specifying 'on' also sets the 'OOBPred' value to 'on'.
- 'Method' Either 'classification' or 'regression'. Regression requires a numeric Y.
- 'NVarToSample' Number of variables to select at random for each decision split. Default is the square root of the number of variables for classification and one third of the number of variables for regression. Valid values are 'all' or a positive integer. Setting this argument to any valid value but 'all' invokes Breiman's 'random forest' algorithm.

'NPrint'	Number of training cycles (grown trees) after which TreeBagger displays a diagnostic message showing training progress. Default is no diagnostic messages.
'MinLeaf'	Minimum number of observations per tree leaf. Default is 1 for classification and 5 for regression.
'Options'	<p>A structure that specifies options that govern the computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to <code>statset</code>. You can retrieve values of the individual fields with a call to <code>statget</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"><li>• 'UseParallel' — If true and if a parpool of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a parpool is not open, computation occurs in serial mode. Default is false, or serial computation.</li><li>• 'UseSubstreams' — If true select each bootstrap replicate using a separate Substream of the random number generator (aka Stream). This option is available only with RandStream types that support Substreams: 'mlfg6331_64' or 'mrg32k3a'. Default is false, do not use a different Substream to compute each bootstrap replicate.</li><li>• Streams — A RandStream object or cell array of such objects. If you do not specify Streams,</li></ul>

TreeBagger uses the default stream or streams. If you choose to specify Streams, use a single object except in the case

- You have an open Parallel pool
- UseParallel is true
- UseSubstreams is false

In that case, use a cell array the same size as the Parallel pool.

'Prior'

Prior probabilities for each class. Specify as one of:

- A string:
  - 'Empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities. This is the default.
  - 'Uniform' sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure S with two fields:
  - S.ClassNames containing the class names as a categorical variable, character array, or cell array of strings
  - S.ClassProbs containing a vector of corresponding probabilities

If you set values for both Weights and Prior, the weights are renormalized to add up to the value of the prior probability in the respective class.

If Prior is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very

low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.

`CategoricalPredictors` Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following.

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `X`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `X` is a categorical variable.
- A cell array of strings, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

In addition to the optional arguments above, this method accepts all optional `fitctree` and `fitrtree` arguments with the exception of `'minparent'`. Refer to the documentation for `fitctree` and `fitrtree` for more detail.

## Examples

### Train a Bagged Ensemble of Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

# TreeBagger

---

Train a bagged ensemble of classification trees using the data and specifying 50 weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
BaggedEnsemble = TreeBagger(50,meas,species,'OOBPred','On')
```

```
BaggedEnsemble =
```

```
TreeBagger
Ensemble with 50 bagged decision trees:
      Training X:      [150x4]
      Training Y:      [150x1]
      Method:      classification
      Nvars:      4
      NVarToSample:      2
      MinLeaf:      1
      FBoot:      1
      SampleWithReplacement:      1
      ComputeOOBPrediction:      1
      ComputeOOBVarImp:      0
      Proximity:      []
      ClassNames:      'setosa' 'versicolor' 'virginica'
```

BaggedEnsemble is a TreeBagger ensemble.

BaggedEnsemble.OOBIndices stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
plot(oobError(BaggedEnsemble))
xlabel('Number of grown trees')
ylabel('Out-of-bag classification error')
```

The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `BaggedEnsemble` to `oobPredict`.

## Algorithms

TreeBagger generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly

skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

## **Tips**

Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector.

## **How To**

- “Ensemble Methods” on page 16-64
- “Grouping Variables” on page 2-52

**Purpose** Plot tree

---

**Note** `treedisp` will be removed in a future release. Use `classregtree.view` instead.

---

**Syntax**

```
treedisp(t)
treedisp(t,param1,va11,param2,va12,...)
```

**Description**

---

**Note** This function is superseded by the `view` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t` created with the `classregtree` constructor.

---

`treedisp(t)` takes as input a decision tree `t` as computed by the `treefit` function, and displays it in a figure window. Each branch in the tree is labeled with its decision rule, and each terminal node is labeled with the predicted value for that node.

For each branch node, the left child node corresponds to the points that satisfy the condition, and the right child node corresponds to the points that do not satisfy the condition.

The **Click to display** pop-up menu at the top of the figure enables you to display more information about each node, as described in the following table.

Menu Choice	Displays
Identity	The node number, whether the node is a branch or a leaf, and the rule that governs the node
Variable ranges	The range of each of the predictor variables for that node
Node statistics	Descriptive statistics for the observations falling into this node

# treedisp

---

After you select the type of information you want, click any node to display the information for that node.

The **Pruning level** button displays the number of levels that have been cut from the tree and the number of levels in the unpruned tree. For example, 1 of 6 indicates that the unpruned tree has six levels, and that one level has been cut from the tree. Use the spin button to change the pruning level.

`treedisp(t,param1,val1,param2,val2,...)` specifies optional parameter name-value pairs, listed in the following table.

Parameter	Value
'names'	A cell array of names for the predictor variables, in the order in which they appear in the X matrix from which the tree was created (see <code>treefit</code> )
'prunelevel'	Initial pruning level to display

## Examples

Create and graph classification tree for Fisher's iris data. The names in this example are abbreviations for the column contents (sepal length, sepal width, petal length, and petal width).

```
load fisheriris;
t = treefit(meas,species);
treedisp(t,'names',{'SL' 'SW' 'PL' 'PW'});
```

Click to display:  Magnification:  Pruning level:

---

**Note** treefit will be removed in a future release. Use classregtree instead.

---

**Syntax**

```
t = treefit(X,y)
t = treefit(X,y,param1,val1,param2,val2,...)
```

**Description**

---

**Note** This function is superseded by the classregtree constructor of the classregtree class and is maintained only for backwards compatibility. It returns objects **t** in the classregtree class.

---

`t = treefit(X,y)` creates a decision tree **t** for predicting response **y** as a function of predictors **X**. **X** is an *n*-by-*m* matrix of predictor values. **y** is either a vector of *n* response values (for regression), or a character array or cell array of strings containing *n* class names (for classification). Either way, **t** is a binary tree where each non-terminal node is split based on the values of a column of **X**.

`t = treefit(X,y,param1,val1,param2,val2,...)` specifies optional parameter name-value pairs. Valid parameter strings are:

The following table lists parameters available for all trees.

Parameter	Value
'catidx'	Vector of indices of the columns of <b>X</b> . <code>treefit</code> treats these columns as unordered categorical values.
'method'	Either 'classification' (default if <b>y</b> is text) or 'regression' (default if <b>y</b> is numeric).

Parameter	Value
'splitmin'	A number $n$ such that impure nodes must have $n$ or more observations to be split (default 10).
'prune'	'on' (default) to compute the full tree and a sequence of pruned subtrees, or 'off' for the full tree without pruning.

The following table lists parameters available for classification trees only.

Parameter	Value
'cost'	$p$ -by- $p$ matrix $C$ , where $p$ is the number of distinct response values or class names in the input $y$ . $C(i, j)$ is the cost of classifying a point into class $j$ if its true class is $i$ . (The default has $C(i, j)=1$ if $i \neq j$ , and $C(i, j)=0$ if $i=j$ .) $C$ can also be a structure $S$ with two fields: $S.group$ containing the group names, and $S.cost$ containing a matrix of cost values.
'splitcriterion'	Criterion for choosing a split: either 'gdi' (default) for Gini's diversity index, 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction.
'priorprob'	Prior probabilities for each class, specified as a vector (one value for each distinct group name) or as a structure $S$ with two fields: $S.group$ containing the group names, and $S.prob$ containing a vector of corresponding probabilities.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;
t = treefit(meas,species);
treedisp(t,'names',{'SL' 'SW' 'PL' 'PW'});
```

# treefit

Click to display:  Magnification:  Pruning level:

## How To

- “Grouping Variables” on page 2-52

**Purpose**

Prune tree

---

**Note** treeprune will be removed in a future release. Use `classregtree.prune` instead.

---

**Syntax**

```
t2 = treeprune(t1,'level',level)
t2 = treeprune(t1,'nodes',nodes)
t2 = treeprune(t1)
```

**Description**

---

**Note** This function is superseded by the `prune` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t1` created with the `classregtree` constructor and returns objects `t2` in the `classregtree` class.

---

`t2 = treeprune(t1,'level',level)` takes a decision tree `t1` as created by the `treefit` function, and a pruning level, and returns the decision tree `t2` pruned to that level. Setting `level` to 0 means no pruning. Trees are pruned based on an optimal pruning scheme that first prunes branches giving less improvement in error cost.

`t2 = treeprune(t1,'nodes',nodes)` prunes the nodes listed in the `nodes` vector from the tree. Any `t1` branch nodes listed in `nodes` become leaf nodes in `t2`, unless their parent nodes are also pruned. The `treedisp` function can display the node numbers for any node you select.

`t2 = treeprune(t1)` returns the decision tree `t2` that is the same as `t1`, but with the optimal pruning information added. This is useful only if you created `t1` by pruning another tree, or by using the `treefit` function with pruning set 'off'. If you plan to prune a tree multiple times, it is more efficient to create the optimal pruning sequence first.

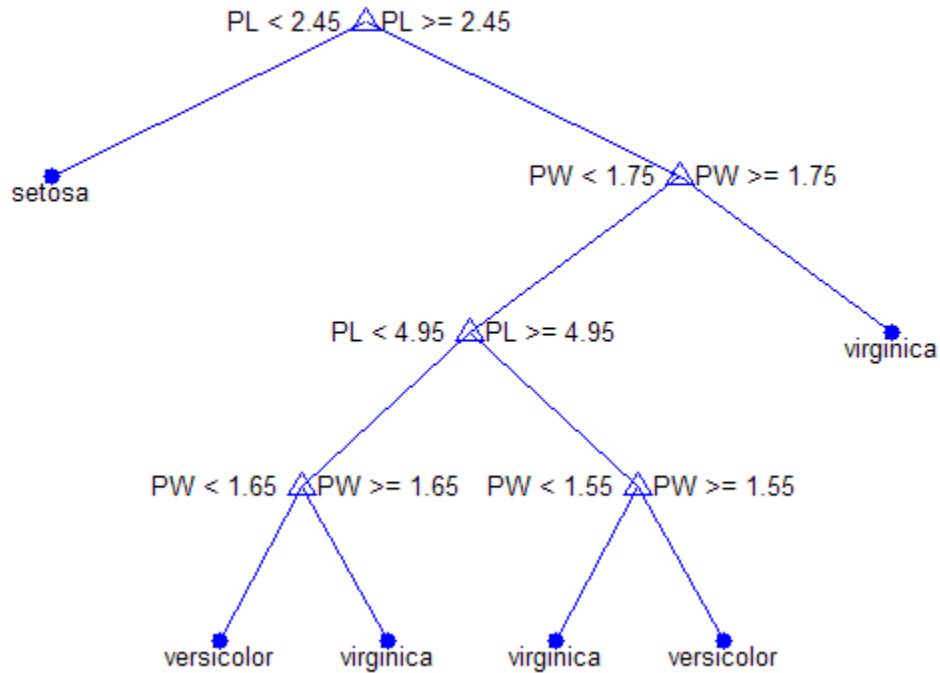

Pruning is the process of reducing a tree by turning some branch nodes into leaf nodes, and removing the leaf nodes under the original branch.

# treeprune

## Examples

Display the full tree for Fisher's iris data, as well as the next largest tree from the optimal pruning sequence:

```
load fisheriris;  
t1 = treefit(meas,species,'splitmin',5);  
treedisp(t1,'names',{'SL' 'SW' 'PL' 'PW'});
```

```
t2 = treeprune(t1,'level',1);  
treedisp(t2,'names',{'SL' 'SW' 'PL' 'PW'});
```

Click to display:  Magnification:  Pruning level:

# TreeBagger.Trees property

---

**Purpose** Decision trees in ensemble

**Description** The Trees property is a cell array of size NTrees-by-1 containing the trees in the ensemble.

**See Also** NTrees

**Purpose**

Error rate

**Syntax**

```
cost = treetest(t,'resubstitution')
cost = treetest(t,'test',X,y)
cost = treetest(t,'crossvalidate',X,y)
[cost,secost,ntnodes,bestlevel] = treetest(...)
[...] = treetest(...,param1,val1,param2,val2,...)
```

---

**Note** `treetest` will be removed in a future release. Use `classregtree.test` instead.

---

**Description**

---

**Note** This function is superseded by the `test` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t` created with the `classregtree` constructor.

---

`cost = treetest(t,'resubstitution')` computes the cost of the tree `t` using a resubstitution method. `t` is a decision tree as created by the `treefit` function. The cost of the tree is the sum over all terminal nodes of the estimated probability of that node times the node's cost. If `t` is a classification tree, the cost of a node is the sum of the misclassification costs of the observations in that node. If `t` is a regression tree, the cost of a node is the average squared error over the observations in that node. `cost` is a vector of cost values for each subtree in the optimal pruning sequence for `t`. The resubstitution cost is based on the same sample that was used to create the original tree, so it underestimates the likely cost of applying the tree to new data.

`cost = treetest(t,'test',X,y)` uses the predictor matrix `X` and response `y` as a test sample, applies the decision tree `t` to that sample, and returns a vector `cost` of cost values computed for the test sample. `X` and `y` should not be the same as the learning sample, which is the sample that was used to fit the tree `t`.

`cost = treetest(t, 'crossvalidate', X, y)` uses 10-fold cross-validation to compute the cost vector. `X` and `y` should be the learning sample, which is the sample that was used to fit the tree `t`. The function partitions the sample into 10 subsamples, chosen randomly but with roughly equal size. For classification trees, the subsamples also have roughly the same class proportions. For each subsample, `treetest` fits a tree to the remaining data and uses it to predict the subsample. It pools the information from all subsamples to compute the cost for the whole sample.

`[cost, secost, ntnodes, bestlevel] = treetest(...)` also returns the vector `secost` containing the standard error of each cost value, the vector `ntnodes` containing number of terminal nodes for each subtree, and the scalar `bestlevel` containing the estimated best level of pruning. `bestlevel = 0` means no pruning, i.e., the full unpruned tree. The best level is the one that produces the smallest tree that is within one standard error of the minimum-cost subtree.

`[...] = treetest(..., param1, val1, param2, val2, ...)` specifies optional parameter name-value pairs chosen from the following table.

Parameter	Value
'nsamples'	The number of cross-validation samples (default is 10)
'treesize'	Either 'se' (default) to choose the smallest tree whose cost is within one standard error of the minimum cost, or 'min' to choose the minimal cost tree.

## Examples

Find the best tree for Fisher's iris data using cross-validation. The solid line shows the estimated cost for each tree size, the dashed line marks one standard error above the minimum, and the square marks the smallest tree under the dashed line.

```
% Start with a large tree.  
load fisheriris;  
t = treefit(meas, species', 'splitmin', 5);
```

```
% Find the minimum-cost tree.
[c,s,n,best] = treetest(t,'cross',meas,species);
tmin = treeprune(t,'level',best);

% Plot smallest tree within 1 std of minimum cost tree.
[mincost,minloc] = min(c);
plot(n,c,'b-o',...
      n(best+1),c(best+1),'bs',...
      n,(mincost+s(minloc))*ones(size(n)), 'k--');
xlabel('Tree size (number of terminal nodes)')
ylabel('Cost')
```

# treetest

---

treefit | treedisp

**Purpose** Predicted responses

---

**Note** treeval will be removed in a future release. Use `classregtree.eval` instead.

---

**Syntax**

```
yfit = treeval(t,X)
yfit = treeval(t,X,subtrees)
[yfit,node] = treeval(...)
[yfit,node,cname] = treeval(...)
```

**Description**

---

**Note** This function is superseded by the `eval` method of the `classregtree` class and is maintained only for backwards compatibility. It accepts objects `t` created with the `classregtree` constructor.

---

`yfit = treeval(t,X)` takes a classification or regression tree `t` as produced by the `treefit` function and a matrix `X` of predictor values, and produces a vector `yfit` of predicted response values. For a regression tree, `yfit(i)` is the fitted response value for a point having the predictor values `X(i,:)`. For a classification tree, `yfit(i)` is the class number into which the tree would assign the point with data `X(i,:)`. To convert the number into a class name, use the third output argument, `cname` (described below).

`yfit = treeval(t,X,subtrees)` takes an additional vector `subtrees` of pruning levels, with 0 representing the full, unpruned tree. `T` must include a pruning sequence as created by the `treefit` or `prunetree` function. If `subtree` has  $k$  elements and `X` has  $n$  rows, the output `yfit` is an  $n$ -by- $k$  matrix, with the  $j$ th column containing the fitted values produced by the `subtrees(j)` subtree. `subtrees` must be sorted in ascending order.

`[yfit,node] = treeval(...)` also returns an array `node` of the same size as `yfit` containing the node number assigned to each row of `X`. The `treedisp` function can display the node numbers for any node you select.

# treeval

---

[yfit,node,cname] = treeval(...) is valid only for classification trees. It returns a cell array cname containing the predicted class names.

## Examples

Find the predicted classifications for Fisher's iris data:

```
load fisheriris;
t = treefit(meas,species); % Create decision tree
sfit = treeval(t,meas); % Find assigned class numbers
sfit = t.classname(sfit); % Get class names
mean(strcmp(sfit,species)) % Proportion in correct class
ans =
    0.9800
```

**Superclasses** ParametricTruncatableDistribution

**Purpose** Triangular probability distribution object

**Description** `prob.TriangularDistribution` is an object consisting of parameters and a model description for a triangular probability distribution. Create a probability distribution object with specified parameters using `makedist`.

**Construction** `pd = makedist('Triangular')` creates a triangular probability distribution object using the default parameter values.

`pd = makedist('Triangular', 'a', a, 'b', b, 'c', c)` creates a triangular distribution object using the specified parameter values.

## Input Arguments

### **a** - Lower limit

0 (default) | scalar value

Lower limit for the triangular distribution, specified as a scalar value.

### Data Types

single | double

### **b** - Peak location

0.5 (default) | scalar value

Peak location for the triangular distribution, specified as a scalar value greater than or equal to **a**.

### Data Types

single | double

### **c** - Upper limit

1 (default) | scalar value

Upper limit for the triangular distribution, specified as a scalar value greater than or equal to **b**.

# prob.TriangularDistribution

---

## Data Types

single | double

## Properties

### **a - Lower limit**

scalar value

Lower limit for the triangular distribution, stored as a scalar value.

## Data Types

single | double

### **b - Peak location**

scalar value

Location of the peak for the triangular distribution, stored as a scalar value greater than or equal to a.

## Data Types

single | double

### **c - Upper limit**

scalar value

Upper limit for the triangular distribution, stored as a scalar value greater than or equal to b.

## Data Types

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

### **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## **ParameterDescription - Distribution parameter descriptions**

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## **ParameterValues - Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

# prob.TriangularDistribution

---

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries.

This property is read-only.

## Data Types

single | double

## Methods

## Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object

mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions **Triangular Distribution**

The triangular distribution is frequently used in simulations when limited sample data is available. The lower and upper limits represent the smallest and largest values, and the location of the peak represents an estimate of the mode.

The triangular distribution uses the following parameters.

Parameter	Description	Support
a	Lower limit	$a \leq b$
b	Peak location	$a \leq b \leq c$
c	Upper limit	$c \geq b$

The probability density function (pdf) is

$$f(x | a, b, c) = \begin{cases} \frac{2(x-a)}{(c-a)(b-a)} & ; a \leq x \leq b \\ \frac{2(c-x)}{(c-a)(c-b)} & ; b < x \leq c \\ 0 & ; x < a, x > c \end{cases} .$$

and

# prob.TriangularDistribution

---

$$f(x|a,b,c) = \frac{2(c-x)}{(c-a)(c-b)} ; b < x \leq c.$$

The value of the pdf is 0 when  $x < a$  or  $x > c$ .

## Examples

### Create a Triangular Distribution Object Using Default Parameters

Create a triangular distribution object using the default parameter values.

```
pd = makedist('Triangular')
```

```
pd =
```

```
TriangularDistribution
```

```
A = 0, B = 0.5, C = 1
```

### Create a Triangular Distribution Object Using Specified Parameters

Create a triangular distribution object by specifying parameter values.

```
pd = makedist('Triangular', 'a', -2, 'b', 1, 'c', 5)
```

```
pd =
```

```
TriangularDistribution
```

```
A = -2, B = 1, C = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1.3333
```

**See Also**

makedist

**Concepts**

- Class Attributes
- Property Attributes

# trimmean

---

**Purpose** Mean excluding outliers

**Syntax**

```
m = trimmean(X,percent)
trimmean(X,percent,dim)
m = trimmean(X,percent,flag)
m = trimmean(x,percent,flag,dim)
```

**Description** `m = trimmean(X,percent)` calculates the trimmed mean of the values in `X`. For a vector input, `m` is the mean of `X`, excluding the highest and lowest `k` data values, where  $k = n * (\text{percent} / 100) / 2$  and where `n` is the number of values in `X`. For a matrix input, `m` is a row vector containing the trimmed mean of each column of `X`. For `n`-D arrays, `trimmean` operates along the first non-singleton dimension. `percent` is a scalar between 0 and 100.

`trimmean(X,percent,dim)` takes the trimmed mean along dimension `dim` of `X`.

`m = trimmean(X,percent,flag)` controls how to trim when `k` is not an integer. `flag` can be chosen from the following:

'round'	Round <code>k</code> to the nearest integer (round to a smaller integer if <code>k</code> is a half integer). This is the default.
'floor'	Round <code>k</code> down to the next smaller integer.
'weight'	If $k = i + f$ where <code>i</code> is the integer part and <code>f</code> is the fraction, compute a weighted mean with weight $(1 - f)$ for the $(i + 1)$ th and $(n - i)$ th values, and full weight for the values between them.

`m = trimmean(x,percent,flag,dim)` takes the trimmed mean along dimension `dim` of `x`.

**Tips** The trimmed mean is a robust estimate of the location of a sample. If there are outliers in the data, the trimmed mean is a more representative estimate of the center of the body of the data than the mean. However, if the data is all from the same probability distribution,

then the trimmed mean is less efficient than the sample mean as an estimator of the location of the data.

## Examples

### Efficiency of the Trimmed Mean

Generate a 100-by-100 matrix of random numbers from the standard normal distribution. This represents 100 samples, each containing 100 data points.

```
rng('default'); % For reproducibility
x = normrnd(0,1,100,100);
```

Compute the sample mean and the 10% trimmed mean for each column of the data matrix.

```
m = mean(x);
trim = trimmean(x,10);
```

Compute the efficiency of the 10% trimmed mean relative to the sample mean for the data.

```
sm = std(m);
strim = std(trim);
efficiency = (sm/strim).^2
```

```
efficiency =

    0.9663
```

### Trimmed Mean for Distributions with Outliers

Generate random data from the  $t$  location-scale distribution, which tends to have outliers.

```
rng('default') % For reproducibility
```

# trimmean

---

```
x = trnd(1,40,1);
```

Visualize the distribution using a normal probability plot.

```
probplot(x)
```

Although the distribution is symmetric around zero, there are several outliers which will affect the mean. The trimmed mean is closer to zero, which is more representative of the data.

```
mean = mean(x)
tmean = trimmean(x,25)
```

```
mean =
      2.7991
```

```
tmean =
      0.8797
```

## See Also

[mean](#) | [median](#) | [geomean](#) | [harmmean](#)

# trnd

---

**Purpose** Student's *t* random numbers

**Syntax**  
R = trnd(V)  
R = trnd(V,m,n,...)  
R = trnd(V,[m,n,...])

**Description** R = trnd(V) generates random numbers from Student's *t* distribution with V degrees of freedom. V can be a vector, a matrix, or a multidimensional array. The size of R is the size of V.  
R = trnd(V,m,n,...) or R = trnd(V,[m,n,...]) generates an m-by-n-by-... array. The V parameter can be a scalar or an array of the same size as R.

**Examples**

```
noisy = trnd(ones(1,6))
noisy =
    19.7250    0.3488    0.2843    0.4034    0.4816   -2.4190

numbers = trnd(1:6,[1 6])
numbers =
   -1.9500   -0.9611   -0.9038    0.0754    0.9820    1.0115

numbers = trnd(3,2,6)
numbers =
   -0.3177  -0.0812  -0.6627    0.1905  -1.5585  -0.0433
    0.2536    0.5502    0.8646    0.8060  -0.5216    0.0891
```

# prob.TruncatableDistribution.truncate

---

**Purpose** Truncate probability distribution object

**Syntax** `t = truncate(pd, lower, upper)`

**Description** `t = truncate(pd, lower, upper)` returns a probability distribution **t**, which is the probability distribution **pd** truncated to the specified interval with lower limit, **lower**, and upper limit, **upper**.

## Input Arguments

### **pd - Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

### **lower - Lower truncation limit**

scalar value

Lower truncation limit, specified as a scalar value.

### **Data Types**

single | double

### **upper - Upper truncation limit**

scalar value

Upper truncation limit, specified as a scalar value.

### **Data Types**

single | double

## Output Arguments

### **t - Truncated distribution**

probability distribution object

Truncated distribution, returned as a probability distribution object. The pdf of **t** is 0 outside the truncation interval. Inside the truncation interval, the pdf of **t** is equal to the pdf of **pd**, but divided by the probability assigned to that interval by **pd**.

## Examples

### Truncate a Probability Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

Truncate the distribution to have a lower limit of -2 and an upper limit of 2.

```
t = truncate(pd,-2,2)
```

```
t =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

```
Truncated to the interval [-2, 2]
```

Plot the pdf of the original and truncated distributions for a visual comparison.

```
x = -3:.1:3;
```

```
figure;
```

```
plot(x,pdf(pd,x),'Color','red','LineWidth',2)
```

```
hold on;
```

```
plot(x,pdf(t,x),'Color','blue','LineWidth',2)
```

```
hold off;
```

# prob.TruncatableDistribution.truncate

---

## Generate Random Numbers from a Truncated Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
  mu = 0
  sigma = 1
```

Truncate the distribution by restricting it to positive values. Set the lower limit to 0 and the upper limit to infinity.

```
t = truncate(pd,0,inf)
```

```
t =
```

```
NormalDistribution

Normal distribution
  mu = 0
  sigma = 1
Truncated to the interval [0, Inf]
```

Generate random numbers from the truncated distribution and visualize with a histogram.

```
r = random(t,10000,1);
hist(r,100)
```

# prob.TruncatableDistribution.truncate

---

**See Also**      `makedist` | `fitdist` | `dffitool`

**Purpose** Student's  $t$  mean and variance

**Syntax** `[M,V] = tstat(NU)`

**Description** `[M,V] = tstat(NU)` returns the mean of and variance for Student's  $t$  distribution using the degrees of freedom in `NU`. `M` and `V` are the same size as `NU`.

The mean of the Student's  $t$  distribution with parameter  $\nu$  is zero for values of  $\nu$  greater than 1. If  $\nu$  is one, the mean does not exist. The variance for values of  $\nu$  greater than 2 is  $\nu/(\nu-2)$ .

**Examples** Find the mean of and variance for 1 to 30 degrees of freedom.

```
[m,v] = tstat(reshape(1:30,6,5))
```

```
m =
```

```

# ttest

---

**Purpose** One-sample and paired-sample *t*-test

**Syntax**

```
h = ttest(x)

h = ttest(x,y)
h = ttest(x,y,Name,Value)

h = ttest(x,m)
h = ttest(x,m,Name,Value)

[h,p] = ttest( ___ )
[h,p,ci,stats] = ttest( ___ )
```

**Description** `h = ttest(x)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean equal to zero and unknown variance, using the one-sample *t*-test. The alternative hypothesis is that the population distribution does not have a mean equal to zero. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest(x,y)` returns a test decision for the null hypothesis that the data in `x` `y` comes from a normal distribution with mean equal to zero and unknown variance, using the paired-sample *t*-test.

`h = ttest(x,y,Name,Value)` returns a test decision for the paired-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`h = ttest(x,m)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean `m` and unknown variance. The alternative hypothesis is that the mean is not `m`.

`h = ttest(x,m,Name,Value)` returns a test decision for the one-sample *t*-test with additional options specified by one or more name-value

pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ttest( ___ )` also returns the  $p$ -value,  $p$ , of the test, using any of the input arguments from the previous syntax groups.

`[h,p,ci,stats] = ttest( ___ )` also returns the confidence interval  $ci$  for the mean of  $x$ , or of  $x - y$  for the paired  $t$ -test, and the structure  $stats$  containing information about the test statistic.

## Input Arguments

### **x - Sample data**

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest` performs a separate  $t$ -test along each column and returns a vector of results. If  $y$  sample data is specified,  $x$  and  $y$  must be the same size.

#### **Data Types**

single | double

### **y - Sample data**

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. If  $y$  sample data is specified,  $x$  and  $y$  must be the same size.

#### **Data Types**

single | double

### **m - Hypothesized population mean**

0 (default) | scalar value

Hypothesized population mean, specified as a scalar value.

#### **Data Types**

single | double

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '`). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Tail','right','Alpha',0.01` conducts a right-tailed hypothesis test at the 1% significance level.

### **'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

**Example:** `'Alpha',0.01`

### **Data Types**

single | double

### **'Dim' - Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim',1` tests the column means, while `'Dim',2` tests the row means.

**Example:** `'Dim',2`

### **Data Types**

single | double

### **'Tail' - Type of alternative hypothesis**

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Test the alternative hypothesis that the population mean is not $m$ .
'right'	Test the alternative hypothesis that the population mean is greater than $m$ .
'left'	Test the alternative hypothesis that the population mean is less than $m$ .

Example: 'Tail', 'right'

## Output Arguments

### **h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p - p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

### **ci - Confidence interval**

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **stats - Test statistics**

structure

Test statistics, returned as a structure containing the following:

# ttest

---

- `tstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `sd` — Estimated population standard deviation. For a paired *t*-test, this is the standard deviation of  $x - y$ .

## Examples

### Test for a Mean Equal to Zero

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns;  
x = stocks(:,3);
```

Test the null hypothesis that the sample data comes from a population with mean equal to zero.

```
[h,p,ci,stats] = ttest(x)
```

```
h =  
    1
```

```
p =  
  
    0.0106
```

```
ci =  
   -0.7357  
   -0.0997
```

```
stats =  
    tstat: -2.6065  
        df: 99  
        sd: 1.6027
```

The returned value `h = 1` indicates that `ttest` rejects the null hypothesis at the 5% significance level.

## Test Hypothesis at a Different Significance Level

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns;  
x = stocks(:,3);
```

Test the null hypothesis that the sample data are from a population with mean equal to zero at the 1% significance level.

```
h = ttest(x,0,'Alpha',0.01)
```

```
h =  
    0
```

The returned value  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

## Paired-Sample t-Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;  
x = grades(:,1);  
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors  $x$  and  $y$  has a mean equal to zero.

```
[h,p] = ttest(x,y)
```

```
h =  
    0  
  
p =  
    0.9805
```

The returned value of  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the default 5% significance level.

## Paired-Sample t-Test at a Different Significance Level

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;  
x = grades(:,1);  
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors  $x$  and  $y$  has a mean equal to zero at the 1% significance level.

```
[h,p] = ttest(x,y,'Alpha',0.01)
```

```
h =  
    0
```

```
p =  
    0.9805
```

The returned value of  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

## Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that sample data comes from a distribution with mean  $m = 75$ .

```
h = ttest(x,75)
```

```
h =
```

0

The returned value of  $h = 0$  indicates that `ttest` does not reject the null hypothesis at the 5% significance level.

### One-Sided Hypothesis Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that the data comes from a population with mean equal to 65, against the alternative that the mean is greater than 65.

```
h = ttest(x,65,'Tail','right')
```

```
h =  
    1
```

The returned value of  $h = 1$  indicates that `ttest` rejects the null hypothesis at the 5% significance level, in favor of the alternate hypothesis that the data comes from a population with a mean greater than 65.

## Definitions

### One-Sample $t$ -Test

The one-sample  $t$ -test is a parametric test of the location parameter when the population standard deviation is unknown.

The test statistic is

$$t = \frac{\bar{x} - \mu}{s / \sqrt{n}},$$

where  $\bar{x}$  is the sample mean,  $\mu$  is the hypothesized population mean,  $s$  is the sample standard deviation, and  $n$  is the sample size. Under

the null hypothesis, the test statistic has Student's  $t$  distribution with  $n - 1$  degrees of freedom.

## **Multidimensional Array**

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

## **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

The result <code>h</code> is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.</p> <p><code>h = ttest2(x,y,Name,Value)</code> returns a test decision for the two-sample <i>t</i>-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct the test without assuming equal variances.</p> <p><code>[h,p] = ttest2( ___ )</code> also returns the <i>p</i>-value, <code>p</code>, of the test, using any of the input arguments in the previous syntaxes.</p> <p><code>[h,p,ci,stats] = ttest2( ___ )</code> also returns the confidence interval on the difference of the population means, <code>ci</code>, and the structure <code>stats</code> containing information about the test statistic.</p>
<b>Input Arguments</b>	<p><b>x - Sample data</b> vector   matrix   multidimensional array</p> <p>Sample data, specified as a vector, matrix, or multidimensional array. <code>ttest2</code> treats NaN values as missing data and ignores them.</p> <ul style="list-style-type: none"><li>• If <code>x</code> and <code>y</code> are specified as vectors, they do not need to be the same length.</li></ul>

- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays, they must have the same size along all but the first nonsingleton dimension.

## Data Types

`single` | `double`

## `y` - Sample data

`vector` | `matrix` | `multidimensional array`

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays, they must have the same size along all but the first nonsingleton dimension. `ttest2` works along the first nonsingleton dimension.

## Data Types

`single` | `double`

## Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( `' '` ). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Tail','right','Alpha',0.01,'Vartype','unequal'` specifies a right-tailed test at the 1% significance level, and does not assume that `x` and `y` have equal population variances.

**'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

**Data Types**

single | double

**'Dim' - Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the column means, while 'Dim',2 tests the row means.

**Example:** 'Dim',2

**Data Types**

single | double

**'Tail' - Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- |         |  |
|---------|--|
| 'both'  | Test the alternative hypothesis that the population means are not equal.                                     |
| 'right' | Test the alternative hypothesis that the population mean of $x$ is greater than the population mean of $y$ . |
| 'left'  | Test the alternative hypothesis that the population mean of $x$ is less than the population mean of $y$ .    |

**Example:** 'Tail','right'

## 'Vartype' - Variance type

'equal' (default) | 'unequal'

Variance type, specified as the comma-separated pair consisting of 'Vartype' and one of the following.

- |           |  |
|-----------|--|
| 'equal'   | Conduct test using the assumption that $x$ and $y$ are from normal distributions with unknown but equal variances.   |
| 'unequal' | Conduct test using the assumption that $x$ and $y$ are from normal distributions with unknown and unequal variances. This is called the Behrens-Fisher problem. <code>ttest2</code> uses Satterthwaite's approximation for the effective degrees of freedom. |

Vartype must be a single string, even when  $x$  is a matrix or a multidimensional array.

**Example:** 'Vartype', 'unequal'

## Output Arguments

### **h** - Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### **p** - **p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

**ci - Confidence interval**

vector

Confidence interval for the difference in population means of  $x$  and  $y$ , returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

**stats - Test statistics**

structure

Test statistics for the two-sample  $t$ -test, returned as a structure containing the following:

- `tstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `sd` — Pooled estimate of the population standard deviation (for the equal variance case) or a vector containing the unpooled estimates of the population standard deviations (for the unequal variance case).

**Examples****Test for Equal Means**

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data samples are from populations with equal means.

```
[h,p,ci,stats] = ttest2(x,y)
```

```
h =
    0
```

```
p =
    0.9867
```

```
ci =  
    -1.9438  
     1.9771  
  
stats =  
    tstat: 0.0167  
     df: 238  
     sd: 7.7084
```

The returned value of  $h = 0$  indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level.

### Test for Equal Means Without Assuming Equal Variances

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;  
x = grades(:,1);  
y = grades(:,2);
```

Test the null hypothesis that the two data vectors are from populations with equal means, without assuming that the populations also have equal variances.

```
[h,p] = ttest2(x,y,'Vartype','unequal')
```

```
h =  
    0  
  
p =  
    0.9867
```

The returned value of  $h = 0$  indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level even if equal variances are not assumed.

## Definitions

### Two-Sample *t*-test

The two-sample *t*-test is a parametric test that compares the location parameter of two independent data samples.

The test statistic is

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_x^2}{n} + \frac{s_y^2}{m}}},$$

where  $\bar{x}$  and  $\bar{y}$  are the sample means,  $s_x$  and  $s_y$  are the sample standard deviations, and  $n$  and  $m$  are the sample sizes.

In the case where it is assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has Student's *t* distribution with  $n + m - 2$  degrees of freedom, and the sample standard deviations are replaced by the pooled standard deviation

$$s = \sqrt{\frac{(n-1)s_x^2 + (m-1)s_y^2}{n+m-2}}.$$

In the case where it is not assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has an approximate Student's *t* distribution with a number of degrees of freedom given by Satterthwaite's approximation. This test is sometimes called Welch's *t*-test.

### Multidimensional Array

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

## grandset.Type property

---

**Purpose** Name of sequence on which point set P is based

**Description** P.Type returns a string that contains the name of the sequence on which the point set P is based, for example 'Sobol'. You cannot change the Type property for a point set.

**Purpose**

Convert categorical array to unsigned 8-bit integers

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax**

```
B = uint8(A)
```

**Description**

`B = uint8(A)` converts the categorical array `A` to unsigned 8-bit integers. Each element of `B` contains the internal categorical level code for the corresponding element of `A`. Undefined elements of `A` are assigned the value 0 in `B`. If `A` contains more than `intmax('uint8')` levels, the internal codes will saturate to `intmax('uint8')` when cast to `int8`.

**See Also**

`double` | `int8`

# categorical.uint16

---

## **Purpose**

Convert categorical array to unsigned 16-bit integers

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`B = uint16(A)`

## **Description**

`B = uint16(A)` converts the categorical array `A` to unsigned 16-bit integers. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.

Undefined elements of `A` are assigned the value 0 in `B`.

## **See Also**

`double` | `int16`

**Purpose** Convert categorical array to unsigned 32-bit integers

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Syntax** `B = uint32(A)`

**Description** `B = uint32(A)` converts the categorical array `A` to unsigned 32-bit integers. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.

Undefined elements of `A` are assigned the value 0 in `B`.

**See Also** `double` | `int32`

# categorical.uint64

---

## **Purpose**

Convert categorical array to unsigned 64-bit integers

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## **Syntax**

`B = uint64(A)`

## **Description**

`B = uint64(A)` converts the categorical array `A` to unsigned 64-bit integers. Each element of `B` contains the internal categorical level code for the corresponding element of `A`.

Undefined elements of `A` are assigned the value 0 in `B`.

## **See Also**

`double` | `int64`

**Purpose**

Text label for undefined levels

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

**Description**

Text label for undefined levels. Constant property with value '`<undefined>`'.

# prob.UniformDistribution

---

**Superclasses** ParametricTruncatableDistribution

**Purpose** Uniform probability distribution object

**Description** prob.UniformDistribution is an object consisting of parameters and a model description for a uniform probability distribution. Create a probability distribution object with specified parameters using `makedist`.

**Construction** `pd = makedist('Uniform')` creates a uniform probability distribution object using the default parameter values.

`pd = makedist('Uniform', 'Lower', lower, 'Upper', upper)` creates a uniform distribution object using the specified parameter values.

## Input Arguments

### **lower - Lower parameter**

0 (default) | scalar value

Lower limit for the uniform distribution, specified as a scalar value.

### **Data Types**

single | double

### **upper - Upper parameter**

1 (default) | scalar value

Upper parameter for the uniform distribution, specified as a scalar value greater than lower.

### **Data Types**

single | double

## Properties

### **lower - Lower parameter**

scalar value

Lower parameter for the uniform distribution, stored as a scalar value.

## Data Types

single | double

### **upper - Upper parameter**

scalar value

Upper parameter for the uniform distribution, stored as a scalar value greater than lower.

## Data Types

single | double

### **DistributionName - Probability distribution name**

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

### **IsTruncated - Logical flag for truncated distribution**

0 | 1

Logical flag for truncated distribution, stored as a logical value. If IsTruncated equals 0, the distribution is not truncated. If IsTruncated equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

### **NumParameters - Number of parameters**

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

### **ParameterDescription - Distribution parameter descriptions**

cell array of strings

# prob.UniformDistribution

---

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## ParameterNames - Distribution parameter names

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

## Data Types

char

## ParameterValues - Distribution parameter values

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

## Data Types

single | double

## Truncation - Truncation interval

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

## Data Types

single | double

## Methods

### Inherited Methods

cdf	Cumulative distribution function of probability distribution object
icdf	Inverse cumulative distribution function of probability distribution object
iqr	Interquartile range of probability distribution object
median	Median of probability distribution object
pdf	Probability density function of probability distribution object
random	Generate random numbers from probability distribution object
truncate	Truncate probability distribution object
mean	Mean of probability distribution object
std	Standard deviation of probability distribution object
var	Variance of probability distribution object

## Definitions

### Uniform Distribution

The uniform distribution has a constant probability density function between its two parameters, lower (the minimum) and upper (the maximum). This distribution is appropriate for representing round-off errors in values tabulated to a particular number of decimal places.

The uniform distribution uses the following parameters.

# prob.UniformDistribution

---

Parameter	Description	Support
lower	Lower parameter	$-\infty < lower < upper$
upper	Upper parameter	$lower < upper < \infty$

The probability density function (pdf) is

$$f(x | lower, upper) = \begin{cases} \left( \frac{1}{upper - lower} \right) & ; \quad lower \leq x \leq upper \\ 0 & ; \quad otherwise \end{cases} .$$

and 0 otherwise.

## Examples

### Create a Uniform Distribution Object Using Default Parameters

Create a uniform distribution object using the default parameter values.

```
pd = makedist('Uniform')
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = 0
```

```
Upper = 1
```

### Create a Uniform Distribution Object Using Specified Parameters

Create a uniform distribution object by specifying parameter values.

```
pd = makedist('Uniform', 'Lower', -4, 'Upper', 2)
```

```
pd =
```

```
UniformDistribution
```

```
Uniform distribution
```

```
Lower = -4
```

```
Upper = 2
```

Compute the interquartile range of the distribution

```
r = iqr(pd)
```

```
r =
```

```
3
```

# dataset.union

---

## Purpose

Set union for dataset array observations

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
C = union(A,B)
C = union(A,B,vars)
C = union(A,B,vars,setOrder)
[C,iA,iB] = union( __ )
```

## Description

`C = union(A,B)` for dataset arrays `A` and `B` returns the combined set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = union(A,B,vars)` returns the combined set of observations from the two arrays, with repetitions of unique combinations of the variables specified in `vars` removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`, or from `A` if there are common observations in both `A` and `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = union(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = union( __ )` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are common observations in `A` and `B`, then `union` returns only the index from `A`, in `iA`. If there are repeated observations in `A` or `B`, then the index of the first occurrence is returned. You can use any of the previous input arguments.

## Input Arguments

**A,B**

Input dataset arrays.

**vars**

Cell array of strings containing variable names or a vector of integers containing variable column numbers, indicating the variables for which `union` removes repetitions of unique combinations of the variables.

Specify `vars` as `[]` to use its default value of all variables.

**setOrder**

Flag indicating the sorting order for the observations in `C`. The possible values of `setOrder` are:

'sorted'	Observations in <code>C</code> are in sorted order (default).
'stable'	Observations in <code>C</code> are in the same order that they appear in <code>A</code> , then <code>B</code> .

**Output Arguments****C**

Dataset array with the combined observations of `A` and `B`, with repetitions removed. `C` is in sorted order (by default), or the order specified by `setOrder`.

**iA**

Index vector, indicating the observations in `A` that contribute to the union. `iA` contains the index to the first occurrence of any repeated observations in `A`.

**iB**

Index vector, indicating the observations in `B` that contribute to the union. If there are common observations in `A` and `B`, then `union` returns only the index from `A`, in `iA`. `iB` contains the index to the first occurrence of any repeated observations in `B`.

## Examples

### Union of Two Dataset Arrays

Navigate to the folder containing sample data, and load sample data.

```
cd(matlabroot)
cd('help/toolbox/stats/examples')

A = dataset('XLSFile','hospitalSmall.xlsx');
B = dataset('XLSFile','hospitalSmall.xlsx','Sheet',2);
[length(A) length(B)]
```

```
ans =

    14     8
```

The first dataset array, A, has 14 observations. The second dataset array, B, has 8 observations.

Return the union.

```
C = union(A,B);
length(C)
```

```
ans =

    21
```

The union of the two dataset arrays has 21 observations, indicating that there was one observation replicated in A and B.

## Related Examples

- “Create a Dataset Array from a File” on page 2-73
- “Merge Dataset Arrays” on page 2-103

## Concepts

- “Dataset Arrays” on page 2-137

## Purpose

Unique observations in dataset array

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

---

**Note** The behavior of `dataset.unique` is consistent with the MATLAB function `unique`. For a demonstration of using the `'legacy'` flag to preserve the behavior from R2012b and prior in your existing code, see the documentation for `unique`.

---

## Syntax

```
C = unique(A)
[C,ia,ic] = unique(A)
C = unique(A,vars)
[C,ia,ic] = unique(A,vars)
[...] = unique(A,vars,occurrence)
[...] = unique(...,'R2012a')
[...] = unique(...,'legacy')
[...] = unique(A,vars,setOrder)
```

## Description

`C = unique(A)` returns a copy of the dataset `A` that contains only the sorted unique observations. `A` must contain only variables whose class has a `unique` method, including:

- numeric
- character
- logical
- categorical
- cell arrays of strings

For a variable with multiple columns, its class's `unique` method must support the `'rows'` flag.

# dataset.unique

---

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A = C(ic,:)`.

`C = unique(A,vars)` returns a dataset that contains only one observation for each unique combination of values for the variables in `A` specified in `vars`. `vars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. `C` includes all variables from `A`. The values in `C` for the variables not specified in `vars` are taken from the last occurrence among observations in `A` with each unique combination of values for the variables specified in `vars`.

`[C,ia,ic] = unique(A,vars)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A(:,vars) = C(ic,vars)`.

`[...] = unique(A,vars,occurrence)` specifies which index is returned in `ia` in the case of repeated observations in `A`. The default value is `occurrence='last'`, which returns the index of the last occurrence of each repeated observation in `A`. `occurrence='first'` returns the index of the first occurrence of each repeated observation in `A`. The values in `C` for variables not specified in `vars` are taken from the observations `A(ia,:)`. Specify `vars` as `[]` to use the default value of all variables.

`[...] = unique(...,'R2012a')` adopts the future behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(...,'legacy')` preserves the current behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(A,vars,setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values of `C` in sorted order. `setOrder='stable'` returns the values of `C` in the same order as `A`. If there are repeated observations in `A`, then `ia` returns the index of the first occurrence of each repeated observation. Specify `vars` as `[]` to use the default value of all variables.

## See Also

## **Purpose**

Units of variables in data set

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Description**

A cell array of strings giving the units of the variables in the data set. This property may be empty, but if not empty, the number of strings must equal the number of variables. Any individual string may be empty for a variable that does not have units defined. The default is an empty cell array.

# unidcdf

---

**Purpose** Discrete uniform cumulative distribution function

**Syntax**  
`p = unidcdf(x,N)`  
`p = unidcdf(x,N,'upper')`

**Description** `p = unidcdf(x,N)` returns the discrete uniform cdf at each value in `x` using the corresponding maximum observable value in `N`. `x` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The maximum observable values in `N` must be positive integers.

`p = unidcdf(x,N,'upper')` returns the complement of the discrete uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The discrete uniform cdf is

$$p = F(x | N) = \frac{\text{floor}(x)}{N} I_{(1, \dots, N)}(x)$$

The result,  $p$ , is the probability that a single observation from the discrete uniform distribution with maximum  $N$  will be a positive integer less than or equal to  $x$ . The values  $x$  do not need to be integers.

## Examples **Compute Discrete Uniform Distribution cdf**

What is the probability of drawing a number 20 or less from a hat with the numbers from 1 to 50 inside?

```
probability = unidcdf(20,50)
```

```
probability =  
    0.4000
```

**See Also** `cdf` | `unidpdf` | `unidinv` | `unidstat` | `unidrnd` | `mle`

**How To** • “Uniform Distribution (Discrete)” on page B-153

**Purpose** Discrete uniform inverse cumulative distribution function

**Syntax** `X = unidinv(P,N)`

**Description** `X = unidinv(P,N)` returns the smallest positive integer  $X$  such that the discrete uniform cdf evaluated at  $X$  is equal to or exceeds  $P$ . You can think of  $P$  as the probability of drawing a number as large as  $X$  out of a hat with the numbers 1 through  $N$  inside.

$P$  and  $N$  can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of  $X$ . A scalar input for  $N$  or  $P$  is expanded to a constant array with the same dimensions as the other input. The values in  $P$  must lie on the interval  $[0\ 1]$  and the values in  $N$  must be positive integers.

**Examples** `x = unidinv(0.7,20)`

```
x =
    14
```

```
y = unidinv(0.7 + eps,20)
```

```
y =
    15
```

A small change in the first parameter produces a large jump in output. The cdf and its inverse are both step functions. The example shows what happens at a step.

**How To** • “Uniform Distribution (Discrete)” on page B-153

# unidpdf

---

**Purpose** Discrete uniform probability density function

**Syntax** `Y = unidpdf(X,N)`

**Description** `Y = unidpdf(X,N)` computes the discrete uniform pdf at each of the values in `X` using the corresponding maximum observable value in `N`. `X` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `N` must be positive integers.

The discrete uniform pdf is

$$y = f(x | N) = \frac{1}{N} I_{(1, \dots, N)}(x)$$

You can think of `y` as the probability of observing any one number between 1 and `n`.

**Examples** For fixed `n`, the uniform discrete pdf is a constant.

```
y = unidpdf(1:6,10)
y =
    0.1000    0.1000    0.1000    0.1000    0.1000    0.1000
```

Now fix `x`, and vary `n`.

```
likelihood = unidpdf(5,4:9)
likelihood =
    0    0.2000    0.1667    0.1429    0.1250    0.1111
```

# unidstat

---

**Purpose** Discrete uniform mean and variance

**Syntax** `[M,V] = unidstat(N)`

**Description** `[M,V] = unidstat(N)` returns the mean and variance of the discrete uniform distribution with minimum value 1 and maximum value  $N$ .

The mean of the discrete uniform distribution with parameter  $N$  is  $(N + 1)/2$ . The variance is  $(N^2 - 1)/12$ .

**Examples**

```
[m,v] = unidstat(1:6)
m =
    1.0000    1.5000    2.0000    2.5000    3.0000    3.5000
v =
    0    0.2500    0.6667    1.2500    2.0000    2.9167
```

**See Also** `unidpdf` | `unidcdf` | `unidinv` | `unidrnd`

**How To**

- “Uniform Distribution (Discrete)” on page B-153

**Purpose** Continuous uniform cumulative distribution function

**Syntax**  
`p = unifcdf(x,a,b)`  
`p = unifcdf(x,a,b,'upper')`

**Description** `p = unifcdf(x,a,b)` returns the uniform cdf at each value in `x` using the corresponding lower endpoint (minimum), `a` and upper endpoint (maximum), `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`p = unifcdf(x,a,b,'upper')` returns the complement of the uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The uniform cdf is

$$p = F(x | a, b) = \frac{x - a}{b - a} I_{[a, b]}(x)$$

The standard uniform distribution has `a = 0` and `b = 1`.

## Examples **Compute Uniform Distribution cdf**

What is the probability that an observation from a standard uniform distribution will be less than 0.75?

```
probability = unifcdf(0.75)
```

```
probability =  
    0.7500
```

What is the probability that an observation from a uniform distribution with `a = -1` and `b = 1` will be less than 0.75?

```
probability = unifcdf(0.75, -1, 1)
```

```
probability =  
    0.8750
```

## How To

- “Uniform Distribution (Continuous)” on page B-147

<b>Purpose</b>	Continuous uniform inverse cumulative distribution function
<b>Syntax</b>	<code>X = unifinv(P,A,B)</code>
<b>Description</b>	<p><code>X = unifinv(P,A,B)</code> computes the inverse of the uniform cdf with parameters A and B (the minimum and maximum values, respectively) at the corresponding probabilities in P. P, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.</p> <p>The inverse of the uniform cdf is</p> $x = F^{-1}(p   a, b) = a + p(b - a)I_{[0,1]}(p)$ <p>The standard uniform distribution has A = 0 and B = 1.</p>
<b>Examples</b>	<p>What is the median of the standard uniform distribution?</p> <pre>median_value = unifinv(0.5) median_value =     0.5000</pre> <p>What is the 99th percentile of the uniform distribution between -1 and 1?</p> <pre>percentile = unifinv(0.99, -1, 1) percentile =     0.9800</pre>
<b>See Also</b>	<code>icdf</code>   <code>unifcdf</code>   <code>unifpdf</code>   <code>unifstat</code>   <code>unifit</code>   <code>unifrnd</code>
<b>How To</b>	<ul style="list-style-type: none"><li>• “Uniform Distribution (Continuous)” on page B-147</li></ul>

# unifit

---

**Purpose** Continuous uniform parameter estimates

**Syntax**  
`[ahat,bhat] = unifit(data)`  
`[ahat,bhat,ACI,BCI] = unifit(data)`  
`[ahat,bhat,ACI,BCI] = unifit(data,alpha)`

**Description** `[ahat,bhat] = unifit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the uniform distribution given the data in `data`.

`[ahat,bhat,ACI,BCI] = unifit(data)` also returns 95% confidence intervals, `ACI` and `BCI`, which are matrices with two rows. The first row contains the lower bound of the interval for each column of the matrix `data`. The second row contains the upper bound of the interval.

`[ahat,bhat,ACI,BCI] = unifit(data,alpha)` enables you to control of the confidence level `alpha`. For example, if `alpha = 0.01` then `ACI` and `BCI` are 99% confidence intervals.

**Examples**

```
r = unifrnd(10,12,100,2);  
[ahat,bhat,aci,bci] = unifit(r)  
ahat =  
    10.0154    10.0060  
bhat =  
    11.9989    11.9743  
aci =  
    9.9551    9.9461  
    10.0154    10.0060  
bci =  
    11.9989    11.9743  
    12.0592    12.0341
```

**See Also** `mle` | `unifpdf` | `unifcdf` | `unifinv` | `unifstat` | `unifrnd`

**How To** • “Uniform Distribution (Continuous)” on page B-147

**Purpose** Continuous uniform probability density function

**Syntax** `Y = unifpdf(X,A,B)`

**Description** `Y = unifpdf(X,A,B)` computes the continuous uniform pdf at each of the values in `X` using the corresponding lower endpoint (minimum), `A` and upper endpoint (maximum), `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `B` must be greater than those in `A`.

The continuous uniform distribution pdf is

$$y = f(x | a, b) = \frac{1}{b - a} I_{[a, b]}(x)$$

The standard uniform distribution has `A = 0` and `B = 1`.

**Examples** For fixed `a` and `b`, the uniform pdf is constant.

```
x = 0.1:0.1:0.6;
y = unifpdf(x)
y =
    1    1    1    1    1    1
```

What if `x` is not between `a` and `b`?

```
y = unifpdf(-1,0,1)
y =
    0
```

**See Also** `pdf` | `unifcdf` | `unifinv` | `unifstat` | `unifit` | `unifrnd`

**How To** • “Uniform Distribution (Continuous)” on page B-147

# unifrnd

---

**Purpose** Continuous uniform random numbers

**Syntax**  
R = unifrnd(A,B)  
R = unifrnd(A,B,m,n,...)  
R = unifrnd(A,B,[m,n,...])

**Description** R = unifrnd(A,B) returns an array R of random numbers generated from the continuous uniform distributions with lower and upper endpoints specified by A and B, respectively. If A and B are arrays, R(i,j) is generated from the distribution specified by the corresponding elements of A and B. If either A or B is a scalar, it is expanded to the size of the other input.

R = unifrnd(A,B,m,n,...) or R = unifrnd(A,B,[m,n,...]) returns an m-by-n-by-... array. If A and B are scalars, all elements of R are generated from the same distribution. If either A or B is an array, they must be m-by-n-by-... .

**Examples** Generate one random number each from the continuous uniform distributions on the intervals (0,1), (0,2), ..., (0,5):

```
a = 0; b = 1:5;  
r1 = unifrnd(a,b)  
r1 =  
    0.8147    1.8116    0.3810    3.6535    3.1618
```

Generate five random numbers each from the same distributions:

```
B = repmat(b,5,1);  
R = unifrnd(a,B)  
R =  
    0.0975    0.3152    0.4257    2.6230    3.7887  
    0.2785    1.9412    1.2653    0.1428    3.7157  
    0.5469    1.9143    2.7472    3.3965    1.9611  
    0.9575    0.9708    2.3766    3.7360    3.2774  
    0.9649    1.6006    2.8785    2.7149    0.8559
```

Generate five random numbers from the continuous uniform distribution on (0,2):

```
r2 = unifrnd(a,b(2),1,5)
r2 =
    1.4121    0.0637    0.5538    0.0923    0.1943
```

**How To**

- “Uniform Distribution (Continuous)” on page B-147

# unifstat

---

**Purpose** Continuous uniform mean and variance

**Syntax** `[M,V] = unifstat(A,B)`

**Description** `[M,V] = unifstat(A,B)` returns the mean of and variance for the continuous uniform distribution using the corresponding lower endpoint (minimum), A and upper endpoint (maximum), B. Vector or matrix inputs for A and B must have the same size, which is also the size of M and V. A scalar input for A or B is expanded to a constant matrix with the same dimensions as the other input.

The mean of the continuous uniform distribution with parameters  $a$  and  $b$  is  $(a + b)/2$ , and the variance is  $(a - b)^2/12$ .

## Examples

```
a = 1:6;
b = 2.*a;
[m,v] = unifstat(a,b)
m =
    1.5000    3.0000    4.5000    6.0000    7.5000    9.0000
v =
    0.0833    0.3333    0.7500    1.3333    2.0833    3.0000
```

**How To** • “Uniform Distribution (Continuous)” on page B-147

<b>Purpose</b>	Set union for categorical arrays
<b>Compatibility</b>	The nominal and ordinal array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB categorical data type instead.
<b>Syntax</b>	<pre>C = union(A,B) [C,IA,IB] = union(A,B) [...] = union(A,B,'rows') [...] = union(...,'legacy') [...] = union(A,B,setOrder) [...] = union(A,B,'rows',setOrder)</pre>
<b>Description</b>	<p><code>C = union(A,B)</code> for categorical vectors <code>A</code> and <code>B</code>, returns a categorical vector <code>C</code> containing the combined values from <code>A</code> and <code>B</code> with no repetitions. The result <code>C</code> is sorted. The set of categorical levels for <code>C</code> is the sorted union of the sets of levels of the inputs, as determined by their labels.</p> <p><code>[C,IA,IB] = union(A,B)</code> also returns index vectors <code>IA</code> and <code>IB</code> such that <code>C</code> is a sorted combination of the elements <code>A(IA)</code> and <code>B(IB)</code>. If there are common values in <code>A</code> and <code>B</code>, then the index is returned in <code>IB</code>. If there are repeated values in <code>A</code> or <code>B</code>, then the index of the last occurrence of each repeated value is returned.</p> <p><code>[...] = union(A,B,'rows')</code> for categorical matrices <code>A</code> and <code>B</code> with the same number of columns, returns the combined rows from the two matrices with no repetitions. The rows of the matrix <code>C</code> are sorted. The set of categorical levels for <code>C</code> is the sorted union of the sets of levels of the inputs. The optional outputs <code>IA</code> and <code>IB</code> are index vectors such that <code>C</code> is the sorted combination of the rows <code>C = A(IA,:)</code> and <code>C = B(IB,:)</code>.</p> <p><code>[...] = union(...,'legacy')</code> preserves the pre-2012a behavior of <code>union</code>. You can specify the flag as the final argument with any previous syntax that accepts <code>A</code>, <code>B</code>, or <code>'rows'</code>.</p> <p><code>[...] = union(A,B,setOrder)</code> and <code>[...] = union(A,B,'rows',setOrder)</code> returns the observations of <code>C</code> in a</p>

## categorical.union

---

specific order. `setOrder='sorted'` returns the values or rows of `C` in sorted order. `setOrder='stable'` returns the values or rows of `C` in the same order as `A`, then `B`. If `A` and `B` are row vectors, then `C` is also a row vector. Otherwise, `C` is a column vector. `IA` and `IB` are column vectors. If there are repeated common values in `A` or `B`, then the index of the first occurrence of each repeated value is returned.

**Purpose**

Unstack data from single variable into multiple variables

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

**Syntax**

```
wide = unstack(tall,datavar,indvar)
[wide,itall] = unstack(tall,datavar,indvar)
wide = unstack(tall,datavar,indvar,'Parameter',value)
```

**Description**

`wide = unstack(tall,datavar,indvar)` converts a dataset array `tall` to an equivalent dataset array `wide` that is in wide format, by unstacking a single variable in `tall` into multiple variables in `wide`. In general `wide` contains more variables, but fewer observations, than `tall`.

`datavar` specifies the data variable in `tall` to unstack. `indvar` specifies an indicator variable in `tall` that determines which variable in `wide` each value in `datavar` is unstacked into. `unstack` treats the remaining variables in `tall` as grouping variables. Each unique combination of their values defines a group of observations in `tall` that will be unstacked into a single observation in `wide`.

`unstack` creates `m` data variables in `wide`, where `m` is the number of group levels in `indvar`. The values in `indvar` indicate which of those `m` variables receive which values from `datavar`. The `j`-th data variable in `wide` contains the values from `datavar` that correspond to observations whose `indvar` value was the `j`-th of the `m` possible levels. Elements of those `m` variables for which no corresponding data value in `tall` exists contain a default value.

`datavar` is a positive integer, a variable name, or a logical vector containing a single true value. `indvar` is a positive integer, a variable name, or a logical vector containing a single true value.

`[wide,itall] = unstack(tall,datavar,indvar)` returns an index vector `itall` indicating the correspondence between observations in `wide` and those in `tall`. For each observation in `wide`, `itall` contains the index of the first in the corresponding group of observations in `tall`.

# dataset.unstack

---

For more information on grouping variables, see “Grouping Variables” on page 2-52.

## Input Arguments

`wide = unstack(tall, datavar, indvar, 'Parameter', value)` uses the following parameter name/value pairs to control how `unstack` converts variables in `tall` to variables in `wide`:

'GroupVars '	Grouping variables in <code>tall</code> that define groups of observations. <code>groupvars</code> is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. The default is all variables in <code>tall</code> not listed in <code>datavar</code> or <code>indvar</code> .
'NewDataVarNames '	A cell array of strings containing names for the data variables <code>unstack</code> should create in <code>wide</code> . Default is the group names of the grouping variable specified in <code>indvar</code> .
'AggregationFun '	A function handle that accepts a subset of values from <code>datavar</code> and returns a single value. <code>stack</code> applies this function to observations from the same group that have the same value of <code>indvar</code> . The function must aggregate the data values into a single value, and in such cases it is not possible to recover <code>tall</code> from <code>wide</code> using <code>stack</code> . The default is <code>@sum</code> for numeric data variables. For non-numeric variables, there is no default, and you must specify 'AggregationFun' if multiple observations in the same group have the same values of <code>indvar</code> .
'ConstVars '	Variables in <code>tall</code> to copy to <code>wide</code> without unstacking. The values for these variables in <code>wide</code> are taken from the first observation in each group in <code>tall</code> , so these variables

should typically be constant within each group. `ConstVars` is a positive integer, a vector of positive integers, a variable name, a cell array containing one or more variable names, or a logical vector. The default is no variables.

You can also specify more than one data variable in `tall`, each of which becomes a set of `m` variables in `wide`. In this case, specify `datavar` as a vector of positive integers, a cell array containing variable names, or a logical vector. You may specify only one variable with `indvar`. The names of each set of data variables in `wide` are the name of the corresponding data variable in `tall` concatenated with the names specified in `'NewDataVarNames'`. The function specified in `'AggregationFun'` must return a value with a single row.

## Examples

Convert a "wide format" data set to "tall format", and then back to a different "wide format":

```
load flu

% FLU has a 'Date' variable, and 10 variables for estimated
% influenza rates (in 9 different regions, estimated from
% Google searches, plus a nationwide estimate from the
% CDC). Combine those 10 variables into a "tall" array that
% has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate
% is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')

% The second observation in FLU is for 10/16/2005. Find the
% observations in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)

% Use the 'Date' variable from that tall array to split
% 'FluRate' into 52 separate variables, each containing the
% estimated influenza rates for each unique date. The new
```

# dataset.unstack

---

```
% "wide" array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames',dateNames)

% Since observations in FLU3 represent regions, IFLU2
% indicates the first occurrence in FLU2 of each region.
flu2(iflu2,:)
```

## How To

- “Grouping Variables” on page 2-52

**Purpose** Upper Pareto tails parameters

**Syntax** `params = upperparams(obj)`

**Description** `params = upperparams(obj)` returns the 2-element vector `params` of shape and scale parameters, respectively, of the upper tail of the Pareto tails object `obj`. `upperparams` does not return a location parameter.

**Examples** Fit Pareto tails to a  $t$  distribution at cumulative probabilities 0.1 and 0.9:

```
t = trnd(3,100,1);  
obj = paretotails(t,0.1,0.9);
```

```
lowerparams(obj)  
ans =  
    -0.1901    1.1898  
upperparams(obj)  
ans =  
    0.3646    0.5103
```

# prob.ToolboxFittableParametricDistribution.var

---

**Purpose** Variance of probability distribution object

**Syntax** `v = var(pd)`

**Description** `v = var(pd)` returns the variance `v` of the probability distribution `pd`.

**Input Arguments** **pd - Probability distribution**  
probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`. Alternatively, create a probability distribution object by fitting it to data using `fitdist` or the Distribution Fitting app.

**Output Arguments** **v - Variance**  
nonnegative scalar value

Variance of the probability distribution, returned as a nonnegative scalar value.

**Examples** **Variance of a Fitted Distribution**

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 75.0083    [73.4321, 76.5846]  
sigma = 8.7202    [7.7391, 9.98843]
```

Compute the variance of the fitted distribution.

```
v = var(pd)
```

```
v =
```

```
76.0419
```

For a normal distribution, the variance is equal to the square of the parameter `sigma`.

## Variance of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v =
```

```
5.3650
```

# dataset.VarDescription property

---

## **Purpose**

Cell array of strings giving descriptions of variables in data set

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Description**

A cell array of strings giving the descriptions of the variables in the data set. This property may be empty, but if not empty, the number of strings must equal the number of variables. Any individual string may be empty for a variable that does not have a description defined. The default is an empty cell array.

<b>Purpose</b>	Compute embedded estimates of input feature importance
<b>Syntax</b>	<code>imp = varimportance(t)</code>
<b>Description</b>	<code>imp = varimportance(t)</code> computes estimates of input feature importance for tree <code>t</code> by summing changes in the risk due to splits on every feature. The returned vector <code>imp</code> has one element for each input variable in the data used to train this tree. At each node, the risk is estimated as node impurity if impurity was used to split nodes and node error otherwise. This risk is weighted by the node probability. Variable importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.
<b>See Also</b>	<code>risk</code>

# dataset.VarNames property

---

## **Purpose**

Cell array giving names of variables in data set

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## **Description**

A cell array of nonempty, distinct strings giving the names of the variables in the data set. The number of strings must equal the number of variables. The default is the cell array of string names for the variables used to create the data set.

# TreeBagger.VarNames property

---

**Purpose**

Variable names

**Description**

The `VarNames` property is a cell array containing the names of the predictor variables (features). `TreeBagger` takes these names from the optional `'names'` parameter. The default names are `'x1'`, `'x2'`, etc.

# vartest

---

**Purpose** Chi-square variance test

**Syntax**  
`h = vartest(x,v)`  
`h = vartest(x,v,Name,Value)`  
`[h,p] = vartest( ___ )`  
`[h,p,ci,stats] = vartest( ___ )`

**Description** `h = vartest(x,v)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with variance `v`, using the chi-square variance test. The alternative hypothesis is that `x` comes from a normal distribution with a different variance. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest(x,v,Name,Value)` performs the chi-square variance test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest( ___ )` also returns the  $p$ -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest( ___ )` also returns the confidence interval for the true variance, `ci`, and the structure `stats` containing information about the test statistic.

## Input Arguments

**x - Sample data**  
vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. For matrices, `vartest` performs separate tests along each column of `x`, and returns a row vector of results. For multidimensional arrays, `vartest` works along the first nonsingleton dimension of `x`.

**Data Types**  
single | double

**v - Hypothesized variance**

nonnegative scalar value

Hypothesized variance, specified as a nonnegative scalar value.

**Data Types**

single | double

**Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1`, `Value1`, ..., `NameN`, `ValueN`.

**Example:** `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

**'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

**Example:** `'Alpha', 0.01`

**Data Types**

single | double

**'Dim' - Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the data in each column for equality to the hypothesized variance, while `'Dim', 2` tests the data in each row.

**Example:** `'Dim', 2`

## Data Types

single | double

## 'Tail' - Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the population variance is not $v$ .
'right'	Test the alternative hypothesis that the population variance is greater than $v$ .
'left'	Test the alternative hypothesis that the population variance is less than $v$ .

Example: 'Tail', 'right'

## Output Arguments

### h - Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

### p - p-value

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

### ci - Confidence interval

vector

Confidence interval for the true variance, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

### **stats - Test statistics**

structure

Test statistics for the chi-square variance test, returned as a structure containing:

- `chisqstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.

## **Examples**

### **Test for a Specified Variance**

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25.

```
[h,p,ci,stats] = vartest(x,25)
```

```
h =
     1
```

```
p =
     0
```

```
ci =
    59.8936
    99.7688
```

```
stats =
```

```
chisqstat: 361.9597
df: 119
```

The returned value  $h = 1$  indicates that `vartest` rejects the null hypothesis at the default 5% significance level. `ci` shows the lower and upper boundaries of the 95% confidence interval for the true variance, and suggests that the true variance is greater than 25.

## One-Sided Hypothesis Test

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25, against the alternative hypothesis that the variance is greater than 25.

```
[h,p] = vartest(x,25,'Tail','right')
```

```
h =
    1
```

```
p =
 2.4269e-26
```

The returned value of  $h = 1$  indicates that `vartest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the variance is greater than 25.

## Definitions

### Chi-Square Variance Test

The chi-square variance test is used to test if the variance of a population is equal to a hypothesized value.

The test statistic is

$$T = \frac{(N-1)}{\left(\frac{s}{\sigma_0}\right)^2},$$

where  $N$  is the sample size,  $s$  is the sample standard deviation, and  $\sigma_0$  is the hypothesized standard deviation. The denominator is the ratio of the sample standard deviation to the hypothesized standard deviation. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. The test statistic  $T$  has a chi-square distribution with  $N - 1$  degrees of freedom under the null hypothesis.

### **Multidimensional Array**

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

### **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

### **See Also**

vartest2 | vartestn

# vartest2

---

**Purpose** Two-sample  $F$ -test for equal variances

**Syntax**

```
h = vartest2(x,y)
h = vartest2(x,y,Name,Value)
[h,p] = vartest2( ___ )
[h,p,ci,stats] = vartest2( ___ )
```

**Description** `h = vartest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from normal distributions with the same variance, using the two-sample  $F$ -test. The alternative hypothesis is that they come from normal distributions with different variances. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest2(x,y,Name,Value)` returns a test decision for the two-sample  $F$ -test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest2( ___ )` also returns the  $p$ -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest2( ___ )` also returns the confidence interval for the true variance ratio, `ci`, and the structure `stats` containing information about the test statistic.

## Input Arguments

**x - Sample data**  
vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `vartest2` performs separate tests along each column and returns a vector of the results.

- If `x` and `y` are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension.

### Data Types

single | double

### `y` - Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `vartest2` performs separate tests along each column and returns a vector of the results.
- If `x` and `y` are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Tail','right','Alpha',0.01` specifies a right-tailed hypothesis test at the 1% significance level.

### 'Alpha' - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

## **Data Types**

single | double

## **'Dim' - Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the data in each column for variance equality, while 'Dim',2 tests the data in each row.

**Example:** 'Dim',2

## **Data Types**

single | double

## **'Tail' - Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate using the  $F$ -test, specified as the comma-separated pair consisting of 'Tail' and one of the following.

- |         |   |
|---------|---|
| 'both'  | Test the alternative hypothesis that the population variances are not equal.                      |
| 'right' | Test the alternative hypothesis that the population variance of $x$ is greater than that of $y$ . |
| 'left'  | Test the alternative hypothesis that the population variance of $x$ is less than that of $y$ .    |

**Example:** 'Tail','right'

## **Output Arguments**

### **h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

**p - p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

**ci - Confidence interval**

vector

Confidence interval for the true ratio of the population variances, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

**stats - Test statistics**

structure

Test statistics for the hypothesis test, returned as a structure containing:

- `fstat` — Value of the test statistic.
- `df1` — Numerator degrees of freedom of the test.
- `df2` — Denominator degrees of freedom of the test.

**Examples****Test for Equal Variances**

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;  
x = grades(:,1);  
y = grades(:,2);
```

## vartest2

---

Test the null hypothesis that the data in  $x$  and  $y$  comes from distributions with the same variance.

```
[h,p,ci,stats] = vartest2(x,y)
```

```
h =
```

```
    1
```

```
p =
```

```
    0.0019
```

```
ci =
```

```
    1.2383
```

```
    2.5494
```

```
stats =
```

```
    fstat: 1.7768
```

```
    df1: 119
```

```
    df2: 119
```

The returned result  $h = 1$  indicates that `vartest2` rejects the null hypothesis at the default 5% significance level. `ci` contains the lower and upper boundaries of the 95% confidence interval for the true variance ratio. `stats` contains the value of the test statistic for the  $F$ -test and the numerator and denominator degrees of freedom.

### One-Sided Hypothesis Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
```

```
x = grades(:,1);
```

```
y = grades(:,2);
```

Test the null hypothesis that the data in  $x$  and  $y$  comes from distributions with the same variance, against the alternative that the population variance of  $x$  is greater than that of  $y$ .

```
vartest2(x,y, 'Tail', 'right')
```

```
h =  
    1
```

```
p =  
    9.4364e-04
```

The returned result  $h = 1$  indicates that `vartest2` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population variance of  $x$  is greater than that of  $y$ .

## Definitions

### Two-Sample $F$ -Test

The two-sample  $F$ -test is used to test if the variances of two populations are equal.

The test statistic is

$$F = \frac{s_1^2}{s_2^2},$$

where  $s_1$  and  $s_2$  are the sample variances. The test statistic is a ratio of the two sample variances. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. Under the null hypothesis, the test statistic  $F$  has a  $F$ -distribution with numerator degrees of freedom equal to  $N_1 - 1$  and denominator degrees of freedom equal to  $N_2 - 1$ , where  $N_1$  and  $N_2$  are the sample sizes of the two data sets.

### Multidimensional Array

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

## **First Nonsingleton Dimension**

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if `x` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `x`.

## **See Also**

`vartest` | `vartestn`

**Purpose**

Multiple-sample tests for equal variances

**Syntax**

```
vartestn(x)
vartestn(x,Name,Value)

vartestn(x,group)
vartestn(x,group,Name,Value)

p = vartestn( ___ )
[p,stats] = vartestn( ___ )
```

**Description**

`vartestn(x)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the columns of data vector `x` come from normal distributions with the same variance. The alternative hypothesis is that not all columns of data have the same variance.

`vartestn(x,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`vartestn(x,group)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the data in each categorical group comes from normal distributions with the same variance. The alternative hypothesis is that not all groups have the same variance.

`vartestn(x,group,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`p = vartestn( ___ )` also returns the  $p$ -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[p,stats] = vartestn( ___ )` also returns the structure `stats` containing information about the test statistic.

## Input Arguments

### **x - Sample data**

matrix | vector

Sample data, specified as a matrix or vector. If a grouping variable `group` is specified, `x` must be a vector. If a grouping variable is not specified, `x` must be a matrix. In either case, `vartestn` treats NaN values as missing values and ignores them.

### **Data Types**

single | double

### **group - Grouping variable**

categorical array | logical or numeric vector | cell array of strings

Grouping variable, specified as a categorical array, logical or numeric vector, or cell array of strings with one row for each element of `x`. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of strings with values 'Male' and 'Female', you can use `Gender` as a grouping variable to test your data by gender.

**Example:** Gender

### **Data Types**

single | double | logical | cell | char

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:**

```
'TestType','BrownForsythe','Alpha',0.01,'Display','off'
```

specifies a Brown-Forsythe test at the 1% significance level, and omits the plot of the results.

**'Alpha' - Significance level**

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

**Data Types**

single | double

**'Dim' - Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the variances, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the column variances, while 'Dim',2 tests the row variances.

**Example:** 'Dim',2

**Data Types**

single | double

**'Display' - Display settings for test results**

'on' (default) | 'off'

Display settings for test results, specified as the comma-separated pair consisting of 'Display' and one of the following.

- 'on'            Display a box plot and table of summary statistics.
- 'off'           Do not display a box plot and table of summary statistics.

**Example:** 'display','off'

## 'TestType' - Type of hypothesis test

'Bartlett' (default) | 'LeveneQuadratic' | 'LeveneAbsolute' | 'BrownForsythe' | 'OBrien'

Type of hypothesis test to perform, specified as the comma-separated pair consisting of 'TestType' and one of the following.

'Bartlett'	Bartlett's test.
'LeveneQuadratic'	Levene's test computed by performing ANOVA on the squared deviations of the data values from their group means.
'LeveneAbsolute'	Levene's test computed by performing ANOVA on the absolute deviations of the data values from their group means.
'BrownForsythe'	Brown-Forsythe test computed by performing ANOVA on the absolute deviations of the data values from the group medians.
'OBrien'	O'Brien's modification of Levene's test with $W = 0.5$ .

**Example:** 'TestType', 'OBrien'

## Output Arguments

### **p** - p-value

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

### **stats** - Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- **chistat:** Value of the test statistic.

- df: Degrees of freedom of the test.

## Examples

### Test Data for Equal Variances

Load the sample data.

```
load examgrades;
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`.

```
vartestn(grades)
```

Group Summary Table			
Group	Count	Mean	Std Dev
1	120	75.0083	8.7202
2	120	74.9917	6.54204
3	120	74.9917	7.43091
4	120	75.0333	8.60128
5	120	74.9917	5.25884
Pooled	600	75.0033	7.42558
Bartlett's statistic	38.7332		
Degrees of freedom	4		
p-value	0		

The low  $p$ -value,  $p = 0$ , indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

### Test Grouped Data for Equal Variances

Load the sample data.

```
load carsmall;
```

Test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
vartestn(MPG,Model_Year)
```

Group Summary Table			
Group	Count	Mean	Std Dev
70	29	17.6897	5.33923
76	34	21.5735	5.8893
82	31	31.7097	5.39255
Pooled	94	23.7181	5.562
Bartlett's statistic	0.36619		
Degrees of freedom	2		
p-value	0.83269		

The high  $p$ -value,  $p = 0.83269$ , indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

### Test for Equal Variances Using Levene's Test

Load the sample data.

```
load carsmall;
```

Use Levene's test to test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
p = vartestn(MPG,Model_Year,'TestType','LeveneAbsolute')
```

p =

0.6320

Group Summary Table			
Group	Count	Mean	Std Dev
70	29	17.6897	5.33923
76	34	21.5735	5.8893
82	31	31.7097	5.39255
Pooled	94	23.7181	5.562
Levene's statistic (absolute)	0.46126		
Degrees of freedom	2, 91		
p-value	0.63195		

The high  $p$ -value,  $p = 0.63195$ , indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

### Test for Equal Variances Using the Brown-Forsythe Test

Load the sample data.

```
load examgrades;
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`, using the Brown-Forsythe test. Suppress the display of the summary table of statistics and the box plot.

```
[p,stats] = vartestn(grades,'TestType','BrownForsythe','Display','off')
```

```
p =
```

```
1.3121e-06
```

```
stats =
```

```
fstat: 8.4160
df: [4 595]
```

The low  $p$ -value,  $p = 1.3121e-06$ , indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

## Definitions

### Bartlett's Test

Bartlett's test is used to test whether multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$T = \frac{(N - k) \ln s_p^2 - \sum_{i=1}^k (N_i - 1) \ln s_i^2}{1 + (1 / (3(k - 1))) \left( \left( \sum_{i=1}^k 1 / (N_i - 1) \right) - 1 / (N - k) \right)},$$

where  $s_i^2$  is the variance of the  $i$ th group,  $N$  is the total sample size,  $N_i$  is the sample size of the  $i$ th group,  $k$  is the number of groups, and  $s_p^2$  is the pooled variance. The pooled variance is defined as

$$s_p^2 = \sum_{i=1}^k (N_i - 1) s_i^2 / (N - k).$$

The test statistic has a chi-square distribution with  $k - 1$  degrees of freedom under the null hypothesis.

Bartlett's test is sensitive to departures from normality. If your data comes from a nonnormal distribution, Levene's test could provide a more accurate result.

### Levene, Brown-Forsythe, and O'Brien Tests

The Levene, Brown-Forsythe, and O'Brien tests are used to test if multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$W = \frac{(N - k) \sum_{i=1}^k N_i (\bar{Z}_i - \bar{Z}_{..})^2}{(k - 1) \sum_{i=1}^k \sum_{j=1}^{N_i} (Z_{ij} - \bar{Z}_i)^2},$$

where  $N_i$  is the sample size of the  $i$ th group, and  $k$  is the number of groups. Depending on the type of test specified with the `TestType` name-value pair arguments,  $Z_{ij}$  can have one of four definitions:

- If you specify `LeveneAbsolute`, `vartestn` uses  $Z_{ij} = |Y_{ij} - \bar{Y}_i|$ , where  $\bar{Y}_i$  is the mean of the  $i$ th subgroup.

- If you specify `LeveneQuadratic`, `vartestn` uses  $Z_{ij}^2 = (Y_{ij} - \bar{Y}_i)^2$ , where  $\bar{Y}_i$  is the mean of the  $i$ th subgroup.
- If you specify `BrownForsythe`, `vartestn` uses  $Z_{ij} = |Y_{ij} - \tilde{Y}_i|$ , where  $\tilde{Y}_i$  is the median of the  $i$ th subgroup.
- If you specify `OBrien`, `vartestn` uses

$$Z_{ij} = \frac{(0.5 + n_i - 2)n_i(y_{ij} - \bar{y}_i)^2 - 0.5(n_i - 1)\sigma_i^2}{(n_i - 1)(n_i - 2)},$$

where  $n_i$  is the size of the  $i$ th group,  $\sigma_i^2$  is its sample variance.

In all cases, the test statistic has an  $F$ -distribution with  $k - 1$  numerator degrees of freedom, and  $N - k$  denominator degrees of freedom.

The Levene, Brown-Forsythe, and O'Brien tests are less sensitive to departures from normality than Bartlett's test, so they are useful alternatives if you suspect the samples come from nonnormal distributions.

## See Also

`anova1` | `vartest` | `vartest2`

# categorical.vertcat

---

## Purpose

Vertical concatenation for categorical arrays

The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the MATLAB `categorical` data type instead.

## Syntax

`C = vertcat(dim,A,B,...)`

`C = vertcat(A,B)`

## Description

`C = vertcat(dim,A,B,...)` vertically concatenates the categorical arrays `A,B,...`. For matrices, all inputs must have the same number of rows. For n-D arrays, all inputs must have the same sizes except in the second dimension. The set of categorical levels for `C` is the sorted union of the sets of levels of the inputs, as determined by their labels.

`C = vertcat(A,B)` is called for the syntax `[A B]`.

## See Also

`cat` | `horzcat`

## Purpose

Vertical concatenation for dataset arrays

The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB `table` data type instead. See MATLAB `table` documentation for more information.

## Syntax

```
ds = vertcat(ds1, ds2, ...)
```

## Description

`ds = vertcat(ds1, ds2, ...)` vertically concatenates the dataset arrays `ds1`, `ds2`, ... . Observation names, when present, must be unique across datasets. `vertcat` fills in default observation names for the output when some of the inputs have names and some do not.

Variable names for all dataset arrays must be identical except for order. `vertcat` concatenates by matching variable names. `vertcat` assigns values for the "per-variable" properties (e.g., `Units` and `VarDescription`) in `ds` from the corresponding property values in `ds1`.

## See Also

`cat` | `horzcat`

# classregtree.view

---

**Purpose** Plot tree

**Syntax** `view(t)`  
`view(t,param1,val1,param2,val2,...)`

**Description** `view(t)` displays the decision tree `t` as computed by `classregtree` in a figure window. Each branch in the tree is labeled with its decision rule, and each terminal node is labeled with the predicted value for that node. Click any node to get more information about it. The information displayed is specified by the **Click to display** pop-up menu at the top of the figure.

`view(t,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs:

- 'names' — A cell array of names for the predictor variables, in the order in which they appear in the matrix `X` from which the tree was created. (See `classregtree`.)
- 'prunelevel' — Initial pruning level to display.

For each branch node, the left child node corresponds to the points that satisfy the condition, and the right child node corresponds to the points that do not satisfy the condition.

## Examples

Create a classification tree for Fisher's iris data:

```
load fisheriris;

t = classregtree(meas,species,...
                'names',{'SL' 'SW' 'PL' 'PW'})
t =
Decision tree for classification
1  if PL<2.45 then node 2 elseif PL>=2.45 then node 3 else setosa
2  class = setosa
3  if PW<1.75 then node 4 elseif PW>=1.75 then node 5 else versicolor
4  if PL<4.95 then node 6 elseif PL>=4.95 then node 7 else versicolor
5  class = virginica
```

```
6 if PW<1.65 then node 8 elseif PW>=1.65 then node 9 else versicolor
7 class = virginica
8 class = versicolor
9 class = virginica

view(t)
```

Click to display:  Magnification:  Pruning level:

# clustering.evaluation.ClusterCriterion.compact

---

<b>Purpose</b>	Compact clustering evaluation object
<b>Syntax</b>	<code>c = compact(eva)</code>
<b>Description</b>	<code>c = compact(eva)</code> returns a compact clustering evaluation object, which contains a subset of information about the clustering solution in <code>eva</code> . Compacting a clustering evaluation object reduces the memory requirements of the object, which is useful when clustering a large data set.
<b>Input Arguments</b>	<b>eva - Clustering evaluation data</b> clustering evaluation object  Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using <code>evalclusters</code> .
<b>Output Arguments</b>	<b>c - Compact clustering evaluation object</b> clustering evaluation object  Compact clustering evaluation object, returned as a clustering evaluation object. The compact object includes the clustering evaluation results. In the compact object, the properties for the input data <code>X</code> , optimal clustering solution <code>OptimalY</code> , and the list of excluded data <code>Missing</code> are empty.
<b>Examples</b>	<b>Create a Compact Clustering Evaluation Object</b>  Create a compact clustering evaluation object from a full clustering evaluation object.  Load the sample data.  <pre>load fisheriris;</pre>  The data contains length and width measurements from the sepals and petals of three species of iris flowers.

# clustering.evaluation.ClusterCriterion.compact

---

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the gap criterion.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','Gap','KList',[1:6])

eva =

    GapEvaluation with properties:

        NumObservations: 150
        InspectedK: [1 2 3 4 5 6]
        CriterionValues: [0.0747 0.5906 0.8737 1.0055 1.0466 0.9848]
        OptimalK: 4
```

Create a compact clustering evaluation object from `eva`.

```
c = compact(eva)

c =

    GapEvaluation with properties:

        NumObservations: 150
        InspectedK: [1 2 3 4 5 6]
        CriterionValues: [0.0747 0.5906 0.8737 1.0055 1.0466 0.9848]
        OptimalK: 4
```

The displayed output of the compact object `c` is the same as the original object `eva`, but some properties not shown in the display are different. For example, in the compact object, the properties `x`, `OptimalY`, and `Missing` are empty.

Display the optimal clustering solution `OptimalY` for `c`.

```
c.OptimalY

ans =
```

# CompactClassificationTree.view

---

**Purpose** View tree

**Syntax** `view(tree)`  
`view(tree,Name,Value)`

**Description** `view(tree)` returns a text description of `tree`, a decision tree.  
`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

**Input Arguments** **tree**  
A classification tree or compact classification tree created by `fitctree` or `compact`.

## **Name-Value Pair Arguments**

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

### **'mode'**

String describing the display of `tree`, either 'graph' or 'text'. 'graph' opens a user interface displaying `tree`, and containing controls for querying the tree. 'text' sends output to the Command Window describing `tree`.

**Default:** 'text'

**Examples** View the classification tree for Fisher's iris model in both textual and graphical displays:

```
load fisheriris
tree = fitctree(meas,species);
view(tree)
```

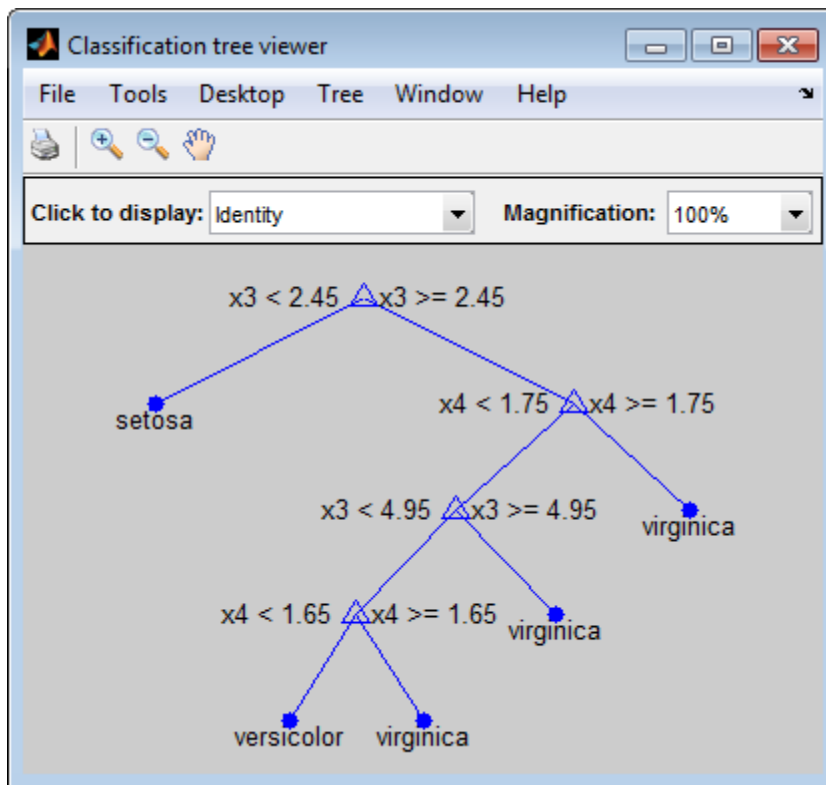

# CompactClassificationTree.view

---

```
Decision tree for classification

# wblcdf

---

**Purpose** Weibull cumulative distribution function

**Syntax**

```
p = wblcdf(x,a,b)
[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)
[p,plo,pup] = wblcdf( __ , 'upper' )
```

**Description** `p = wblcdf(x,a,b)` returns the cdf of the Weibull distribution with scale parameter `a` and shape parameter `b`, at each value in `x`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `a` and `b` are both 1. The parameters `a` and `b` must be positive.

`[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)` returns confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is the 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = wblcdf( __ , 'upper' )` returns the complement of the Weibull cdf for each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use 'upper' with any of the previous syntaxes.

The function `wblcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\hat{b}(\log x - \log \hat{a})$$

and then transforms those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The Weibull cdf is

$$p = F(x | a, b) = \int_0^x b a^{-b} t^{b-1} e^{-\left(\frac{t}{a}\right)^b} dt = 1 - e^{-\left(\frac{x}{a}\right)^b} I_{(0, \infty)}(x)$$

**Examples****Weibull Distribution cdf**

What is the probability that a value from a Weibull distribution with parameters  $a = 0.15$  and  $b = 0.8$  is less than 0.5?

```
probability = wblcdf(0.5, 0.15, 0.8)
```

```
probability =  
0.9272
```

How sensitive is this result to small changes in the parameters?

```
[A, B] = meshgrid(0.1:0.05:0.2, 0.2:0.05:0.3);  
probability = wblcdf(0.5, A, B)
```

```
probability =  
0.7484 0.7198 0.6991  
0.7758 0.7411 0.7156  
0.8022 0.7619 0.7319
```

**See Also**

**How To**

- “Weibull Distribution” on page B-156

**Purpose** Weibull parameter estimates

**Syntax**

```
parmhat = wblfit(data)
[parmhat,parmci] = wblfit(data)
[parmhat,parmci] = wblfit(data,alpha)
[...] = wblfit(data,alpha,censoring)
[...] = wblfit(data,alpha,censoring,freq)
[...] = wblfit(...,options)
```

**Description** `parmhat = wblfit(data)` returns the maximum likelihood estimates, `parmhat`, of the parameters of the Weibull distribution given the values in the vector `data`, which must be positive. `parmhat` is a two-element row vector: `parmhat(1)` estimates the Weibull parameter  $a$ , and `parmhat(2)` estimates the Weibull parameter  $b$ , in the pdf

$$y = f(x | a, b) = ba^{-b} x^{b-1} e^{-\left(\frac{x}{a}\right)^b} I_{(0, \infty)}(x)$$

`[parmhat,parmci] = wblfit(data)` returns 95% confidence intervals for the estimates of  $a$  and  $b$  in the 2-by-2 matrix `parmci`. The first row contains the lower bounds of the confidence intervals for the parameters, and the second row contains the upper bounds of the confidence intervals.

`[[parmhat,parmci] = wblfit(data,alpha)` returns  $100(1 - \text{alpha})\%$  confidence intervals for the parameter estimates.

`[...] = wblfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wblfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any non-negative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

[...] = wblfit(...,options) accepts a structure, options, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The Weibull fit function accepts an options structure that can be created using the function statset. Enter statset ('wblfit') to see the names and default values of the parameters that lognfit accepts in the options structure. See the reference page for statset for more information about these options.

## Examples

```
data = wblrnd(0.5,0.8,100,1);
[paramhat, parmci] = wblfit(data)
paramhat =
    0.5861    0.8567
parmci =
    0.4606    0.7360
    0.7459    0.9973
```

## How To

- “Weibull Distribution” on page B-156

# wblinv

---

**Purpose** Weibull inverse cumulative distribution function

**Syntax**  
`X = wblinv(P,A,B)`  
`[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)`

**Description** `X = wblinv(P,A,B)` returns the inverse cumulative distribution function (cdf) for a Weibull distribution with scale parameter `A` and shape parameter `B`, evaluated at the values in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `A` and `B` are both 1.

`[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)` returns confidence bounds for `X` when the input parameters `A` and `B` are estimates. `PCOV` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `wblinv` computes confidence bounds for `X` using a normal approximation to the distribution of the estimate

$$\log a + \frac{\log q}{b}$$

where `q` is the `P`th quantile from a Weibull distribution with scale and shape parameters both equal to 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `PCOV` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The inverse of the Weibull cdf is

$$x = F^{-1}(p | a, b) = -a [\ln(1 - p)]^{1/b} I_{[0,1]}(p)$$

**Examples** The lifetimes (in hours) of a batch of light bulbs has a Weibull distribution with parameters `a = 200` and `b = 6`.

Find the median lifetime of the bulbs:

```
life = wblinv(0.5, 200, 6)
life =
    188.1486
```

---

Generate 100 random values from this distribution, and estimate the 90th percentile (with confidence bounds) from the random sample

```
x = wblrnd(200,6,100,1);
p = wblfit(x)
[nlogl,pcov] = wbllike(p,x)
[q90,q90lo,q90up] = wblinv(0.9,p(1),p(2),pcov)
p =
```

```
    204.8918    6.3920
```

```
nlogl =
```

```
    496.8915
```

```
pcov =
```

```
    11.3392    0.5233
     0.5233    0.2573
```

```
q90 =
```

```
    233.4489
```

```
q90lo =
```

226.0092

q90up =

241.1335

## **How To**

- “Weibull Distribution” on page B-156

**Purpose**

Weibull negative log-likelihood

**Syntax**

```
nlogL = wbllike(params,data)
[logL,AVAR] = wbllike(params,data)
[...] = wbllike(params,data,censoring)
[...] = wbllike(params,data,censoring,freq)
```

**Description**

`nlogL = wbllike(params,data)` returns the Weibull log-likelihood. `params(1)` is the scale parameter, `A`, and `params(2)` is the shape parameter, `B`.

`[logL,AVAR] = wbllike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = wbllike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wbllike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

The Weibull negative log-likelihood for uncensored data is

$$(-\log L) = -\log \prod_{i=1}^n f(a,b | x_i) = -\sum_{i=1}^n \log f(a,b | x_i)$$

where  $f$  is the Weibull pdf.

`wbllike` is a utility function for maximum likelihood estimation.

**Examples**

This example continues the example from `wblfit`.

```
r = wblrnd(0.5,0.8,100,1);
```

```
[logL, AVAR] = wbllike(wblfit(r),r)
logL =
    47.3349
AVAR =
    0.0048    0.0014
    0.0014    0.0040
```

## How To

- “Weibull Distribution” on page B-156

**Purpose** Weibull probability density function

**Syntax** `Y = wblpdf(X,A,B)`

**Description** `Y = wblpdf(X,A,B)` computes the Weibull pdf at each of the values in `X` using the corresponding scale parameter, `A` and shape parameter, `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The parameters in `A` and `B` must be positive.

The Weibull pdf is

$$f(x | a, b) = \frac{b}{a} \left( \frac{x}{a} \right)^{b-1} e^{-(x/a)^b}.$$

Some references refer to the Weibull distribution with a single parameter. This corresponds to `wblpdf` with `A = 1`.

**Examples** The exponential distribution is a special case of the Weibull distribution.

```
lambda = 1:6;
y = wblpdf(0.1:0.1:0.6,lambda,1)
y =
    0.9048    0.4524    0.3016    0.2262    0.1810    0.1508

y1 = exppdf(0.1:0.1:0.6,lambda)
y1 =
    0.9048    0.4524    0.3016    0.2262    0.1810    0.1508
```

## How To

- `wblfit`
- `wblinv`
- `wbllike`
- `wblplot`
- `wblrnd`
- `wblstat`
- “Weibull Distribution” on page B-156

**Purpose** Weibull probability plot

**Syntax** `wblplot(X)`  
`h = wblplot(X)`

**Description** `wblplot(X)` displays a Weibull probability plot of the data in `X`. If `X` is a matrix, `wblplot` displays a plot for each column.

`h = wblplot(X)` returns handles to the plotted lines.

The purpose of a Weibull probability plot is to graphically assess whether the data in `X` could come from a Weibull distribution. If the data are Weibull the plot will be linear. Other distribution types might introduce curvature in the plot. `wblplot` uses midpoint probability plotting positions. Use `probplot` when the data included censored observations.

## **Examples** **Create a Weibull Probability Plot**

Generate a vector `r` containing 50 random numbers from a Weibull distribution with parameters `A = 1.2` and `B = 1.5`.

```
rng('default'); % For reproducibility
r = wblrnd(1.2,1.5,50,1);
```

Create a Weibull probability plot to visually determine if the data comes from a Weibull distribution.

```
figure;
wblplot(r)
```

The plot indicates that the data likely comes from a Weibull distribution.

- wblstat
- “Weibull Distribution” on page B-156

# wblrnd

---

**Purpose** Weibull random numbers

**Syntax**  
R = wblrnd(A,B)  
R = wblrnd(A,B,m,n,...)  
R = wblrnd(A,B,[m,n,...])

**Description** R = wblrnd(A,B) generates random numbers for the Weibull distribution with scale parameter, A and shape parameter, B. The input arguments A and B can be either scalars or matrices. A and B, can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input.

R = wblrnd(A,B,m,n,...) or R = wblrnd(A,B,[m,n,...]) generates an m-by-n-by-... array. The A, B parameters can each be scalars or arrays of the same size as R.

Devroye [1] refers to the Weibull distribution with a single parameter; this is wblrnd with A = 1.

**Examples**  
n1 = wblrnd(0.5:0.5:2,0.5:0.5:2)  
n1 =  
0.0178 0.0860 2.5216 0.9124

n2 = wblrnd(1/2,1/2,[1 6])  
n2 =  
0.0046 1.7214 2.2108 0.0367 0.0531 0.0917

**References** [1] Devroye, L. *Non-Uniform Random Variate Generation*. New York: Springer-Verlag, 1986.

**How To** • “Weibull Distribution” on page B-156

**Purpose** Weibull mean and variance

**Syntax** `[M,V] = wblstat(A,B)`

**Description** `[M,V] = wblstat(A,B)` returns the mean of and variance for the Weibull distribution with scale parameter, A and shape parameter, B. Vector or matrix inputs for A and B must have the same size, which is also the size of M and V. A scalar input for A or B is expanded to a constant matrix with the same dimensions as the other input.

The mean of the Weibull distribution with parameters  $a$  and  $b$  is

$$a \left[ \Gamma(1+b^{-1}) \right]$$

and the variance is

$$a^2 \left[ \Gamma(1+2b^{-1}) - \Gamma(1+b^{-1})^2 \right]$$

### Examples

```
[m,v] = wblstat(1:4,1:4)
m =
    1.0000    1.7725    2.6789    3.6256
v =
    1.0000    0.8584    0.9480    1.0346
```

```
wblstat(0.5,0.7)
ans =
    0.6329
```

# prob.WeibullDistribution

---

**Superclasses** ToolboxFittableParametricDistribution

**Purpose** Weibull probability distribution object

**Description** `prob.WeibullDistribution` is an object consisting of parameters, a model description, and sample data for a Weibull probability distribution.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a distribution to data using `fitdist` or the Distribution Fitting app.

**Construction** `pd = makedist('Weibull')` creates a Weibull probability distribution object using the default parameter values.

`pd = makedist('Weibull','a',a,'b',b)` creates a Weibull probability distribution object using the specified parameter values.

## Input Arguments

### **a** - Scale parameter

1 (default) | positive scalar value

Scale parameter of the Weibull distribution, specified as a positive scalar value.

### Data Types

single | double

### **b** - Shape parameter

1 (default) | positive scalar value

Shape parameter of the Weibull distribution, specified as a positive scalar value.

### Data Types

single | double

**Properties** **a** - Scale parameter

positive scalar value

Scale parameter of the Weibull distribution, stored as a positive scalar value.

## Data Types

single | double

## **b** - Shape parameter

positive scalar value

Shape parameter of the Weibull distribution, stored as a positive scalar value.

## Data Types

single | double

## **DistributionName** - Probability distribution name

probability distribution name string

Probability distribution name, stored as a valid probability distribution name string. This property is read-only.

## Data Types

char

## **InputData** - Data used for distribution fitting

structure

Data used for distribution fitting, stored as a structure containing the following:

- data: Data vector used for distribution fitting.
- cens: Censoring vector, or empty if none.
- freq: Frequency vector, or empty if none.

This property is read-only.

## Data Types

struct

## **IsTruncated** - Logical flag for truncated distribution

0 | 1

# prob.WeibullDistribution

---

Logical flag for truncated distribution, stored as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated. This property is read-only.

## Data Types

logical

## NumParameters - Number of parameters

positive integer value

Number of parameters for the probability distribution, stored as a positive integer value. This property is read-only.

## Data Types

single | double

## ParameterCovariance - Covariance matrix of the parameter estimates

matrix of scalar values

Covariance matrix of the parameter estimates, stored as a  $p$ -by- $p$  matrix, where  $p$  is the number of parameters in the distribution. The  $(i,j)$  element is the covariance between the estimates of the  $i$ th parameter and the  $j$ th parameter. The  $(i,i)$  element is the estimated variance of the  $i$ th parameter. If parameter  $i$  is fixed rather than estimated by fitting the distribution to data, then the  $(i,i)$  elements of the covariance matrix are 0. This property is read-only.

## Data Types

single | double

## ParameterDescription - Distribution parameter descriptions

cell array of strings

Distribution parameter descriptions, stored as a cell array of strings. Each cell contains a short description of one distribution parameter. This property is read-only.

## Data Types

char

## **ParameterIsFixed - Logical flag for fixed parameters**

array of logical values

Logical flag for fixed parameters, stored as an array of logical values. If 0, the corresponding parameter in the ParameterNames array is not fixed. If 1, the corresponding parameter in the ParameterNames array is fixed. This property is read-only.

### **Data Types**

logical

## **ParameterNames - Distribution parameter names**

cell array of strings

Distribution parameter names, stored as a cell array of strings. This property is read-only.

### **Data Types**

char

## **ParameterValues - Distribution parameter values**

vector of scalar values

Distribution parameter values, stored as a vector. This property is read-only.

### **Data Types**

single | double

## **Truncation - Truncation interval**

vector of scalar values

Truncation interval for the probability distribution, stored as a vector containing the lower and upper truncation boundaries. This property is read-only.

### **Data Types**

single | double

## Definitions

### Weibull Distribution

The Weibull distribution is used in reliability and lifetime modeling, and to model the breaking strength of materials.

The Weibull distribution uses the following parameters.

Parameter	Description	Support
a	Scale parameter	$a > 0$
b	Shape parameter	$b > 0$

The probability density function (pdf) is

$$f(x | a, b) = \frac{b}{a} \left(\frac{x}{a}\right)^{b-1} \exp\left\{-\left(\frac{x}{a}\right)^b\right\} ; x \geq 0.$$

## Examples

### Create a Weibull Distribution Object Using Default Parameters

Create a Weibull distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

```
pd =
```

```
WeibullDistribution
```

```
Weibull distribution
```

```
A = 1
```

```
B = 1

# TreeBagger.X property

---

**Purpose** X data used to create ensemble

**Description** The X property is a numeric matrix of size Nobs-by-Nvars, where Nobs is the number of observations (rows) and Nvars is the number of variables (columns) in the training data. This matrix contains the predictor (or feature) values.

---

<b>Purpose</b>	Create table from data stored in SAS XPORT format file
<b>Syntax</b>	<pre>data = xptread data = xptread(filename) [data,missing] = xptread(filename) xptread(...,'ReadObsNames',true)</pre>
<b>Description</b>	<p><code>data = xptread</code> displays a dialog box for selecting a file, then reads data from the file into a table. The file must be in the SAS XPORT format.</p> <p><code>data = xptread(filename)</code> retrieves data from a SAS XPORT format file <code>filename</code>. The XPORT format allows for 28 missing data types, represented in the file by an upper case letter, '.' or '_'. <code>xptread</code> converts all missing data to NaN values in <code>data</code>. However, if you need the specific missing types then you can recover this information by specifying a second output.</p> <p><code>[data,missing] = xptread(filename)</code> returns a nominal array, <code>missing</code>, of the same size as <code>data</code> containing the missing data type information from the xport format file. The entries are undefined for values that are not present and are one of '.', '_', 'A', ..., 'Z' for missing values.</p> <p><code>xptread(...,'ReadObsNames',true)</code> treats the first variable in the file as observation names. The default value is false.</p> <p><code>xptread</code> only supports single data sets per file. <code>xptread</code> does not support compressed files.</p>
<b>Examples</b>	<p><b>Read In SAS XPORT Data</b></p> <p>Read in SAS XPORT format data.</p> <pre>data = xptread('sample.xpt');</pre>
<b>See Also</b>	<code>table</code>

**Purpose** Convert predictor matrix to design matrix

**Syntax**

```
D = x2fx(X,model)
D = x2fx(X,model,categ)
D = x2fx(X,model,categ,catlevels)
```

**Description** `D = x2fx(X,model)` converts a matrix of predictors `X` to a design matrix `D` for regression analysis. Distinct predictor variables should appear in different columns of `X`.

The optional input `model` controls the regression model. By default, `x2fx` returns the design matrix for a linear additive model with a constant term. `model` is one of the following strings:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

If `X` has  $n$  columns, the order of the columns of `D` for a full quadratic model is:

- 1 The constant term
- 2 The linear terms (the columns of `X`, in order 1, 2, ...,  $n$ )
- 3 The interaction terms (pairwise products of the columns of `X`, in order (1, 2), (1, 3), ..., (1,  $n$ ), (2, 3), ..., ( $n-1$ ,  $n$ ))
- 4 The squared terms (in order 1, 2, ...,  $n$ )

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each column in `X` and one row for each term in the model. The entries in any row of `model` are powers for the corresponding columns of `X`. For example, if `X` has columns `X1`, `X2`, and `X3`, then a row `[0 1 2]` in `model`

specifies the term  $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$ . A row of all zeros in *model* specifies a constant term, which can be omitted.

`D = x2fx(X,model,categ)` treats columns with numbers listed in the vector *categ* as categorical variables. Terms involving categorical variables produce dummy variable columns in *D*. Dummy variables are computed under the assumption that possible categorical levels are completely enumerated by the unique values that appear in the corresponding column of *X*.

`D = x2fx(X,model,categ,catlevels)` accepts a vector *catlevels* the same length as *categ*, specifying the number of levels in each categorical variable. In this case, values in the corresponding column of *X* must be integers in the range from 1 to the specified number of levels. Not all of the levels need to appear in *X*.

## Examples

### Example 1

The following converts 2 predictors *X1* and *X2* (the columns of *X*) into a design matrix for a full quadratic model with terms constant, *X1*, *X2*,  $X1 \cdot X2$ ,  $X1.^2$ , and  $X2.^2$ .

```
X = [1 10
     2 20
     3 10
     4 20
     5 15
     6 15];
```

```
D = x2fx(X,'quadratic')
D =
     1     1    10    10     1    100
     1     2    20    40     4    400
     1     3    10    30     9    100
     1     4    20    80    16    400
     1     5    15    75    25    225
     1     6    15    90    36    225
```

**Example 2**

The following converts 2 predictors X1 and X2 (the columns of X) into a design matrix for a quadratic model with terms constant, X1, X2, X1.\*X2, and X1.^2.

```
X = [1 10
      2 20
      3 10
      4 20
      5 15
      6 15];
model = [0 0
         1 0
         0 1
         1 1
         2 0];

D = x2fx(X,model)
D =
     1     1    10    10     1
     1     2    20    40     4
     1     3    10    30     9
     1     4    20    80    16
     1     5    15    75    25
     1     6    15    90    36
```

**See Also**

[regstats](#) | [rstool](#) | [candexch](#) | [candgen](#) | [cordexch](#) | [rowexch](#)

**Purpose** Y data used to create ensemble

**Description** The Y property is an array of true class labels for classification, or response values for regression. Y can be a numeric column vector, a character matrix, or a cell array of strings.

# zscore

---

**Purpose** Standardized  $z$ -scores

**Syntax**

```
Z = zscore(X)
Z = zscore(X, flag)
Z = zscore(X, flag, dim)
[Z, mu, sigma] = zscore( ___ )
```

**Description** `Z = zscore(X)` returns the  $z$ -score for each element of  $X$  such that columns of  $X$  are centered to have mean 0 and scaled to have standard deviation 1.  $Z$  is the same size as  $X$ .

- If  $X$  is a vector, then  $Z$  is a vector of  $z$ -scores.
- If  $X$  is a matrix, then  $Z$  is a matrix of the same size as  $X$ , and each column of  $Z$  has mean 0 and standard deviation 1.
- For multidimensional arrays,  $z$ -scores in  $Z$  are computed along the first nonsingleton dimension of  $X$ .

`Z = zscore(X, flag)` scales  $X$  using the standard deviation indicated by `flag`.

- If `flag` is 0 (default), then `zscore` scales  $X$  using the sample standard deviation, with  $n - 1$  in the denominator of the standard deviation formula. `zscore(X, 0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales  $X$  using the population standard deviation, with  $n$  in the denominator of standard deviation formula.

`Z = zscore(X, flag, dim)` standardizes  $X$  along dimension `dim`. For example, for a matrix  $X$ , if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of  $X$ , if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of  $X$ .

`[Z, mu, sigma] = zscore( ___ )` also returns the means and standard deviations used for centering and scaling, `mu` and `sigma`, respectively. You can use any of the input arguments in the previous syntaxes.

## Input Arguments

### **X - Input data**

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

### **Data Types**

double | single

### **flag - Indicator for the standard deviation**

0 (default) | 1

Indicator for the standard deviation used to compute the  $z$ -scores, specified as 0 or 1.

- If `flag` is 0 (default), then `zscore` scales  $X$  using the sample standard deviation. `zscore(X,0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales  $X$  using the population standard deviation.

### **dim - Dimension**

1 (default) | positive integer

Dimension along which to calculate the  $z$ -scores of  $X$ , specified as a positive integer. For example, for a matrix  $X$ , if `dim` = 1, then `zscore` uses the means and standard deviations along the columns of  $X$ , if `dim` = 2, then `zscore` uses the means and standard deviations along the rows of  $X$ .

## Output Arguments

### **Z - z-scores**

vector | matrix | multidimensional array

$z$ -scores, returned as a vector, matrix, or multidimensional array. A vector of  $z$ -scores has mean 0 and variance 1.

- If  $X$  is a vector, then  $Z$  is a vector of  $z$ -scores.
- If  $X$  is an array, then `zscore` is an array, with each column or row standardized to have mean 0 and variance 1 (depending on `dim`). If `dim` is not specified, `zscore` standardizes along the first nonsingleton dimension of  $X$ .

## **mu - Mean**

scalar | vector

Mean of  $X$  used to compute the  $z$ -scores, returned as a scalar or vector.

- If  $X$  is a vector, then  $\mu$  is a scalar.
- If  $X$  is a matrix, then  $\mu$  is a row vector if `zscore` calculates the means along the columns of  $X$  ( $\text{dim} = 1$ ), and a column vector if `zscore` calculates the means along the rows of  $X$  ( $\text{dim} = 2$ ).

## **sigma - Standard deviation**

scalar | vector

Standard deviation of  $X$  used to compute the  $z$ -scores, returned as a scalar or vector.

- If  $X$  is a vector, then  $\sigma$  is a scalar.
- If  $X$  is a matrix, then  $\sigma$  is a row vector if `zscore` calculates the standard deviations along the columns of  $X$  ( $\text{dim} = 1$ ), and a column vector if `zscore` calculates the standard deviations along the rows of  $X$  ( $\text{dim} = 2$ ).

## **Examples**

### **Z-Scores of Two Data Vectors**

Compute and plot the  $z$ -scores of two data vectors, and then compare the results.

Load the sample data.

```
load('lawdata.mat')
```

Two variables load into the workspace: `gpa` and `lsat`.

Plot both variables on the same axes.

```
plot([gpa,lsat])  
legend('gpa','lsat','Location','East')
```

It is difficult to compare these two measures because they are on a very different scale.

Plot the z-scores of gpa and lsat on the same axes.

```
Zgpa = zscore(gpa);  
Zlsat = zscore(lsat);  
plot([Zgpa, Zlsat])  
legend('gpa z-scores', 'lsat z-scores', 'Location', 'Northeast')
```

## zscore

Now, you can see the relative performance of individuals with respect to both their `gpa` and `lsat` results. For example, the third individual's `gpa` and `lsat` results are both one standard deviation below the sample mean. The eleventh individual's `gpa` is around the sample mean but has an `lsat` score almost 1.25 standard deviations above the sample average.

Check the mean and standard deviation of the `z`-scores you created.

```
mean([Zgpa,Zlsat])
```

```
ans =
    1.0e-14 *
    -0.1088    0.0357

std([Zgpa,Zlsat])
```

```
ans =
    1    1
```

By definition,  $z$ -scores of gpa and lsat have mean 0 and standard deviation 1.

### **Z-Scores for a Population vs. Sample**

Load the sample data.

```
load('lawdata.mat')
```

Two variables load into the workspace: gpa and lsat.

Compute the  $z$ -scores of gpa using the population formula for standard deviation.

```
Z1 = zscore(gpa,1); % population formula
Z0 = zscore(gpa,0); % sample formula
disp([Z1 Z0])
```

```
    1.2554    1.2128
    0.8728    0.8432
   -1.2100   -1.1690
   -0.2749   -0.2656
    1.4679    1.4181
   -0.1049   -0.1013
   -0.4024   -0.3888
    1.4254    1.3771
    1.1279    1.0896
```

```
0.1502    0.1451
0.1077    0.1040
-1.5076   -1.4565
-1.4226   -1.3743
-0.9125   -0.8815
-0.5724   -0.5530
```

For a sample from a population, the population standard deviation formula with  $n$  in the denominator corresponds to the maximum likelihood estimate of the population standard deviation, and might be biased. The sample standard deviation formula, on the other hand, is the unbiased estimator of the population standard deviation for a sample.

### Z-Scores of a Data Matrix

Compute  $z$ -scores using the mean and standard deviation computed along the columns or rows of a data matrix.

Load the sample data.

```
load('flu.mat')
```

The dataset array `flu` is loaded in the workplace. `flu` has 52 observations on 11 variables. The first variable contains dates (in weeks). The other variables contain the flu estimates for different regions in the U.S.

Convert the dataset array to a data matrix.

```
flu2 = double(flu(:,2:end));
```

The new data matrix, `flu2`, is a 52-by-10 double data matrix. The rows correspond to the weeks and the columns correspond to the U.S. regions in the data set array `flu`.

Standardize the flu estimate for each region (the *columns* of `flu2`).

```
Z1 = zscore(flu2,[ ],1);
```

You can see the  $z$ -scores in the variable editor by double-clicking on the matrix Z1 created in the workspace.

Standardize the flu estimate for each week (the *rows* of flu2).

```
Z2 = zscore(flu2,[ ],2);
```

### **Z-Scores, Mean, and Standard Deviation**

Return the mean and standard deviation used to compute the  $z$ -scores.

Load the sample data.

```
load('lawdata.mat')
```

Two variables load into the workspace: gpa and lsat.

Return the  $z$ -scores, mean, and standard deviation of gpa.

```
[Z,gpamean,gpastdev] = zscore(gpa)
```

```
Z =
```

```
    1.2128  
    0.8432  
   -1.1690  
   -0.2656  
    1.4181  
   -0.1013  
   -0.3888  
    1.3771  
    1.0896  
    0.1451  
    0.1040  
   -1.4565  
   -1.3743  
   -0.8815  
   -0.5530
```

gpamean =

3.0947

gpastdev =

0.2435

## Definitions

### Z-Score

For a random variable  $X$  with mean  $\mu$  and standard deviation  $\sigma$ , the  $z$ -score of a value  $x$  is

$$z = \frac{(x - \mu)}{\sigma}.$$

For sample data with mean  $\bar{X}$  and standard deviation  $S$ , the  $z$ -score of a data point  $x$  is

$$z = \frac{(x - \bar{X})}{S}.$$

$z$ -scores measure the distance of a data point from the mean in terms of the standard deviation. This is also called *standardization* of data. The standardized data set has mean 0 and standard deviation 1, and retains the shape properties of the original data set (same skewness and kurtosis).

You can use  $z$ -scores to put data on the same scale before further analysis. This lets you to compare two or more data sets with different units.

### Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if  $X$  is a 1-by-3-by-4 array, then  $X$  is a three-dimensional array.

### First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if  $X$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $X$ .

### Sample Standard Deviation

The *sample standard deviation*,  $S$ , is given by

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n - 1}}.$$

$S$  is the square root of an unbiased estimator of the variance of the population from which  $X$  is drawn, as long as  $X$  consists of independent, identically distributed samples.

Notice that the denominator in this variance formula is  $n - 1$ .

### Population Standard Deviation

If the data is the entire population of values, then you can use the *population standard deviation*,

$$\sigma = \sqrt{\frac{\sum_{i=1}^n (x_i - \mu)^2}{n}}.$$

If  $X$  is a random sample from a population, then  $\mu$  is estimated by the sample mean, and  $\sigma$  is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is  $n$ .

## Algorithms

`zscore` returns NaNs for any sample containing NaNs.

`zscore` returns 0s for any sample that is constant (all values are the same). For example, if  $X$  is a vector of the same numeric value, then  $Z$  is a vector of 0s. If  $X$  is a matrix with a column of consisting of the same value, then that column of  $Z$  consists of 0s.

## zscore

---

### See Also

[mean](#) | [std](#)

**Purpose**

`z-test`

**Syntax**

```
h = ztest(x,m,sigma)
h= ztest(x,m,sigma,Name,Value)
[h,p] = ztest( ___ )
[h,p,ci,zval] = ztest( ___ )
```

**Description**

`h = ztest(x,m,sigma)` returns a test decision for the null hypothesis that the data in the vector `x` comes from a normal distribution with mean `m` and a standard deviation `sigma`, using the *z*-test. The alternative hypothesis is that the mean is not `m`. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h= ztest(x,m,sigma,Name,Value)` returns a test decision for the *z*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ztest( ___ )` also returns the *p*-value of the test, using any of the input arguments from previous syntaxes.

`[h,p,ci,zval] = ztest( ___ )` also returns the confidence interval of the population mean, `ci`, and the value of the test statistic, `zval`.

**Input Arguments****`x` - Sample data**

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` is specified as a vector, `ztest` returns a single value for each output argument.
- If `x` is specified as a matrix, `ztest` performs a separate *z*-test along each column of `x` and returns a vector of results.

- If `x` is specified as a multidimensional array, `ztest` works along the first nonsingleton dimension of `x`.

In all cases, `ztest` treats NaN values as missing data and ignores them.

### Data Types

single | double

### **m** - Hypothesized mean

scalar value

Hypothesized mean, specified as a scalar value.

### Data Types

single | double

### **sigma** - Population standard deviation

scalar value

Population standard deviation, specified as a scalar value.

### Data Types

single | double

### Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes ( ' '). You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

**Example:** `'Tail','right','Alpha',0.01` specifies a right-tailed hypothesis test at the 1% significance level.

### **'Alpha'** - Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

**Example:** 'Alpha',0.01

### **Data Types**

single | double

### **'Dim' - Dimension**

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of 'Dim' and a positive integer value. For example, specifying 'Dim',1 tests the column means, while 'Dim',2 tests the row means.

**Example:** 'Dim',2

### **Data Types**

single | double

### **'Tail' - Type of alternative hypothesis**

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the population mean is not equal to $m$ .
'right'	Test the alternative hypothesis that the population mean is greater than $m$ .
'left'	Test the alternative hypothesis that the population mean is less than $m$ .

**Example:** 'Tail','right'

## **Output Arguments**

### **h - Hypothesis test result**

1 | 0

Hypothesis test result, returned as a logical value.

- If  $h = 1$ , this indicates the rejection of the null hypothesis at the Alpha significance level.
- If  $h = 0$ , this indicates a failure to reject the null hypothesis at the Alpha significance level.

## **p - p-value**

scalar value in the range [0,1]

$p$ -value of the test, returned as a scalar value in the range [0,1].  $p$  is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of  $p$  cast doubt on the validity of the null hypothesis.

## **ci - Confidence interval**

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the  $100 \times (1 - \text{Alpha})\%$  confidence interval.

## **zval - Test statistic**

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

## **Examples**

### **Test for a Hypothesized Mean**

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean  $m = 75$  and standard deviation  $\sigma = 10$ .

```
[h,p,ci,zval] = ztest(x,75,10)
```

```
h =
```

```
0
p =
    0.9927
ci =
    73.2191
    76.7975
zval =
    0.0091
```

The returned value of  $h = 0$  indicates that `ztest` does not reject the null hypothesis at the default 5% significance level.

### One-Sided Hypothesis Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean  $m = 65$  and standard deviation  $\sigma = 10$ , against the alternative that the mean is greater than 65.

```
[h,p] = ztest(x,65,10,'Tail','right')
h =
    1
p =
    2.8596e-28
```

The returned value of  $h = 1$  indicates that `ztest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population mean is greater than 65.

## Definitions

### z-Test

The  $z$ -test is a parametric hypothesis test used to determine whether a sample data set comes from a population with a particular mean. The test assumes the sample data comes from a population with a normal distribution and a known standard deviation.

The test statistic is

$$z = \frac{\bar{x} - \mu}{\sigma / \sqrt{n}},$$

where  $\bar{x}$  is the sample mean,  $\mu$  is the population mean,  $\sigma$  is the population standard deviation, and  $n$  is the sample size. Under the null hypothesis, the test statistic has a standard normal distribution.

### Multidimensional Array

A multidimensional array has more than two dimensions. For example, if  $x$  is a 1-by-3-by-4 array, then  $x$  is a three-dimensional array.

### First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if  $x$  is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of  $x$ .

# Sample Data Sets

---

Statistics Toolbox software includes the sample data sets in the following table.

To load a data set into the MATLAB workspace, type:

```
load filename
```

where *filename* is one of the files listed in the table.

Data sets contain individual data variables, description variables with references, and dataset arrays encapsulating the data set and its description, as appropriate.

<b>File</b>	<b>Description of Data Set</b>
acetylene.mat	Chemical reaction data with correlated predictors
arrhythmia.mat	Cardiac arrhythmia data from the UCI machine learning repository
carbig.mat	Measurements of cars, 1970–1982

## Bernoulli Distribution

### In this section...

“Overview” on page B-3

“Parameters” on page B-3

“Probability Mass Function” on page B-3

“Descriptive Statistics” on page B-3

“Relationship to Other Distributions” on page B-4

### Overview

The Bernoulli distribution is a discrete probability distribution with the only two possible values for the random variable. Each instance of an event with a Bernoulli distribution is called a Bernoulli trial.

### Parameters

The Bernoulli distribution uses the following parameter.

Parameter	Description	Support
$p$	Probability of success	$0 \leq p \leq 1$

### Probability Mass Function

The probability mass function (pmf) is

$$f(x | p) = \begin{cases} 1 - p & , \quad x = 0, \\ p & , \quad x = 1 \end{cases} .$$

### Descriptive Statistics

The mean is

$$\text{mean} = p .$$

The variance is

$$\text{var} = p(1 - p).$$

### **Relationship to Other Distributions**

The Bernoulli distribution is a special case of the binomial distribution, with the number of trials  $n = 1$ . The geometric distribution models the number of Bernoulli trials before the first success (or first failure).

## Beta Distribution

### In this section...

“Definition” on page B-5  
 “Background” on page B-5  
 “Parameters” on page B-6  
 “Example” on page B-7

### Definition

The beta pdf is

$$y = f(x | a, b) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1} I_{(0,1)}(x)$$

where  $B(\cdot)$  is the Beta function. The indicator function  $I_{(0,1)}(x)$  ensures that only values of  $x$  in the range  $(0, 1)$  have nonzero probability.

### Background

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval  $(0, 1)$ . A more general version of the function assigns parameters to the endpoints of the interval.

The beta cdf is the same as the incomplete beta function.

The beta distribution has a functional relationship with the  $t$  distribution. If  $Y$  is an observation from Student's  $t$  distribution with  $\nu$  degrees of freedom, then the following transformation generates  $X$ , which is beta distributed.

$$X = \frac{1}{2} + \frac{1}{2} \frac{Y}{\sqrt{\nu + Y^2}}$$

If  $Y \sim t(\nu)$ , then  $X \sim \beta\left(\frac{\nu}{2}, \frac{\nu}{2}\right)$

This relationship is used to compute values of the  $t$  cdf and inverse function as well as generating  $t$  distributed random numbers.

## Parameters

Suppose you are collecting data that has hard lower and upper bounds of zero and one respectively. Parameter estimation is the process of determining the parameters of the beta distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the beta pdf. But for the pdf, the parameters are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. Maximum likelihood estimation (MLE) involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `betafit` returns the MLEs and confidence intervals for the parameters of the beta distribution. Here is an example using random numbers from the beta distribution with  $a = 5$  and  $b = 0.2$ .

```
rng('default'); % For reproducibility
r = betarnd(5,0.2,100,1);
[phat, pci] = betafit(r)
```

```
phat =
    7.4911    0.2135
```

```
pci =
    5.0861    0.1744
   11.0334    0.2614
```

The MLE for parameter  $a$  is 7.4911, compared to the true value of 5. The 95% confidence interval for  $a$  goes from 2.8051 to 6.2610, which does not include

the true value. While this is an unlikely result, it does sometimes happen when estimating distribution parameters.

Similarly the MLE for parameter  $b$  is 0.2135, compared to the true value of 0.2. The 95% confidence interval for  $b$  goes from 0.1771 to 0.2832, which does include the true value. In this made-up example you know the “true value.” In experimentation you do not.

## Example

The shape of the beta distribution is quite variable depending on the values of the parameters, as illustrated by the plot below.

```
X = 0:.01:1;
y1 = betapdf(X,0.75,0.75);
y2 = betapdf(X,1,1);
y3 = betapdf(X,4,4);

figure;
plot(X,y1,'Color','r','LineWidth',2);
hold on;
plot(X,y2,'LineStyle','-','Color','b','LineWidth',2);
plot(X,y3,'LineStyle',':','Color','g','LineWidth',2);
legend({'a = b = 0.75','a = b = 1','a = b = 4'},'Location','NorthEast');
hold off;
```

The constant pdf (the flat line) shows that the standard uniform distribution is a special case of the beta distribution, which occurs when  $a = b = 1$ .

# Binomial Distribution

In this section...
“Overview” on page B-9
“Parameters” on page B-9
“Probability Density Function” on page B-9
“Descriptive Statistics” on page B-10
“Relationship to Other Distributions” on page B-10
“Example” on page B-10

## Overview

The binomial distribution models the total number of successes in repeated trials from an infinite population under the following conditions:

- Only two outcomes are possible on each of  $n$  trials.
- The probability of success for each trial is constant.
- All trials are independent of each other.

## Parameters

The binomial distribution uses the following parameters.

Parameter	Description	Support
$N$	Number of trials	positive integer
$p$	Probability of success	$0 \leq p \leq 1$

## Probability Density Function

The probability density function (pdf) is

$$f(x | n, p) = \binom{n}{x} p^x (1-p)^{n-x} \quad ; \quad x = 0, 1, 2, \dots, n,$$

where  $x$  is the number of successes in  $n$  trials of a Bernoulli process with probability of success  $p$ .

## **Descriptive Statistics**

The mean is

$$\text{mean} = np.$$

The variance is

$$\text{var} = np(1 - p).$$

## **Relationship to Other Distributions**

The binomial distribution is a generalization of the Bernoulli distribution, allowing for a number of trials  $n$  greater than 1. The binomial distribution generalizes to the multinomial distribution when there are more than two possible outcomes for each trial.

## **Example**

Suppose you are collecting data from a widget manufacturing process, and you record the number of widgets within specification in each batch of 100. You might be interested in the probability that an individual widget is within specification. Parameter estimation is the process of determining the parameter,  $p$ , of the binomial distribution that fits this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the binomial pdf above. But for the pdf, the parameters ( $n$  and  $p$ ) are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the value of  $p$  that give the highest likelihood given the particular set of data.

The function `binofit` returns the MLEs and confidence intervals for the parameters of the binomial distribution. Here is an example using random numbers from the binomial distribution with  $n = 100$  and  $p = 0.9$ .

```
rng('default'); % For reproducibility
r = binornd(100,0.9)
[phat, pci] = binofit(r,100)
```

```
r =
    85

phat =
    0.8500

pci =
    0.7647    0.9135
```

The MLE for parameter  $p$  is 0.8800, compared to the true value of 0.9. The 95% confidence interval for  $p$  goes from 0.7998 to 0.9364, which includes the true value. In this made-up example you know the “true value” of  $p$ . In experimentation you do not.

The following commands generate a plot of the binomial pdf for  $n = 10$  and  $p = 1/2$ .

```
x = 0:10;
y = binopdf(x,10,0.5);
plot(x,y, '+' )
```

## Birnbau-Saunders Distribution

### In this section...

“Definition” on page B-13

“Background” on page B-13

“Parameters” on page B-14

### Definition

The Birnbau-Saunders distribution has the density function

$$\frac{1}{\sqrt{2\pi}} \exp \left\{ -\frac{\left( \sqrt{x/\beta} - \sqrt{\beta/x} \right)^2}{2\gamma^2} \right\} \left( \frac{\sqrt{x/\beta} + \sqrt{\beta/x}}{2\gamma x} \right)$$

with scale parameter  $\beta > 0$  and shape parameter  $\gamma > 0$ , for  $x > 0$ .

If  $x$  has a Birnbau-Saunders distribution with parameters  $\beta$  and  $\gamma$ , then

$$\frac{\left( \sqrt{x/\beta} - \sqrt{\beta/x} \right)}{\gamma}$$

has a standard normal distribution.

### Background

The Birnbau-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner’s Rule suggests that the damage occurring after  $n$  cycles, at a stress level with an expected lifetime of  $N$  cycles, is proportional to  $n / N$ . Whenever Miner’s Rule applies, the Birnbau-Saunders model is a reasonable choice for a lifetime distribution model.

## **Parameters**

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

## Burr Type XII Distribution

### In this section...

“Definition” on page B-15

“Burr pdf for Various Parameters” on page B-22

“Survival and Hazard Functions of Burr Distribution” on page B-23

“Divergence of Parameter Estimates” on page B-25

### Definition

The Burr type XII distribution is a three-parameter family of distributions on the positive real line. The cumulative distribution function (cdf) of the Burr distribution is

$$F(x | \alpha, c, k) = 1 - \frac{1}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^k}, \quad x > 0, \alpha > 0, c > 0, k > 0,$$

where  $c$  and  $k$  are the shape parameters and  $\alpha$  is the scale parameter. The probability density function (pdf) is

$$f(x | \alpha, c, k) = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^{k+1}}, \quad x > 0, \alpha > 0, c > 0, k > 0.$$

The density of the Burr type XII distribution is L-shaped if  $c \leq 1$  and unimodal, otherwise.

## Background

Burr distribution was first discussed by Burr (1942) as a two-parameter family. An additional scale parameter was introduced by Tadikamalla (1980). It is a very flexible distribution family that can express a wide range of distribution shapes. The Burr distribution includes, overlaps, or has as a limiting case, many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). Some compound distributions also correspond to the Burr distribution. For example, compounding a Weibull distribution with a gamma distribution for its scale parameter results in a Burr distribution. Similarly, compounding an exponential distribution with a gamma distribution for its rate parameter,  $1/\mu$ , also yields a Burr distribution. The Burr distribution also has two asymptotic limiting cases: Weibull and Pareto Type I.

The Burr distribution can fit a wide range of empirical data. Different values of its parameters cover a broad set of skewness and kurtosis. Hence, it is used in various fields such as finance, hydrology, and reliability to model a variety of data types. Examples of data modeled by the Burr distribution are household income, crop prices, insurance risk, travel time, flood levels, and failure data.

The survival and hazard functions of Burr type XII distribution are, respectively,

$$S(x | \alpha, c, k) = \frac{1}{\left[1 + \left(\frac{x}{\alpha}\right)^c\right]^k}$$

and

$$h(x | \alpha, c, k) = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{1 + \left(\frac{x}{\alpha}\right)^c}.$$

If  $c > 1$ , the hazard function  $h(x)$  is non-monotonic with a mode at  $x = \alpha(c - 1)^{1/c}$ .

## Parameters

The three-parameter Burr distribution is defined by its scale parameter  $\alpha$  and shape parameters  $c$  and  $k$ . You can estimate the parameters using `mle` or `fitdist`. Both functions support censored data for Burr distribution.

Generate sample data from a Burr distribution with scale parameter 0.5 and shape parameters 2 and 5.

```
rng('default')
R = random('burr',0.5,2,5,1000,1);
```

Estimate the parameters and the confidence intervals.

```
[phat,pci] = mle(R,'distribution','burr')
```

```
phat =
```

```
    0.4154    2.1217    4.0550
```

```
pci =
```

```
    0.2985    1.9560    2.4079
    0.5782    2.3014    6.8288
```

The default 95% confidence intervals for the parameters include the true parameter values.

The three-parameter Burr distribution converges asymptotically to one of the two limiting forms as its parameters diverge:

- If  $k \rightarrow 0$ ,  $c \rightarrow \infty$ ,  $ck = \lambda$ , then the Burr distribution reduces to a two-parameter Pareto distribution with the cdf

$$F_P = 1 - \left(\frac{x}{\alpha}\right)^{-\lambda}, \quad x \geq \alpha.$$

- If  $k \rightarrow \infty$ ,  $\alpha \rightarrow \infty$ ,  $\alpha/k^{1/c} = \theta$ , then the Burr distribution reduces to a two-parameter Weibull distribution with the cdf

$$F_W(x | c, \theta) = 1 - \exp\left[\left(\frac{x}{\alpha}\right)^{-c}\right].$$

If `mle` or `fitdist` detects such divergence, it returns an error message, but informs you of the limiting distribution and corresponding parameter estimates for that distribution.

## Fit a Burr Distribution and Draw the cdf

This example shows how to fit a Burr distribution to data, draw the cdf, and construct a histogram with a Burr distribution fit.

1. Load the sample data.

```
load('arrhythmia.mat')
```

The fifth column in `X` contains a measurement obtained from electrocardiograms, called QRS duration.

2. Fit a Burr distribution to the QRS duration data, and get the parameter estimates.

```
PD = fitdist(X(:,5), 'burr');
```

`PD` has the maximum likelihood estimates of the Burr distribution parameters in the property `Param`. The estimates are  $\alpha = 80.4515$ ,  $c = 18.9251$ ,  $k = 0.4492$ .

3. Plot the cdf of the QRS duration data.

```
QRScdf=cdf('burr', sortrows(X(:,5)), 80.4515, 18.9251, 0.4492);  
plot(sortrows(X(:,5)), QRScdf)  
xlabel('QRS Duration')
```

#### **cdf of QRS duration data**

4. Draw the histogram of QRS duration data with 15 bins and the pdf of the Burr distribution fit.

```
histfit(X(:,5),15,'burr')  
xlabel('QRS Duration')
```

**Histogram of QRS data with a Burr distribution fit**

## Compare Lognormal and Burr pdfs

This example shows how to compare the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.

1. Generate the income data.

```
rng('default') % for reproducibility  
y = random('logn',log(25000),0.65,500,1);
```

2. Fit a Burr distribution.

```
pd = fitdist(y,'burr');
```

3. Plot both the Burr and lognormal pdfs of income data on the same axis.

```
p = pdf('burr',sortrows(y),26007,2.6374,1.0966);  
p2 = pdf('logn',sortrows(y),log(25000),0.65);  
plot(sortrows(y),p,'g',sortrows(y),p2,'r','LineWidth',2)  
legend('burr','lognormal')
```

**Burr and Lognormal pdfs fitted to income data**

## Burr pdf for Various Parameters

This example shows how to create a variety of shapes for probability density functions of the Burr distribution.

```
X = 0:0.01:5;
c = [0.5 0.95 2 5];
k = [0.5 0.75 2 5];
alpha = [0.5 1 2 5];
colors = ['b';'g';'r';'k']

figure
for i = 1:1:4
pdf1(i,:) = pdf('burr',X,1,c(i),0.5);
pdf2(i,:) = pdf('burr',X,1,2,k(i));
pdf3(i,:) = pdf('burr',X,alpha(i),2,0.5);

axC = subplot(3,1,1);
pC(i) = plot(X,pdf1(i,:),colors(i),'LineWidth',2);
title('Effect of c, \alpha = 1, k = 0.5'),xlabel('x')
hold on

axK = subplot(3,1,2);
pK(i) = plot(X,pdf2(i,:),colors(i),'LineWidth',2);
title('Effect of k, \alpha = 1, c = 2'),xlabel('x')
hold on

axAlpha = subplot(3,1,3);
pAlpha(i) = plot(X,pdf3(i,:),colors(i),'LineWidth',2);
title('Effect of \alpha, c = 2, k = 0.5'),xlabel('x')
hold on
end

set(axC,'XLim',[0 3],'YLim',[0 1.2]);
set(axK,'XLim',[0 3],'YLim',[0 2.1]);
set(axAlpha,'XLim',[0 5],'YLim',[0 1]);

legend(axC,'c=0.5','c=0.95','c=2','c=5');
legend(axK,'k=0.5','k=0.75','k=2','k=5');
legend(axAlpha,'\alpha=0.5','\alpha=1','\alpha=2','\alpha=5');
```

This figure illustrates how the shape and scale of the Burr distribution changes for different values of its parameters.

## Survival and Hazard Functions of Burr Distribution

This example shows how to find and plot the survival and hazard functions for a sample coming from a Burr distribution.

1. Generate the data.

```
X = 0:0.015:2.5;
```

2. Evaluate the pdf and cdf of data in X.

```
Xpdf = pdf('burr',X,0.2,5,0.5);  
Xcdf = cdf('burr',X,0.2,5,0.5);
```

3. Evaluate and plot the survival function of data in X.

```
S = 1.-Xcdf; % survival function  
plot(X,S,'LineWidth',2)  
xlabel('x')
```

**Survival function**

4. Evaluate and plot the hazard function of data in X.

```
H = Xpdf./S; % hazard function
plot(X,H,'r','LineWidth',2)
xlabel('x')
```

**Hazard function**

### **Divergence of Parameter Estimates**

This example shows how to interpret the display when the parameter estimates diverge when fitting a Burr distribution to input data.

1. Generate sample data from the Weibull distribution with parameters 0.5 and 2.

```
rng('default') % for reproducibility
X = wblrnd(0.5,2,100,1);
```

2. Fit a Burr distribution.

```
PD = fitdist(X,'burr');
```

```
Error using addburr>burrfit (line 566)
The data are not fit by a Burr distribution with finite
parameters. The maximum likelihood fit is provided by the
k->Inf, alpha->Inf limiting form of the Burr distribution: a
Weibull distribution with the parameters below.
```

```
  a (scale): 0.476817
  b (shape): 1.96219
```

```
Error in fitdata (line 24)
      p = F(x,fixedparams{:},0.05,opts{:});
```

```
Error in ProbDistUnivParam.fit (line 94)
pd = fitdata(pd,spec,x,cens,freq,fixedparams,options);
```

```
Error in fitdist (line 124)
      pd =
      ProbDistUnivParam.fit(x,distname,'cens',cens,'freq',freq,args{:});
```

The error message tells you that the Weibull family seems to fit the data better and gives you the parameter estimates from a Weibull fit. You can use those estimates directly. If you need covariance estimates for the parameters or other information about the fit, you can refit a Weibull distribution to the data.

3. Fit a Weibull distribution to the data and find the confidence intervals for the parameter estimates.

```
PD = fitdist(X,'weibull');
paramci(PD)
```

```
ans =
```

0.4291	1.6821
0.5298	2.2890

These are the 95% confidence intervals of the parameter estimates for the Weibull distribution fit.

## Chi-Square Distribution

In this section...
“Overview” on page B-28
“Parameters” on page B-28
“Probability Density Function” on page B-28
“Cumulative Distribution Function” on page B-29
“Descriptive Statistics” on page B-29
“Relationship to Other Distributions” on page B-29
“Examples” on page B-29

### Overview

The chi-square distribution is commonly used in hypothesis testing, particularly the chi-squared test for goodness of fit.

### Parameters

The chi-square distribution uses the following parameter.

Parameter	Description	Support
$\nu$	Degrees of freedom	$\nu$ is a nonnegative integer value

### Probability Density Function

The probability density function (pdf) is

$$y = f(x | \nu) = \frac{x^{(\nu-2)/2} e^{-x/2}}{2^{\nu/2} \Gamma(\nu/2)}$$

where  $\Gamma(\cdot)$  is the Gamma function,  $\nu$  is the degrees of freedom, and  $x \geq 0$ .

## Cumulative Distribution Function

The cumulative distribution function (cdf) is

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt$$

where  $\Gamma(\cdot)$  is the Gamma function,  $\nu$  is the degrees of freedom, and  $x \geq 0$ .

## Descriptive Statistics

The mean is  $\nu$ .

The variance is  $2\nu$ .

## Relationship to Other Distributions

The  $\chi^2$  distribution is a special case of the gamma distribution where  $b = 2$  in the equation for gamma distribution below.

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The  $\chi^2$  distribution gets special attention because of its importance in normal sampling theory. If a set of  $n$  observations is normally distributed with variance  $\sigma^2$ , and  $s^2$  is the sample standard deviation, then

$$\frac{(n-1)s^2}{\sigma^2} \sim \chi^2(n-1)$$

This relationship is used to calculate confidence intervals for the estimate of the normal parameter  $\sigma^2$  in the function `normfit`.

## Examples

### Compute Chi-Square Distribution pdf

Compute the pdf of a chi-square distribution with 4 degrees of freedom.

```
x = 0:0.2:15;  
y = chi2pdf(x,4);
```

Plot the pdf.

```
figure;  
plot(x,y)
```

The chi-square distribution is skewed to the right, especially for few degrees of freedom.

# Copulas

See “Copulas: Generate Correlated Samples” on page 5-129.

## Custom Distributions

User-defined custom distributions, created using files and function handles, are supported by the Statistics Toolbox functions `pdf`, `cdf`, `icdf`, and `mle`, and the Statistics Toolbox Distribution Fitting app.

# Exponential Distribution

**In this section...**

“Definition” on page B-33

“Background” on page B-33

“Parameters” on page B-33

“Examples” on page B-34

## Definition

The exponential pdf is

$$y = f(x | \mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

## Background

Like the chi-square distribution, the exponential distribution is a special case of the gamma distribution (obtained by setting  $\alpha = 1$ )

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

The exponential distribution is special because of its utility in modeling events that occur randomly over time. The main application area is in studies of lifetimes.

## Parameters

Suppose you are stress testing light bulbs and collecting data on their lifetimes. You assume that these lifetimes follow an exponential distribution. You want to know how long you can expect the average light bulb to last.

Parameter estimation is the process of determining the parameters of the exponential distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the exponential pdf above. But for the pdf, the parameters are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `expfit` returns the MLEs and confidence intervals for the parameters of the exponential distribution. Here is an example using random numbers from the exponential distribution with  $\mu = 700$ .

```
lifetimes = exprnd(700,100,1);  
[muhat, mucu] = expfit(lifetimes)
```

```
muhat =  
  
    672.8207
```

```
mucu =  
  
    547.4338  
    810.9437
```

The MLE for parameter  $\mu$  is 672, compared to the true value of 700. The 95% confidence interval for  $\mu$  goes from 547 to 811, which includes the true value.

In the life tests you do not know the true value of  $\mu$  so it is nice to have a confidence interval on the parameter to give a range of likely values.

## Examples

### Exponentially Distributed Lifetime Data

For exponentially distributed lifetimes, the probability that an item will survive an extra unit of time is independent of the current age of the item. The example shows a specific case of this special property.

```
l = 10:10:60;
lpd = l+0.1;
deltap = (expcdf(lpd,50)-expcdf(l,50))./(1-expcdf(l,50))

deltap =
    0.0020    0.0020    0.0020    0.0020    0.0020    0.0020
```

### **Compute the Exponential Distribution pdf**

Compute the pdf of an exponential distribution with parameter  $\mu = 2$ .

```
x = 0:0.1:10;
y = exppdf(x,2);
```

Plot the pdf.

```
figure;
plot(x,y)
```

## Extreme Value Distribution

### In this section...

“Definition” on page B-37

“Background” on page B-37

“Parameters” on page B-40

“Examples” on page B-41

### Definition

The probability density function for the extreme value distribution with location parameter  $\mu$  and scale parameter  $\sigma$  is

$$y = f(x | \mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

If  $T$  has a Weibull distribution with parameters  $a$  and  $b$ , then  $\log T$  has an extreme value distribution with parameters  $\mu = \log a$  and  $\sigma = 1/b$ .

### Background

Extreme value distributions are often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

For example, the following fits an extreme value distribution to minimum values taken over 1000 sets of 500 observations from a normal distribution.

```
rng('default'); % For reproducibility
```

```
xMinima = min(randn(1000,500), [], 2);  
paramEstsMinima = evfit(xMinima);  
y = linspace(-5,-1.5,1001);  
hist(xMinima,-4.75:.25:-1.75);  
p = evpdf(y,paramEstsMinima(1),paramEstsMinima(2));  
line(y,.25*length(xMinima)*p,'color','r')
```

The following fits an extreme value distribution to the maximum values in each set of observations.

```
rng('default'); % For reproducibility
```

```
xMaxima = max(randn(1000,500), [], 2);  
paramEstsMaxima = evfit(-xMaxima);  
y = linspace(1.5,5,1001);  
hist(xMaxima,1.75:.25:4.75);  
p = evpdf(-y,paramEstsMaxima(1),paramEstsMaxima(2));  
line(y,.25*length(xMaxima)*p,'color','r')
```

Although the extreme value distribution is most often used as a model for extreme values, you can also use it as a model for other types of continuous data. For example, extreme value distributions are closely related to the

Weibull distribution. If  $T$  has a Weibull distribution, then  $\log(T)$  has a type 1 extreme value distribution.

## Parameters

The function `evfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the extreme value distribution. The following example shows how to fit some sample data using `evfit`, including estimates of the mean and variance from the fitted distribution.

Suppose you want to model the size of the smallest washer in each batch of 1000 from a manufacturing process. If you believe that the sizes are independent within and between each batch, you can fit an extreme value distribution to measurements of the minimum diameter from a series of eight experimental batches. The following code returns the MLEs of the distribution parameters as `parmhat` and the confidence intervals as the columns of `parmci`.

```
x = [19.774 20.141 19.44 20.511 21.377 19.003 19.66 18.83];  
[parmhat, parmci] = evfit(x)
```

```
parmhat =  
    20.2506    0.8223
```

```
parmci =  
    19.644 0.49861  
    20.857 1.3562
```

You can find mean and variance of the extreme value distribution with these parameters using the function `evstat`.

```
[meanfit, varfit] = evstat(parmhat(1),parmhat(2))
```

```
meanfit =  
    19.776
```

```
varfit =  
    1.1123
```

## Examples

### Compute the Extreme Value Distribution pdf

Compute the pdf of an extreme value distribution.

```
t = [-5:.01:2];  
y = evpdf(t);
```

Plot the pdf.

```
figure;  
plot(t,y)
```

The extreme value distribution is skewed to the left, and its general shape remains the same for all parameter values. The location parameter,  $\mu$ , shifts the distribution along the real line, and the scale parameter,  $\sigma$ , expands or contracts the distribution.

The following plots the probability function for different combinations of  $\mu$  and  $\sigma$ .

```
x = -15:.01:5;  
plot(x,evpdf(x,2,1),'-', ...
```

```
x, evpdf(x, 0, 2), ':' , ...  
x, evpdf(x, -2, 4), '-.' );  
legend({'mu = 2, sigma = 1', ...  
      'mu = 0, sigma = 2', ...  
      'mu = -2, sigma = 4'}, ...  
      'Location', 'NW')  
xlabel('x')  
ylabel('f(x|mu, sigma)')
```

## F Distribution

### In this section...

“Definition” on page B-44

“Background” on page B-44

“Examples” on page B-45

### Definition

The pdf for the  $F$  distribution is

$$y = f(x | v_1, v_2) = \frac{\Gamma\left[\frac{(v_1 + v_2)}{2}\right] \left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}} x^{\frac{v_1-2}{2}}}{\Gamma\left(\frac{v_1}{2}\right) \Gamma\left(\frac{v_2}{2}\right) \left[1 + \left(\frac{v_1}{v_2}\right)x\right]^{\frac{v_1+v_2}{2}}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

### Background

The  $F$  distribution has a natural relationship with the chi-square distribution. If  $\chi_1$  and  $\chi_2$  are both chi-square with  $v_1$  and  $v_2$  degrees of freedom respectively, then the statistic  $F$  below is  $F$ -distributed.

$$F(v_1, v_2) = \frac{\chi_1 / v_1}{\chi_2 / v_2}$$

The two parameters,  $v_1$  and  $v_2$ , are the numerator and denominator degrees of freedom. That is,  $v_1$  and  $v_2$  are the number of independent pieces of information used to calculate  $\chi_1$  and  $\chi_2$ , respectively.

## Examples

### Compute the $F$ Distribution pdf

Compute the pdf of an  $F$  distribution with 5 numerator degrees of freedom and 3 denominator degrees of freedom.

```
x = 0:0.01:10;  
y = fpdf(x,5,3);
```

Plot the pdf.

```
figure;  
plot(x,y)
```

The plot shows that the  $F$  distribution exists on positive real numbers and is skewed to the right.

## Gamma Distribution

### In this section...

“Definition” on page B-47

“Background” on page B-47

“Parameters” on page B-48

“Examples” on page B-49

### Definition

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

### Background

The gamma distribution models sums of exponentially distributed random variables.

The gamma distribution family is based on two parameters. The chi-square and exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution has the following relationship with the incomplete Gamma function.

$$f(x | a, b) = \text{gammainc}\left(\frac{x}{b}, a\right)$$

When  $a$  is large, the gamma distribution closely approximates a normal distribution with the advantage that the gamma distribution has density only for positive real numbers.

## Parameters

Suppose you are stress testing computer memory chips and collecting data on their lifetimes. You assume that these lifetimes follow a gamma distribution. You want to know how long you can expect the average computer memory chip to last. Parameter estimation is the process of determining the parameters of the gamma distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the gamma pdf above. But for the pdf, the parameters are known constants and the variable is  $x$ . The likelihood function reverses the roles of the variables. Here, the sample values (the  $x$ 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `gamfit` returns the MLEs and confidence intervals for the parameters of the gamma distribution. Here is an example using random numbers from the gamma distribution with  $\alpha = 10$  and  $b = 5$ .

```
lifetimes = gamrnd(10,5,100,1);
[phat, pci] = gamfit(lifetimes)
```

```
phat =
```

```
    10.9821    4.7258
```

```
pci =
```

```
    7.4001    3.1543
   14.5640    6.2974
```

Note  $\text{phat}(1) = \hat{a}$  and  $\text{phat}(2) = \hat{b}$ . The MLE for parameter  $a$  is 10.98, compared to the true value of 10. The 95% confidence interval for  $a$  goes from 7.4 to 14.6, which includes the true value.

Similarly the MLE for parameter  $b$  is 4.7, compared to the true value of 5. The 95% confidence interval for  $b$  goes from 3.2 to 6.3, which also includes the true value.

In the life tests you do not know the true value of  $a$  and  $b$  so it is nice to have a confidence interval on the parameters to give a range of likely values.

## Examples

### Compute the Gamma Distribution pdf

Compute the pdf of a gamma distribution with parameters  $A = 100$  and  $B = 10$ . For comparison, also compute the pdf of a normal distribution with parameters  $\mu = 1000$  and  $\sigma = 100$ .

```
x = gaminv((0.005:0.01:0.995),100,10);  
y = gampdf(x,100,10);  
y1 = normpdf(x,1000,100);
```

Plot the pdfs of the gamma distribution and the normal distribution on the same figure.

```
figure;  
plot(x,y,'-',x,y1,'-.')
```

## **Gaussian Distribution**

See “Normal Distribution” on page B-123.

## **Gaussian Mixture Distributions**

See the discussion of the `gmdistribution` class in “Gaussian Mixture Models” on page 5-119.

## Generalized Extreme Value Distribution

### In this section...

“Definition” on page B-53

“Background” on page B-53

“Parameters” on page B-54

“Examples” on page B-56

### Definition

The probability density function for the generalized extreme value distribution with location parameter  $\mu$ , scale parameter  $\sigma$ , and shape parameter  $k \neq 0$  is

$$y = f(x | k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left[-\left(1 + k \frac{(x - \mu)}{\sigma}\right)^{\frac{1}{k}}\right] \left(1 + k \frac{(x - \mu)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for

$$1 + k \frac{(x - \mu)}{\sigma} > 0$$

$k > 0$  corresponds to the Type II case, while  $k < 0$  corresponds to the Type III case. For  $k = 0$ , corresponding to the Type I case, the density is

$$y = f(x | 0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x - \mu)}{\sigma}\right) - \frac{(x - \mu)}{\sigma}\right)$$

### Background

Like the extreme value distribution, the generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. For example, you might have batches of 1000 washers from a manufacturing process. If you record the size of the largest

washer in each batch, the data are known as block maxima (or minima if you record the smallest). You can use the generalized extreme value distribution as a model for those block maxima.

The generalized extreme value combines three simpler distributions into a single form, allowing a continuous range of possible shapes that includes all three of the simpler distributions. You can use any one of those distributions to model a particular dataset of block maxima. The generalized extreme value distribution allows you to “let the data decide” which distribution is appropriate.

The three cases covered by the generalized extreme value distribution are often referred to as the Types I, II, and III. Each type corresponds to the limiting distribution of block maxima from a different class of underlying distributions. Distributions whose tails decrease exponentially, such as the normal, lead to the Type I. Distributions whose tails decrease as a polynomial, such as Student’s  $t$ , lead to the Type II. Distributions whose tails are finite, such as the beta, lead to the Type III.

Types I, II, and III are sometimes also referred to as the Gumbel, Frechet, and Weibull types, though this terminology can be slightly confusing. The Type I (Gumbel) and Type III (Weibull) cases actually correspond to the mirror images of the usual Gumbel and Weibull distributions, for example, as computed by the functions `evcdf` and `evfit`, or `wblcdf` and `wblfit`, respectively. Finally, the Type II (Frechet) case is equivalent to taking the reciprocal of values from a standard Weibull distribution.

## Parameters

If you generate 250 blocks of 1000 random values drawn from Student’s  $t$  distribution with 5 degrees of freedom, and take their maxima, you can fit a generalized extreme value distribution to those maxima.

```
blocksize = 1000;
nblocks = 250;
rng('default'); % For reproducibility
t = trnd(5,blocksize,nblocks);
x = max(t); % 250 column maxima
paramEsts = gevfit(x)
```

```
paramEsts =  
    0.1185    1.4530    5.8929
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on block maxima from a Student's  $t$  distribution.

```
hist(x,2:20);  
set(get(gca,'child'),'FaceColor',[.8 .8 1])  
xgrid = linspace(2,20,1000);  
line(xgrid,nblocks*...  
      gevpdf(xgrid,paramEsts(1),paramEsts(2),paramEsts(3)));
```

## Examples

### Compute the Generalized Extreme Value Distribution pdf

Generate examples of probability density functions for the three basic forms of the generalized extreme value distribution.

```
x = linspace(-3,6,1000);  
y1 = gevpdf(x,-.5,1,0);  
y2 = gevpdf(x,0,1,0);
```

```

y3 = gevpdf(x, .5, 1, 0);
plot(x, y1, '--', x, y2, '-.-', x, y3, ':')
legend({'K < 0, Type III' 'K = 0, Type I' 'K > 0, Type II'})

```

Notice that for  $k = 0$ , the distribution has zero probability density for  $x$  such that  $x < -\sigma/k + \mu$ .

For  $k = 0$ , the distribution has zero probability density for  $x > -\sigma/k + \mu$ .

For  $k = 0$ , there is no upper or lower bound.

### Compute the Generalized Extreme Value Distribution pdf

Generate examples of probability density functions for the three basic forms of the generalized extreme value distribution.

```
x = linspace(-3,6,1000);  
y1 = gevpdf(x,-.5,1,0);  
y2 = gevpdf(x,0,1,0);  
y3 = gevpdf(x,.5,1,0);  
plot(x,y1,'- ', x,y2,'-- ', x,y3,': ');  
legend({'K < 0, Type III' 'K = 0, Type I' 'K > 0, Type II'})
```

Notice that for  $k = 0$ , the distribution has zero probability density for  $x$  such that  $x < -\sigma/k + \mu$ .

For  $k = 0$ , the distribution has zero probability density for  $x > -\sigma/k + \mu$ .

For  $k = 0$ , there is no upper or lower bound.

## Generalized Pareto Distribution

### In this section...

“Definition” on page B-60

“Background” on page B-60

“Parameters” on page B-61

“Examples” on page B-63

### Definition

The probability density function for the generalized Pareto distribution with shape parameter  $k \neq 0$ , scale parameter  $\sigma$ , and threshold parameter  $\theta$ , is

$$y = f(x | k, \sigma, \theta) = \left( \frac{1}{\sigma} \right) \left( 1 + k \frac{(x - \theta)}{\sigma} \right)^{-1 - \frac{1}{k}}$$

for  $\theta < x$ , when  $k > 0$ , or for  $\theta < x < \theta - \sigma/k$  when  $k < 0$ .

For  $k = 0$ , the density is

$$y = f(x | 0, \sigma, \theta) = \left( \frac{1}{\sigma} \right) e^{-\frac{(x - \theta)}{\sigma}}$$

for  $\theta < x$ .

If  $k = 0$  and  $\theta = 0$ , the generalized Pareto distribution is equivalent to the exponential distribution. If  $k > 0$  and  $\theta = \sigma/k$ , the generalized Pareto distribution is equivalent to the Pareto distribution.

### Background

Like the exponential distribution, the generalized Pareto distribution is often used to model the tails of another distribution. For example, you might have washers from a manufacturing process. If random influences in the process lead to differences in the sizes of the washers, a standard probability distribution, such as the normal, could be used to model those sizes. However,

while the normal distribution might be a good model near its mode, it might not be a good fit to real data in the tails and a more complex model might be needed to describe the full range of the data. On the other hand, only recording the sizes of washers larger (or smaller) than a certain threshold means you can fit a separate model to those tail data, which are known as *exceedences*. You can use the generalized Pareto distribution in this way, to provide a good fit to extremes of complicated data.

The generalized Pareto distribution allows a continuous range of possible shapes that includes both the exponential and Pareto distributions as special cases. You can use either of those distributions to model a particular dataset of exceedences. The generalized Pareto distribution allows you to “let the data decide” which distribution is appropriate.

The generalized Pareto distribution has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease as a polynomial, such as Student’s  $t$ , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution is used in the tails of distribution fit objects of the `paretotails` class.

## Parameters

If you generate a large number of random values from a Student’s  $t$  distribution with 5 degrees of freedom, and then discard everything less than 2, you can fit a generalized Pareto distribution to those exceedences.

```
rng('default'); % For reproducibility
t = trnd(5,5000,1);
y = t(t > 2) - 2;
paramEsts = gpfity
```

```
paramEsts =  
    0.1445    0.7225
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on exceedences from a Student's  $t$  distribution.

```
hist(y+2,2.25:.5:11.75);  
set(get(gca,'child'),'FaceColor',[.8 .8 1])  
xgrid = linspace(2,12,1000);  
line(xgrid,.5*length(y)*...  
      gppdf(xgrid,paramEsts(1),paramEsts(2),2));
```

## Examples

### Compute Generalized Pareto Distribution pdf

Compute the pdf of three generalized Pareto distributions. The first has shape parameter  $k = -0.25$ , the second has  $k = 0$ , and the third has  $k = 1$ .

```
x = linspace(0,10,1000);  
y1 = gppdf(x, -0.25, 1, 0);  
y2 = gppdf(x, 0, 1, 0);
```

```
y3 = gppdf(x,1,1,0);
```

Plot the three pdfs on the same figure.

```
figure;  
plot(x,y1,'- ', x,y2,'-- ', x,y3,': ');  
legend({'K < 0' 'K = 0' 'K > 0'});
```

## Geometric Distribution

In this section...
“Overview” on page B-65
“Parameters” on page B-65
“Probability Mass Function” on page B-65
“Descriptive Statistics” on page B-66
“Relationship to Other Distributions” on page B-66
“Examples” on page B-66

### Overview

The geometric distribution is discrete, existing only on the nonnegative integers. It models the number of successes before one failure in an independent succession of tests where each test results in success or failure.

### Parameters

The geometric distribution uses the following parameter.

Parameter	Description	Support
$p$	Probability of success	$0 \leq p \leq 1$

### Probability Mass Function

The probability mass function (pmf) is

$$f(x | p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \dots, \infty .$$

## **Descriptive Statistics**

The mean is

$$\text{mean} = \frac{1 - p}{p} .$$

The variance is

$$\text{var} = \frac{1 - p}{p^2} .$$

## **Relationship to Other Distributions**

The geometric distribution is a special case of the negative binomial distribution, with  $r = 1$ .

## **Examples**

### **Compute Geometric Distribution Probabilities**

This example shows how to compute the probability of a particular series of outcomes when the event follows a geometric distribution.

Suppose the probability of a five-year-old battery failing in cold weather is 0.03. What is the probability of starting 25 consecutive days during a long cold snap?

```
1 - geocdf(25,0.03)
```

```
ans =
```

```
0.4530
```

The plot shows the cdf for this scenario.

```
x = 0:25;  
y = geocdf(x,0.03);  
stairs(x,y)
```

## Hypergeometric Distribution

### In this section...

“Definition” on page B-68

“Background” on page B-68

“Examples” on page B-69

### Definition

The hypergeometric pdf is

$$y = f(x | M, K, n) = \frac{\binom{K}{x} \binom{M-K}{n-x}}{\binom{M}{n}}$$

### Background

The hypergeometric distribution models the total number of successes in a fixed-size sample drawn without replacement from a finite population.

The distribution is discrete, existing only for nonnegative integers less than the number of samples or the number of possible successes, whichever is greater. The hypergeometric distribution differs from the binomial only in that the population is finite and the sampling from the population is without replacement.

The hypergeometric distribution has three parameters that have direct physical interpretations.

- $M$  is the size of the population.
- $K$  is the number of items with the desired characteristic in the population.
- $n$  is the number of samples drawn.

Sampling “without replacement” means that once a particular sample is chosen, it is removed from the relevant population for all subsequent selections.

## Examples

### Compute and Plot Hypergeometric Distribution CDF

This example shows how to compute and plot the cdf of a hypergeometric distribution.

Compute the cdf of a hypergeometric distribution that draws 20 samples from a group of 1000 items, when the group contains 50 items of the desired type.

```
x = 0:10;  
y = hygecdf(x,1000,50,20);
```

Plot the cdf.

```
stairs(x,y)
```

The x-axis of the plot shows the number of items drawn that are of the desired type. The y-axis shows the corresponding cdf values.

# Inverse Gaussian Distribution

**In this section...**

“Definition” on page B-71

“Background” on page B-71

“Parameters” on page B-71

## Definition

The inverse Gaussian distribution has the density function

$$\sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x-\mu)^2\right\}$$

## Background

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. The distribution originated in the theory of Brownian motion, but has been used to model diverse phenomena. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

## Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

## Inverse Wishart Distribution

### Definition

The probability density function of the  $d$ -dimensional Inverse Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|T|^{(\nu/2)} e^{\left(-\frac{1}{2}\text{trace}(TX^{-1})\right)}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |X|^{(\nu+d+1)/2} \Gamma(\nu/2) \dots \Gamma(\nu - (d-1)/2)},$$

where  $X$  and  $T$  are  $d$ -by- $d$  symmetric positive definite matrices, and  $\nu$  is a scalar greater than or equal to  $d$ . While it is possible to define the Inverse Wishart for singular  $T$ , the density cannot be written as above.

If a random matrix has a Wishart distribution with parameters  $T^{-1}$  and  $\nu$ , then the inverse of that random matrix has an inverse Wishart distribution with parameters  $T$  and  $\nu$ . The mean of the distribution is given by

$$\frac{1}{\nu - d - 1} T$$

where  $d$  is the number of rows and columns in  $T$ .

Only random matrix generation is supported for the inverse Wishart, including both singular and nonsingular  $T$ .

### Background

The inverse Wishart distribution is based on the Wishart distribution. In Bayesian statistics it is used as the conjugate prior for the covariance matrix of a multivariate normal distribution.

### Example

Notice that the sampling variability is quite large when the degrees of freedom is small.

```
Tau = [1 .5; .5 2];
df = 10; S1 = iwishrnd(Tau,df)*(df-2-1)
```

```
S1 =
    1.7959    0.64107
    0.64107    1.5496

df = 1000; S2 = iwishrnd(Tau,df)*(df-2-1)

S2 =
    0.9842    0.50158
    0.50158    2.1682
```

“Kernel Smoothing Function” on page B-75

“Bandwidth” on page B-82

## Overview

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. This distribution is defined by a smoothing function and a bandwidth value that controls the smoothness of the resulting density curve.

## Kernel Density Estimator

The kernel density estimator is the estimated probability density function (pdf) of the random variable. Its formula is given by the equation

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right) ; \quad -\infty < x < \infty,$$

where  $n$  is the sample size,  $K(\square)$  is the kernel smoothing function,  $h$  is the bandwidth.

## Kernel Smoothing Function

The kernel smoothing function defines the shape of the curve used to generate the pdf. Similar to a histogram, the kernel distribution builds a function to represent the probability distribution using the sample data. But unlike a histogram, which places the values into discrete bins, a kernel distribution sums the component smoothing functions for each data value to produce a smooth, continuous probability curve. The following plots show a visual

comparison of a histogram and a kernel distribution generated from the same sample data.

A histogram represents the probability distribution by establishing bins and placing each data value in the appropriate bin.

```
SixMPG = [13;15;23;29;32;34];  
figure;  
hist(SixMPG)
```

Because of this bin count approach, the histogram produces a discrete probability density function. This might be unsuitable for certain applications, such as generating random numbers from a fitted distribution.

Alternatively, the kernel distribution builds the pdf by creating an individual probability density curve for each data value, then summing the smooth curves. This approach creates one smooth, continuous probability density function for the data set.

```
figure;
pdSix = fitdist(SixMPG, 'Kernel', 'BandWidth', 4);
x = 0:.1:45;
ySix = pdf(pdSix, x);
plot(x, ySix, 'k-', 'LineWidth', 2);

% Plot each individual pdf and scale its appearance on the plot
hold on;
for i=1:6
    pd = makedist('Normal', 'mu', SixMPG(i), 'sigma', 4);
    y = pdf(pd, x);
    y = y/6;
    plot(x, y, 'b:');
end
hold off;
```

The smaller dashed curves are the probability distributions for each value in the sample data, scaled to fit the plot. The larger solid curve is the overall kernel distribution of the SixMPG data. The kernel smoothing function refers to the shape of those smaller component curves, which have a normal distribution in this example.

You can choose one of several options for the kernel smoothing function. This plot shows the shapes of the available smoothing functions.

Set plot specifications

```
hname = {'normal' 'epanechnikov' 'box' 'triangle'};
colors = {'r' 'b' 'g' 'm'};
lines = {'-', '-.', '--', ':'};

% Generate a sample of each kernel smoothing function and plot
data = [0];
figure;
for j=1:4
    pd = fitdist(data, 'kernel', 'Kernel', hname{j});
    x = -3:.1:3;
    y = pdf(pd,x);
    plot(x,y, 'Color', colors{j}, 'LineStyle', lines{j});
    hold on;
end
legend(hname{:});
hold off;
```

To understand the effect of different kernel smoothing functions on the shape of the resulting pdf estimate, compare plots of the mileage data (MPG) from `carbig.mat` using each available kernel function.

```
load carbig;  
% Set plot specifications  
hname = {'normal' 'epanechnikov' 'box' 'triangle'};  
colors = {'r' 'b' 'g' 'm'};  
lines = {'-' '-.' '--' ':'};
```

```
% Generate kernel distribution objects and plot
figure;
for j=1:4
    pd = fitdist(MPG,'kernel','Kernel',hname{j});
    x = -10:1:60;
    y = pdf(pd,x);
    plot(x,y,'Color',colors{j},'LineStyle',lines{j});
    hold on;
end
legend(hname{:});
hold off;
```

Each density curve uses the same input data, but applies a different kernel smoothing function to generate the pdf. The density estimates are roughly comparable, but the shape of each curve varies slightly. For example, the box kernel produces a density curve that is less smooth than the others.

## **Bandwidth**

The choice of bandwidth value controls the smoothness of the resulting probability density curve. This plot shows the density estimate for the same

MPG data, using a normal kernel smoothing function with three different bandwidths.

Create kernel distribution objects

```
pd1 = fitdist(MPG,'kernel');
pd2 = fitdist(MPG,'kernel','BandWidth',1);
pd3 = fitdist(MPG,'kernel','BandWidth',5);

% Compute each pdf
x = -10:1:60;
y1 = pdf(pd1,x);
y2 = pdf(pd2,x);
y3 = pdf(pd3,x);

% Plot each pdf
plot(x,y1,'Color','r','LineStyle','-');
hold on;
plot(x,y2,'Color','k','LineStyle',':');
plot(x,y3,'Color','b','LineStyle','--');
legend({'BandWidth = Default','BandWidth = 1','BandWidth = 5'});
hold off;
```

The default bandwidth, which is theoretically optimal for estimating densities for the normal distribution, produces a reasonably smooth curve. Specifying a smaller bandwidth produces a very rough curve, but reveals that there might be two major peaks in the data. Specifying a larger bandwidth produces a curve nearly identical to the kernel function, and is so smooth that it obscures potentially important features of the data.

## Logistic Distribution

In this section...
“Overview” on page B-86
“Parameters” on page B-86
“Probability Density Function” on page B-86
“Relationship to Other Distributions” on page B-87

### Overview

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

### Parameters

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

### Probability Density Function

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{\exp\left\{\frac{x - \mu}{\sigma}\right\}}{\sigma \left(1 + \exp\left\{\frac{x - \mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty.$$

## **Relationship to Other Distributions**

The loglogistic distribution is closely related to the logistic distribution. If  $x$  is distributed loglogistically with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed logistically with mean and standard deviation.

## Loglogistic Distribution

In this section...
“Overview” on page B-88
“Parameters” on page B-88
“Probability Density Function” on page B-88
“Relationship to Other Distributions” on page B-89

### Overview

The loglogistic distribution is a probability distribution whose logarithm has a logistic distribution. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease. It is also known as the Fisk distribution in economics applications.

### Parameters

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$\mu > 0$
sigma	Log scale parameter	$\sigma > 0$

### Probability Density Function

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1 + e^z)^2} ; \quad x \geq 0,$$

where  $z = \frac{\log(x) - \mu}{\sigma}$ .

## **Relationship to Other Distributions**

The loglogistic distribution is closely related to the logistic distribution. If  $x$  is distributed loglogistically with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed logistically with mean and standard deviation. The relationship is similar to that between the lognormal and normal distribution.

## Lognormal Distribution

In this section...
“Overview” on page B-90
“Parameters” on page B-90
“Probability Density Function” on page B-90
“Descriptive Statistics” on page B-91
“Relationship to Other Distributions” on page B-91
“Examples” on page B-91

### Overview

The lognormal distribution is a probability distribution whose logarithm has a normal distribution. It is sometimes called the Galton distribution. The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(x)$  exists only when  $x$  is positive.

### Parameters

The lognormal distribution uses the following parameters.

Parameter	Description	Support
mu	Log mean	$-\infty < \mu < \infty$
sigma	Log standard deviation	$\sigma \geq 0$

### Probability Density Function

The probability density function (pdf) of the lognormal distribution is

$$f(x | \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\ln x - \mu)^2}{2\sigma^2}\right\} ; x > 0.$$

## Descriptive Statistics

The mean is

$$\text{mean} = \exp\left(\mu + \frac{\sigma^2}{2}\right).$$

The variance is

$$\text{var} = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1).$$

You can compute these descriptive statistics using the `lognstat` function.

## Relationship to Other Distributions

The lognormal distribution is closely related to the normal distribution. If  $x$  is distributed lognormally with parameters  $\mu$  and  $\sigma$ , then  $\log(x)$  is distributed normally with mean  $\mu$  and standard deviation  $\sigma$ . The lognormal distribution is applicable when the quantity of interest must be positive, since  $\log(x)$  exists only when  $x$  is positive.

## Examples

### Compute the Lognormal Distribution pdf

Suppose the income of a family of four in the United States follows a lognormal distribution with  $\mu = \log(20,000)$  and  $\sigma = 1$ . Compute and plot the income density.

```
x = (10:1000:125010)';
y = lognpdf(x, log(20000), 1.0);

figure;
plot(x,y)
set(gca,'xtick',[0 30000 60000 90000 120000])
set(gca,'xticklabel',{'0', '$30,000', '$60,000', ...
                    '$90,000', '$120,000'})
```

# Multinomial Distribution

## In this section...

“Overview” on page B-93

“Parameter” on page B-93

“Probability Density Function” on page B-93

“Descriptive Statistics” on page B-94

“Relationship to Other Distributions” on page B-94

## Overview

Multinomial distribution models the probability of each combination of successes in a series of independent trials. Use this distribution when there are more than two possible mutually exclusive outcomes for each trial, and each outcome has a fixed probability of success.

## Parameter

Multinomial distribution uses the following parameter.

Parameter	Description	Constraints
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

## Probability Density Function

The multinomial pdf is

$$f(x | n, p) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},$$

where  $k$  is the number of possible mutually exclusive outcomes for each trial, and  $n$  is the total number of trials. The vector  $x = (x_1 \dots x_k)$  is the number of observations of each  $k$  outcome, and contains nonnegative integer components

that sum to  $n$ . The vector  $p = (p_1 \dots p_k)$  is the fixed probability of each  $k$  outcome, and contains nonnegative scalar components that sum to 1.

## **Descriptive Statistics**

The expected number of observations of outcome  $i$  in  $n$  trials is

$$E\{x_i\} = np_i,$$

where  $p_i$  is the fixed probability of outcome  $i$ .

The variance is of outcome  $i$  is

$$\text{var}(x_i) = np_i(1 - p_i).$$

The covariance of outcomes  $i$  and  $j$  is

$$\text{cov}(x_i, x_j) = -np_i p_j, i \neq j.$$

## **Relationship to Other Distributions**

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in  $n$  independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in  $n$  independent trials of a  $k$ -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities  $p_1, \dots, p_k$ .

## **Multivariate Gaussian Distribution**

See “Multivariate Normal Distribution” on page B-96.

## Multivariate Normal Distribution

### In this section...

“Definition” on page B-96

“Background” on page B-96

“Examples” on page B-97

### Definition

The probability density function of the  $d$ -dimensional multivariate normal distribution is given by

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|} (2\pi)^d} e^{-\frac{1}{2}(x-\mu) \Sigma^{-1}(x-\mu)'}$$

where  $x$  and  $\mu$  are 1-by- $d$  vectors and  $\Sigma$  is a  $d$ -by- $d$  symmetric positive definite matrix. While it is possible to define the multivariate normal for singular  $\Sigma$ , the density cannot be written as above. Only random vector generation is supported for the singular case. Note that while most textbooks define the multivariate normal with  $x$  and  $\mu$  oriented as column vectors, for the purposes of data analysis software, it is more convenient to orient them as row vectors, and Statistics Toolbox software uses that orientation.

### Background

The multivariate normal distribution is a generalization of the univariate normal to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate normal distribution. In the simplest case, there is no correlation among variables, and elements of the vectors are independent univariate normal random variables.

The multivariate normal distribution is parameterized with a mean vector,  $\mu$ , and a covariance matrix,  $\Sigma$ . These are analogous to the mean  $\mu$  and variance  $\sigma^2$  parameters of a univariate normal distribution. The diagonal elements of  $\Sigma$  contain the variances for each variable, while the off-diagonal elements of  $\Sigma$  contain the covariances between variables.

The multivariate normal distribution is often used as a model for multivariate data, primarily because it is one of the few multivariate distributions that is tractable to work with.

## Examples

### Compute the Multivariate Normal pdf

Compute and plot the pdf of a multivariate normal distribution.

```
mu = [0 0];  
Sigma = [.25 .3; .3 1];  
x1 = -3:.2:3; x2 = -3:.2:3;  
[X1,X2] = meshgrid(x1,x2);  
F = mvnpdf([X1(:) X2(:)],mu,Sigma);  
F = reshape(F,length(x2),length(x1));  
surf(x1,x2,F);  
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);  
axis([-3 3 -3 3 0 .4])  
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');
```

### Compute the Multivariate Normal cdf

Compute and plot the cdf of a multivariate normal distribution with parameters  $\mu = [1 \ -1]$  and  $\text{SIGMA} = [.9 \ .4; \ .4 \ .3]$ .

```
mu = [1 -1];  
SIGMA = [.9 .4; .4 .3];  
figure;  
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');  
X = [X1(:) X2(:)];  
p = mvncdf(X,mu,SIGMA);
```

```
surf(X1,X2,reshape(p,25,25));
```

### Compute Cumulative Probabilities Over Regions

Since the bivariate normal distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions.

Compute the probability contained within the unit square, and create a contour plot of the results.

```
mu = [0 0];
```

```
Sigma = [.25 .3; .3 1];  
x1 = -3:.2:3; x2 = -3:.2:3;  
[X1,X2] = meshgrid(x1,x2);  
F = mvnpdf([X1(:) X2(:)],mu,Sigma);  
F = reshape(F,length(x2),length(x1));  
  
mvncdf([0 0],[1 1],mu,Sigma);  
contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);  
xlabel('x'); ylabel('y');  
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvncdf` function computes values to less than full machine precision, and returns an estimate of the error as an optional second output.

```
[F,err] = mvncdf([0 0],[1 1],mu,Sigma)
```

```
F =
```

```
0.2097
```

```
err =
```

```
1.0000e-08
```

## Multivariate $t$ Distribution

### In this section...

“Definition” on page B-102

“Background” on page B-102

“Example” on page B-103

### Definition

The probability density function of the  $d$ -dimensional multivariate Student’s  $t$  distribution is given by

$$f(x, \Sigma, \nu) = \frac{1}{|\Sigma|^{1/2}} \frac{1}{\sqrt{(\nu\pi)^d}} \frac{\Gamma((\nu + d) / 2)}{\Gamma(\nu / 2)} \left( 1 + \frac{x' \Sigma^{-1} x}{\nu} \right)^{-(\nu+d)/2}.$$

where  $x$  is a 1-by- $d$  vector,  $\Sigma$  is a  $d$ -by- $d$  symmetric, positive definite matrix, and  $\nu$  is a positive scalar. While it is possible to define the multivariate Student’s  $t$  for singular  $\Sigma$ , the density cannot be written as above. For the singular case, only random number generation is supported. Note that while most textbooks define the multivariate Student’s  $t$  with  $x$  oriented as a column vector, for the purposes of data analysis software, it is more convenient to orient  $x$  as a row vector, and Statistics Toolbox software uses that orientation.

### Background

The multivariate Student’s  $t$  distribution is a generalization of the univariate Student’s  $t$  to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate Student’s  $t$  distribution. In the same way as the univariate Student’s  $t$  distribution can be constructed by dividing a standard univariate normal random variable by the square root of a univariate chi-square random variable, the multivariate Student’s  $t$  distribution can be constructed by dividing a multivariate normal random vector having zero mean and unit variances by a univariate chi-square random variable.

The multivariate Student’s  $t$  distribution is parameterized with a correlation matrix,  $\Sigma$ , and a positive scalar degrees of freedom parameter,  $\nu$ .  $\nu$  is

analogous to the degrees of freedom parameter of a univariate Student's  $t$  distribution. The off-diagonal elements of  $\Sigma$  contain the correlations between variables. Note that when  $\Sigma$  is the identity matrix, variables are uncorrelated; however, they are not independent.

The multivariate Student's  $t$  distribution is often used as a substitute for the multivariate normal distribution in situations where it is known that the marginal distributions of the individual variables have fatter tails than the normal.

## Example

### Plot PDF and CDF of Multivariate $t$ -Distribution

Plot the pdf of a bivariate Student's  $t$  distribution. You can use this distribution for a higher number of dimensions as well, although visualization is not easy.

```
Rho = [1 .6; .6 1];
nu = 5;
x1 = -3:.2:3; x2 = -3:.2:3;
[X1,X2] = meshgrid(x1,x2);
F = mvtpdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 .2])
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');
```

Plot the cdf of a bivariate Student's  $t$  distribution.

```
F = mvtcdf([X1(:) X2(:)],Rho,nu);
F = reshape(F,length(x2),length(x1));
surf(x1,x2,F);
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);
axis([-3 3 -3 3 0 1])
xlabel('x1'); ylabel('x2'); zlabel('Cumulative Probability');
```

Since the bivariate Student's  $t$  distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions. For example, this contour plot illustrates the computation that follows, of the probability contained within the unit square shown in the figure.

```
contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');
```

Compute the value of the probability contained within the unit square.

```
F = mvtcdf([0 0],[1 1],Rho,nu)
```

F =

0.1401

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvtcdf` function computes values to less than full machine precision and returns an estimate of the error, as an optional second output.

```
[F,err] = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F =
```

```
0.1401
```

```
err =
```

```
1.0000e-08
```

## Nakagami Distribution

### In this section...

“Definition” on page B-108

“Background” on page B-108

“Parameters” on page B-108

### Definition

The Nakagami distribution has the density function

$$2\left(\frac{\mu}{\omega}\right)^{\mu} \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} e^{-\frac{\mu}{\omega}x^2}$$

with shape parameter  $\mu$  and scale parameter  $\omega > 0$ , for  $x > 0$ . If  $x$  has a Nakagami distribution with parameters  $\mu$  and  $\omega$ , then  $x^2$  has a gamma distribution with shape parameter  $\mu$  and scale parameter  $\omega/\mu$ .

### Background

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

### Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

# Negative Binomial Distribution

## In this section...

“Definition” on page B-109

“Background” on page B-109

“Parameters” on page B-110

“Example” on page B-112

## Definition

When the  $r$  parameter is an integer, the negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

where  $q = 1 - p$ . When  $r$  is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

## Background

In its simplest form (when  $r$  is an integer), the negative binomial distribution models the number of failures  $x$  before a specified number of successes is reached in a series of independent, identical trials. Its parameters are the probability of success in a single trial,  $p$ , and the number of successes,  $r$ . A special case of the negative binomial distribution, when  $r = 1$ , is the geometric distribution, which models the number of failures before the first success.

More generally,  $r$  can take on non-integer values. This form of the negative binomial distribution has no interpretation in terms of repeated trials, but, like the Poisson distribution, it is useful in modeling count data. The negative binomial distribution is more general than the Poisson distribution because it has a variance that is greater than its mean, making it suitable for count data that do not meet the assumptions of the Poisson distribution. In the limit,

as  $r$  increases to infinity, the negative binomial distribution approaches the Poisson distribution.

## Parameters

Suppose you are collecting data on the number of auto accidents on a busy highway, and would like to be able to model the number of accidents per day. Because these are count data, and because there are a very large number of cars and a small probability of an accident for any specific car, you might think to use the Poisson distribution. However, the probability of having an accident is likely to vary from day to day as the weather and amount of traffic change, and so the assumptions needed for the Poisson distribution are not met. In particular, the variance of this type of count data sometimes exceeds the mean by a large amount. The data below exhibit this effect: most days have few or no accidents, and a few days have a large number.

```
accident = [2 3 4 2 3 1 12 8 14 31 23 1 10 7 0];  
m = mean(accident)  
v = var(accident)
```

```
m =
```

```
8.0667
```

```
v =
```

```
79.3524
```

The negative binomial distribution is more general than the Poisson, and is often suitable for count data when the Poisson is not. The function `nbinf` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the negative binomial distribution. Here are the results from fitting the accident data:

```
[phat,pci] = nbinf(accident)
```

```
phat =  
  
    1.0060    0.1109
```

```
pci =  
  
    0.2152    0.0171  
    1.7968    0.2046
```

It is difficult to give a physical interpretation in this case to the individual parameters. However, the estimated parameters can be used in a model for the number of daily accidents. For example, a plot of the estimated cumulative probability function shows that while there is an estimated 10% chance of no accidents on a given day, there is also about a 10% chance that there will be 20 or more accidents.

```
plot(0:50,nbincdf(0:50,phat(1),phat(2)),'.-');  
xlabel('Accidents per Day')  
ylabel('Cumulative Probability')
```

## Example

### Compute and Plot Negative Binomial Distribution PDF

Compute and plot the pdf using four different values for the parameter  $r$ , the desired number of successes: .1, 1, 3, and 6. In each case, the probability of success  $p$  is .5.

```
x = 0:10;  
plot(x,nbinpdf(x,.1,.5),'s-', ...
```

```

x,nbinpdf(x,1,.5),'o-', ...
x,nbinpdf(x,3,.5),'d-', ...
x,nbinpdf(x,6,.5),'^-',);
legend({'r = .1' 'r = 1' 'r = 3' 'r = 6'})
xlabel('x')
ylabel('f(x|r,p)')

```

The plot shows that the negative binomial distribution can take on a variety of shapes, ranging from very skewed to nearly symmetric, depending on the value of  $r$ .

## Noncentral Chi-Square Distribution

### In this section...

“Definition” on page B-114

“Background” on page B-114

“Examples” on page B-115

### Definition

There are many equivalent formulas for the noncentral chi-square distribution function. One formulation uses a modified Bessel function of the first kind. Another uses the generalized Laguerre polynomials. The cumulative distribution function is computed using a weighted sum of  $\chi^2$  probabilities with the weights equal to the probabilities of a Poisson distribution. The Poisson parameter is one-half of the noncentrality parameter of the noncentral chi-square

$$F(x | \nu, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{\nu+2j}^2 \leq x]$$

where  $\delta$  is the noncentrality parameter.

### Background

The  $\chi^2$  distribution is actually a simple special case of the noncentral chi-square distribution. One way to generate random numbers with a  $\chi^2$  distribution (with  $\nu$  degrees of freedom) is to sum the squares of  $\nu$  standard normal random numbers (mean equal to zero.)

What if the normally distributed quantities have a mean other than zero? The sum of squares of these numbers yields the noncentral chi-square distribution. The noncentral chi-square distribution requires two parameters: the degrees of freedom and the noncentrality parameter. The noncentrality parameter is the sum of the squared means of the normally distributed quantities.

The noncentral chi-square has scientific application in thermodynamics and signal processing. The literature in these areas may refer to it as the “Rician Distribution” on page B-136 or generalized “Rayleigh Distribution” on page B-133.

## Examples

### Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom  $V = 4$  and noncentrality parameter  $\text{DELTA} = 2$ . For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';  
ncx2 = ncx2pdf(x,4,2);  
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g-','LineWidth',2)  
legend('ncx2','chi2')
```

## Noncentral F Distribution

### In this section...

“Definition” on page B-117

“Background” on page B-117

“Examples” on page B-118

### Definition

Similar to the noncentral  $\chi^2$  distribution, the toolbox calculates noncentral  $F$  distribution probabilities as a weighted sum of incomplete beta functions using Poisson probabilities as the weights.

$$F(x | v_1, v_2, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{v_1 \cdot x}{v_2 + v_1 \cdot x} \middle| \frac{v_1}{2} + j, \frac{v_2}{2}\right)$$

$I(x | a, b)$  is the incomplete beta function with parameters  $a$  and  $b$ , and  $\delta$  is the noncentrality parameter.

### Background

As with the  $\chi^2$  distribution, the  $F$  distribution is a special case of the noncentral  $F$  distribution. The  $F$  distribution is the result of taking the ratio of  $\chi^2$  random variables each divided by its degrees of freedom.

If the numerator of the ratio is a noncentral chi-square random variable divided by its degrees of freedom, the resulting distribution is the noncentral  $F$  distribution.

The main application of the noncentral  $F$  distribution is to calculate the power of a hypothesis test relative to a particular alternative.

## Examples

### Compute Noncentral $F$ Distribution pdf

Compute the pdf of a noncentral  $F$  distribution with degrees of freedom  $NU1 = 5$  and  $NU2 = 20$ , and noncentrality parameter  $DELTA = 10$ . For comparison, also compute the pdf of an  $F$  distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x,5,20,10);  
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral  $F$  distribution and the pdf of the  $F$  distribution on the same figure.

```
figure;  
plot(x,p1,'b-', 'LineWidth',2)  
hold on  
plot(x,p,'g--', 'LineWidth',2)  
legend('Noncentral F', 'F distribution')
```

## Noncentral $t$ Distribution

### In this section...

“Definition” on page B-120

“Background” on page B-120

“Examples” on page B-121

### Definition

The most general representation of the noncentral  $t$  distribution is quite complicated. Johnson and Kotz [60] give a formula for the probability that a noncentral  $t$  variate falls in the range  $[-u, u]$ .

$$P(-u < x < u | \nu, \delta) = \sum_{j=0}^{\infty} \left( \frac{\left(\frac{1}{2}\delta^2\right)^j}{j!} e^{-\frac{\delta^2}{2}} \right) I\left(\frac{u^2}{\nu + u^2} \middle| \frac{1}{2} + j, \frac{\nu}{2}\right)$$

$I(x | \nu, \delta)$  is the incomplete beta function with parameters  $\nu$  and  $\delta$ .  $\delta$  is the noncentrality parameter, and  $\nu$  is the number of degrees of freedom.

### Background

The noncentral  $t$  distribution is a generalization of Student’s  $t$  distribution.

Student’s  $t$  distribution with  $n - 1$  degrees of freedom models the  $t$ -statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where  $\bar{x}$  is the sample mean and  $s$  is the sample standard deviation of a random sample of size  $n$  from a normal population with mean  $\mu$ . If the population mean is actually  $\mu_0$ , then the  $t$ -statistic has a noncentral  $t$  distribution with noncentrality parameter

$$\delta = \frac{\mu_0 - \mu}{\sigma / \sqrt{n}}$$

The noncentrality parameter is the normalized difference between  $\mu_0$  and  $\mu$ .

The noncentral  $t$  distribution gives the probability that a  $t$  test will correctly reject a false null hypothesis of mean  $\mu$  when the population mean is actually  $\mu_0$ ; that is, it gives the power of the  $t$  test. The power increases as the difference  $\mu_0 - \mu$  increases, and also as the sample size  $n$  increases.

## Examples

### Compute Noncentral $t$ Distribution pdf

Compute the pdf of a noncentral  $t$  distribution with degrees of freedom  $V = 10$  and noncentrality parameter  $\text{DELTA} = 1$ . For comparison, also compute the pdf of a  $t$  distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';  
nct = nctpdf(x,10,1);  
t = tpdf(x,10);
```

Plot the pdf of the noncentral  $t$  distribution and the pdf of the  $t$  distribution on the same figure.

```
plot(x,nct,'b-', 'LineWidth',2)  
hold on  
plot(x,t,'g--', 'LineWidth',2)  
legend('nct','t')
```

# Normal Distribution

**In this section...**

“Definition” on page B-123

“Background” on page B-123

“Parameters” on page B-124

“Examples” on page B-125

## Definition

The normal pdf is

$$y = f(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

## Background

The normal distribution is a two-parameter family of curves. The first parameter,  $\mu$ , is the mean. The second,  $\sigma$ , is the standard deviation. The standard normal distribution (written  $\Phi(x)$ ) sets  $\mu$  to 0 and  $\sigma$  to 1.

$\Phi(x)$  is functionally related to the error function, *erf*.

$$\text{erf}(x) = 2\Phi(x\sqrt{2}) - 1$$

The first use of the normal distribution was as a continuous approximation to the binomial.

The usual justification for using the normal distribution for modeling is the Central Limit Theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

## Parameters

To use statistical parameters such as mean and standard deviation reliably, you need to have a good estimator for them. The maximum likelihood estimates (MLEs) provide one such estimator. However, an MLE might be biased, which means that its expected value of the parameter might not equal the parameter being estimated. For example, an MLE is biased for estimating the variance of a normal distribution. An unbiased estimator that is commonly used to estimate the parameters of the normal distribution is the *minimum variance unbiased estimator (MVUE)*. The MVUE has the minimum variance of all unbiased estimators of a parameter.

The MVUEs of parameters  $\mu$  and  $\sigma^2$  for the normal distribution are the sample mean and variance. The sample mean is also the MLE for  $\mu$ . The following are two common formulas for the variance.

$$s^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2 \quad (\text{B-1})$$

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2 \quad (\text{B-2})$$

where

$$\bar{x} = \sum_{i=1}^n \frac{x_i}{n}$$

Equation 1 is the maximum likelihood estimator for  $\sigma^2$ , and equation 2 is the MVUE.

As an example, suppose you want to estimate the mean,  $\mu$ , and the variance,  $\sigma^2$ , of the heights of all fourth grade children in the United States. The function `normfit` returns the MVUE for  $\mu$ , the square root of the MVUE for  $\sigma^2$ , and confidence intervals for  $\mu$  and  $\sigma^2$ . Here is a playful example modeling the heights in inches of a randomly chosen fourth grade class.

```
rng('default'); % For reproducibility
height = normrnd(50,2,30,1); % Simulate heights
[mu,s,muci,sci] = normfit(height)
```

```
mu =  
    51.1038
```

```
s =  
    2.6001
```

```
muci =  
    50.1329  
    52.0747
```

```
sci =  
    2.0707  
    3.4954
```

Note that  $s^2$  is the MVUE of the variance.

```
s^2
```

```
ans =  
    6.7605
```

## Examples

### Compute the Normal Distribution pdf

Compute the pdf of a standard normal distribution, with parameters  $\mu = 0$  and  $\sigma = 1$ .

```
x = [-3:.1:3];  
norm = normpdf(x,0,1);
```

Plot the pdf.

```
figure;  
plot(x,norm)
```

# Piecewise Linear Distribution

In this section...
“Overview” on page B-129
“Parameters” on page B-129
“Cumulative Distribution Function” on page B-129
“Relationship to Other Distributions” on page B-129

## Overview

The piecewise linear distribution creates a nonparametric representation of the cumulative distribution function (cdf) by linearly connecting the known cdf values from the sample data.

## Parameters

The piecewise linear distribution uses the following parameters.

Parameter	Description
$x$	Vector of $x$ values at which the cdf changes slope
$F_x$	Vector of cdf values that correspond to each value in $x$

## Cumulative Distribution Function

The piecewise linear distribution constructs a continuous cumulative distribution function (cdf) by connecting the empirical cdf values such that the cdf increases linearly between  $x(j)$  and  $x(j + 1)$ .

## Relationship to Other Distributions

The piecewise linear distribution is a continuous version of the discrete empirical cumulative distribution function (ecdf).

## Poisson Distribution

In this section...
“Definition” on page B-130
“Background” on page B-130
“Parameters” on page B-131
“Examples” on page B-131

### Definition

The Poisson pdf is

$$f(x | \lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty.$$

### Background

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. Sample applications that involve Poisson distributions include the number of Geiger counter clicks per second, the number of people walking into a store in an hour, and the number of flaws per 1000 feet of video tape.

The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter,  $\lambda$ , is both the mean and the variance of the distribution. Thus, as the size of the numbers in a particular sample of Poisson random numbers gets larger, so does the variability of the numbers.

The Poisson distribution is the limiting case of a binomial distribution where  $N$  approaches infinity and  $p$  goes to zero while  $Np = \lambda$ .

The Poisson and exponential distributions are related. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

## Parameters

The MLE and the MVUE of the Poisson parameter,  $\lambda$ , is the sample mean. The sum of independent Poisson random variables is also Poisson distributed with the parameter equal to the sum of the individual parameters. This is used to calculate confidence intervals  $\lambda$ . As  $\lambda$  gets large the Poisson distribution can be approximated by a normal distribution with  $\mu = \lambda$  and  $\sigma^2 = \lambda$ . This approximation is used to calculate confidence intervals for values of  $\lambda$  greater than 100.

## Examples

### Compute and Plot Poisson Distribution PDF

Compute and plot the pdf of a Poisson distribution with parameter  $\lambda = 5$ .

```
x = 0:15;  
y = poisspdf(x,5);  
plot(x,y, '+')
```

# Rayleigh Distribution

## In this section...

“Definition” on page B-133

“Background” on page B-133

“Parameters” on page B-134

“Examples” on page B-134

## Definition

The Rayleigh pdf is

$$y = f(x | b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

## Background

The Rayleigh distribution is a special case of the Weibull distribution. If  $A$  and  $B$  are the parameters of the Weibull distribution, then the Rayleigh distribution with parameter  $b$  is equivalent to the Weibull distribution with parameters  $A = \sqrt{2}b$  and  $B = 2$ .

If the component velocities of a particle in the  $x$  and  $y$  directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time is distributed Rayleigh.

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

## Parameters

The `raylfit` function returns the MLE of the Rayleigh parameter. This estimate is

$$b = \sqrt{\frac{1}{2n} \sum_{i=1}^n x_i^2}$$

## Examples

### Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter  $B = 0.5$ .

```
x = [0:0.01:2];  
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;  
plot(x,p)
```

## Rician Distribution

In this section...
“Definition” on page B-136
“Background” on page B-136
“Parameters” on page B-136

### Definition

The Rician distribution has the density function

$$I_0\left(\frac{xs}{\sigma^2}\right)\frac{x}{\sigma^2}e^{-\left(\frac{x^2+s^2}{2\sigma^2}\right)}$$

with noncentrality parameter  $s \geq 0$  and scale parameter  $\sigma > 0$ , for  $x > 0$ .  $I_0$  is the zero-order modified Bessel function of the first kind. If  $x$  has a Rician distribution with parameters  $s$  and  $\sigma$ , then  $(x/\sigma)^2$  has a noncentral chi-square distribution with two degrees of freedom and noncentrality parameter  $(s/\sigma)^2$ .

### Background

In communications theory, Nakagami distributions, Rician distributions, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

### Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

## Student's $t$ Distribution

### In this section...

“Definition” on page B-137

“Background” on page B-137

“Example” on page B-138

### Definition

Student's  $t$  pdf is

$$y = f(x | \nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where  $\Gamma(\cdot)$  is the Gamma function.

### Background

The  $t$  distribution is a family of curves depending on a single parameter  $\nu$  (the degrees of freedom). As  $\nu$  goes to infinity, the  $t$  distribution approaches the standard normal distribution.

W. S. Gossett discovered the distribution through his work at the Guinness brewery. At the time, Guinness did not allow its staff to publish, so Gossett used the pseudonym “Student.”

If  $x$  is a random sample of size  $n$  from a normal distribution with mean  $\mu$ , then the statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where  $\bar{x}$  is the sample mean and  $s$  is the sample standard deviation, has Student's  $t$  distribution with  $n - 1$  degrees of freedom.

## Example

### Compare Student's $t$ and Normal Distribution pdfs

Compute the pdf for a Student's  $t$  distribution with parameter  $\text{nu} = 5$ , and for a standard normal distribution.

```
x = -5:0.1:5;  
y = tpdf(x,5);  
z = normpdf(x,0,1);
```

Plot the Student's  $t$  and standard normal pdfs on the same figure. The standard normal pdf (dashed line) has shorter tails than the Student's  $t$  pdf (solid line).

```
figure;  
plot(x,y,'-',x,z,'-.-')
```

## t Location-Scale Distribution

### In this section...

“Definition” on page B-140

“Background” on page B-140

“Parameters” on page B-140

### Definition

The  $t$  location-scale distribution has the density function

$$\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sigma\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left[ \frac{\nu + \left(\frac{x-\mu}{\sigma}\right)^2}{\nu} \right]^{-\left(\frac{\nu+1}{2}\right)}$$

with location parameter  $\mu$ , scale parameter  $\sigma > 0$ , and shape parameter  $\nu > 0$ . If  $x$  has a  $t$  location-scale distribution, with parameters  $\mu$ ,  $\sigma$ , and  $\nu$ , then

$$\frac{x - \mu}{\sigma}$$

has a Student’s  $t$  distribution with  $\nu$  degrees of freedom.

### Background

The  $t$  location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as  $\nu$  approaches infinity, and smaller values of  $\nu$  yield heavier tails.

### Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitting app.

# Triangular Distribution

## In this section...

“Overview” on page B-141

“Parameters” on page B-141

“Probability Density Function” on page B-142

“Cumulative Distribution Function” on page B-143

“Descriptive Statistics” on page B-145

## Overview

The triangular distribution provides a simplistic representation of the probability distribution when limited sample data is available. Its parameters are the minimum, maximum, and mode of the data. Common applications include business and economic simulations, project management planning, natural phenomena modeling, and audio dithering.

## Parameters

The triangular distribution uses the following parameters.

Parameter	Description	Constraints
$a$	Lower limit	$a \leq b$
$b$	Peak location	$a \leq b \leq c$
$c$	Upper limit	$c \geq b$

## Parameter Estimation

Typically, you estimate triangular distribution parameters using subjectively reasonable values based on the sample data. You can estimate the lower and upper limit parameters  $a$  and  $c$  using the minimum and maximum values of the sample data, respectively. You can estimate the peak location parameter  $b$  using the sample mean, median, mode, or any other subjectively reasonable estimate of the population mode.

## Probability Density Function

The probability density function (pdf) of the triangular distribution is

$$f(x|a,b,c) = \begin{cases} \frac{2(x-a)}{(c-a)(b-a)} & ; a \leq x \leq b \\ \frac{2(c-x)}{(c-a)(c-b)} & ; b < x \leq c \\ 0 & ; x < a, x > c \end{cases} .$$

This plot shows how changing the value of the parameters  $a$ ,  $b$ , and  $c$  alters the shape of the pdf.

```
% Create four distribution objects with different parameters
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);

% Compute the pdfs
x = -2:.01:2;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
pdf4 = pdf(pd4,x);

% Plot the pdfs
figure;
plot(x,pdf1,'r','LineWidth',2)
hold on;
plot(x,pdf2,'k','LineWidth',2);
plot(x,pdf3,'b-.','LineWidth',2);
plot(x,pdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
       'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

As the distance between  $a$  and  $c$  increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases. The location of the peak parameter  $b$  determines whether the pdf skews right or left, or if it is symmetrical.

## Cumulative Distribution Function

The cumulative distribution function (cdf) of the triangular distribution is

$$F(x|a,b,c) = \begin{cases} 0 & , x < a \\ \frac{(x-a)^2}{(c-a)(b-a)} & , a \leq x \leq b \\ 1 - \frac{(c-x)^2}{(c-a)(c-b)} & , b < x \leq c \\ 1 & , x > c \end{cases} .$$

This plot shows how changing the value of the parameters  $a$ ,  $b$ , and  $c$  alters the shape of the cdf.

```
% Create four distribution objects with different parameters
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);

% Compute the cdfs
x = -1.2:.01:1.2;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
cdf4 = cdf(pd4,x);

% Plot the cdfs
figure;
plot(x,cdf1,'r','LineWidth',2)
xlim([-1.2 1.2]);
ylim([0 1.1]);hold on;
plot(x,cdf2,'k','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
plot(x,cdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
       'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

## Descriptive Statistics

The mean and variance of the triangular distribution are related to the parameters  $a$ ,  $b$ , and  $c$ .

The mean is

$$\text{mean} = \left( \frac{a + b + c}{3} \right).$$

The variance is

$$\text{var} = \left( \frac{a^2 + b^2 + c^2 - ab - ac - bc}{18} \right).$$

**Related  
Examples**

## Uniform Distribution (Continuous)

In this section...
“Overview” on page B-147
“Parameters” on page B-147
“Probability Density Function” on page B-148
“Cumulative Distribution Function” on page B-149
“Descriptive Statistics” on page B-151
“Relationship to Other Distributions” on page B-152

### Overview

The uniform distribution (also called the rectangular distribution) is notable because it has a constant probability distribution function (pdf) between its two bounding parameters. It is appropriate for representing the distribution of round-off errors in values tabulated to a particular number of decimal places, and is used in random number generating techniques such as the inversion method.

### Parameters

The uniform distribution uses the following parameters.

Parameter	Description	Constraints
lower	Lower limit	$-\infty < \text{lower} < \text{upper}$
upper	Upper limit	$\text{lower} < \text{upper} < \infty$

### Parameter Estimation

The maximum likelihood estimator (MLE) for *lower* is the sample minimum. The MLE for *upper* is the sample maximum.

## Probability Density Function

The probability density function (pdf) of the continuous uniform distribution is

$$f(x | lower, upper) = \begin{cases} \left( \frac{1}{upper - lower} \right) & ; \text{ } lower \leq x \leq upper \\ 0 & ; \text{ } otherwise \end{cases} .$$

The pdf is constant between *lower* and *upper*.

This plot illustrates how changing the value of the parameters *lower* and *upper* affects the shape of the pdf.

```
% Create three distribution objects with different parameters
pd1 = makedist('Uniform');
pd2 = makedist('Uniform','lower',-2,'upper',2);
pd3 = makedist('Uniform','lower',-2,'upper',1);

% Compute the pdfs
x = -3:.01:3;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);

% Plot the pdfs
figure;
stairs(x,pdf1,'r','LineWidth',2);
hold on;
stairs(x,pdf2,'k:','LineWidth',2);
stairs(x,pdf3,'b-.','LineWidth',2);
ylim([0 1.1]);
legend({'lower = 0, upper = 1','lower = -2, upper = 2',...
       'lower = -2, upper = 1'},'Location','NW');
hold off;
```

As the distance between *lower* and *upper* increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases.

## Cumulative Distribution Function

The cumulative distribution function (cdf) of the continuous uniform distribution is

$$F(x | lower, upper) = \begin{cases} 0 & ; \quad x < lower \\ \frac{x - lower}{upper - lower} & ; \quad lower \leq x < upper . \\ 1 & ; \quad x \geq upper \end{cases}$$

This plot illustrates how changing the value of the parameters *lower* and *upper* affects the shape of the cdf.

```
% Create three distribution objects with different parameters
pd1 = makedist('Uniform');
pd2 = makedist('Uniform','lower',-2,'upper',2);
pd3 = makedist('Uniform','lower',-2,'upper',1);

% Compute the cdfs
x = -3:.01:3;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);

% Plot the cdfs
figure;
plot(x,cdf1,'r','LineWidth',2);
hold on;
plot(x,cdf2,'k','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
ylim([0 1.1]);
legend({'lower = 0, upper = 1','lower = -2, upper = 2',...
       'lower = -2, upper = 1'},'Location','NW');
hold off;
```

## Descriptive Statistics

The mean and variance of the continuous uniform distribution are related to the parameters *lower* and *upper*.

The mean is

$$\text{mean} = \frac{1}{2}(\text{lower} + \text{upper}).$$

The variance is

$$\text{var} = \frac{1}{12}(\text{upper} - \text{lower})^2.$$

## Relationship to Other Distributions

The standard uniform distribution (lower = 0 and upper = 1) is a special case of the beta distribution obtained by setting the beta distribution parameters  $a = 1$  and  $b = 1$ .

The inversion method uses the continuous standard uniform distribution to generate random numbers for any other continuous distribution. The inversion method relies on the principle that continuous cumulative distribution functions (cdfs) range uniformly over the open interval (0,1). If  $u$  is a uniform random number on (0,1), then  $x = F^{-1}(u)$  generates a random number  $x$  from any continuous distribution with the specified cdf  $F$ .

## Uniform Distribution (Discrete)

### In this section...

“Definition” on page B-153

“Background” on page B-153

“Examples” on page B-153

### Definition

The discrete uniform pdf is

$$y = f(x | N) = \frac{1}{N} I_{(1, \dots, N)}(x)$$

### Background

The discrete uniform distribution is a simple distribution that puts equal weight on the integers from one to  $N$ .

### Examples

#### Plot a Discrete Uniform Distribution cdf

As for all discrete distributions, the cdf is a step function. The plot shows the discrete uniform cdf for  $N = 10$ .

```
x = 0:10;  
y = unidcdf(x,10);  
figure;  
stairs(x,y)  
set(gca, 'Xlim', [0 11])
```

### **Generate Discrete Uniform Random Numbers**

This example shows how to generate random numbers from a discrete uniform distribution.

Pick a random sample of 10 from a list of 553 items.

```
rng('default'); % For reproducibility
numbers = unidrnd(553,1,10)
```

```
numbers =
```

```
451 501 71 506 350 54 155 303 530 534
```

## Weibull Distribution

In this section...
“Definition” on page B-156
“Background” on page B-156
“Parameters” on page B-157
“Example” on page B-157

### Definition

The Weibull pdf is positive only for positive values of  $x$ , and is zero otherwise. For strictly positive values of the shape parameter  $b$  and scale parameter  $a$ , the density is

$$f(x | a, b) = \frac{b}{a} \left(\frac{x}{a}\right)^{b-1} e^{-(x/a)^b}.$$

### Background

Waloddi Weibull offered the distribution that bears his name as an appropriate analytical tool for modeling the breaking strength of materials. Current usage also includes reliability and lifetime modeling. The Weibull distribution is more flexible than the exponential for these purposes.

To see why, consider the hazard rate function (instantaneous failure rate). If  $f(t)$  and  $F(t)$  are the pdf and cdf of a distribution, then the hazard rate is

$$h(t) = \frac{f(t)}{1 - F(t)}$$

Substituting the pdf and cdf of the exponential distribution for  $f(t)$  and  $F(t)$  above yields a constant. The example below shows that the hazard rate for the Weibull distribution can vary.

## Parameters

Suppose you want to model the tensile strength of a thin filament using the Weibull distribution. The function `wblfit` gives maximum likelihood estimates and confidence intervals for the Weibull parameters.

```
rng('default'); % For reproducibility
strength = wblrnd(0.5,2,100,1); % Simulated strengths
[p,ci] = wblfit(strength)
```

```
p =
    0.4768    1.9622
```

```
ci =
    0.4291    1.6821
    0.5298    2.2890
```

The default 95% confidence interval for each parameter contains the true value.

## Example

The exponential distribution has a constant hazard function, which is not generally the case for the Weibull distribution. The plot shows the hazard function for exponential (dashed line) and Weibull (solid line) distributions having the same mean life. The Weibull hazard rate here increases with age (a reasonable assumption).

```
t = 0:0.1:4.5;
h1 = exppdf(t,0.6267) ./ (1-expcdf(t,0.6267));
h2 = wblpdf(t,2,2) ./ (1-wblcdf(t,2,2));
plot(t,h1,'--',t,h2,'-')
```

## Wishart Distribution

### In this section...

“Definition” on page B-159

“Background” on page B-159

“Example” on page B-160

“See Also” on page B-160

### Definition

The probability density function of the  $d$ -dimensional Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|X|^{(\nu-d-1)/2} e^{\left(-\frac{1}{2}\text{trace}(\Sigma^{-1}X)\right)}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |\Sigma|^{\nu/2} \Gamma(\nu/2) \dots \Gamma(\nu-(d-1))/2}$$

where  $X$  and  $\Sigma$  are  $d$ -by- $d$  symmetric positive definite matrices, and  $\nu$  is a scalar greater than  $d - 1$ . While it is possible to define the Wishart for singular  $\Sigma$ , the density cannot be written as above.

Only random matrix generation is supported for the Wishart distribution, including both singular and nonsingular  $\Sigma$ .

### Background

The Wishart distribution is a generalization of the univariate chi-square distribution to two or more variables. It is a distribution for symmetric positive semidefinite matrices, typically covariance matrices, the diagonal elements of which are each chi-square random variables. In the same way as the chi-square distribution can be constructed by summing the squares of independent, identically distributed, zero-mean univariate normal random variables, the Wishart distribution can be constructed by summing the inner products of independent, identically distributed, zero-mean multivariate normal random vectors.

The Wishart distribution is parameterized with a symmetric, positive semidefinite matrix,  $\Sigma$ , and a positive scalar degrees of freedom parameter,  $\nu$ .  $\nu$  is analogous to the degrees of freedom parameter of a univariate chi-square distribution, and  $\Sigma\nu$  is the mean of the distribution.

The Wishart distribution is often used as a model for the distribution of the sample covariance matrix for multivariate normal random data, after scaling by the sample size.

### Example

If  $x$  is a bivariate normal random vector with mean zero and covariance matrix

$$\Sigma = \begin{pmatrix} 1 & .5 \\ .5 & 2 \end{pmatrix}$$

then you can use the Wishart distribution to generate a sample covariance matrix without explicitly generating  $x$  itself. Notice how the sampling variability is quite large when the degrees of freedom is small.

```
Sigma = [1 .5; .5 2];  
df = 10; S1 = wishrnd(Sigma,df)/df
```

```
S1 =  
    1.7959    0.64107  
    0.64107    1.5496
```

```
df = 1000; S2 = wishrnd(Sigma,df)/df
```

```
S2 =  
    0.9842    0.50158  
    0.50158    2.1682
```
